Special Collection: Abstracts from IUNS-ICN Paris 2025

Congress Details:

- Name: 23rd Edition of IUNS International Congress of Nutrition
- Theme: Sustainable Food for Global Health
- Date: 24th – 29th August 2025
- Location: Paris, France

Organisers:

- International Union of Nutritional Sciences (IUNS)
- Société Française de Nutrition
- Fédération Française de Nutrition

Total Contributions:

- Participants: 3,805
- Plenary lectures: 7
- Special lectures: 36
- Symposia: 160
- Abstracts: 2,302

Submission Description:
This special collection comprises the abstracts presented at the 23rd edition of the IUNS International Congress of Nutrition (IUNS-ICN Paris 2025), covering a broad range of topics within nutritional science, including:

- The future of nutrition recommendations
- Climate change, sustainability and nutrition
- Food science, gastronomy and life quality
- Global health and planetary nutrition
- Public health and nutrition throughout the life cycle
- Non-communicable diseases
- Precision and clinical nutrition
- Basic research in nutrition

All abstracts were received via the IUNS-ICN Paris 2025 submission system and reviewed in accordance with the IUNS-ICN Paris 2025's scientific review procedures.

Disclaimer:
The abstracts in this supplement were supplied and compiled by the congress organisers. They were reviewed under the direction of the IUNS-ICN Paris 2025 Scientific Committee, with support from more than 200 volunteer reviewers. The content has not been peer reviewed, edited, proofread, or verified by Cambridge University Press, Journal of Nutritional Science, or its Editorial Board. Cambridge University Press bears no responsibility for the accuracy, quality, or integrity of the material. The abstracts have not been styled, formatted, or typeset to match the journal's style and are published exactly as provided by the organisers. The organisers have confirmed that appropriate permissions have been obtained from all authors and contributors.

Corresponding Contacts:

- Name: J. Alfredo Martinez / Jacques Delarue
- Email: office@iuns.org
- Role: Scientific Committee, 23rd Edition of IUNS-ICN Paris 2025

ORAL ABSTRACT PRESENTATIONS (OAP)

THE FUTURE OF NUTRITION RECOMMENDATIONS 16

OAP 01 - The future of nutrition recommendations 16
The Future of Nutritional Assessment: A Digital Solution Using Facial Morphometrics 16
Exploring the ability of Nutri-Score and NOVA Food Classification in Nutritional Quality Assessment of selected foods available in the Southeast Asia food market 18
The Risk of Non-Communicable Diseases in Adulthood Associated with Childhood and Adolescence Exposure to Malnutrition in Low- to Middle-Income Countries: A Systematic Review and Meta-analysis of Observational Studies 20
Analyzing concordance between MUAC, MUACZ, and WHZ in diagnosing acute malnutrition among children under 5 in Somalia 22
Effect of plant-based meat analogue vs animal-based meat diets on micronutrient intake and biological status of healthy adults – An 8-week randomized controlled trial 24
Transforming Local Food Systems Using Urban Agriculture for Better Nutrition Outcomes 26
Positioning nutrient profiling as a strategy to assess school food policy: Evidence and implications from Canadian school food programs 28
Eating architecture and cardiometabolic health in children and early adolescence 30
Organic food consumption and risk of cancer, type 2 diabetes mellitus and cardiovascular disease in the Danish Diet, Cancer and Health cohort 31

OAP 18 - The future of nutrition recommendations 33
To be climate-friendly, food-based dietary guidelines must include limits on total meat consumption – modeling from the case of France 33
Australian Nutrition Science: a programmatic approach to implementing a national strategic development plan 35
Does vitamin A intake adversely affect bone health? 37
From Apps to Bites: The Impacts of The Developing Technology on Food Marketing to School-Aged Children Food Preferences 38
Important revisions to the Nutri-Score to enhance consistency with the Nordic Nutrition Recommendations - insights from the NewTools project 40
Optimizing Antenatal Multiple Micronutrient Supplement Adherence in Cambodia: A Socio-Ecological Approach to Increasing Uptake 42
Associations of Global Burden of Diseases study-derived dietary scores with mortality and chronic disease risk: a comprehensive analysis from the prospective NutriNet-Santé study 43
Proposed Nutrient Profiles for Alternative Protein Foods 44

OAP 34 - The future of nutrition recommendations 45
Artificial intelligence and large language models to make nutrition information more accessible 45
The consumption of poultry and rabbit products enriched with algal DHA is an interesting strategy for reducing the deficit of this fatty acid in the French population 47
Associations between the consumption of artificial sweeteners, excess weight gain and gut microbiota diversity in the NutriNet-Santé prospective cohort study 49
Planetary Health Diet Compared to Dutch Dietary Guidelines: Nutritional Content and Food Groups Contributions 52
Mapping spatial patterns of the physical food environment of Kuala Lumpur Malaysia: A GIS and participatory approach 54
Recommendations to address the shortfalls of the EAT–Lancet planetary health diet from a plant-forward perspective 56
Impact of ultra-processed and minimally processed diets following UK dietary guidance on physical fitness: a randomised, cross-over, controlled feeding clinical trial 58
Novel Application of System Science Tools in Strategic Planning for the Future of Nutrition 60

OAP 49 - The future of nutrition recommendations 62
Understanding Trade-Offs: Cost-Efficiency vs. Coverage in Vitamin A Supplementation Strategies in Côte d'Ivoire 62

https://doi.org/10.1017/jns.2026.10126 Published online by Cambridge University Press

Leveraging Binti Groups (Antenatal (ANC) Groups) to empower pregnant adolescent girls and youths to address health and nutrition needs for maternal and infant well-being 63
Food database remains the most challenging for the AI-applied nutrition consultation system in dietary intake measurement and meal planning 65
Nutrient composition of plant-based milk alternatives compared to cow's milk 67
Relationship between implementation of provisions of the International Code of Marketing of Breast-milk Substitutes and maternity protection and expenditure of commercial milk formula in East Asia Pacific 70
Towards Healthier and More Environmentally Sustainable Diets in Iceland: A Preliminary Application of a Five-Step Framework for Sustainable Food-Based Dietary Guidelines 72
Navigating Nutritional Challenges and Opportunities in School Food Programs: Aligning Practices with Dietary Recommendations 73
Expert guidelines on improving the quality of published aquatic food nutrient composition data for their inclusion in FCTs, FCDs, and evidenced based nutritional plans, policies and programmes 74

OAP 66 - The future of nutrition recommendations 76
Long-term effects of chronic consumption of sugars and non-nutritive sweeteners on decision-making 76
The health effects of micro-vegetable consumption: a systematic review of in-vitro and in-vivo studies 78
Are sustainable diets good for our metabolic health? Exploring phenotypic response to the MyPlanetDiet RCT 80
A literature-based data scanning and prioritisation study to guide systematic literature reviews for evidence-based cancer prevention recommendations 82
The effect of N-acetylcysteine supplementation on sports performance in amateur endurance athletes 84
Adherence to the new Nordic Nutrition Recommendations for animal-based food groups by education level in Finnish adults 85
Reevaluating Dairy Fat: Emerging Evidence on the Health Benefits of Full-Fat Dairy and the Role of Milk Fat Globule Membrane on Postprandial Lipemia and Cardiovascular Health 87
A Systematic Review of Nutrient Profiling Models that Promote a Healthy Diet 88

CLIMATE CHANGE, SUSTAINABILITY AND NUTRITION 90

OAP 12 - Climate change, sustainability and nutrition 90
Food-based dietary guidelines for children and adolescents and planetary health: Update of the Optimized Mixed Diet 90
The potential of climate change menu labels to promote healthy and sustainable diets 92
Co-exposure to multiple mycotoxins may synergistically contribute to colorectal cancer risk 93
Factors Associated with Sustainable Dietary Patterns: A Multidimensional Assessment of Portuguese Adults' Diets 94
Exploring the Association between Mediterranean Diet, Sustainable Eating, and Eco-Anxiety: A Cross-Sectional Study on Food Choices 95
Association Between Mindful Eating and Plant-Based Diet: Findings from a French cohort 97
Bioavailability of vitamin B12 produced by Propionibacterium freudenreichii fermentation to faba bean bread: A randomised cross-over trial in healthy volunteers 98
Similarity index (NSI) for interchanging food products: from qualitative classifications to quantitative indicators 99
Does water insecurity mediate the associations between climate events and food insecurity? An analysis from 25 low- and middle-income countries 100

OAP 14 - Climate change, sustainability and nutrition 102
Social interactions for sustainable food choices: Meeting the target for meat intake in the United Kingdom 102
Enhancing Resilience and Livelihoods for Vulnerable Populations through NUCS Adoption 103
Comprehensive geographic targeting index for a multi-sectoral nutrition initiative in Nepal 104
Food environment resilience in the context of a changing climate in Cambodia 105
Bridging Knowledge Systems: A Community-Based Participatory Food Systems Approach to Indigenous Food Security and Food Sovereignty 106
Greening School Lunch: A Path to Sustainable Nutrition in Education 108
Linking Climate Change and Malnutrition Indicators in Children Under Five 109
Assessing the acceptability and health impacts of a healthy and sustainable dietary pattern (MED_EAT-IT): findings from the INSTEAD study 111

OAP 07 - Climate change, sustainability and nutrition 113
Species richness of fruit and vegetables and diet quality of Italian adults 113
Linking Dietary patterns to Food Waste Management: Insights from Malaysian Online Survey 115
Effects of Wildfires Burned Area on Consumer Food Price Worldwide: A Consequence of Climate Change 116
Transition towards healthier and more sustainable food habits: What is the actual cost for parents facing financial hardship? 117

THE FUTURE OF NUTRITIONAL ASSESSMENT: A DIGITAL SOLUTION USING FACIAL MORPHOMETRICS

Rina Yu Chin Quek[1]; Wesley Li Wen Tay,[1]; Joseph Lim,[1]; Bhupinder Kaur,[1]; Shalini Ponnalagu,[1]; Darel Wei Kiat Toh,[1]; Melvin Khee Shing Leow,[1]; Christiani Jeyakumar Henry[1, 2]
[1]Nutrition, A*STAR's Singapore Institute of Food and Biotechnology Innovation (SIFBI), Singapore, Singapore; [2]Global Centre for Asian Women's Health, Yong Loo Lin School of Medicine, Singapore, Singapore

Background and objectives
Current nutritional assessment METHODS are often time-consuming, expensive, and require specialized equipment and clinician expertise. This research proposes a paradigm shift towards accessible, scalable, and efficient digital solutions by utilizing facial morphometrics and machine learning to predict key nutritional parameters.
METHODS

https://doi.org/10.1017/jns.2026.10126 Published online by Cambridge University Press

A total of 71 (30 males, 41 females) free-living Chinese adults, aged 50-85, participated in this cross-sectional observational study. 3D facial scans captured from readily available smartphone technology was employed to predict nutritional parameters. Predictive accuracy of two machine-learning models; the Random Forest (RF) and Extreme Gradient Boosting (XGB) was assessed using 10-fold stratified cross-validation.

RESULTS
The RF model was found to be superior to the XGB model, demonstrating strong predictive accuracy (median r^2 0.51 to 0.92) across six parameters – muscle mass, basal metabolic rate (BMR), visceral fat index, appendicular skeletal muscle mass index, total body fat percentage, and hand grip strength. Muscle mass ($r^2 = 0.92$) and BMR ($r^2 = 0.88$) exhibited the strongest associations, indicating highest predictive accuracy.

CONCLUSIONS
This non-invasive, cost-effective technology offers a scalable approach to nutritional assessment with significant implications for public health. The accurate prediction of muscle mass and BMR, for example, enables efficient community-based screening for undernutrition and frailty in older adults, while assessment of body fat percentage can aid in detecting overnutrition and associated health risks. This digital solution holds considerable promise for improving population-level health outcomes through early detection and intervention.

EXPLORING THE ABILITY OF NUTRI-SCORE AND NOVA FOOD CLASSIFICATION IN NUTRITIONAL QUALITY ASSESSMENT OF SELECTED FOODS AVAILABLE IN THE SOUTHEAST ASIA FOOD MARKET

Melvin Bernardino[1]; Natalia Rosso,[2]; Claudio Tiribelli[2]
[1]Life Science, University of Trieste, Trieste, Italy; [2]MASLD Unit, Fondazione Italiana Fegato Onlus, Basovizza, Italy

Background and objectives
The rising prevalence of metabolic dysfunction-associated steatosis liver disease (MASLD) in Southeast Asia, with a 29% prevalence rate—the highest in the Asian region—represents a significant public health challenge.[1] MASLD is closely linked to poor dietary habits characterized by excessive consumption of calorie-dense, nutrient-poor foods and an increasing reliance on ultra-processed food products.[2] This has led to the development of simplified nutrition labels to guide consumers toward healthier choices, with prominent examples including Nutri-Score and the NOVA food classification. However, their effectiveness and suitability for Southeast Asia remain unclear, making the population vulnerable to diet-related diseases.[3] This study aims to explore the ability of Nutri-Score and NOVA classifications on selected foods available in the Southeast Asia market to discriminate the fat, saturated fat, sugar, and salt content of foods

METHODS
Information about (a) the nutrient composition (b) nutritional quality (Nutriscore), and (c) the degree of processing (NOVA classification) of food was obtained from the Open Food Facts database-a freely accessible online database. Spearman correlation analysis was performed to explore the relationships between each food classification score of the Nutri-Score and NOVA systems and the nutrient content of the selected food items

RESULTS
The study analyzed 4,668 food products. Of these, 2,068 were classified using the NOVA system, with 71% in NOVA 4. Using NutriScore, 4,568 products were classified, with most falling under NutriScore D (26%) and E (26%) Spearman's correlation revealed that Nutri-Score exhibited stronger and more comprehensive correlations with nutrient content, particularly for saturated fat ($R = 0.364$, $P < 0.001$), sugar ($R = 0.355$, $P < 0.001$), and fiber ($R = -0.175$, $P < 0.001$), underscoring its effectiveness in differentiating the nutritional quality of foods. In contrast, NOVA classification demonstrated weaker correlations, with its strongest associations observed for sugar ($R = 0.149$, $P < 0.001$) and salt ($R = 0.138$, $P < 0.001$), reflecting its focus on the degree of food processing rather than nutrient composition.

CONCLUSIONS
These findings suggest that Nutri-Score and NOVA classifications serve as complementary tools, with Nutri-Score excelling in guiding healthier food choices based on nutrient content, while NOVA provides valuable insights into the level of food processing. This study supports developing better front-of-pack labels in Southeast Asia by addressing both aspects.

THE RISK OF NON-COMMUNICABLE DISEASES IN ADULTHOOD ASSOCIATED WITH CHILDHOOD AND ADOLESCENCE EXPOSURE TO MALNUTRITION IN LOW- TO MIDDLE-INCOME COUNTRIES: A SYSTEMATIC REVIEW AND META-ANALYSIS OF OBSERVATIONAL STUDIES

Frehiwot Birhanu Zurga[1]; Catharine AK Fleming[2]; Haider Mannan[3]; Mirkuzie Woldie[4]; Evan Atlantis[5]
[1]School of Health Science , Western Sydney University , Sydney, Australia; [2]School of Health Science, Western Sydney University , Sydney, Australia; [3]Translational Health Research Institute and School of Medicine, Western Sydney University, Sydney, Australia; [4]Fenot Project, Harvard T.H. Chan School of Public Health, Addis Ababa, Ethiopia; [5]School of Health Science, Western Sydney University, Sydney, Australia

Background and objectives
Despite the significant global burden of all forms of malnutrition and non-communicable diseases (NCDs), the long-term NCDs risks associated with childhood and adolescence malnutrition in Low- to Middle-Income Countries (LMICs) remain poorly understood. This review aims to synthesise evidence on the adulthood NCDs risks associated with childhood and adolescence exposure to all forms of malnutrition in LMICs.

METHODS
A systematic review was conducted, searching Ovid Embase, Ovid Medline, Web of Science, and Google Scholar for studies published from 2019 to 2024. Studies in children under 19 years exposed to undernutrition (stunting, wasting, and underweight), micronutrient deficiency, or overnutrition (overweight, obesity) compared to controls. Those reporting main types of NCDs, including cardiovascular disease (CVD), cancer, diabetes, hypertension, and chronic respiratory diseases, were eligible. As there was heterogeneity between studies assessed by Cochran's Q test, I^2 and τ^2 statistics, random-effects models using risk ratios (RR) and 95% confidence intervals were used to conduct the meta-analysis. To assess heterogeneity by study level characteristics, we considered multivariable meta-regression using a mixed-effects model.

RESULTS
Of 4,326 studies identified, 40 observational studies from 10 LMICs were included. Childhood undernutrition was consistently associated with an increased risk of hypertension (RR: 1·36, 95% CI: 1·16–1·59; $Q < 0·001$, $I^2 = 99·6\%$, $\tau^2 = 0.09$), diabetes (RR: 1·40, 95% CI: 1·20–1·64; $Q < 0·001$, $I^2 = 97\%$, $\tau^2 = 0·06$), CVD (RR: 1·63, 95% CI: 1·12–2·37; $Q < 0·001$, $I^2 = 99\%$, $\tau^2 = 0·3$), and chronic respiratory disease (RR: 1·48, 95% CI: 1·13–1·94; $Q < 0·05$, $I^2 = 42\%$, $\tau^2 = 0·01$). Childhood overnutrition was also associated with an increased risk of hypertension (RR: 3·0, 95% CI: 2·29–4·08; $Q < 0·01$, $I^2 = 82\%$, $\tau^2 = 0·07$), as well as diabetes, and CVD outcomes in our narrative summary. The heterogeneity between studies was often attributed to sample size, study quality, and age at exposure and outcome measurement.

CONCLUSIONS
Exposure to both undernutrition and overnutrition during childhood and adolescence increases the risk of several major types of NCDs in adulthood in LMICs. To address the burden of NCDs in LMICs, future research should focus on strategies to prevent all forms of undernutrition and reduce the growing prevalence of overweight and obesity in this region.

ANALYZING CONCORDANCE BETWEEN MUAC, MUACZ, AND WHZ IN DIAGNOSING ACUTE MALNUTRITION AMONG CHILDREN UNDER 5 IN SOMALIA

Sydney Garretson[1]; Shelley Walton[1]; Kemish Alier[1]; Samantha Grounds[1]; Qundeel Khattak[2]; Said Mohamoud[3]; Abdullahi Arays[3]; Fabrizio Loddo[2]; Tripaldi Marina[2]; Farhan Mohamud[4]; Abdullahi Muse Mohamoud[4]; Nadia Akseer[1]
[1]Department of International Health, Johns Hopkins University, Baltimore, United States of America; [2]Humanitarian Response, Save the Children, London, United Kingdom; [3]Research, Save the Children International, Garowe, Somalia; [4]Nutrition Section, Somali Ministry of Health, Muqdisho, Somalia

Background and objectives
Acute malnutrition (wasting) affected an estimated 45 million children under 5 (CU5) globally in 2023. Wasting is measured using a child's mid-upper arm circumference (MUAC<12.5cm), weight-for-height z-score (WHZ<-2 SD), or nutritional edema. In low-resource contexts and community health screenings, MUAC is often the only measurement used to regularly screen for malnutrition, but recent research suggests using MUAC alone fails to diagnose 25%-80% of WHZ-wasted children. MUACZ, an age-adjusted MUAC z-score, may identify additional cases missed by MUAC alone. The aim of this analysis was to examine concordance between MUAC, MUACZ, and WHZ prevalence estimates of wasting among 1,408 CU5 enrolled in a cluster-randomized controlled trial in two regions of Somalia.

METHODS
Anthropometric data was collected in December 2023. This analysis explored wasting prevalences across anthropometric indicators, concordance between indicator pairs, linear regression modelling with WHZ as the outcome, and receiver operating characteristic (ROC) analysis using WHZ as a gold standard to examine alternative MUAC and MUACZ thresholds. Stratified analyses by age (9-23 months vs. 24-59 months) and region were also conducted.

RESULTS
Wasting prevalence was 1.5% by MUAC, 8.5% by MUACZ, and 14.8% by WHZ. MUAC alone failed to identify 94% of WHZ-wasted children. There was slight concordance between MUAC and WHZ (κ=0.089) and fair concordance between MUACZ and WHZ (κ=0.385). In regression models, MUAC, age, sex, and stunting were all statistically significant variables ($p<0.001$) for estimating child WHZ and age confounded the relationship between MUAC and WHZ. Using WHZ as a gold standard, a MUAC of 13.7cm and MUACZ of –0.9 SD both accurately diagnosed >82% of wasted children ages 9-23 months. A MUAC of 14.4cm and MUACZ of -1 SD both accurately diagnosed >76% of wasted children ages 24-59 months.

CONCLUSIONS
Poor concordance between MUAC and WHZ in the literature and this analysis should prompt review of wasting measurement guidelines. Stratified analyses and regression modelling showed increased MUAC with age > 24 months among CU5. Practitioners should consider revising organizational and programmatic guidelines to include age-specific MUAC thresholds, MUACZ, or WHZ in screening procedures in order to accurately target and treat all malnourished children. Policymakers should consider how adapting screening guidelines impacts health centers and treatment availability in humanitarian settings. Future studies should evaluate morbidity and mortality associated with increased MUAC thresholds.

EFFECT OF PLANT-BASED MEAT ANALOGUE VS ANIMAL-BASED MEAT DIETS ON MICRONUTRIENT INTAKE AND BIOLOGICAL STATUS OF HEALTHY ADULTS – AN 8-WEEK RANDOMIZED CONTROLLED TRIAL

Amanda Simin Fu[1]; Farhana Osman[1]; Nicole Lam[1]; Kervyn Mehta[1]; Sumanto Haldar[2, 1]; Melvin Khee Shing Leow,[1, 3]; Christiani Jeyakumar Henry[1]; David Cameron-Smith[1]; Darel Wee Kiat Toh[1]
[1]Nutrition, Singapore Institute of Food and Biotechnology Innovation (SIFBI), A*STAR, Singapore, Singapore; [2]Nutrition Science, Bournemouth university, Bournemouth, United Kingdom; [3]Human Development, Institute for Human Development and Potential, A*STAR, Singapore, Singapore

Background and objectives
Plant based meat analogues (PBMA) have gained popularity due to concerns over planetary and human health and safety(1). Designed to replicate the organoleptic qualities of meat, PBMAs have distinct nutritional profiles, necessitating an evaluation of how dietary substitution impacts overall nutrient status and health, although there remains paucity in evidence(2). This study investigated the impact of protein-matched PBMA diets (PBMD) and animal-based meat diets (ABMD) on nutrient intake, circulating micronutrient status, and bone mineral density (BMD) in a Singaporean, Chinese adult population.

METHODS
In an 8-week parallel randomised controlled trial, 89 healthy participants replaced their habitual protein rich food with protein matched quantities of either animal-based meats or their corresponding PBMAs, while maintaining the other components of their habitual diet. Complete micronutrient analysis of cooked intervention foods was conducted, and nutrient density was assessed using the nutrient rich food index (NRFI)(3). Dietary intake was assessed using 3-day food records, biological micronutrient status was determined via vitamin and mineral levels in fasting blood samples, and BMD via dual energy X-ray absorptiometry (DXA) were analysed at both baseline and at the end of the study period.

RESULTS
After the intervention, PBMD group had significantly greater consumption of thiamine, vitamin B6, folate, sodium, potassium, magnesium, iron and calcium ($p < 0.001$) with the PBMAs having higher NRFI scores. ABMD group had greater intakes of riboflavin, niacin and zinc ($p < 0.05$). Significant changes in biological micronutrient status were only observed for vitamin B12 (ABMD: -10.40 pmol, PBMD: 22.97 pmol, $p = 0.004$), folate (ABMD: -2.93 nmol, PBMD: 2.75 nmol, $p = 0.004$) and selenium (ABMD: -0.05 umol, PBMD: 0.04 umol, $p = 0.006$). These observations allude to differences in bioavailability of micronutrients from the different diets. Although changes in whole body BMD were statistically significant ($p = 0.03$), the magnitude of change appears marginal. This may be supported by calcium status and bone turnover biomarkers RESULTS where no significant differences were observed.

CONCLUSIONS
Collectively, substantial differences observed in micronutrient intakes between diets did not correlate with changes in circulating micronutrient status. These RESULTS emphasize that the effect of PBMA fortification on micronutrient status is influenced by other factors such as bioavailability and absorption. Hence, further studies are warranted to evaluate the impact of plant-based meat consumption on dietary intake, micronutrient status, and health outcomes.

TRANSFORMING LOCAL FOOD SYSTEMS USING URBAN AGRICULTURE FOR BETTER NUTRITION OUTCOMES

Xolile Mkhize[1]; Carin Napier[2]; Kevin Duffy[3]; Wilna Oldewage-Theron[4]
[1]Department of Community Extension, Mangosuthu University of Technology, Durban, South Africa; [2]School of Population Health, University of Auckland, University of Auckland, Grafton Campus, Auckland, New Zealand; [3]Insitute of Systems Science, Durban University Of Technology - Ritson Campus, Berea, South Africa; [4]Department of Sustainable Food Systems & Development, University of the Free State, Bloemfontein, South Africa

Background and objectives
Urban food and nutrition insecurity continues to expose the gaps within the food system, largely affecting communities to have access to affordable nutritious foods. The study aimed to educate and train farmers on nutrition-sensitive and sustainable food production approaches using legumes. An operationalised food and nutrition education programme was rolled out for a two-year period. Thereafter nutrition outcomes were examined to determine nutritional status, including production outcomes.

METHODS
The intervention study involved two case controls (n=103) that comprised of an experimental group (EG: n=53) and a control group (CG: n=50). Data was obtained for both groups for yields of legume production, dietary intake, and biochemical data. The data was analysed using Analysis of Variance (ANOVA), Food Finder software and a Wilcoxon test statistic (W) for the same group on a single independent variable analysis. Correlation was considered significant at the 0.05 level.

RESULTS
There was a high significance ($p=0.001$) amongst the six legume varieties produced, showing the highest yield for P. vulgaris L compared with other varieties. Dietary diversity score (DDS) of legume intake with a FGDS mean was from 2.4 (SD ± 1.35) to 5.7 (SD ± 2.56) showed improvement. Statistical significance was observed when comparing the pre- and post-intervals for these variables. The EG blood RESULTS indicated nutrient improvement with $p<=0.05$ for blood glucose ($p=0.003$) and cholesterol ($p=0.001$) as opposed to the CG.

CONCLUSIONS
Better nutrition outcomes are achievable when using urban agriculture for sustainable food production and can contribute to household food and nutrition security.

POSITIONING NUTRIENT PROFILING AS A STRATEGY TO ASSESS SCHOOL FOOD POLICY: EVIDENCE AND IMPLICATIONS FROM CANADIAN SCHOOL FOOD PROGRAMS

Annette Blais[1]; Sarah Jeong,[1]; Mavra Ahmed[1]; Mary L'abbe[1]; Daniel Sellen,[1, 2]; Vasanti Malik,[1, 3]
[1]Department of Nutritional Sciences, University of Toronto, Toronto, Canada; [2]Department of Anthropology, University of Toronto, Toronto, Canada; [3]Department of Nutrition, Harvard University, Cambridge, United States of America

Background and objectives
School food programs (SFPs) influence children's dietary behaviors, health, and academic performance worldwide. However, many SFPs lack standardized frameworks for evaluating nutritional quality, limiting their long-term effectiveness. While Canada's recently released National School Food Policy emphasizes consistent and transparent monitoring, it does not mandate nutrition evaluation, and the variability among Canadian SFPs complicates routine assessment. This study introduces the Canadian Food Scoring System (CFSS), a nutrient profiling model (NPM) based on Canadian labelling regulations and Canada's Food Guide (CFG) 2019, to evaluate the nutritional quality of food items in Canadian SFPs. NPMs like the CFSS can support policy implementation by providing consistent, policy-driven tools for nutritional assessment, promoting healthier and more sustainable school food environments.

METHODS
SFP menu data were collected from school food providers across Canada. The nutritional quality of individual food items was assessed using the CFSS. Scores were weighted and summed based on the proportion of the Health Canada-defined Reference Amount (RA) each item contributed to the meal, with the total representing the meal's overall nutritional quality. Based on CFSS scores, meals and food items were classified into one of five categories: "excellent," "good," "fair," "poor," or "very poor" choice. Pearson's correlation was used to compare CFSS scores with Healthy Eating Food Index (HEFI) 2019 scores, an index of dietary quality measuring adherence to CFG 2019.

RESULTS
RESULTS from 70 SFPs serving over 20% of Canadian schools revealed CFSS scores of 65% of the maximum score for breakfasts, 56% for lunches, and 67% for snacks. Overall, 60% of food items and 57% of meals were classified as "good" or "excellent" choices, while 26% of food items and 15% of meals were classified as "poor" or "very poor" choices in accordance with CFG 2019 guidance. CFSS scores were moderately correlated with HEFI scores (r=0.67).

CONCLUSIONS
Although Canadian SFPs demonstrate moderate adherence to CFG 2019, a need remains for nationally harmonized systems to monitor their nutritional quality, particularly given the resource and capacity constraints faced by many existing programs. The CFSS and similar NPMs offer strong potential for routine SFP monitoring, supporting policy-driven nutritional improvements, informing future nutrition recommendations, and contributing to more sustainable school food systems both in Canada and globally.

EATING ARCHITECTURE AND CARDIOMETABOLIC HEALTH IN CHILDREN AND EARLY ADOLESCENCE

Francisca Ibacache[1]
[1]Bristol Medical School, University of Bristol, Bristol, United Kingdom

BACKGROUND AND OBJECTIVES

Existing findings on the relationship between eating architecture (EA) –which refers to the timing, size, and frequency of eating –and cardiometabolic health are both conflicting and limited mostly to adult populations. Little is known about how EA evolves during childhood and its implications for health. This study aims to examine the development of EA from childhood to adolescence and its relationship with cardiometabolic health.

METHODS

Linear regression was performed to study the associations between eating architecture (EA) patterns from principal component analysis (PCA) and cardiometabolic health indicators (e.g., BMI, waist circumference (WC), lipid profile, blood pressure) at ages 7 (n=7285), 10 (n=7470) and 13 years (n=6106) using data from the Avon Longitudinal Study of Parents and Children (ALSPAC), adjusting for relevant covariates. Sensitivity analyses assessed the impact of energy intake under-reporting. Estimates are presented as standardised coefficients (β), representing the change in the outcome variable (e.g., BMI) in standard deviations (SD) for each 1 SD change in the explanatory variable (i.e., EA patterns).

RESULTS

The 'Lunch' pattern was consistently associated with higher cardiometabolic risk across timepoints, exemplified at age 10y by its positive associations with BMI (β=0.09, 95% CI=0.06, 0.12, p<0.0001), WC (β=0.10, 95% CI=0.07, 0.12, p<0.0001), and triglycerides (β=0.05, 95% CI=0.01, 0.09, p=0.01), in addition to total energy intake (β=0.37, 95% CI=0.35, 0.39, p<0.0001). These associations were consistent in magnitude and direction across all timepoints. In contrast, the 'Breakfast' pattern showed little evidence of an association with increased cardiometabolic risk. While some associations were attenuated when analyses were restricted to valid reporters, such as between the 'Evening' and 'Late-evening' patterns and BMI, others, including 'Lunch' and 'Breakfast' pattern's associations with adiposity measures, remained robust.

CONCLUSIONS

Overall, earlier eating patterns were associated with more favourable health outcomes, while the 'Lunch' pattern was linked to higher cardiometabolic risk. These findings highlight the importance of considering the structure of eating throughout the day, beyond just diet composition, offering an opportunity to design targeted nutritional interventions that improve health by better managing eating patterns. Longitudinal analyses will further clarify the long-term impact of eating architecture on health, providing insights into how dietary behaviours evolve and persist over time.

ORGANIC FOOD CONSUMPTION AND RISK OF CANCER, TYPE 2 DIABETES MELLITUS AND CARDIOVASCULAR DISEASE IN THE DANISH DIET, CANCER AND HEALTH COHORT

Julie Louise Munk Andersen[1]; Kirsten Frederiksen,[2]; Cecilie Kyrø[1]; Christina C. Dahm[3]; Christian Sørensen Bork[4]; Kim Overvad[3]; Johnni Hansen,[5]; Ole Raaschou-Nielsen[5]; Anne Tjønneland[1]; Anja Olsen,[1]
[1]Diet, Cancer and Health, Danish Cancer Institute, København, Denmark; [2]Statistics and data analysis, Danish Cancer Institute, København, Denmark; [3]Public Health, Aarhus University, Bartholins Alle 2, Århus, Denmark; [4]Cardiology, Aalborg University Hospital, Aalborg, Ålborg, Denmark; [5]Work, environment and cancer, Danish Cancer Institute, København, Denmark

BACKGROUND AND OBJECTIVES

Organic agriculture and food consumption has grown substantially in recent decades. One major reason of organic food consumption is the perception of its potential health benefits, though evidence supporting these claims is limited. This study aimed to examine associations between organic food consumption and the risk of developing cancer, type 2 diabetes mellitus (T2DM), and cardiovascular disease (CVD).

METHODS

Data were obtained from the Danish Diet, Cancer, and Health cohort, comprising over 41,000 participants. Participants reported their organic food consumption for vegetables, fruits, dairy, eggs, meat, and bread/cereal products on a frequency scale: never, sometimes, often, and always. A composite organic food score was constructed and analyzed as both a continuous variable and in categories (never, low, medium, and high consumption). During follow-up, cases of cancer (n = 9,675), T2DM (n = 4,843), and CVD (n = 5,365) were identified through national health registries. Cox proportional hazards models, adjusted for sociodemographic and lifestyle factors, were used to estimate associations between organic food consumption and disease risk.

RESULTS

Overall organic food consumption was not associated with the risk of overall cancer and a number of major cancer sites. However, compared to never consuming organic foods, organic food intake was associated with a lower risk of stomach cancer (low: HR = 0.50, 95% CI: 0.32–0.78; medium: HR = 0.50, 95% CI: 0.32–0.80; high: HR = 0.54, 95% CI: 0.27–1.07) and a higher risk of non-Hodgkin lymphoma (low: HR = 1.45, 95% CI: 1.01–2.10; medium: HR = 1.35, 95% CI: 0.93–1.96; high: HR = 1.97, 95% CI: 1.28–3.04). Overall organic food consumption was linearly associated with a tendency towards a lower incidence of T2DM (Women, HR: 0.94, 95% CI: 0.89–1.00, Men, HR: 0.95, 95% CI: 0.90–1.00), and a lower incidence of CVD (both women and men, HR: 0.94, 95% CI: 0.89-0.99). Organic food consumption frequencies showed HRs below 1 for T2DM and CVD but were not statistically significant.

CONCLUSIONS

Organic food consumption was not associated with a lower cancer risk but demonstrated modest associations with lower risks of T2DM and CVD.

OAP18_01

TO BE CLIMATE-FRIENDLY, FOOD-BASED DIETARY GUIDELINES MUST INCLUDE LIMITS ON TOTAL MEAT CONSUMPTION – MODELING FROM THE CASE OF FRANCE

Emmanuelle Kesse-Guyot[1]; Julia Baudry[1]; Justine Berlivet[1]; Elie Perraud[2]; Chantal Julia[1]; Mathilde Touvier[1]; Benjamin Allès[1]; Denis Lairon[3]; Serge Hercberg[1]; Hélène Fouillet[2]; Philippe Pointereau[4]; François Mariotti[2]
[1]Équipe de Recherche en Épidémiologie Nutritionnelle (EREN), Sorbonne Paris Nord University, Inserm, CNAM, INRAE, Bobigny, France; [2]UMR PNCA, Université Paris-Saclay, AgroParisTech, INRAE, Palaiseau, France; [3]C2VN, AixMarseille Université, Inserm, INRAE, Marseille, France; [4]Solagro, Solagro, Toulouse, France

BACKGROUND AND OBJECTIVES

Although food-based dietary guidelines (FBDG) include guidelines for meat consumption, their setting most often do not explicitly include environmental considerations. For instance, in France, FBDG recommend consuming no more than 500 g of red meat and 150 g of processed meat per week. This study uses modeling to investigate the range of greenhouse gas emissions (GHGe) that can be achieved under FBDG compliance.

METHODS

The study analyzed data collected in 2014 from 29,413 NutriNet-Santé participants to assess their adherence to the French FBDG. GHGe, cumulative energy demand (CED), and land occupation (LO) for organic and conventional foods were obtained from the DIALECTE database.Diets adequate in nutrients, culturally acceptable, and consistent with FBDG were modeled under different GHGe constraints. Environmental, nutritional, and health criteria were then calculated. Models have been developed to modify red meat recommendations by imposing maximum thresholds on total meat consumption.

RESULTS

The average observed adequacy to FBDG was low (19%, SD=25%) and GHGe were 4.34 (SD=2.7%) kgCO2eq/d. The GHGe range of the diets varied from 1.16 to 6.99 kgCO2eq/d, depending up to ~85% on the level of meat consumption. Similar associations were observed for CED, LO and Health Risk Score. At isoenergetic diets, the diet with the lowest emissions had a higher proportion of vegetables, whole grains, and plant-based substitutes. This diet had a lower CED, LO, and a greater proportion of organic foods when compared to the diet with the highest emissions.

Decreasing the upper limit for total meat consumption from 500 to 200g/wk when identifying the healthy diets induced a decrease in their maximum total diet-related GHGe value, from 6.44 to 4.38 kgCO2eq/d.

CONCLUSIONS

While French dietary guidelines contribute, on average, to mitigating climate change and promoting health, this study emphasizes levers in recommended food consumption to more efficiently reduce diets' GHGe and points to total meat as the critical issue to better account for pressure on climate change. Other environmental pressures should also be considered when designing dietary guidelines.

AUSTRALIAN NUTRITION SCIENCE: A PROGRAMMATIC APPROACH TO IMPLEMENTING A NATIONAL STRATEGIC DEVELOPMENT PLAN

Helen Truby[1]; Margaret Allman-Farinelli[2]; Eleanor Beck,[3]; Emma Beckett,[3]; Catherine Bondonno,[4]; Aimee Dordevic,[5]; Katherine Livingstone[6]; Jane Willcox,[7]; Shelley Wilkinson[8]
[1]School of Primary and Allied Healthcare, Monash University, Melbourne, Australia; [2]Faculty of Medicine and Health, University of Sydney, Sydney, Australia; [3]School of Health Sciences, UNSW Sydney, Sydney, Australia; [4]Nutrition and Health Innovation Research Insitute, Edith Cowan University, Perth, Australia; [5]Dept Nutrition, Dietetics and Food, Monash un, Melbourne, Australia; [6]Institute of Physical Activity and Nutrition, Deakin, Melboune, Australia; [7]Faculty of Health, Charles Darwin University, Casuarina, Australia; [8]Obstetric Medicine, Mater Hospital Brisbane, South Brisbane, Australia

BACKGROUND AND OBJECTIVES

In 2019, the Australian Academy of Science supported a 10-year conceptual development plan entitled "Nourishing Australia: a decadal plan for the science of nutrition". The 2020 COVID-19 pandemic significantly impacted implementation activities. By 2022, a review of progress towards its stated goals (societal determinants, nutrition mechanisms, precision and personalised nutrition and education and training) and its envisioned new science platforms (a digital national data capability and a 'trusted voice' for nutrition science) was timely. This consultative process aimed to reflect on contemporary food, nutrition and health relationships and revise the goals of the decadal plan to reflect pertinent issues and co-design a five-year implementation strategy.

METHODS

Two separate engagement events, held during 2023, bringing together over 150 experienced, mid- and early-career nutritionists with the Academy. Facilitated reflection and discussion led to the co-creation of implementation logic models aligned with revised goals.

RESULTS

There was a clearly identified need for a greater focus on respectful engagement with Aboriginal and Torres Strait Islander communities and a sustained effort to build cross-disciplinary collaboration to realise the plan's societal determinants goals. A synthesis of the goals in the decadal plan resulted in a revised model which integrated precision and personalised nutrition with nutrition mechanisms and education and training became central to the plan rather than a cross-cutting theme. Achievement of work packages in these areas were determined to be necessary to demonstrate the need and support for a national nutrition data capability. A new collaborative of nutrition agencies, the 'Alliance for Nutrition Science Australia' was proposed to become a unified advocacy voice.

CONCLUSIONS

A national approach to develop nutrition science in Australia has been a valuable process, providing a model for engagement with early and mid-career nutritionists. The decadal plan supports aspirational goals. By applying programmatic implementation science processes, the necessary incremental steps towards those goals has commenced: building capacity and capability of the nutrition community. The implementation process provided opportunities to reflect on contemporary issues, including how to influence and build trust in the science of nutrition.

DOES VITAMIN A INTAKE ADVERSELY AFFECT BONE HEALTH?

Ionut Craciun[1]; Torsten Bohn[2]; Nena Karavasiloglou[1]; Georg Lietz[3]; Androniki Naska[4]; Giovanni Passeri[5]; Martínez, Silvia Valtueña[6]
[1]Nutrition and Food Innovation Unit, European Food Safety Authority, Parma, Italy; [2]Nutrition and Health Research Group, Department of Precision Health, Luxembourg Institute of Health, Strassen, Luxembourg; [3]Population Health Sciences Institute, Human Nutrition and Exercise Research Centre, Newcastle University, Newcastle upon Tyne, United Kingdom; [4]Dept. of Hygiene, Epidemiology and Medical Statistics, School of Medicine, National and Kapodistrian University of Athens, Athnes, Greece; [5]Department of Medicine and Surgery, University if Parma, Parma, Italy; [6]Nutrition and Food Innovation, European Food Safety Authority, Parma, Italy

BACKGROUND AND OBJECTIVES

Use of high-dose vitamin A supplements and/or frequent consumption of liver and offal may pose significant health risks. High intakes of preformed vitamin A (retinol and retinyl esters) have been associated with adverse effects on bone in animals and humans. However, preformed vitamin A, an essential nutrient, also plays a role in bone development and turnover. This systematic review focused on the relationship between preformed vitamin A intake, bone mineral density (BMD) and fracture risk in humans to determine whether preformed vitamin A adversely impacts bone health at daily doses below the current tolerable upper intake level (UL) of 3000 µg retinol equivalents (RE).

METHODS

The literature was searched in MEDLINE, Embase, and Cochrane Central Register of Controlled Trials to retrieve prospective cohort (PC) studies and randomised controlled trials (RCTs) that assessed the relationship between preformed vitamin A intake and changes in BMD and/or fracture risk.

RESULTS

Seventeen PC studies met the inclusion criteria; no eligible RCTs were identified. Nine PC studies reported on bone fractures, five on BMD, and three on both outcomes. The findings were mixed. Two studies in postmenopausal women indicated an increased risk of hip fractures at intakes of >1500 µg RE/day (OR 2.05; 95% CI 1.05–3.98) and >2000 µg RE/day (RR 1.89; 95% CI 1.33–2.68) compared to intakes <500 µg RE/day, whereas one study in older men reported an increased risk of any fracture (HR 2.00; 95% CI 1.00–3.99) at intakes >1500 compared to <500 µg RE/day. The remaining studies found no significant associations. Available data on BMD was likewise fragmented. Genetic, environmental, and age-related factors, including diet and medication use, were only partially and heterogeneously accounted for in the studies, adding to the uncertainties in characterising the exposure and interpreting the divergent evidence. A meta-analysis was not performed due to the insufficient number of studies and nature of potential sources of heterogeneity.

CONCLUSIONS

This review highlights the conflicting evidence regarding the relationship between preformed vitamin A on bone health in humans at intakes below the UL. While some PC studies report a higher risk of bone fracture at intakes between 1500 and 3000 ug RE/day, the overall body of evidence does not support the causality of such association. To better understand these potential risks, future RCTs testing doses within this range should include bone health outcomes as pre-specified endpoints or safety assessments.

FROM APPS TO BITES: THE IMPACTS OF THE DEVELOPING TECHNOLOGY ON FOOD MARKETING TO SCHOOL-AGED CHILDREN FOOD PREFERENCES

Nadhila Beladina[1]; Avita Usfar[1]; Esther Novalia[1]; Azka Fitri[1]; Iwan Ariawan[1]
[1]Research, Reconstra Utama Integra, Jakarta, Indonesia

BACKGROUND AND OBJECTIVES

The rising prevalence of non-communicable diseases (NCDs) in children marks a critical shift in global health, with conditions once common in adults increasingly affecting younger populations. Among the key factors is poor dietary pattern including consumption of energy-dense and nutrient-poor food. Technological advancements shape this behavior by influencing food preferences, promoting unhealthy eating through ads, and simplify access to such foods. This study explores how technological advancements—specifically social media, online food delivery platforms, and e-wallets—impact the eating behavior and food preferences of school-aged children, offering critical insights into the intersection of technology and childhood nutrition.

METHODS

Eight focus group discussions were held with 39 students from four junior and senior high schools in November 2024. Schools were intentionally selected from diverse socioeconomic areas to capture variability. Data were gathered and analyzed thematically.

RESULTS

All participants are actively using social media, online food delivery apps, and e-wallets. TikTok and Instagram effectively promote snacks, drinks, and "viral foods", which are often high in calories and sugar, persuading students to purchase them. Key convincing factors include influencers' credibility, engaging language, appealing visuals, promotion techniques, and number of positive feedback in their comment section. The delivery apps provide easy access to diverse food options, particularly when school or home offerings are limited, with no schools were observed to restrict their use. Promotional deals and discounts drive frequent orders. The students use the app 1-3 times weekly, often buying foods seen on social media out of curiosity. While all participants have e-wallets, daily usage was minimal. Students noted that higher e-wallet balances led to increased spending. Students from lower socioeconomic areas use delivery apps and e-wallets less often and limiting their spending to IDR 30,000 per food or beverage item, while students from higher socioeconomic areas spend between IDR 50,000 and 100,000 for a single product.

CONCLUSIONS

Technological advancements come as influences to students' food preferences and consumption patterns, which vary between the socioeconomic level. The study calls for future strategies to address technology-driven dietary behavior by highlighting salt, sugar, and fat content in a product and promoting nutrient-rich, healthier foods with minimal harmful components to support long-term health of school-aged children.

IMPORTANT REVISIONS TO THE NUTRI-SCORE TO ENHANCE CONSISTENCY WITH THE NORDIC NUTRITION RECOMMENDATIONS - INSIGHTS FROM THE NEWTOOLS PROJECT

Anna Amberntsson[1, 2]; Mari Mohn Paulsen[2, 1]; Marta Bianchi[3]; Bryndís Eva Birgisdóttir[4]; Anja Pia Biltoft-Jensen[5]; Dina Moxness Konglevoll[6]; Anne Lise Brantsæter[1, 2]; Kaja Lund-Iversen[7, 2]; Lene Frost Andersen[6]; Marianne Hope Abel[8, 9, 2]

[1]Department for Food Safety, Norwegian Institute of Public Health, Oslo, Norway; [2]Centre for Sustainable Diets, Norwegian Institute of Public Health, Oslo, Norway; [3]Food and Agriculture, Rise Research Institutes Of Sweden, Gothenburg, Sweden; [4]Unit for Nutrition Research, Faculty of Food Science and Nutrition, University of Iceland, Reykjavík, Iceland; [5]National Food Institute, Technical University of Denmark, Copenhagen, Denmark; [6]Department of Nutrition, University of Oslo, Oslo, Norway; [7]Research Administrative Support, Norwegian Institute of Public Health, Oslo, Norway; [8]Department of Physical Health and Ageing, Norwegian Institute of Public Health, Oslo, Norway; [9]Centre for Evaluation of Public Health Measures, Norwegian Institute of Public Health, Oslo, Norway

BACKGROUND AND OBJECTIVES

The Nutri-Score is a potential candidate for being a harmonized front-of-pack nutrition label in the European Union. However, inconsistencies between Nutri-Score, the Nordic Nutrition Recommendations and the Nordic Keyhole label have been identified within the NewTools project. This study aims to propose and evaluate revisions to the Nutri-Score 2023 algorithms to improve the overall performance and enhance the relevance of the nutrition label in the Nordic countries.

METHODS

Food items in the Norwegian pre-packed foods databases Tradesolution and Unil (n=26,610) were classified using the Nutri-Score 2023 version. To improve discrimination by carbohydrate quality, we propose a penalty for low fibre content in carbohydrate-rich foods and the sugar scale was compressed. To reward fish for its nutritional quality, we propose protein points for all fish products. To improve the variability for high-fat foods, we suggest several revisions, such as extending the scale and points for saturated fat, change the cut-off for inclusion in the algorithm for high-fat foods, and introduce a reward for favourable fat quality in oils. The distribution of Nutri-Score was calculated before and after applying the proposed revisions.

RESULTS

In total, 11% of all products were moved to a different class, of which 3% were moved to a better class and 8% to a poorer class. Most refined pastas shifted from A to B/C, while whole grain pasta largely remained A. Sugar-rich breakfast cereals could no longer obtain a B, and keyhole-labelled fish products could no longer get an E. Products with a high unsaturated fat content, such as mayonnaise, shifted from C/D to B/C. Cheese and cream products obtained much larger variations in scores by fat content.

CONCLUSIONS

The proposed revisions to the Nutri-Score enhanced the alignment with the Nordic Nutrition Recommendations and the Nordic Keyhole label improving its ability to guide towards healthier food choices. The proposed revisions also hold relevance for other European countries and should therefore be considered in future updates of the Nutri-Score algorithms.

OPTIMIZING ANTENATAL MULTIPLE MICRONUTRIENT SUPPLEMENT ADHERENCE IN CAMBODIA: A SOCIO-ECOLOGICAL APPROACH TO INCREASING UPTAKE

Mai-Anh Hoang[1]; Sambo Sreang[2]; Sokchea Meng[2]; Cassandra Sauer[3]; Aman Sen Gupta[4]; Kroeun Hou[2]; Rolf Klemm,[1, 5]; Crystal Karakochuk[6]
[1]Nutrition, Helen Keller Intl, New York, United States of America; [2]Nutrition, Helen Keller Intl Cambodia, Phnom Penh, Cambodia; [3]Food, Nutrition and Health, The University of British Columbia, Vancouver, Canada; [4]Nutrition, Helen Keller Intl Nepal, Lalitpur, Nepal; [5]Global Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, United States of America; [6]Food, Nutrition, and Health, The University of British Columbia, Vancouver, Canada

BACKGROUND AND OBJECTIVES

Many low and middle-income countries are considering a transition from iron-folic acid (IFA) to multiple micronutrient supplements (MMS) in antenatal care but require context-specific evidence on adherence to guide implementation. This study aimed to 1) identify factors associated with high and low adherence to MMS and 2) identify strategies to optimize adherence among pregnant women in Cambodia.

METHODS

This study analyzed data from 516 pregnant women who received 180 tablets of MMS at their first ANC visit during a cluster randomized controlled non-inferiority trial in Kampong Thom province Cambodia. Adherence to MMS was calculated by pill counts, and women were categorized as low adherers (<80% compliance), high adherers (>95% compliance), or those who discontinued MMS before their delivery. A purposive sample of 36 pregnant women (n=12 per category) across all three operational districts were selected to participate in semi-structured, in-depth interviews that explored perceptions, knowledge, and social influences on MMS adherence framed by the socio-ecological model.

RESULTS

Thematic analysis revealed that individual, interpersonal, and societal factors influenced adherence. Individual barriers included forgetfulness and negative pregnancy experiences (e.g., nausea, fatigue), while high adherence was linked to setting up routines to form a habit around taking MMS daily, placing the bottle in a strategic location in the home to act as visual reminders, and having positive beliefs in MMS benefits. Interpersonal barriers included strong norms around IFA and discouragement by family/friends from MMS intake during pregnancy-related symptoms. In contrast, reminders and positive reinforcement from family and endorsement by healthcare professionals during antenatal counseling visits were enablers for high adherence. Societal barriers included apprehension about the "newness" of MMS while social norms supporting prenatal vitamins facilitated adherence. Product characteristics like taste and ease of swallowing show minimal impact on adherence.

CONCLUSIONS

This study highlights the importance of a socio-ecological approach in understanding and improving MMS adherence among pregnant Cambodian women. Key factors include family involvement, targeted education, and reinforcing MMS benefits. To implement these findings, ANC programs should guide women in establishing reminders and routines, train providers in effective counseling, involve family members, implement reminder systems, address societal concerns through community education, and tailor interventions to individual needs.

ASSOCIATIONS OF GLOBAL BURDEN OF DISEASES STUDY-DERIVED DIETARY SCORES WITH MORTALITY AND CHRONIC DISEASE RISK: A COMPREHENSIVE ANALYSIS FROM THE PROSPECTIVE NUTRINET-SANTÉ STUDY

Emmanuelle Kesse-Guyot[1]; Julia Baudry[1]; Justine Berlivet[1]; Elie Perraud[2]; Benjamin Allès[1]; Chantal Julia[1]; Léopold Fezeu[1]; Serge Hercberg[1]; François Mariotti[2]; Mathilde Touvier[1]; Hélène Fouillet[2]
[1]Équipe de Recherche en Épidémiologie Nutritionnelle (EREN), Sorbonne Paris Nord University, Inserm, CNAM, INRAE, Bobigny, France; [2]UMR PNCA, Université Paris-Saclay, AgroParisTech, INRAE, Palaiseau, France

BACKGROUND AND OBJECTIVES
To reduce diet-induced morbimortality from chronic disease, the Global Burden of Disease (GBD) network has defined theoretical minimum risk exposure levels (TMREL) for specific food groups and nutrients. TMREL can inform dietary scores for health risk assessment in individual studies, constructed using various METHODS. The validity of these TMREL scores must be evaluated through associations with health outcomes in prospective cohorts.

METHODS
In this study conducted within the NutriNet-Santé cohort, four dietary scores (TMREL-Risk Score, TMREL-Probability of adequacy, TMREL-standardized distance, and TMREL dietary score) were developed using different scoring METHODS, where higher scores indicate less healthy diets. Associations between these scores and the risk of type 2 diabetes, cancer, cardiovascular diseases (CVD), and mortality were estimated using multivariable Cox proportional hazards models, adjusted for a wide range of covariates. Counterfactual and marginal structural models were used to infer causality. Analyses included up to 103,324 participants (78.3% women, mean age of 43.6 years [SD=14.6]), followed for a median of 8.47 years (IQR=14.7) from 2009 to 2024.

RESULTS

The associations were globally significant but varied in magnitude depending on the score used and health outcome considered. HRs ranged as follows: for mortality, from 1.12 (95%CI =1.07-1.18) for TMREL-Stdis to 1.18 (95%CI =1.12-1.24) for TMREL-DI; for overall cancer, from 1.07 (95%CI =1.03-1.12) for TMREL-RS to 1.09 (1.04-1.13) for TMREL-PA; for CVD, from 1.07 (95%CI =1.00-1.16) for TMREL-PA to 1.12 (95%CI =1.04-1.20) for TMREL-RS; and for type 2 diabetes, from 1.33 (95%CI =1.23-1.43) for TMREL-DI to 1.47 (95%CI =1.36-1.59) for TMREL-PA. Marginal structural Cox models strengthened all associations compared to classical analyses. Standardized survival curves revealed clear associations, particularly for cancer and type 2 diabetes risk.

CONCLUSIONS

Dietary scores based on GBD's TMREL can serve as key indicators for assessing diet quality in relation to long-term health, and the use of different scoring systems helped evaluate the robustness of these associations.

PROPOSED NUTRIENT PROFILES FOR ALTERNATIVE PROTEIN FOODS

Antonios Vlassopoulos[1]; Fatima Hachem[2]; Maria Xipsiti[2]
[1]Food Science & Human Nutrition, Agricultural University of Athens, Athina, Greece; [2]Food and Nutrition Division, Food and Agriculture Organization of the United Nations, Roma, Italy

BACKGROUND AND OBJECTIVES

At the 43rd Session of the Codex Committee of Nutrition and Foods for Special Dietary Uses, a proposal for "Guidelines including General Principles for the Nutritional Composition of Foods and Beverages made from Plant-based and other Alternative Protein Sources" and scientific advice from the Food and Agriculture Organisation (FAO) was requested.

METHODS

The derivation of nutrient profiles for meat and dairy imitation foods and beverages was organised in a series of three tasks. 1) a review of the literature on the nutritional composition of existing alternative protein sources , 2) a review of the existing regulatory or scientific composition standards (nutrient profiles) for meat/dairy imitations and 3) the proposal of a set of nutrient targets, nutrient profile, for meat/dairy imitation products. A pilot branded food composition database for existing meat/dairy imitation products was created from open access food data sources, to test the feasibility of the proposed nutrient and test the performance of the proposed nutrient profiles on real-life data.

RESULTS

The literature review identified 82,366 published reports, including n=45 reports on the nutritional composition of marketed alternative protein foods, n=58 reports on experimental foods and n=28 reports on the nutritive values of insects and insect-derived proteins. The most striking differences in composition were seen in plant-based dairy products as compared to their animal counterparts and mostly in cheese and milk imitations, which have significantly lower protein content than their animal-based counterparts. In the case of meat and fish imitations, the nutritional composition of imitations to their animal-based counterparts is comparable to a great extent. Examining regulatory and scientific standards across multiple regions the report found a lack of specific nutrient profiles tailored to alternative proteins while two Front-of-Pack labelling schemes propose nutrient targets for plant-based foods. The importance of considering protein quality indices was highlighted in the regulation without a clear consensus across countries.

CONCLUSIONS

The proposed nutrient profiles include protein, sodium, total fat and micronutrient targets and so acceptable feasibility.Although the protein and micronutrient targets are the main and most immediate interest in setting nutrient profiles for such foods and beverages, consideration of their nutrient profiles in a more holistic manner is needed to address their shortcomings in sodium and fat content. Protein quality adjustments may be of interest in the regulation of alternative protein foods but no proposal was currently made towards it.

OAP 34 - THE FUTURE OF NUTRITION RECOMMENDATIONS

OAP34_01

ARTIFICIAL INTELLIGENCE AND LARGE LANGUAGE MODELS TO MAKE NUTRITION INFORMATION MORE ACCESSIBLE

Samantha Huey[1]; Xingbo Wang[2]; Fei Wang[2]; Julia Finkelstein[1]; Saurabh Mehta[1]
[1]Joan Klein Jacobs Center for Precision Nutrition and Health, Cornell University, Ithaca, United States of America; [2]Population Health Sciences, Weill Cornell Medical College, New York, United States of America

BACKGROUND AND OBJECTIVES

Nutrition research is a complex field resulting in large amounts of data that need to be synthesized and disseminated. Large language models (LLMs) may be useful for managing these data in two ways: 1) distilling and extracting granular data from publications to allow for efficient evidence synthesis, and 2) making research accessible and disseminate over the 'last mile' for individuals who can directly apply them to their needs. User-friendly, AI-based chatbot interfaces represent a useful, modern approach to democratizing data access and distillation for multiple audiences/user-groups, including students, researchers, consumers, and policymakers.

METHODS

Through collaboration between domain knowledge experts in nutrition and specialists in the field of human-computer interaction, we have developed three LLM-based chatbots. These include 1) "Chat with Your Data" (CWYD), where users can upload a dataset and ask the chatbot questions about the dataset; 2) "SciDaSynth", which automatically extracts data from articles for evidence synthesis based on prompts from the user, trained on a micronutrient retention systematic review dataset; 3) "AI Health Information", a chatbot restricted to reputable/trustworthy sources on health and nutrition such as Cochrane, Campbell, Office of Dietary Supplements, and WHO. Coding for all chatbots was done in R and Python. For SciDaSynth, data extraction and structuring were done through retrieval augmented generation (RAG)-based technical framework using LLMs. Guardrails against hallucination, a common issue with LLMs, were also integrated into each chatbot.

RESULTS

CWYD successfully answers users' questions and generates visuals, tables, and plain language summaries from datasets, easily transferable to presentations for dissemination. SciDaSynth usability and effectiveness was tested among users who routinely conduct systematic reviews, finding favorable opinions as well as faster task completion times compared to traditional METHODS. Finally, AI Health Information deploys Fact Sheet-style output into the following format: Problem, Current WHO Recommendations, Current State of the Evidence, and Ongoing Clinical Trials, and includes citations, to assist multiple user groups in finding reputable information on a health or nutrition question quickly.

CONCLUSIONS

LLM-based chatbots can investigate users' questions from key data sources and output plain-language answers to questions, visualizations, as well as extract data for systematic reviews. LLMs represent a key innovation for evidence synthesis tasks as well as dissemination.

OAP34_02

THE CONSUMPTION OF POULTRY AND RABBIT PRODUCTS ENRICHED WITH ALGAL DHA IS AN INTERESTING STRATEGY FOR REDUCING THE DEFICIT OF THIS FATTY ACID IN THE FRENCH POPULATION

Clarisse Palacios[1]; Jacques Delarue[2]; Anne-Yvonne Prigent[3]; Michel Colin[4]
[1]Human Nutrition, COPRI SAS, Ploudalmézeau, France; [2]ER7479 SPURBO, Faculty of Medicine/University of Brest, Brest, France; [3]Finistère, EARL 3L, Ploudalmézeau, France; [4]Finistère, COPRI SAS, Ploudalmézeau, France

BACKGROUND AND OBJECTIVES

The average French consumption of DHA is lower than the official recommendations (1,750 mg / week) because the only significant sources are fish and certain offal's. However, it is possible to enrich egg, rabbit and chicken meat with DHA by incorporating algal DHA into the feed (1) with benefits presented here.

METHODS

Weekly DHA intakes were calculated for the average population and for a one consuming all the products presenting significant DHA intakes in 10 scenarios corresponding to the enrichment or not of the products mentioned above (STANDARD and ENRICHED) and to 5 types of food consumption: consumption corresponding to the INCA 3 study (A), consumption A without fish consumption (B), consumption B but doubling of egg consumption (C), consumption B but with increase of the rabbit meat consumption (the one of the 1980s) (D), consumption B with an increase in both egg and rabbit meat consumption (E). The DHA contents used in these calculations come from the Ciqual tables (2) for the standards products and from our researches for the enriched ones (1).

RESULTS

Table 1. Quantity of DHA mg/week with 'ENRICHED' and 'STANDARD' products

Diet	Average population		Product consumers	
	Quantity of DHA mg/week		Quantity of DHA mg/week	
	STANDARD	ENRICHED	STANDARD	ENRICHED
A	931	1 201	2 558	3 735
B	66	336	242	1 419
C	110	508	384	1 973
D	71	395	262	1 646
E	114	562	403	2 190

The DHA intake of consumers of DHA enriched eggs and rabbit/chicken meat increases significantly. It exceeds 3,500 mg/week when fish is also consumed, and 1,750 mg/week when not; if egg consumption doubles. However, the average intake of the population approaches 1,750 mg/week only when fish and enriched products are consumed.

CONCLUSIONS

Consumption of eggs and rabbit/chicken meat enriched with DHA makes it possible to achieve the primary prevention level even in the absence of fish, and the secondary prevention one in its presence. Increasing

https://doi.org/10.1017/jns.2026.10126 Published online by Cambridge University Press

consumption of DHA-enriched eggs and rabbit meat is an interesting strategy for reducing deficiency in this fatty acid.

ASSOCIATIONS BETWEEN THE CONSUMPTION OF ARTIFICIAL SWEETENERS, EXCESS WEIGHT GAIN AND GUT MICROBIOTA DIVERSITY IN THE NUTRINET-SANTÉ PROSPECTIVE COHORT STUDY

Leopold Beeker[1]; Guillaume Javaux[1]; Fabien Szabo De Edelenyi[1]; Cédric Agaësse[1]; Alexandre De Sa[1]; Anaïs Hasenböhler[1]; Marie Payen de la Garanderie[1]; Serge Hercberg[1]; Bernard Srour[1]; Benoit Chassaing[2, 3]; Mathilde Touvier[1, 3]; Mélanie Deschasaux-Tanguy[1, 3]
[1]Centre of Research in Epidemiology and StatisticS, Nutritional Epidemiology Research Team (EREN), Université Sorbonne Paris Nord and Université Paris Cité, INSERM, INRAE, CNAM, Bobigny, France; [2]Microbiome/Host Interactions Team, Institut Pasteur, INSERM, Université Paris Cité, Paris, France; [3]Co-last, Authors, Paris, France

BACKGROUND AND OBJECTIVES
Reducing sugar intake to prevent chronic diseases is recommended by the WHO. As an alternative, the use of artificial sweeteners in food and beverage has increased. Yet, the long-term impact of using artificial sweeteners on weight status or chronic disease incidence is still debated, notably in light of experimental and epidemiological RESULTS showing adverse outcomes, including through alterations of the gut microbiota. Our study's objective was therefore to investigate associations between the consumption of artificial sweeteners and excess weight gain, as well as gut microbiota diversity.

METHODS

Our analyses included 101,182 adults from the French NutriNet-Santé prospective cohort study followed since 2009. Repeated 24-hour dietary records, including brands for industrial products, linked with data on qualitative and quantitative content in food additives, were used to assess intakes of artificial sweeteners from all dietary sources. Weight and height were collected every 6 months through a validated online questionnaire. Fecal microbiota profiles were derived from 16S rRNA sequencing of stool samples collected in a subcohort in 2024. Associations between intake of artificial sweeteners (total and most consumed: aspartame, acesulfame K, sucralose), BMI gain, risk of excess weight, and fecal microbiota alpha-diversity were studied using multi-adjusted mixed, Cox or ANCOVA models, respectively.

RESULTS

Compared with non-consumption, a higher intake of artificial sweeteners (> sex-specific median) was associated with higher BMI gain (β higher consumers x time = 0.02, P < 0.001) as well as a higher risk of overweight (9641 / 367,549 person-years; HR=1.37 [1.28-1.47], P-trend < 0.001) and obesity (4062 / 531,650 person-years; HR=1.45 [1.32-1.59], P-trend < 0.001). Preliminary analyses including 3659 fecal microbiota profiles also suggested a trend toward lower diversity (richness: β= -3.18, P=0.02; Shannon index: β= -0.04, P=0.05) associated with higher consumption of artificial sweeteners.

CONCLUSIONS
In this study, a higher consumption of artificial sweeteners was associated with a higher risk of excess weight gain, and with a lower gut microbiota diversity (preliminary data). These RESULTS suggest potential long-term adverse effects of the consumption of artificial sweeteners at doses below the admissible daily intake, and therefore provide important data for safety assessment. Further analyses of gut microbiota composition are ongoing.

CONFLICTS OF INTERESTS
The authors have no conflict of interest.

BACKGROUND AND OBJECTIVES

The consumption and supply of plant-based analogues of meat and animal products, such as plant drinks made from soya or oats, patties or burgers made from cereals or pulses, have developed considerably in recent years. However, there is no questionnaire that is both short and comprehensive enough to provide a detailed estimate of the diversity of consumption of these relatively new foods. The main aim of this study was to create a short food frequency questionnaire (FFQ) targeting these products. The secondary objective was to analyse the data obtained from this questionnaire in order to estimate the consumption of these foods in a large sample from a prospective French cohort.

METHODS

The questionnaire was designed on the basis of a litterature review, with a focus on existing FFQs. A survey of products available on the French market was also carried out. The design of the FFQ items was based on the validated METHODS of measurement of both frequencies and quantities from the SU.VI.MAX and NutriNet-Santé studies. Preliminary descriptive statistics aimed to describe the frequency of consumption of these foods, in the total sample and by groups of individuals following diets that reduce or exclude animal products (vegetarianisms), using univariate statistical tests.

RESULTS

We identified 1,941 foods that were gathered into 6 dietary analogue groups based on their main ingredient (e.g. legumes or cereals), corresponding to 128 food items in the final questionnaire. The highest frequencies of foods that participants declared to consume weekly were: vegetable drinks (13.8% of the sample), vegetable patties, burgers or steak (7.9%) and tofu (3.9%). The percentage of individuals consuming these analogues on a weekly basis by types of diet is presented in the following table:

Plant foods	Tot. n = 14,928	Meat eaters, n = 3,591	Meat reducers n = 9,729	Fish eaters n=675	Vegetarians n = 620	Vegan n = 313	p-value (Chi²)
Milks	13,8%	6,4%	12,4%	29,5%	37,4%	59,7%	<0,001
Burgers	7,9%	1,8%	6,1%	28,3%	31,8%	41,9%	<0,001

https://doi.org/10.1017/jns.2026.10126 Published online by Cambridge University Press

Tofu	3,9%	0,8%	2,3%	11,9%	20,6%	41,9%	<0,001

CONCLUSIONS

The questionnaire enabled a detailed measurement of the consumption of plant based analogs of animal products. This questionnaire should provide a better understanding of their impact on health over time to enhance future dietary guidelines.

CONFLICTS OF INTERESTS

The authors have no conflict of interest.

OAP34_05

PLANETARY HEALTH DIET COMPARED TO DUTCH DIETARY GUIDELINES: NUTRITIONAL CONTENT AND FOOD GROUPS CONTRIBUTIONS

Julieth Uriza-Pinzón[1]; Fleur Verstraete Femke[2]; Oscar H Franco[1]; Vicente Artola Arita[1]; Mary Nicolaou[3]; Yvonne Van Der Schouw[1]
[1]Global Public Health and Bioethics, UMC Utrecht, Utrecht, Netherlands; [2]Nutrition, Wageningen University & Research, Wageningen, Netherlands; [3]Department of Public and Occupational Health, VU University Medical Center, Amsterdam, Netherlands

BACKGROUND AND OBJECTIVES

To compare the PHD with DDG in terms of food groups, servings, nutritional content, and food groups contributions.

METHODS

We modeled two theoretical diets, the PHD (PHD-NL) and another based on the DDG (DDG-NL), using the Dutch National Food Consumption Survey (FCS-2016) and Dutch Food Composition Database to calculate the nutritional content and compared it within the food groups contributions for all the nutrients.

RESULTS

The PHD included higher quantities of vegetables, fish, legumes, and nuts, while the DDG suggested more significant amounts of cereals, tubers, starchy vegetables, dairy, and red meat. We observed differences in macronutrient distribution; while both diets lacked sufficient vitamin D, calcium content was lower in the PHD-NL. The PHD-NL had higher levels of fiber, vegetable protein, unsaturated fats, and non-heme iron, while vitamins B2, B6, B12, and calcium were lower than in the DDG-NL diet. In these healthy, sustainable diets, rice, wheat, corn, and whole grains had a contribution ≥30% of total content for nutrients like polysaccharides, fiber, copper, iron non-heme, iodine, magnesium, sodium, phosphorus, and zinc. Dark green vegetables had the biggest contributions of beta-carotene and vitamin K. Dairy contributed ≥30% of total content for animal protein, calcium, iodine, and vitamin B2. Chicken, meat, and eggs had ≥30% of total content for hem iron, retinol, and vitamin B12. Fish for polyunsaturated fats (EPA, DHA). Spreadable fats and cooking fats had a contribution ≥30% of total content for unsaturated fats, folic acid artificially added, vitamin D, and E.

CONCLUSIONS

Flexitarian diet orientations like PHD and DDG included a variety of food groups. Plant-based food groups like whole grains and dark green vegetables contribute significantly to achieving a diet with nutritional density. Also, some animal food groups like dairy, chicken, meat, eggs, and fish have good contributions for different nutrients, with major attention to calcium, hem iron, vitamin B12, retinol, and marine fatty acids. Finally, fats, mainly plant-based, had an important contribution to vitamins D and E in front of other food groups. These findings have implications for the adoption of healthy, sustainable diets according to the contributions from different food groups, even with limitations or less consumption, as they are a good source of nutrients.

MAPPING SPATIAL PATTERNS OF THE PHYSICAL FOOD ENVIRONMENT OF KUALA LUMPUR MALAYSIA: A GIS AND PARTICIPATORY APPROACH

Scott Hastie[1]; Siew Siew Lee[1]; Trylee Nyasha Matongera,[1]; Festo Massawe,[1]; Ee Von Goh[2]; Alex Lechner,[3]
[1]School of Biosciences, University of Nottingham Malaysia, Semenyih, Malaysia; [2]Healthy Diets Flagship, World Vegetable Center, Tainan, Taiwan; [3]Urban Design, Monash University, Indonesia, Jakarta, Indonesia

BACKGROUND AND OBJECTIVES
The food environment is closely associated with community health status. However, the food environment is less well understood in a low-middle income country like Malaysia, due to its complex landscape, shaped by diversity, economic disparity, and the co-existence of formal and informal food outlets. The heterogeneity of METHODS in mapping the physical food environment has resulted in divergent findings. This study aims to map spatial patterns of the physical food environment and determine the availability of different food outlet typologies in Kuala Lumpur, Malaysia.

METHODS

This cross-sectional study maps formal and informal food outlets using secondary data and public participatory GIS (PPGIS). Participants will help empirically map the food environment, followed by ground-truthing field census to validate geographic data. Attributes of food outlets will include typology, operating hours, availability of delivery service, and categorisation as healthy, unhealthy or mixed. Descriptive analyses will be conducted to describe the overall availability, count and density of different food outlet typologies and its categories. Pearson chi squared test and logistic regression will be performed to test the associations between food outlet typologies and health status of the participants collected from the PPGIS survey. Geo-coding and analysis will be performed using ArcGIS Pro Version 3.3.

RESULTS

It is anticipated that mapping the physical food environment will reveal a higher density of informal food outlets in lower-income neighbourhoods compared to formal outlets. The spatial analyses are expected to reveal clustering of unhealthy food outlets, particularly in urban poor areas, potentially contributing to the prevalence of diet-related NCDs. The PPGIS data may uncover additional food outlets not previously recorded through secondary data. Ground-truthing will validate most of the data, with discrepancies arising mainly in areas where informal outlets are undocumented. The findings are expected to highlight spatial inequalities in food availability and its association with community health status.

CONCLUSIONS

Mapping the physical food environment in Malaysia is crucial for understanding spatial patterns and identifying opportunities for an improved food environment. This approach integrates empirical evidence with community perspectives to inform upstream public health nutrition policies that support sustainable and healthy diets.

RECOMMENDATIONS TO ADDRESS THE SHORTFALLS OF THE EAT–LANCET PLANETARY HEALTH DIET FROM A PLANT-FORWARD PERSPECTIVE

Anna-Lena Klapp[1]; Nanine Wyma,[2]; Roberta Alessandrini[3]; Catherine Ndinda[4]; Federico Perez-Cueto[5]; Antje Risius[1]
[1]Department of Agricultural Economics and Rural Development, University of Göttingen, Göttingen, Germany; [2]Africa Unit for Transdisciplinary Health Research, North-West University, Potchefstroom, South Africa; [3]Wolfson Institute of Population Health, Queen Mary University of London, London, United Kingdom; [4]Human Sciences Research Council, Human Sciences Research Council, Pretoria, South Africa; [5]Research Group Sustainable Food Transitions, Department of Food, Nutrition & Culinary Science, University of Umea, Umea, Sweden

BACKGROUND AND OBJECTIVES

Shifting to dietary patterns rich in plants and low in animal-source foods could substantially lower emissions from the food sector while reducing the global burden of non-communicable diseases. The EAT–Lancet Commission proposed the planetary health diet (PHD) to emphasise plant-forward diets and set global targets to guide an urgently needed food-system transformation. However, the PHD's meat-reduction approach has attracted criticism and prompted debate on the potential micronutrient shortfalls of the plant-forward dietary approach. Since the planet simply cannot sustain human diets defaulting towards animal-based solutions, the objective of this paper is to provide recommendations that address the shortfalls of the PHD, with an emphasis on plant-based sourcing of food.

METHODS

Beginning with a socioecological framework similar to that used by other food system analyses, we further narrowed down the framework by using the Integrative Sustainability Framework (developed by Ahmed and colleagues, 2019) for evaluating national and regional dietary guidelines. To provide an empirical grounding for this paper, we conducted a review of both the academic and grey literature (in English), with the aim of providing an overview of findings from peer-reviewed articles and relevant reports, and documents from the databases of UN agencies and intergovernmental and non-governmental organisations.

RESULTS

Seven key thematic areas have been identified for further development of the PHD. The thematic areas include the bioavailability of plant-based foods and how to improve them; the inclusion of indigenous foods that are nutrient-rich, climate-resilient, economically affordable, and locally available; the options of fortification and supplementation; greater awareness of dietary inclusiveness, consideration of gender-based differences; a broader perspective on highly processed foods; and the need for an alignment with a holistic approach, such as One Health, which promotes the health of humans, animals, and the environment.

CONCLUSIONS

The evidence clearly shows that people and the planet cannot afford to simply default towards animal-based diet solutions. But it is also clear that we need a holistic view of the opportunities and challenges associated with a plant-forward approach to diets. Sometimes that means looking back and recognising traditional knowledge, and sometimes that means breaking with tradition and being open to new technologies.

IMPACT OF ULTRA-PROCESSED AND MINIMALLY PROCESSED DIETS FOLLOWING UK DIETARY GUIDANCE ON PHYSICAL FITNESS: A RANDOMISED, CROSS-OVER, CONTROLLED FEEDING CLINICAL TRIAL

Samuel Dicken[1]; Friedrich Jassil[2]; Janine Makaronidis[3]; Adrian Brown[3]; Monika Kalis[3]; Tapiwa Ruwona[3]; Kevin Hall[4]; Chris Van Tulleken[5]; Claudia A. M. Gandini Wheeler-Kingshott[6]; Abi Fisher[7]; Rachel L. Batterham[3]

[1]Centre for Obesity Research and Behavioural Science and Health, UCL Main Campus, London, United Kingdom; [2]Service of Endocrinology, Diabetology, Nutrition and Therapeutic Education, University of Geneva, Geneva, Switzerland; [3]Centre for Obesity Research, UCL Main Campus, London, United Kingdom; [4]National Institute of Diabetes and Digestive and Kidney Diseases, NIH, Bethesda, United States of America; [5]Infection and immunity, UCL Main Campus, London, United Kingdom; [6]Institute of Neurology, UCL Main Campus, London, United Kingdom; [7]Behavioural Science and Health, UCL Main Campus, London, United Kingdom

BACKGROUND AND OBJECTIVES

Little is known about the impact of food processing on physical fitness. This study aimed to compare changes in physical fitness between 8-week minimally processed food (MPF) and ultra-processed food (UPF) diets following UK Eatwell Guide (EWG) recommendations.

METHODS

This is a 2x2 crossover randomised controlled feeding trial (NCT05627570). Inclusion criteria included age ≥18, body mass index (BMI) ≥25 and <40 kg/m2, and ≥50% of habitual dietary intake from UPF. Participants were provided with an *ad libitum* 8-week MPF diet and an 8-week *ad libitum* UPF diet, both following EWG recommendations, in a random order. Diets were delivered to participants' homes. Participants were not informed of the food processing groups. Allocation was not concealed from researchers. The primary outcome was percent weight change (reported elsewhere). Exploratory secondary physical fitness outcomes included within-participant differences in the 6-minute walk test (6MWT), sit-to-stand test (STS) and handgrip strength test (HGST) at 8 weeks between UPF/MPF diets. Mixed-effects models were used to assess changes in outcomes.

RESULTS

Between April 2023 and May 2024, 55 individuals were recruited (n=28 to MPF then UPF, n=27 to UPF then MPF diet); 50 participants comprised the intention-to-treat sample. At 8 weeks compared with baseline, 6MWT distance (MPF: 16.3 m (95% confidence interval (95%CI): 4.0, 28.6); UPF: -1.7 m (95%CI: -13.7, 10.4)) was significantly longer on the MPF diet, and STS duration (MPF: -0.7 s (95%CI): -1.1, -0.3); UPF: -0.2 s (95%CI: -0.6, 0.2)) was significantly shorter on the MPF diet, but both were unchanged on the UPF diet. 6MWT post-test heart rate (HR), 6MWT rating of perceived exertion (RPE) and HGST were not significantly different at 8 weeks from baseline on either diet. Improvements in 6MWT distance and STS duration at 8 weeks from baseline were significantly greater on the MPF than UPF diet (Δ6MWT: 18 m (standard error (SE): 7.3), p = 0.017; ΔSTS: -0.5 s (SE: 0.2), p = 0.023). There were no significant differences in changes in 6MWT HR, 6MWT RPE or HGST between diets (6MWT HR: p = 0.070; 6MWT RPE: p = 0.194; HGST right hand max: p = 0.086; HGST left hand max: p = 0.452; HGST dominant hand max: p = 0.196).

CONCLUSIONS

https://doi.org/10.1017/jns.2026.10126 Published online by Cambridge University Press

Eight weeks of diets following national dietary guidance resulted in neutral or favourable changes in physical fitness, with significant differences in 6MWT and STS between diets. The RESULTS highlight important impacts of food processing on physical fitness.

NOVEL APPLICATION OF SYSTEM SCIENCE TOOLS IN STRATEGIC PLANNING FOR THE FUTURE OF NUTRITION

Ihuoma Eneli[1]; Stephanie Gilley[1]; Boyle Kristen[1]; Noel Mueller[1]; Amy Bartoshesky[1]; Richard Boles[1]; Douglas Taren[1]
[1]Section of Nutrition, Department of Pediatrics, University of Colorado School of Medicine, Aurora, United States of America

BACKGROUND AND OBJECTIVES
The complex and shifting landscape of global nutrition challenges the field to re-evaluate our vision and approach to identify future directions. Standard approaches used to build evidence, develop programs, and inform policy fail to consider the complexity of systems, heterogeneity in nutrition and the experience, insight, and priorities of those most affected. System science offers novel METHODS and tools to engage with complex problems, implement potential solutions and develop data for future recommendations.

Using a case study, we describe the application and translation of system science tools for strategic planning at a pediatric nutrition Department.

METHODS

Initial steps included a review of multisector determinants and drivers of nutrition, actionable evidence by authoritative organizations, and analysis of the Department's strengths, weakness, opportunities, and threats in research, education, clinical services, advocacy, and outreach. Information garnered from these processes informed Group Model Building (GMB) workshops, system design, and traditional strategic planning. The Donatella Meadows Framework was used to identify deep leverage points that can drive the future vision and build a pragmatic roadmap.

RESULTS

Department team members and stakeholders engaged in GMB exercises to develop a nutrition causal map. Leverage points within the causal map were overlaid with aligned solutions. Using the Meadows framework, the top four leverage points that were identified to guide the future of the Nutrition Section were (1) creativity & innovation, (2) identity/wellbeing, (3) revenue opportunities/streams, and (4) visibility of the academic pillars of education, research, clinical and community/advocacy. The two deepest leverage points likely to drive a paradigm shift for the Department were diversification of revenue and definition of Department identity, reflecting the tension between idealistic and pragmatic visions. Recommended topical areas within the leverage points that aligned with the Department's mission included public health and nutrition (undernutrition, overnutrition, micronutrient deficiency) through the life cycle, precision nutrition, the intersection of disordered eating and nutrition, and community education.

CONCLUSIONS
System science METHODS were successfully used to determine key leverage points with the highest probability for impact and innovation. Using a similar approach may benefit nutrition organizations who are evaluating their trajectory, vision and future goals.

OAP 49 - THE FUTURE OF NUTRITION RECOMMENDATIONS

OAP49_01

UNDERSTANDING TRADE-OFFS: COST-EFFICIENCY VS. COVERAGE IN VITAMIN A SUPPLEMENTATION STRATEGIES IN CÔTE D'IVOIRE

Melissa Baker[1]; Lyonel Nerolin Doffou Assale,[2]; Ahmenan Claude Liliane Konan,[2]; Ama Emilienne Yao,[3]; Agnes Helen Epse Assagou Mobio,[4]; Oka René Kouame,[3]; Romance Dissieka[2]; David Doledec,[1]; Hubert Zirimwabagabo,[5]
[1]Vitamin A Supplementation, Helen Keller International, Nairobi, Kenya; [2]Vitamin A Supplementation, Helen Keller International - Côte d'Ivoire, Abidjan, Ivory Coast; [3]Programme Nationale de nutrition, Ministère de la Santé et de l'Hygiène Publique, Abidjan, Ivory Coast; [4]Vitamin A Supplementation, Helen Keller Internationa, Abidjan, Ivory Coast; [5]Helen Keller International, Helen Keller International, Abidjan, Ivory Coast

BACKGROUND AND OBJECTIVES

In 2018, Côte d'Ivoire transitioned to routine vitamin A supplementation (VAS) through health facilities, community fixed sites, and door-to-door catch-up events. This study evaluates the cost-effectiveness and coverage of these strategies in Ferkessédougou and Niakaramadougou from July-December 2023.

METHODS

Coverage data were collected from 2,706 households with children aged 6–59 months using post-event coverage surveys with a two-stage cluster sampling design. Cost data were obtained from 91 stakeholders across 16 health facilities, four regional offices, and nine partner organizations. Cost-effectiveness was calculated by dividing total costs per district by the number of children supplemented for each strategy.

RESULTS

In the second half of 2023, the total cost of the VAS program was approximately USD $40,895.95 (47.2% from Ferkessédougou; 52.8% from Niakaramadougou). Among all strategies employed in the two districts, the catch-up strategy in Niakaramadougou (Dec 2023) was the most expensive at USD $8,956.37, while the health-facility distribution strategy in both districts had the lowest costs averaging USD $6,801.11. Ferkessédougou achieved a coverage rate of 8.7% at health facilities and 51.2% for the advanced strategy. In Niakaramadougou, coverage was 20.4% at health facilities and 43.3% for the catch-up strategy. Within the districts, the cost per child supplemented was lowest in Ferkessédougou for the advanced strategy (USD $0.78), while the July 2023 catch-up campaign had the highest cost per child at USD $2.50.

CONCLUSIONS

The study highlights a trade-off between cost-efficiency and coverage, with advanced strategies offering cost-effectiveness and catch-up events providing higher coverage at higher costs.

LEVERAGING BINTI GROUPS (ANTENATAL (ANC) GROUPS) TO EMPOWER PREGNANT ADOLESCENT GIRLS AND YOUTHS TO ADDRESS HEALTH AND NUTRITION NEEDS FOR MATERNAL AND INFANT WELL-BEING

Esther Njeri[1]; Pauline Kariuki[1]; Caleb Ombati[2]; Velma Hongo[1]; Benjamin Kihika[2]; Joan Othieno[3]
[1]Health and Nutrition, Helen Keller Intl-Kenya, Nairobi, Kenya; [2]Health & Nutrition, Helen Keller Intl-Kenya, Nairobi, Kenya; [3]Research and Gender, Helen Keller Intl-Kenya, Nai, Kenya

BACKGROUND AND OBJECTIVES

Pregnant adolescent girls face health risks and complications due to their unformed bodies. Their access to antenatal care services remains low, despite their heightened need for close monitoring. The objective of the Binti group; is to offer a platform to empower them by providing peer support and targeted education on health, nutrition, and self-care during and after pregnancy. This abstract explores how Helen Keller supported Kilifi County, Kenya to use Binti groups in equipping this group with the knowledge, skills, and resources to navigate health and nutritional needs, improve pregnancy outcomes, and foster self-care.

METHODS

The Binti groups used a program implementation approach where the health facility mobilized pregnant women to come for antenatal care on a set date. Later, the women are categorized by age to join Mama -above 25years or Binti-below 24years groups. Each group is given the same return dates for consecutive visits. The adolescent and youth will join the Binti groups and during each month they visit the health facility together where the health workers provide the antenatal services and monitoring and later counsel the women in a group setting providing a free space for learning and consulting. Binti groups utilize a peer-centered approach, integrating antenatal care services with tailored education sessions on maternal nutrition, infant care, and psychosocial well-being. Through participatory learning techniques these groups address barriers to health-seeking behaviors while fostering a sense of community and resilience. These is complemented by support for kitchen gardens and village savings to empower the women.

RESULTS

Findings from two sampled health facilities that started implementing ANC groups in Jan 2023 demonstrated a 59% increase in number of women completing 4 ANC visits and 5% increase in skilled delivery by June 2024. Anecdotal findings indicate that Binti groups improves early attendance and adherence to antenatal care, increase knowledge on diet and improve self-care among the women. By creating a supportive environment, these groups also mitigate stigma and isolation often experienced by pregnant adolescnts.

CONCLUSIONS

Using Binti groups has improved adherence and early attendance to ANC and therefore receiving prenatal supplements early. The groups also provide a safe space for learning good nutrition overall health and preparation for motherhood. Future efforts should focus on scaling up these interventions, integrating them into national ANC frameworks, and assessing their long-term impact on maternal and infant health outcomes.

FOOD DATABASE REMAINS THE MOST CHALLENGING FOR THE AI-APPLIED NUTRITION CONSULTATION SYSTEM IN DIETARY INTAKE MEASUREMENT AND MEAL PLANNING

Ngan Thi Duc Hoang[1]; Tuyen Danh Le[2]; Tran Thanh Duong[3]; Nghien Thi Thao Hoang[4]; Yen Thi Thao Bui[1]; Duc Anh Ha[5]; Hai Ngoc Phung[6]
[1]Community Nutrition Department, National Institute of Nutrition, Hanoi, Vietnam; [2]Department of Nutrition Surveillance and Policy, National Institute of Nutrition, Hanoi, Vietnam; [3]Director, National Institute of Nutrition, Hanoi, Vietnam; [4]University of Medicine and Pharmacy, Vietnam National University, Hanoi, Vietnam; [5]Department of Medical Service Administration, Ministry of Health, Hanoi, Vietnam; [6]School of Detistry and Medicine, Griffith University, Brisbane, Australia

BACKGROUND AND OBJECTIVES

The rapid advancements in artificial intelligence (AI) have paved the way for innovative healthcare solutions, particularly in low- and middle-income countries. This study was to develop the first-ever AI-powered nutrition consultation system in Vietnam.

METHODS

A database of food and meals (1500 food and meals) and anthropometry (over 100,000 records) and a knowledge base on community nutrition and dietetics were developed to design a smart system (an app) to monitor and provide nutritional consultation to communities and patients with overweight, obesity, undernutrition, hypertension, and diabetes in the country. A trial was conducted on approximately 6,000 community users and 4,290 consultations in 4 hospitals. The community users were instructed to access and obtain nutrition consultations from the app. Hospital health workers were trained to utilize the app in their routine health examination and consultation process.

RESULTS

The app was assessed to be accurate and suitable for the participants. The responding time was mainly acceptable, and the general interface was friendly and easy to use. The app provided hypertension levels, assessed nutrition-related disorders, measured dietary intake, and made meal planning for 100% of participants, with 33.3% at a good level and 60% at a fair level. 86.7% of health workers agreed that the app was effective and helpful for their work. The most challenging function was meal planning. Initial evaluations indicate significant potential for improving healthcare outcomes, enhancing patient education, and fostering proactive health management in communities.

CONCLUSIONS

This study highlights the transformative role of AI in addressing challenges in personal health monitoring. It is recommended to enrich the food and meal database to improve the efficacy of the app in healthy meal planning and nutrition consultation.

NUTRIENT COMPOSITION OF PLANT-BASED MILK ALTERNATIVES COMPARED TO COW'S MILK

Hettie Schönfeldt[1]; Elaine Pieterse[1]; Beulah Pretorius[1]
[1]Department of Animal Science, University of Pretoria, Pretoria, South Africa

BACKGROUND AND OBJECTIVES

The world is confronted with two significant challenges: various forms of malnutrition (hunger, obesity, and micronutrient deficiencies) and the rapid depletion of environmental and natural resources. This situation highlights the urgent need for environmentally sustainable diets and conducive to better health. However, there is currently insufficient evidence supporting the nutritional adequacy of plant-based diets. Additionally, research on the environmental impacts of plant-based diets is limited compared to the extensive studies on other food products, like dairy, which have more established life cycle assessments. A healthy diet does not necessarily equate to a lower carbon footprint, and an environmentally sustainable diet is not inherently healthy. Plant-based diets are not conclusively more sustainable and healthier than animal-based diets, and substitutions can sometimes yield unexpected RESULTS. The study aims to determine the nutrient composition of plant-based milk alternatives (PBMA) in the South African retail market and compare it to cow's milk, lactose-free milk, and front-of-pack-label nutrient values.

METHODS

For this analysis, a total of 60 PBMAs and 45 UHT cow's milk product samples were selected. To ensure a representative sample from different batches, the same brands of PBMAs and cow's milk products with three different production dates were chosen. The samples were analysed for moisture, ash, fat, protein, dietary fibre, carbohydrate and mineral content, in duplicate by an accredited laboratory.

RESULTS

The energy content of PBMAs is lower than the energy content of cow's milk, except for coconut PBMA. Except for soy PBMA, the rest of the PBMAs present a low protein and fat content. Except for the unsweetened soy and almond PBMA, the rest of the PBMAs have a high sugar content. Regarding minerals and vitamins, some PBMAs present equal or even higher contents than cow's milk, but bioavailability and absorption of nutrients may be compromised due to the presence of bioactive compounds or antinutrients in PBMAs.

CONCLUSIONS

It is evident that PBMAs are not a replacement for cow's milk and that cow's milk is higher in nutritional value. With fortification, PBMAs can be consumed as a cow's milk alternative, and although not the same as cow's milk, it can also be part of a healthy diet.

Multiple Micronutrient Supplementation Adherence During Pregnancy in Nepal: RESULTS from the Non-inferiority Assessment of Maternal Adherence to Supplementation: A Trial on the Effects of MMS (NAMASTE-MMS)

Sasmita Poudel[1]; Kenda Cunningham[2]; Rolf Klemm,[3, 4]; Mai-Anh Hoang,[3]; Aman Sen Gupta,; Diwakar Mohan[5]; Lila Bikram Thapa[6]

[1]Nutrition, Helen Keller Intl Nepal, Lalitpur, Nepal; [2]Monitoring, Evaluation and Learning, Helen Keller Intl, New York, United States of America; [3]Nutrition, Helen Keller Intl, New York, United States of America; [4]Global Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, United States of America; [5]International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, United States of America; [6]Family Welfare Division, Department of Health Services, Kathmandu, Nepal

BACKGROUND AND OBJECTIVES

Due to micronutrient deficiencies, Nepal faces significant maternal and neonatal health challenges. To improve health outcomes, the Government of Nepal (GoN) intends to transition from iron and folic acid (IFA) to multiple micronutrient supplementation (MMS) for pregnant and postpartum women. To support the GoN, several mixed-METHODS implementation research studies are examining questions regarding adherence and acceptability, health system readiness, policy and logistical challenges of implementing MMS at scale. One of the studies is a three-armed randomized controlled trial known as NAMASTE-MMS.

METHODS

NAMASTE-MMS is being conducted in one of Nepal's seven provinces, Lumbini. A prospective cohort of 2,640 pregnant women across 120 facilities are being assigned to one of three arms: 1) IFA blister, MMS blister, or MMS bottle. The primary outcome is non-inferior adherence, measured via pill counts, to 180 tablets of MMS versus 180 tablets of IFA during pregnancy. Mixed-effects logistics and linear regression models will be used to estimate differences in adherence rates between the groups, with an a priori determined non-inferiority margin of 15%. Secondary outcomes include adherence to MMS at other time points (30-day, 90-day, and 45-days post-partum), as well as acceptance of the supplementation and its distribution (bottle vs. blister). The study received ethical approval from the Nepal Health Research Council.

RESULTS

As of January 24 2025, the enrolment for 2,640 pregnant women has been completed and 2,074 and 1,452 completed their 30- and 90-day follow-up data collection points, respectively. Data collection for the 180-day time point is planned for January through July 2025, at which point RESULTS for the primary outcome will be available.

CONCLUSIONS

RESULTS from this study will provide insights into MMS adherence and acceptability patterns across different supplement packaging at key points during pregnancy. This finding will be complemented by small-sample, quantitative demonstration studies in Nepal's other six provinces, as well as qualitative data from all seven provinces, including a supply readiness assessment and validation studies being conducted in collaboration with John Hopkins University. Together these study findings will provide evidence to GoN to inform its transition from IFA to MMS in Nepal while also contributing to the global knowledge base on MMS implementation.

RELATIONSHIP BETWEEN IMPLEMENTATION OF PROVISIONS OF THE INTERNATIONAL CODE OF MARKETING OF BREAST-MILK SUBSTITUTES AND MATERNITY PROTECTION AND EXPENDITURE OF COMMERCIAL MILK FORMULA IN EAST ASIA PACIFIC

Constance Ching[1]; Tuan Thanh Nguyen[1]; Catherine Pereira-Kotze[2]; Paul Zambrano,[3]; Phillip Baker[4]; Roger Mathisen,[1]
[1]Alive & Thrive, Family Health International, Hanoi, Vietnam; [2]Alive & Thrive, Family Health International, Washington D.C, DC, USA, United States of America; [3]Alive & Thrive, Family Health International, Manila, Philippines; [4]School of Public Health, University of Sydney, Sydney, Australia

BACKGROUND AND OBJECTIVES

The rise of commercial milk formulas (CMF) in the diets of infants and young children raises concern for their health, growth and development. Adoption and monitoring of the International Code of Marketing of Breast-milk Substitutes (the Code) and enacting maternity protection policies at the national level are two of seven critical actions for governments to protect breastfeeding. This study explores the implementation of the Code, maternity protection policies, and the expenditure on CMF in major economies in the East Asia Pacific (EAP) region, as well as determines their associations.

METHODS

Data from 11 countries and one special administrative region in the EAP region were collected and analysed. Descriptive statistics were used to assess the implementation of Code provisions and maternity protection policies in EAP countries and CMF expenditures at the global, regional, and national levels. Regression analyses explored associations between CMF expenditures and the status of the policies, including Code implementation, the scope of CMF products covered under national measures, and the duration of paid maternity leave.

RESULTS

CMF expenditures in EAP have surpassed the global average, contributing to 63% of global expenditures, with toddler formula as the highest-selling category. Sales and per capita expenditures of most CMF types have increased in most countries in the region. Japan and Malaysia have no Code-related legal measures. Australia, New Zealand, and Singapore now have Code-related legal measures where previously found to have none. However, CMF marketing regulations in Australia and New Zealand remain largely voluntary in nature. Just over half (7/12) of countries provide the minimum maternity protection entitlements based on ILO standards. As total scores on the Code implementation increased, per capita CMF expenditure decreased. Most countries with high overall expenditures had no legal measures for the Code. The Philippines, with the highest Code implementation score, showed the lowest per capita expenditure. No significant association was found between CMF expenditures and paid maternity leave duration.

CONCLUSIONS

Overall expenditures on CMF are high, with increasing trends in EAP economies, and this is associated with insufficient implementation of the Code. It is critical to adopt legal measures to give full effect to the Code, including bringing CMF scope to at least 36 months to reduce CMF consumption, strengthen comprehensive maternity protection policies, and cultivate intersectoral policy environments to protect, promote, and support breastfeeding.

TOWARDS HEALTHIER AND MORE ENVIRONMENTALLY SUSTAINABLE DIETS IN ICELAND: A PRELIMINARY APPLICATION OF A FIVE-STEP FRAMEWORK FOR SUSTAINABLE FOOD-BASED DIETARY GUIDELINES

Steina Gunnarsdóttir[1]; Ragnhildur Guðmannsdóttir[1]; Clara Maria Vásquez-Mejía[1]; Sankalp Shrivastava[1]; Guðrún Svana Hilmarsdóttir,[1]; Thorhallur Ingi Halldórsson[1]; Olafur Ogmundarson,[1]; Bryndís Eva Birgisdóttir[1]
[1]Faculty of Food Science and Nutrition, University of Iceland, Reykjavík, Iceland

BACKGROUND AND OBJECTIVES

Food-based dietary guidelines (FBDGs) aim to promote healthy diets and inform public policies, such as the new Nordic dietary recommendations which were published in 2023 (NNR2023). However, country-specific adaptations regarding food traditions and regional environmental impacts are encouraged. Thus, this study applied a five-step framework to create FBDGs for Iceland that prioritize health and align with planetary boundaries.

METHODS

The 2014 Icelandic FBDGs were used as the baseline diet as well as a Nordic archetype diet and the current food consumption, gathered from the FAO food balance sheets (an aggregated mean of 2020-2022). Criteria for healthy diets were based on FBDGs, and macro- and micronutrients according to NNR2023. Included environmental impact indicators were greenhouse gas emissions, cropland use, nitrogen and phosphorus application, water use, and species extinction rate which were assessed through Life Cycle Assessment (LCA) studies. In this first run, LCA RESULTS from similar neighboring countries were used. Currently, we are adapting available Icelandic life cycle assessment data for animal food systems to the methodology used in the framework. The EAT-Lancet commission boundaries were used for included environmental impacts, scaled down to the individual level. Detailed methodology of the framework is described in Wood et al. (2023)

RESULTS

Initial analysis showed that for the nutrition assessment, the baseline diet exceeded the caloric limit and was deficient in monounsaturated fatty acids. However, all the nutrient criteria was met after adjustments (i.e., reducing grain and butter intake, and increasing unsaturated fats). The healthy diet exceeded most environmental boundaries except for freshwater use. Moreover, red meat, dairy, and crustaceans were responsible for the highest environmental pressure on the selected impact categories.

CONCLUSIONS

Current FBDGs have high environmental pressure, except for freshwater use. The first run of this study stresses the importance of integrating both health and environmental criteria when implementing new FBDGs. Next steps include altering the baseline diet to create a foundation for healthier and more sustainable food-based dietary guidelines for Iceland.

NAVIGATING NUTRITIONAL CHALLENGES AND OPPORTUNITIES IN SCHOOL FOOD PROGRAMS: ALIGNING PRACTICES WITH DIETARY RECOMMENDATIONS

Mavra Ahmed[1]; Nina Trask,[1]; Nicole Weber,[1]; Daniel Sellen,[1]
[1]Department of Nutritional Sciences, University of Toronto, Toronto, Canada

BACKGROUND AND OBJECTIVES

School food programs (SFPs) serve a critical function in promoting child nutrition, particularly when structured in accordance with national dietary guidelines. In Canada, adherence to Canada's Food Guide (CFG) and provincial nutrition standards is a priority for the National School Food Policy, yet operational constraints and resource variability pose challenges to achieving existing nutritional standards, if present. This study explores the practices, challenges and opportunities faced by school food coordinators in adherence to dietary recommendations.

METHODS

A cross-sectional survey was conducted among 36 school food coordinators across three of Canada's largest school boards located in Ontario. The survey assessed food selection practices, adherence to CFG, the frequency of offering healthy and less healthy food items in alignment with provincial nutrition standards, and challenges in implementing nutritional policies. Quantitative data were analyzed using descriptive statistics, while qualitative responses provided contextual insights into operational practices.

RESULTS

Most programs (63%) reported serving healthy options daily, emphasizing fruits, whole grains, and protein foods such as dairy and eggs. However, vegetables were less frequently represented compared to fruits, and plant-based proteins were underutilized. Approximately 66% of programs avoided selling high-fat, high-sugar, and high-sodium items, but variability in offering "Sell Less" items was observed, with 8% serving them daily. Reliance on prepackaged and processed foods was common due to operational simplicity and resource constraints, with portion sizes often determined by manufacturers. Programs demonstrated variability in serving sizes, accommodating diverse student appetites, and efforts to manage food waste. Challenges included limited resources, reliance on prepackaging, and gaps in specific guidance from CFG and existing school food nutrition guidelines.

CONCLUSIONS

SFPs in Ontario exhibit strong efforts to align with CFG through consistent provision of healthy options and limited availability of less healthy items. However, variability in practices and reliance on processed foods underscore the need for enhanced resources, clearer school-specific CFG guidance, and greater focus on fresh, minimally processed foods, particularly vegetables and plant-based proteins. Addressing these challenges through targeted policy support and improved resource allocation can ensure equitable and consistent adherence to dietary recommendations and improve SFPs' nutritional impact.

EXPERT GUIDELINES ON IMPROVING THE QUALITY OF PUBLISHED AQUATIC FOOD NUTRIENT COMPOSITION DATA FOR THEIR INCLUSION IN FCTS, FCDS, AND EVIDENCED BASED NUTRITIONAL PLANS, POLICIES AND PROGRAMMES

Thiruchenduran Somasundaram[1]; Rita Hannisdal[2]; Siân Astley[3]; Hettie Schönfeldt[4]; Ananthan Rajendran[5]; Doris Rittenschober[6]; Fernanda Grande[6]; Sitilitha Masangwi[7]; Kendra Byrd[8]; Christina Hicks[9]; Marian Kjellevold[10]; International Community Of Practice On Nutrient Composition Of Aquatic Foods[11]
[1]School of Life and Environmental Sciences, Deakin University, Melbourne, Australia; [2]Seafood and Nutrition, Norwegian Institute of Marine Research, Bergen, Norway; [3]Scientific Unit, EuroFIR AISBL Secretariat, EuroFIR, Brussels, Belgium; [4]Department of Animal Science, University of Pretoria, Pretoria, South Africa; [5]Food Chemistry, National Institute of Nutrition, Hyderabad, Telangana, India, India; [6]Food and Nutrition Division, Food and Agriculture Organization of the United Nations, Roma, Italy; [7]Department of Human Nutrition and Health, LUANAR, Bunda Campus, Lilongwe, Malawi; [8]Food and Markets Department, University of Greenwich, Natural Resources Institute, Chatham Maritime, United Kingdom; [9]Political Ecology, Lancaster University, Lancaster, United Kingdom; [10]Seafood, Nutrition and Environmental State, Norwegian Institute of Marine Research, Bergen, Norway; [11]Aquatic Foods, International, Rome, Italy

BACKGROUND AND OBJECTIVES

Aquatic foods nutrient compositional data have potential to contribute to the development and implementation of national nutrition plans, policies and programmes. Many countries, especially low & lower-middle-income countries (LLMIC), lack comprehensive analytical data on the nutrient composition of locally consumed foods, including aquatic foods, in their food composition tables or databases (FCTs or FCDs). Although data from journal articles and laboratory reports have potential to address these gaps, they are often unusable due to insufficient detail on key aspects. This expert review and guidelines aim to provide checklists that authors can use when publishing their aquatic food nutrient composition data.

METHODS

The international Community of Practice on Nutrient Composition of Aquatic Foods has reviewed the shortcomings in published aquatic food nutrient composition data and compiled a pragmatic checklist applicable to LLMICs and other countries. In addition, a comprehensive checklist is proposed as a gold standard for further enhancing data quality depending on the capacities of the institutions.

RESULTS

Aquatic food FCT and FCD compilers report that around 75% of the studies are excluded due to unclear data expressions such as incorrect use of dry weight and dry matter definitions. Further, it has been reported that around 90% of publications are missing at least one of the essential food descriptions including scientific name, sample origin, sample year, sample month, wild/farmed, body part, processing, sample preparation, or relative weight. Aiming to prevent future data losses arising from substandard reporting practices, the checklist outlines the key aspects that should be described in a paper/report to ensure their inclusion in robust and locally relevant FCTs and FCDs. In addition, gold standard guidelines show additional actions that may help to improve data quality.

CONCLUSIONS

Adhering to the checklist will enhance the data-quality of published aquatic food nutrient composition data arising from LLMIC research and development sectors. Further, general publication of data adhering to minimum-quality standards will facilitate the end-uses and applications of these data in FCTs, FCDs and

https://doi.org/10.1017/jns.2026.10126 Published online by Cambridge University Press

nutritional research, development and policy decisions that may contribute to several SDGs in LLMICs. The gold standard guidelines on aquatic food nutrient composition data best practices will provide a framework of reference for capable laboratories, research organisations, universities and institutions involved in data collection when looking to enhance the quality of their published data.

OAP 66 - THE FUTURE OF NUTRITION RECOMMENDATIONS

OAP66_01

LONG-TERM EFFECTS OF CHRONIC CONSUMPTION OF SUGARS AND NON-NUTRITIVE SWEETENERS ON DECISION-MAKING

Camille Eustache[1]; Sabrina Teyssier[2]; Nicolas Darcel[1]
[1]Physiologie de la Nutrition et du Comportement Alimentaire, Paris-Saclay Agro Campus, AgroParisTech, Palaiseau, France; [2]Laboratoire d'Economie Appliqué de Grenoble, INRAE, Grenoble, France

BACKGROUND AND OBJECTIVES

Non-nutritive sweeteners, such as aspartame and acesulfame-K, are often used as substitutes for simple sugars to improve the taste of food products without increasing their sugar and calorie content. According to a recent study conducted on adult mice, continuous consumption of low doses of sucrose and saccharin significantly alters dopamine levels in the prefrontal cortex and the striatum, which may modify decision-making strategies during food-seeking tasks, in the absence of any metabolic changes. However, the impact of non-nutritive sweeteners on cerebral and cognitive functions remains poorly studied in humans. One of the aims of the SweetBrainDev project is to explore the effects of chronic consumption of non-nutritive sweeteners on decision-making in healthy young adults. This project aims to establish upper limits on non-nutritive sweeteners consumption in the long term.

METHODS

201 young, healthy adults, aged between 18 and 30 years, categorized according to their consumption of sweeteners using a quantitative food frequency questionnaire, were subjected to computerized cognitive tasks. These tasks assessed uncertainty management, risk-taking, altruism and cooperation levels, and emotion regulation. The data from 173 participants were analyzed using logistic regression and ANCOVA tests.

RESULTS

High consumers of non-nutritive sweeteners maximize their expectations of gains and prefer options where the probability of losing large gains is less frequent in uncertain situations, compared to non and low consumers. Moreover, high consumers favor higher-risk options in risk-taking situations, whereas non and low consumers prefer more prudent options. Daily sugar consumption also has a significant impact on the management of uncertainty, risk-taking, and emotional regulation strategies among young participants.

CONCLUSIONS

Our preliminary RESULTS highlight the potential correlation between the chronic consumption of non-nutritive sweeteners and sensitivity to gains and losses during uncertainty management tasks, as well as risk-taking behavior.

OAP66_02

THE HEALTH EFFECTS OF MICRO-VEGETABLE CONSUMPTION: A SYSTEMATIC REVIEW OF IN-VITRO AND IN-VIVO STUDIES

Cealan Henry[1]; Joanna, L. Bowtell[1]; Mary, F. O'leary[1]
[1]Public Health and Sports Sciences, University of Exeter St Luke's Campus, Exeter, United Kingdom

BACKGROUND AND OBJECTIVES

Climate change and soil depletion are altering the nutritional value of fruit/vegetable crops (1). Micro-vegetables (MV) have tightly controlled resource-efficient production requirements (2, 3) and may represent part of the solution. MV have a greater concentration of phytochemicals and vitamins compared to their mature counterparts (4, 5) and have potential for the prevention of malnutrition and non-communicable diseases. These properties have yet to be examined in humans, but experimental in-vitro and in-vivo studies have shown MV can exert a range of effects that are associated with positive health outcomes. The aim of this review was to systematically gather relevant literature on MV and assess their therapeutic potential for human health.

METHODS

The protocol of this review was prospectively registered on the Open Science Framework (6). The research question was formulated as "what are the potential health properties of MV?". This question was refined using the 'PICOS' acronym: Population (P), animal (non-human) or in-vitro experiments; Intervention (I), MV; Comparator (C), control group or a positive/negative control (in-vitro) experiments; Outcome (O), health property, including but not limited to antioxidant, anti-inflammatory, anti-proliferative or metabolic effects; Study type (S), in-vivo or in-vitro.

RESULTS

Following initial searches and removal of duplicates, 2268 articles were screened by reviewing title or abstracts, of which 28 articles fulfilled the inclusion criteria. Twelve articles investigated MV direct antioxidant capacity via in-vitro assays; few studies (n=5) investigated the more physiologically relevant impact of MV on endogenous cellular antioxidant systems. Three murine in-vivo studies demonstrated anti-inflammatory effects of MV supplementation and suggest these effects may be dose-dependent. MV exhibited pro-apoptotic effects in immortalised cell lines. Limited in-vivo animal evidence suggests MV exert lipid and gut microbiota-modifying effects.

CONCLUSIONS

This systematic review provides evidence that MV consumption may have potential benefits for human health. Further, this review signposts outcomes that should be prioritised in human clinical trials; those at cardiometabolic risk are a priority population for such work.

ARE SUSTAINABLE DIETS GOOD FOR OUR METABOLIC HEALTH? EXPLORING PHENOTYPIC RESPONSE TO THE MYPLANETDIET RCT

Katie Davies[1]; Eileen Gibney[1]; Aifric O'sullivan,[1]
[1]UCD Institute of Food and Health, School of Agriculture and Food Science, University College Dublin, Dublin, Ireland

BACKGROUND AND OBJECTIVES

Sustainable healthy diets are expected to deliver improved environmental and metabolic health, but there is a lack of intervention studies testing the effectiveness and acceptability of such diets [1-3]. At the same time, individuals respond differently to the same dietary change due to a myriad of interpersonal factors, including metabolic status or metabolic phenotype [4]. The aim of this work is to better understand diet-related outcomes and metabolic response to more sustainable diets using a phenotyping approach.

METHODS

The MyPlanetDiet RCT recruited healthy adults following diets with moderate-to-high greenhouse gas emissions (GHGE) to receive either personalised feedback based on a sustainable diet (intervention) or based on Healthy Eating Guidelines (control) for 12 weeks [5]. Dietary assessments (24-hour recalls), fasting serum samples (clinical chemistry), and fasting anthropometry were collected at baseline and endpoint. Participants were grouped using *k*-means clustering based on baseline concentrations total-cholesterol, HDL-cholesterol, glucose, and triacylglyerols (TAGs) to assess metabolic response during the study. Changes in dietary intakes and metabolic biomarkers were compared over time and between groups using two-way mixed analysis of covariance using IBM SPSS statistics (Version 29).

RESULTS

Participants (n=292) had significantly lower diet-related GHGE and higher diet quality at the end of the study. While no significant changes in metabolic health were observed in the full sample population, two of the metabolic phenotypes identified exhibited positive metabolic response during the study. The metabolic phenotypes had significantly different demographic and metabolic-related biomarkers but similar dietary intakes at baseline. In the two responsive phenotypes, there were significant decreases in total-cholesterol, TAGs, body mass index, and waist circumference over time. Response within metabolic phenotypes differed depending on food intake and intervention groups.

CONCLUSIONS

A more sustainable diet is achievable with no negative health effects at least in the short-term and positive metabolic health outcomes for sub-groups with distinct metabolic phenotypes. This work can inform future dietary advice for both more sustainable diets and for interventions aimed at improving metabolic health using metabolic phenotyping.

A LITERATURE-BASED DATA SCANNING AND PRIORITISATION STUDY TO GUIDE SYSTEMATIC LITERATURE REVIEWS FOR EVIDENCE-BASED CANCER PREVENTION RECOMMENDATIONS

Doris S. M. Chan[1]; Ahmad Jayedi[1]; Sofia Cividini[1]; Sayada Zartasha Kazmi[1]; Margarita Cariolou[1]; Rita Vieira[1]; Sonia Kiss[1]; Katia Balducci[1]; Dagfinn Aune[1]; Amanda J. Cross[1]; Georgios Markozannes[1, 2]; Konstantinos K. Tsilidis[1, 2]

[1]Department of Epidemiology and Biostatistics, School of Public Health, Imperial College London, London, United Kingdom; [2]Department of Hygiene and Epidemiology, University of Ioannina Medical School, Ioannina, Greece

BACKGROUND AND OBJECTIVES

In 2018, the World Cancer Research Fund (WCRF) and the American Institute for Cancer Research (AICR) published the Third Expert Report (TER) investigating the links between diet, adiposity, physical activity, and the risk of 19 cancers. This report included 10 evidence-based cancer prevention recommendations (1). Since then, new epidemiological findings may provide additional insights that could expand or refine these recommendations. As part of WCRF International's Global Cancer Update Programme (CUP Global) (2), we aimed to identify the next systematic literature reviews (SLRs) to conduct as research priorities.

METHODS

We developed a prioritisation strategy comprising six actions, which was used alongside expert opinions to determine the next SLRs. We scanned PubMed for 1) meta- and pooled analyses, 2) randomised controlled trials (RCTs) and protocols, 3) Mendelian randomisation (MR) studies, and 4) prospective cohort studies (≥100,000 participants) on diet, adiposity, physical activity, sedentary behaviour and cancer risk published after the TER. In action 5, we utilised the fail-safe number and conditional power statistics to estimate the number of additional studies needed to change the TER meta-analytic findings (3-5). In action 6, which integrated data from actions 1-5, we constructed an exposure-based prioritisation score (PS) across all cancer sites, with points awarded or penalised after assessing the number of new studies, the concordance of association measures (direction and statistical significance) against the TER, and the volume of new associations not covered in the TER.

RESULTS

Information covering 151 exposures and 28 cancers from 366 meta-analyses, 121 pooled analyses, 19 RCTs, 368 MR studies and 359 large cohort studies were compared against those from the 1371 meta-analyses in the TER. Most associations observed in the TER are unlikely to change with the few additional new studies identified in contrast to the estimated number of studies needed to change these findings. The median PS score across exposures was 6 (range -11 to 163). Amongst the top-ranking exposures and identified research priorities were sedentary behaviour (PS 64), tea (PS 36), soy (PS 24), isoflavones (PS 23), and soft drinks (PS 22). Although coffee ranked lower (PS 11), its inconsistent association with various cancer sites warrants investigation. In addition, ultra-processed foods are a new research focus and public health priority also selected for review (6).

CONCLUSIONS

The proposed prioritisation strategy helps target SLRs that would most usefully contribute to CUP Global evidence-based cancer prevention recommendations.

THE EFFECT OF N-ACETYLCYSTEINE SUPPLEMENTATION ON SPORTS PERFORMANCE IN AMATEUR ENDURANCE ATHLETES

Marcin Sadowski[1]; Emilia Zawieja[1]; Agata Chmurzynska[1]
[1]Department of Human Nutrition and Dietetics, University of Life Sciences, Poznań, Poland

BACKGROUND AND OBJECTIVES

N-acetylcysteine (NAC) serves as a cysteine donor and supports the synthesis of glutathione, a key antioxidant that neutralizes free radicals. Elevated levels of these reactive molecules are common during and after high-intensity endurance exercise, potentially leading to prolonged muscle soreness and reduced performance in subsequent training sessions. This study aimed to evaluate the efficacy of NAC supplementation in mitigating performance decline during high-intensity endurance tests, particularly in scenarios with short recovery periods.

METHODS

This double-blind, randomized, placebo-controlled crossover study involved 77 participants (41 long-distance runners and 36 cyclists; 20 females and 57 males). Participants completed two endurance tests: the Wingate Anaerobic Test (WAnT) to assess peak power (PP), relative peak power (PP/kg), average power (AP), and relative average power (AP/kg), as well as a sixty-minute time trial (60TT), in which distance covered was the primary outcome. Following baseline testing, participants received a seven-day supply of either NAC or placebo. The tests were repeated after the supplementation. After a three-week washout period, the protocol was repeated with the alternate condition.

RESULTS

No significant time × treatment interactions were observed for 60TT distance in cyclists ($p = 0.238$) or runners ($p = 0.241$). NAC supplementation did not significantly affect PP (cyclists: $p = 0.637$; runners: $p = 0.196$), PP/kg (cyclists: $p = 0.581$; runners: $p = 0.419$), AP (cyclists: $p = 0.988$; runners: $p = 0.222$), or AP/kg (cyclists: $p = 0.637$; runners: $p = 0.078$).

CONCLUSIONS

NAC supplementation has no significant effect on performance in either the WAnT or 60TT across endurance-trained athletes.

OAP66_07

ADHERENCE TO THE NEW NORDIC NUTRITION RECOMMENDATIONS FOR ANIMAL-BASED FOOD GROUPS BY EDUCATION LEVEL IN FINNISH ADULTS

Tiina Suikki[1]
[1]Department of Population Health, THL - Finnish Institute for Health and Welfare - Natural Protection for Finnish people, Helsinki, Finland

BACKGROUND AND OBJECTIVES

The new food-based dietary guidelines (FBDG) included Nordic Nutrition Recommendations (NNR) 2023 set updated targets for the consumption of red and processed meat, fish, and dairy. While adherence to the FBDG is generally low in adults, the role of background factors associated with adherence are less examined. Our aim was to examine the proportion of Finnish men and women meeting the guidelines for animal-based foods focusing the association between education and adherence.

METHODS

The data included 780 men and 875 women (aged 18–74 years) from the national FinDiet 2017 Survey. Dietary data was collected with two non-consecutive 24-h dietary recalls. The National Cancer Institute (NCI) method was used for modelling usual intake distributions of red and processed meat, fish and fish product, and milk and milk products (as milk equivalents). Then, the proportions of men and women in different education groups meeting the FBDG (≤50 g/day, 350-500 ml/day, and 43-64 g/day, respectively) were assessed. Education level was determined by asking participants' total number of school years. These were categorised into tertiles (low, middle, high) according to sex and birth year.

RESULTS

In men, 7% met the target for red and processed meat, 16% for fish, and 11% for milk. In women, the proportions were 31%, 12%, and 20% respectively. When analyzed by education level, both men and women in the highest education group were more likely to meet the target for red and processed meat (men: 16%; women: 44%) compared to those in the lowest education group (men: 5%; women: 19%). Furthermore, in women, a higher proportion in the highest education group (19%) met the target for fish compared to those in the lowest education group (6%). In contrast, adherence to the target for fish did not appear to differ between education groups in men, nor did adherence to the target for dairy in either men or women.

CONCLUSIONS

In general, adherence to the NNR 2023 FBDG for animal-based food groups is generally low in Finnish adults. Although higher education level tended to be associated with better adherence especially for red and processed meat, effective implementation of guidelines is crucial across all population groups. However, the influence of education should be carefully considered in future implementation efforts.

REEVALUATING DAIRY FAT: EMERGING EVIDENCE ON THE HEALTH BENEFITS OF FULL-FAT DAIRY AND THE ROLE OF MILK FAT GLOBULE MEMBRANE ON POSTPRANDIAL LIPEMIA AND CARDIOVASCULAR HEALTH

Marie-Caroline Michalski[1]
[1]CarMeN laboratory, Inserm U1060, Univ Lyon 1, INRAE, Pierre-Bénite, France

BACKGROUND AND OBJECTIVES

Since the 2000s, research suggests that regular-fat dairy foods may not be associated with adverse cardiometabolic health effects. The objective of this review is to update the scientific community on the latest advances in our understanding of the specific composition and structure of milk fat in dairy products, particularly the Milk Fat Globule Membrane (MFGM), and their role in cardiometabolic health. This work aims to contribute to the reevaluation of the place of regular-fat dairy in recommendations for healthy diets.

METHODS

Relevant publications from peer reviewed journals, including food science articles, epidemiological studies, randomized controlled trials, reviews, and meta-analyses from the last decade, were selected and examined to update knowledge on milk fat composition and structure and relevant evidence about the effects of dairy fats and whole-fat dairy consumption on cardiometabolic health. Translational and mechanistic studies, particularly those related to the MFGM, were summarized to explore potential underlying mechanisms.

RESULTS

The specific fat globule structure and the unique, diverse, molecular composition of milk fat (over 400 types of fatty acids; various polar lipids of the MFGM) is highlighted. In cohort studies, dairy fat intake has been associated with a lower risk of type 2 diabetes and has shown to be inversely associated with adiposity and weight gain. Epidemiological studies support neutral to beneficial associations of total or whole-fat dairy intake with lipid metabolism and body weight. Recent research introduces how the matrix of dairy products (e.g., cheese, yogurt vs butter) plays a role in modulating the physiological responses to fat intake. Intervention studies demonstrate positive effects of the cheese matrix, e.g. on reducing postprandial lipemia, increasing HDL cholesterol and inducing less atherogenic LDL particles. Among potential mechanisms (e.g., calcium, fermentation), recent advances suggest benefits of milk polar lipids/MFGM on lipid digestion and absorption, reduction of lipid markers of cardiovascular risk, and potential benefits on metabolic inflammation via modulations of the gut microbiome and of circulating sphingolipids.

CONCLUSIONS

The specific composition and structure of milk lipids within the matrix of full-fat dairy products impacts digestion and absorption and is associated with evidence of neutral to beneficial cardiometabolic health outcomes. This warrants better consideration of whole-fat dairy in nutrition recommendations, and further research to decipher mechanisms of the health impact of the different dairy fat sources and whole-fat dairy matrixes.

A SYSTEMATIC REVIEW OF NUTRIENT PROFILING MODELS THAT PROMOTE A HEALTHY DIET

Lynda O'Neill[1]; Evangelia Kotzakioulafi[1]; Charlotte Debras[1]; Shweta Singh[2]; Marie Tassy,[1]
[1]Nutrition & Digestion, Nestlé Institute of Health Sciences, Lausanne, Switzerland; [2]Nutrition & Digestion, Nestlé Institute of Health Sciences, Singapore, Singapore

BACKGROUND AND OBJECTIVES

Over the past two decades, the field of nutrient profiling, which involves classifying or ranking foods based on their nutritional content, has expanded significantly in relation to the prevention of non-communicable diseases and the promotion of health. Many nutrient profile models (NPMs) focus heavily on the nutrients to limit. Such NPMs can play an important role e.g., traffic light labelling to enable quicker purchasing decisions; however, they fall short in helping individuals establish a healthy diet. Recently, the FAO/WHO[1] has introduced a definition of a healthy diet grounded in four principles: adequacy, diversity, moderation, and balance. Our objective was to identify NPMs that incorporate these principles

METHODS

A systematic literature review was conducted across three databases (PubMed, Scopus, and Cochrane Library) in July 2024 to identify NPMs referenced in peer-reviewed journals. We then assessed which of these models align with the newly defined concept of a healthy diet. NPMs that were limited to single product categories or specific populations were excluded from consideration.

RESULTS

Our search identified 203 studies that cited 119 unique NPMs or included a validation study related to one of these. After applying our criteria focused on the four principles of a healthy diet (i.e., adequacy, diversity, moderation, and balance), we identified eight NPMs that meet these standards. The models include the Canadian Food Scoring System, Carbohydrate Food Quality Score, Diabetes Canada Clinical Practice NPM, EU Pledge Nutrition Criteria, Food Compass, Keyhole, NutriScore, and Singapore Healthier Choice.

CONCLUSIONS

We identified only eight NPMs that effectively consider the four principles of a healthy diet. Among these principles, the balance of macronutrients was the least frequently represented. Although numerous NPMs account for adequacy of protein and fiber, the adequacy of micronutrients is rarely addressed, with only two out of eight models evaluating more than one micronutrient. This review highlights that there are few NPM that translate FAO/WHO guidelines for a healthy diet into product specific criteria, helping public health stakeholders identify NPM with global relevance i.e. including micronutrient adequacy, macronutrient balance as well as food group diversity.

OAP 12 - CLIMATE CHANGE, SUSTAINABILITY AND NUTRITION

OAP12_01

FOOD-BASED DIETARY GUIDELINES FOR CHILDREN AND ADOLESCENTS AND PLANETARY HEALTH: UPDATE OF THE OPTIMIZED MIXED DIET

Hermann Kalhoff[1]; Kersting Mathilde[2]; Luis Moreno Aznar[3]; Leandro Cacau[4]; Thomas Lücke[2]
[1]Pediatric Clinic, Klinikum Dortmund gGmbH Clinic Center Mitte, Dortmund, Germany; [2]Department of Child Nutrition, Ruhr University Bochum Faculty of Medicine, Bochum, Germany; [3]Growth, Exercise, Nutrition and Development (GENUD) Research Group, Universidad de Zaragoza, Zaragoza, Spain; [4]Department of Nutrition, Universidade de São Paulo, São Paulo, Brazil

BACKGROUND AND OBJECTIVES

Introduction/ Objective: As the global climate crisis requires a paradigm shift in dietary concepts, a global reference diet has been suggested by the EAT-Lancet Commission. On this basis, the detailed "Planetary Health Diet Index" (PHDI) has been proposed. In Germany, Food Based Dietary Guidelines (FBDG) for children and adolescents named "Optimized Mixed Diet" (OMD) have been in existence since about 30 years. The OMD is based on a 7-day menu that prefers customary food and dietary habits of German families, with 5 meals per day (3 main meals, 2 snacks). The aim of this evaluation is 1) to apply the PHDI to the OMD in its original composition and 2) to examine how the planetary value of the OMD could be improved by changing the food selection while respecting the special needs of children.

METHODS

METHODS: The PHDI of the original OMD was calculated by assigning the foods of the 7-day menu to the PHDI food groups in order to score them. The diet was then updated by either reducing or increasing individual foods from these food groups in the meals (always respecting practicability and age-specific nutritional needs) resulting in an improved PHDI. To calculate the energy and nutrients intake of both OMD versions, a common software was used. Nutrient values were obtained from the German Food Code and Nutrient Data Base.

RESULTS

The original OMD obtained a PHDI score of 68.2 points, representing 45.5% of the theoretical maximum of 150 points. The updated OMD resulted in increased consumption of 'nuts & peanuts', 'legumes', 'green vegetables', 'whole grains', and decreased consumption of 'tubers & potatoes' and 'red meat'. Overall, the PHDI increased from 68.2 to 81.5 points with the updated OMD, reflecting a 13.3% increase compared to the original diet. Nutrient densities remained high and increased for some nutrients.

CONCLUSIONS

The examination of the current OMD with the PHDI has confirmed that this dietary concept, which is preventive from the ground up, is already quite sustainable. This evaluation is not surprising, because the OMD is based on three simple rules for food selection which are to consume beverages and plant-based foods generously, animal-based foods moderately and high-fat, high-sugar foods sparingly. Furthermore, the OMD focuses on home-cooked meals and therefore limits the use of highly processed foods in line with the sustainability criteria. By applying the PHDI, the sustainability of the original OMD was further improved through a few but targeted changes in individual food groups that can be easily implemented in practice while maintaining high nutrient densities and acceptability for children.

THE POTENTIAL OF CLIMATE CHANGE MENU LABELS TO PROMOTE HEALTHY AND SUSTAINABLE DIETS

Julia Wolfson[1]; Brent Kim,[2]; Raychel Santo[3]; Clara Cho[3]; Nina Carr[1]; Daphene Altema-Johnson[2]; Becky Ramsing,[2]; Jennifer Falbe[4]
[1]Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, United States of America; [2]Center for a Livable Future, Johns Hopkins Bloomberg School of Public Health, Baltimore, United States of America; [3]Food, Land & Water Program, World Resources Institute, Washington, United States of America; [4]Department of Human Ecology, University of California, Davis, Davis, United States of America

BACKGROUND AND OBJECTIVES

In the United States and many other high-income countries, current dietary patterns drive high and growing rates of diet-related chronic diseases and also contribute to climate change. Climate change is an urgent public health threat and reducing food systems-related greenhouse gas emissions (GHGE), which contribute one-third of all GHGE could make a significant impact. Menu labels conveying the GHGE of menu items may be a key strategy to help educate and inform consumers about the climate impacts of their food choices. Climate change menu labels may encourage healthier food choices as well.

METHODS

In this presentation, we will provide an overview of existing evidence of the effectiveness of different climate label designs in promoting healthier and more sustainable food choices. We will highlight RESULTS from two recent studies: one conducted in a university setting in which climate labels were displayed in two dining halls for a four-week period and compared to baseline, and a large online experiment in which ~6000 participants were randomized to view a fast food restaurant menu with one of four climate label designs vs. a control (QR code) label. For the dining hall climate label study, students (n=186) who frequented the dining hall reported their dietary intake using the Prime Diet Quality Screener at baseline and post-intervention via an online survey.

RESULTS

The presentation will describe the process used to estimate the GHGEs of menu items for both studies. The presentation will also focus on challenges and lessons learned regarding estimating GHGE for menu items. The dining hall climate label study did not shift students' dietary intake or dining hall procurement in the short term. The online experiment will be conducted in December 2024. We will present the RESULTS of the online experiment comparing the effects of the label designs on the sustainability (GHGE) and healthfulness (calories and Nutrient Profile Index score) of items ordered. Finally, the presentation will discuss public health policy opportunities and challenges related to advancing climate change menu labels as a strategy to promote healthy and sustainable diets.

CONCLUSIONS

Climate change menu labels are a promising strategy for promoting sustainable and healthy dietary patterns. However, numerous challenges to their implementation in research and real-world settings must be considered. The findings discussed in this presentation will be critical for informing research, voluntary industry actions, and policies to advance climate change menu labels that effectively promote healthy and sustainable diets.

CO-EXPOSURE TO MULTIPLE MYCOTOXINS MAY SYNERGISTICALLY CONTRIBUTE TO COLORECTAL CANCER RISK

Inarie Jacobs[1]; Carine Biessy,[1]; Genevieve Nicolas[1]; Isabelle P Oswald[2]; Julien Vignard[2]; Yasmine Bader[3, 4]; Sarah De Saeger[3, 4]; Marthe De Boevre[3, 4]; Inge Huybrechts[1]
[1]Nutrition and Metabolism branch, International Agency for Research on Cancer, Lyon, France; [2]Toxalim (Research Centre in Food Toxicology), Université de Toulouse, INRAE, ENVT, INP-Purpan, UPS, Tououse, France; [3]Centre of Excellence in Mycotoxicology, Ghent University, Ghent, Belgium; [4]Cancer Research Institute (CRIG), Ghent University, Ghent, Belgium

BACKGROUND AND OBJECTIVES

Food safety is a critical global concern, exacerbated by climate change, population growth, and food crises. One major threat to food security and human health, including cancer, is the presence of mycotoxins in food. This study aimed to investigate the association between co-exposure to multiple mycotoxins and the risk of colorectal cancer (CRC).

METHODS

Using validated and standardized dietary questionnaire data from the European Prospective Investigation into Cancer study combined with mycotoxin food occurrence data compiled by the European Food Safety Authority, we investigated the association between co-exposure of multiple mycotoxins and CRC risk in 410, 286 non-cases and 5851 CRC cases. Mycotoxin patterns were derived using principal component analysis with Pearson correlation matrix from 14 mycotoxins. Hazard ratios (HR) and 95% confidence intervals (CI) were estimated using Cox regression models.

RESULTS

Three distinct mycotoxin patterns were identified, which together explained 66.3% of the total variance. The first pattern (explaining 36.3% of variance) comprised of a co-exposure of fusarium (deoxynivalenol and derivatives, fumonisins, diacetoxyscirpenol, T2HT2, nivalenol and zearalenone & derivatives) ochratoxins and aflatoxins; a second pattern (explaining 13.3% of variance) comprised of both genotoxic and non-genotoxic alternaria toxins; and a third component (explaining 9.4% of variance) comprised of a co-exposure of ergot alkaloids and enniatins. After adjusting for potential confounders trend analysis indicated that the patterns were positively associated with CRC risk (1st pattern HR T3vsT1: 2.19, 95%CI: 1.99-2.42; 2nd pattern HR T3vsT1: 1.33, 95%CI: 1.18-1.51; 3rd pattern HR T3vsT1: 1.12, 95%CI: 1.05-1.20).

CONCLUSIONS

Co-exposure to multiple mycotoxins in the fusarium, ochratoxin and aflatoxin groups, as well as enniatins and ergot alkaloids groups may synergistically contribute to CRC risk, one of the most diagnosed cancers in Europe. These findings warrant further confirmation through additional cohort studies and by examining mycotoxin levels in biological samples, such as blood.

FACTORS ASSOCIATED WITH SUSTAINABLE DIETARY PATTERNS: A MULTIDIMENSIONAL ASSESSMENT OF PORTUGUESE ADULTS' DIETS

Mariana Rei[1, 2]; Catarina Campos Silva[3]; Duarte Torres[1, 2]; Colin Sage[1]; Sara Rodrigues[1, 2]
[1]FCNAUP, University of Porto, Porto, Portugal; [2]ISPUP, University of Porto, Porto, Portugal;
[3]FMUP, University of Porto, Porto, Portugal

BACKGROUND AND OBJECTIVES

As current food production and consumption patterns present substantial risks to both human health and the environment, it is essential to identify and better understand the various factors influencing diet sustainability. This study aims to identify factors associated with the sustainability of Portuguese adults' diets.

METHODS

Data from 2287 participants in the National Food, Nutrition, and Physical Activity Survey (IAN-AF 2015-2016) were analyzed. The Diet Sustainability Score (DSS) was derived from four dimensions: nutritional quality, environmental impact, economic affordability, and sociocultural acceptability. Linear regression models examined the effects of sociodemographic, economic, and lifestyle factors on the DSS, adjusting for sex and age. The Kruskal-Wallis test assessed differences in food group consumption across DSS quintiles. Food intake values were standardized to an energy intake of 2200 kcal/day using the energy density method.

RESULTS

The DSS showed positive associations with female gender, older age, higher education, and higher income. Additionally, individuals with higher DSS exhibited healthier lifestyle behaviors, including non-smoking, non-alcohol consumption, higher organic food intake, and less frequent eating out-of-home habits. Participants with higher DSS consumed more vegetables (203 g/day in Q5 vs. 109 g/day in Q1), fruits (322 g/day in Q5 vs. 117 g/day in Q1), fish and seafood (59 g/day in Q5 vs. 30 g/day in Q1), white meat (35 g/day in Q5 vs. 21 g/day in Q1), and olive oil (14 g/day in Q5 vs. 10 g/day in Q1), while consuming less red and processed meat (35 g/day in Q5 vs. 109 g/day in Q1), sweets, sugar-sweetened beverages and salty snacks (70 g/day in Q5 vs. 299 g/day in Q1). These dietary patterns aligned with the Mediterranean dietary guidelines for Portugal.

CONCLUSIONS

The findings highlight key factors influencing diet sustainability and provide insights into the behaviors and characteristics of individuals with more sustainable diets. This study contributes to a better understanding of the multidimensional aspects of sustainable eating and offers valuable information for future research and policy-making aimed at promoting more sustainable food practices.

EXPLORING THE ASSOCIATION BETWEEN MEDITERRANEAN DIET, SUSTAINABLE EATING, AND ECO-ANXIETY: A CROSS-SECTIONAL STUDY ON FOOD CHOICES

Hatice Merve Bayram[1]; Gizem Uzlu Dolanbay[1]; Tugba Turkcan[1]
[1]Nutrition and Dietetics, Istanbul Gelişim University, İstanbul, Türkiye

BACKGROUND AND OBJECTIVES

Sustainable and healthy eating behaviors have gained increasing attention as a vital aspect of public health, particularly in the context of addressing climate change and promoting ecological well-being. At the same time, rising concerns about environmental issues have led to the emergence of eco-anxiety, a psychological response to perceived environmental threats. Understanding how dietary patterns, sustainable eating behaviors, and eco-anxiety intersect can provide valuable insights into developing comprehensive strategies for improving both individual health and environmental sustainability. This study aims to evaluate the relationships between adherence to the Mediterranean diet, sustainable and healthy eating behaviors, and eco-anxiety levels in adults and how plant and animal product preferences affect these levels.

METHODS

This cross-sectional study was conducted with 149 adults (73.8% female, mean age 28.42 ± 7.50 years) between 15 May and 10 December 2024. An online questionnaire including demographic characteristics, the Mediterranean Diet Adherence Scale (MEDAS), the Sustainable and Healthy Eating Behaviors Scale (SHEB), and the Eco-Anxiety Scale (EA) were performed. Additionally, an online market was created featuring two food groups, including plant- and animal-based products (dairy and meat). Participants were asked to select six items, comprising three products from the dairy group and three from the meat group. Data were analyzed using SPSS 24.0.

RESULTS

The majority of the participants (91.9%) showed low compliance with the Mediterranean diet according to the MEDAS classification, and the mean MEDAS score of the participants was 5.02 ± 1.78, which was higher in women than in men and there was a statistical difference between them (p: 0.022). There was a positive moderate correlation between MEDAS and SHEB scores (r: 0.491, p< 0.001), whereas EA scores did not show any correlation between MEDAS, and SHEB. There was a difference between tertiles 1 and 3 and tertiles 2 and 3 in total plant and animal product selection on the SHEB scale (p: 0.043).

CONCLUSIONS

These RESULTS emphasize the need for targeted interventions to promote sustainable and healthy eating behaviors, particularly focusing on increasing Mediterranean diet compliance to support both individual and environmental health.

BACKGROUND AND OBJECTIVES

Mindful eating (ME) can be globally defined as paying attention to the eating experience with all the senses, and witnessing the emotional and physical reactions that occur before, during, and after the eating experience without judgment or reaction. Scientific evidence suggests that this concept may be an effective approach to promoting healthy plant-based diets, which offer significant health and environmental benefits. However, there is limited data in the literature regarding the relationship between ME and these diets. This cross-sectional study aimed to investigate the association between ME and adherence to plant-based diets.

METHODS

In 2023, 13,768 participants from a large French web-based cohort completed the Mind-Eat Scale, which assesses total ME and its sub-dimensions, along with at least three 24-hour dietary records, and a food choices questionnaire. The contribution of plant-based foods was evaluated using the Plant-based Diet Index (PDI), the healthy PDI (hPDI), and the unhealthy PDI (uPDI). Participants were classified into 4 groups: higher meat/fish eaters, lower meat/fish eaters, vegetarians, and vegans. Multivariable linear and logistic regressions were performed to analyze the association between ME (independent variable), the PDI, hPDI, and uPDI scores, the proportions of meat and fish in the diet, and the 4 diet groups, considered separately (dependent variables), adjusting for socio-demographic and lifestyle factors.

RESULTS

ME was positively associated with PDI (β=1.19; 95%CI: 0.98, 1.41) and hPDI (β=1.00; 95%CI: 0.76, 1.24), and negatively with uPDI (β=-0.48; 95%CI: -0.70, -0.27), and with meat consumption (β=-0.63; 95%CI: -0.76, -0.50). Individuals with higher levels of ME were more likely to be lower meat/fish eaters (OR=1.25; 95%CI: 1.17, 1.35), vegetarians (OR=1.53.; 95%CI: 1.31, 1.79) or vegans (OR=2.14.; 95%CI: 1.54, 2.99). Most of these associations were consistent across ME sub-dimensions.

CONCLUSIONS

Our study showed that participants with higher levels of ME, were more likely to follow healthy plant-based diets. These findings suggest that ME could be a promising strategy for promoting a shift towards a reduction in animal product consumption, which is a crucial step toward achieving global food sustainability. Longitudinal studies are needed to continue exploring this relationship.

BIOAVAILABILITY OF VITAMIN B12 PRODUCED BY PROPIONIBACTERIUM FREUDENREICHII FERMENTATION TO FABA BEAN BREAD: A RANDOMISED CROSS-OVER TRIAL IN HEALTHY VOLUNTEERS

Anne-Maria Pajari[1]; Maj Lundberg[1]; Bhawani Chamlagain[1]; Suvi Itkonen[1]; Tiina Pellinen[1]; Minnamari Edelmann[1]; Susanna Kariluoto[1]; Vieno Piironen[1]; Pekka Varmanen[1]
[1]Department of Food & Nutrition, University of Helsinki, Helsinki, Finland

BACKGROUND AND OBJECTIVES

In Western societies, a dietary shift towards plant-based diets is needed to tackle greenhouse gas emissions and lessen the environmental burden of our current diets. However, vitamin B12, an essential micronutrient for growth and development in children and maintenance of health in adults, is naturally derived only from animal-sourced foods. Therefore, policies to ensure adequate vitamin B12 intake at population level is required. Using precision fermentation with Propionibacterium freudenreichii, we developed faba bean bread (FB bread) enriched with vitamin B12. We conducted a proof-of-concept dietary trial to study whether the vitamin B12 in FB bread is absorbed and available to support B12 status in healthy volunteers.

METHODS

A randomised, controlled, blinded trial with cross-over design was conducted. Healthy adult volunteers were assigned to the following three treatments six times over two days with a 1-week washout between the treatments: 1) FB bread with 5µg of vitamin B12 + placebo tablet; 2) FB control bread without vitamin B12 + tablet with 5µg of vitamin B12; 3) FB control bread + placebo tablet (no vitamin B12). The total dose of vitamin B12 from the bread or tablet was 30µg/2d. Volunteers gave a baseline serum sample after overnight fast, after which they underwent all three treatment periods in random order with a fasting serum sample collected at the end of each period. Total vitamin B12 and holo-transcobalamin (holoTC) were analysed in every sample. Baseline samples were checked for folate, homocysteine, methyl malonic acid, and creatinine. Food intake at baseline and during treatments was assessed by 3-d food records.

RESULTS

Among 20 volunteers completing all 3 treatments, both FB bread enriched with vitamin B12 and vitamin B12 tablet significantly ($p \leq 0.002$) increased the concentration (change pmol/l; mean±SD) of serum holoTC (32.2 ± 25.4 with FB bread; 37.3 ± 20.6 with B12 tablet) in comparison to placebo control (0.20 ± 20.0). The total vitamin B12 concentration was more efficiently increased by vitamin B12 tablet (34.2 ± 36.4; $p=0.004$) even though a trend was seen by FB bread (17.3 ± 32.7; $p=0.27$) in comparison to placebo control (-1.9 ± 23.8).

CONCLUSIONS

Vitamin B12 enriched FB bread significantly increases serum holoTC, the most reliable marker of vitamin B12 status. Our RESULTS demonstrate the potential of precision fermentation to enrich plant-based materials with bioavailable vitamin B12, providing a viable approach to ensure adequate intake of vitamin B12 in shifts towards sustainable diets.

SIMILARITY INDEX (NSI) FOR INTERCHANGING FOOD PRODUCTS: FROM QUALITATIVE CLASSIFICATIONS TO QUANTITATIVE INDICATORS

Thom Huppertz[1, 2]; Stephan Peters[3]
[1]School of Food and Nutritional Sciences, University College Cork, Cork, Ireland; [2]Science & Technology, FrieslandCampina R&D, Amersfoort, Netherlands; [3]Sustainability, Nederlandse Zuivel Organisatie, Den Haag, Netherlands, Netherlands

BACKGROUND AND OBJECTIVES

Life cycle assessment (LCA) is widely used to assess the environmental impact of food items. Outcomes hereof are often erroneously used for comparison of foods and suggesting replacements based on perceived lower environmental impact of foods, without considering (i) nutritional value of products, and (ii) whether products are interchangeable based on nutrient profiling. In nutritional LCA (nLCA) a nutrition-based, rather than a mass-based, functional unit (FU) in LCA is used. This allows balancing nutritional value and environmental impact, but still does not answer the question whether products are interchangeable. Specifically for this purpose, we designed a Nutrient-based Similarly Index (NSI).

METHODS

To enable quantification of the similarity of food items, a Nutrient-based Similarly Index (NSI) was developed. The basis for the NSI is a so-called cosine similarity index, which considers the nutrient profile of a food product as a vector in an *n*-dimensional space, wherein *n* is the number of nutrients considered in the NSI. The cosine of the angle between the vectors of 2 food products represents the NSI; an NSI of 1 indicates an angle of 0° between vectors (*i.e.*, complete similarity) whereas an NSI of 0 indicates a 90° angle between vectors (*i.e.*, complete dissimilarity). The NSI was calculated for >250 food items based on values of *n* ranging from 6 to 21 nutrients to assess interchangeability of food products within food groups and between food groups.

RESULTS

The NSI values calculated for the set of food products within this study and across the different nutrient spaces (n = 6-21) indicates some critical points. Consideration of a higher number of nutrients improved reliability of comparisons. When looking at NSI values within food groups, particularly high similarity was found within the categories of grain, bread and dairy products, often yielding values >0.8. However, NSI values between dairy products and dairy alternatives were always <0.4. within the category of meat products NSI values were mostly >0.6 whereas meat replacers showed some similarity to some meat products. NSI values within the food groups of vegetables and of fruits were also founds to be highly variable with values ranging from <0.2 to >0.8.

CONCLUSIONS

The NSI provides a relatively easy quantitative approach for comparison based on nutrient profiles of food items. NSI values can form the basis for validating the relevance of comparison of products based on e.g., environmental impact and affordable nutrition.

DOES WATER INSECURITY MEDIATE THE ASSOCIATIONS BETWEEN CLIMATE EVENTS AND FOOD INSECURITY? AN ANALYSIS FROM 25 LOW- AND MIDDLE-INCOME COUNTRIES

Indira Bose[1]; Edward A Frongillo[2]; Joshua Miller[3]; Thalia Sparling[1]; Carlo Cafiero[4]; Sara Viviani[4]; Suneetha Kadiyala[1]; Sera Young[5]
[1]Department of Population Health, London School of Hygiene and Tropical Medicine, London, United Kingdom; [2]Department of Health Promotion, Education, and Behavior, University of South Carolina, Columbia, SC, USA, Columbia, United States of America; [3]Department of Nutrition, University of North Carolina at Chapel Hill, Chapel Hill, United States of America; [4]Statistics, Food and Agriculture Organization of the United Nations, Roma, Italy; [5]Department of Anthropology, Northwestern, Evanston, United States of America

BACKGROUND AND OBJECTIVES

Climate events are increasing in frequency and intensity, with greater floods and droughts projected to disrupt food production and undermine food security (1,2). These events may also lead to water insecurity, which in turn may exacerbate food insecurity by limiting the ability to cook certain foods and practice food hygiene (3). The potential mediating role of experiential water insecurity in the relationship between climate and food insecurity, however, is not well understood.

METHODS

Nationally representative data on individual experiences of food and water insecurity, over the preceding 12 months, were collected from 25 countries through the Gallup World Poll from 2020-21 (4). Respondents' geolocations were spatio-temporally linked to flood and drought events recorded in the EM-DAT database (5) to estimate their exposure to at least one month of that event in the corresponding year. Multivariable multinomial and logistic regression models were run to estimate the associations between these climate events and food and water insecurity. All models were survey-weighted and adjusted for socio-demographic covariates: income, education, urbanicity, climate zone, sex, household size, and age. Mediation analysis was conducted to estimate the role of water insecurity in mediating the association of floods with food insecurity.

RESULTS

Individuals exposed to floods had higher odds of experiencing food insecurity (1.22 OR, 95% CI:1.07-1.39), whereas there was no association found between exposure to droughts and food insecurity (0.88 OR, 95% CI:0.67-1.17). Both floods and droughts were associated with greater odds of experiencing higher water insecurity. Furthermore, water-insecure individuals had 2.8 times higher odds of being food insecure than water-secure individuals (95% CI: 2.50-3.12). The association between flood events and food insecurity was attenuated after adjusting for water insecurity, with preliminary analysis estimating that about 30% of the association was mediated through water insecurity.

CONCLUSIONS

Water and food insecurity were closely associated, and water insecurity was a mechanism through which floods were associated with food insecurity. Addressing water insecurity issues to mitigate the potential risks to food insecurity and its nutritional impacts is imperative. Given that climate events like floods are projected to increase in frequency and intensity, efforts to improve the resilience of water and food systems will be essential to safeguard nutrition in the future.

SOCIAL INTERACTIONS FOR SUSTAINABLE FOOD CHOICES: MEETING THE TARGET FOR MEAT INTAKE IN THE UNITED KINGDOM

Angela Fontan[1]; Rosemary Green[2]; Karl Henrik Johansson[1]; Patricia Eustachio Colombo[3]
[1]DIVISION OF DECISION AND CONTROL SYSTEMS, Department of Mathematics, KTH Royal Institute of Technology, Stockholm, Sweden; [2]Centre on Climate Change and Planetary Health, London School of Hygiene & Tropical Medicine, London, United Kingdom; [3]Department of Medicine, Karolinska Institutet, Stockholm, Sweden

BACKGROUND AND OBJECTIVES

Substantial shifts in contemporary diets are needed to halt the growing burden of chronic diseases and the rapidly accelerating climate crisis. Achieving this will require strong action and use of policy instruments that can aid consumers in making the right dietary choices. Real-life evidence on how to change dietary behaviours within complex food systems at scale demands resources and research that might not be realistic to acquire or realise. This project applied innovative models to predict the dietary and environmental effects of broad-scale strategies designed to transform dietary behaviours among consumers.

METHODS

Scenarios were simulated using agent-based opinion dynamics models to evaluate the impact of different levels of governmental influence on people's consumption of meat, vegetables, pulses, and meat alternatives. We considered the problem of influencing the opinions of a group of agents (representing the UK population) connected in a social network over a sequence of campaigns to achieve convergence to two different targets: achieving the UK Climate Change Committee's goal of a 35% and 50% reduction in population-average meat consumption. The opinion dynamics compromised agents (i.e. consumers), with empirically derived baseline food intake patterns (i.e., initial opinions) and sociodemographic attributes. Changes in environmental impacts following changes in consumption were quantified.

RESULTS

In a scenario of high governmental influence, uniform in the population, achievement of the 35% and 50% meat reduction goals corresponded to approximately 5.2 and 8.1 years, respectively. As meat consumption reduced, the average intake of meat alternatives, pulses, and vegetables increased by 30%, 108%, and 84%, respectively (-35% scenario). Greenhouse gas emissions, land use, water use, and scarcity weighted water use reduced notably in both the -35 and -50 scenarios.

CONCLUSIONS

The findings of this project could provide valuable insights for policy-makers and governmental authorities for developing effective influence strategies aimed at promoting/achieving sustainable dietary habits.

ENHANCING RESILIENCE AND LIVELIHOODS FOR VULNERABLE POPULATIONS THROUGH NUCS ADOPTION

Ranjan Kapali[1]; Ojaswi Acharya[2]; Lila Bikram Thapa[3]
[1]Nutrition and Health, Action Against Hunger | ACTION CONTRE LA FAIM (ACF), Lalitpur, Nepal; [2]Country Director, Action Against Hunger | ACTION CONTRE LA FAIM (ACF), Lalitpur, Nepal; [3]Family Welfare Division, Department of Health Services, Kathmandu, Nepal

BACKGROUND AND OBJECTIVES

In partnership with SAHARA Nepal, Action Against Hunger Nepal and Belaka Municipality implemented the Food Security and Livelihood (FSL) project. The project aimed to establish a disaster-resilient food system by promoting Nutritionally Undervalued Crops and Species (NUCS), bamboo cultivation, and mushroom farming. The project focused on empowering women, increasing household dietary diversity, and fostering sustainable livelihoods in a region characterized by hilly terrain, food insecurity, and nutritional challenges.

METHODS

An independent evaluation, commissioned by Action Against Hunger, utilized a convergent mixed-METHODS approach. Quantitative data were collected from 229 households through systematic random sampling, focusing on dietary diversity, agricultural practices, and disaster preparedness. Qualitative data came from Focus Group Discussions (FGDs) and Key Informant Interviews (KIIs) with stakeholders, including local government officials and farmers. Data analysis employed SPSS for quantitative data and thematic analysis in Excel for qualitative data, ensuring a comprehensive evaluation of project outcomes. The evaluation assessed project performance against OECD/DAC criteria—relevance, coherence, effectiveness, efficiency, impact, and sustainability—while also considering gender, social inclusion, and disability inclusion.

RESULTS

The project achieved significant improvements in awareness and utilization of Neglected and Underutilized Crop Species (NUCS), leading to an increase in household dietary diversity scores from 7.2 to 8.5. However, the impact on women's dietary diversity was less pronounced, highlighting the need for targeted interventions. Despite successful promotion of climate-resilient agricultural practices, challenges included insufficient training follow-up and mismatches between training quality and participant satisfaction. The project's relevance and coherence were rated moderate, with areas for improvement in inclusivity and disaster preparedness. Long-term sustainability remains uncertain due to mixed feedback on the adoption of introduced practices.

CONCLUSIONS

The evaluation emphasized the need for comprehensive training, post-training support, and strategic resource allocation. Key recommendations include water harvesting technologies, ongoing skills support, and integrating food demonstrations in nutrition training. These insights will guide future interventions, enhancing the effectiveness and resilience of food security programs in disaster-prone regions.

COMPREHENSIVE GEOGRAPHIC TARGETING INDEX FOR A MULTI-SECTORAL NUTRITION INITIATIVE IN NEPAL

Ramesh Prasad Adhikari,[1]; Akriti Singh[2]; Kenda Cunningham[3]; Pooja Pandey Rana[4]
[1]Monitoring, Evaluation and Learning, Helen Keller Intl Nepal, Lalitpur, Nepal; [2]Nutrition, Helen Keller Intl, New York, United States of America; [3]Monitoring, Evaluation and Learning, Helen Keller Intl, New York, United States of America; [4]Integrated Nutrition Program, Helen Keller Intl Nepal, Lalitpur, Nepal

BACKGROUND AND OBJECTIVES

Targeted, context-specific interventions for vulnerable groups are essential to improving health and nutrition outcomes for women, children, and adolescents. USAID Integrated Nutrition, an at-scale multi-sectoral initiative in Nepal, used national and subnational data on multiple indicators to develop an index that guided the selection of districts for programmatic targeting. The question, however, is how this method compares with other geographic targeting approaches.

METHODS

USAID Integrated Nutrition's multi-stage district selection involved: 1) ranking districts based on their proportion of municipalities with the highest burden of three indicators: child mortality, literacy, and early marriage; 2) ranking districts based on their proportion of municipalities with the highest burden of 13 multi-sectoral indicators spanning health and nutrition service coverage, household socioeconomic status, climate vulnerability, and more; 3) ranking districts by consulting policymakers and planners to ensure alignment with government priorities and minimize duplication; and 4) constructing a composite index by averaging the ranks from the first three stages to identify the 48 highest ranked districts. USAID Integrated Nutrition conducted overlap assessments and correlation analyses to test variations in the four stages.

RESULTS

The overlap analysis revealed that 56% of the priority districts were consistent across METHODS used in all stages. Comparisons between specific METHODS showed varying degrees of overlap: ranging from 53% to 95%. District selection based on a single approach excludes several vulnerable municipalities; for instance, the first approach excludes *terai* municipalities with a sizeable Muslim population in Lumbini Province, while the second approach overlooks the most marginalized municipalities of Madhesh Province. The moderate-to-high correlation of the fourth approach with the first ($r=0.67$ $p<0.001$), second ($r=0.06$ $p=0.607$), and third approaches ($r=0.89$ $p<0.001$) suggest that the fourth approach effectively captures both development and operational priorities.

CONCLUSIONS

These findings highlight the limitations of using a single method for district selection, as it risks excluding vulnerable communities. A multi-stage approach ensures a more comprehensive selection process, accounting for nutritional, geographic, and socio-economic diversity. To optimize resource allocation and target efforts to achieve nutrition outcomes.

FOOD ENVIRONMENT RESILIENCE IN THE CONTEXT OF A CHANGING CLIMATE IN CAMBODIA

Shauna Downs[1]; Swetha Manohar[2]; Serey Sok,[3]; Punleu Thou,[4]; Tepsam Ol Chen,[5]; Chanvuthy Keo,[6]; Leakhena Thoeun,[7]; Jessica Fanzo[8]

[1]Department of Health Behavior, Society and Policy, Rutgers School of Public Health, Newark, United States of America; [2]Nutrition, Diets & Health, International Food Policy Research Institute, Washington, United States of America; [3]Research Office, Royal University of Phnom Penh, Phnom Penh, United States of America; [4]Research Office, Royal University of Phnom Penh, Phnom Penh, Cambodia; [5]Child Rights Foundation, Child Rights Foundation, Phnom Penh, Cambodia; [6]Faculty of Social Science and Humanities, Royal University of Phnom Penh, Phnom Penh, Cambodia; [7]Research Office, Royal Phnom Penh Hospital, ភ្នំពេញ, Cambodia; [8]Columbia Climate School, Columbia University, New York, United States of America

BACKGROUND AND OBJECTIVES

Riverine communities living in the Mekong River regions of Cambodia have access to both water-related natural (wild and cultivated) and built food environments that can support their livelihoods, income sources, and consumption of nutrient-rich foods. However, upstream food systems drivers, including climate variability, have the potential to impact the types of food environments that these communities' access, as well as the foods that they can acquire from within them. The objective of this study was to examine how climate variability is influencing access to diverse food environments and the perceived impacts of those changes on food access now and in the future.

METHODS

We conducted semi-structured interviews with women (n=80) living in eight riverine communes in Cambodia along the Mekong River and Tonle Sap lake to better understand the factors influencing their food choice, the food environments they access across seasons, and how climate variability influences their access to food. Interviews were audio-recorded, translated, and transcribed and subsequently coded and organized according to key themes using a conceptual riverine food environment framework previously published by our team.

RESULTS

We found that participants reported accessing diverse food environment types. They also reported experiencing recent and rapid changes in the types of foods they could grow, collect, or fish from those environments which they attributed to increased floods, drought, higher temperatures, and stronger storms. Moreover, seasonal changes in their ability to grow, rear, collect, and fish food led to an increased reliance on purchasing food from the built food environment, including fish, vegetables, and meat that participants described as being lower in quality than foods acquired in the natural food environment due to the production practices used. Some interviewees noted a trade-off between the need to rely on food acquired from the natural food environment to meet their immediate needs versus conservation efforts and resource management to protect future food sources.

CONCLUSIONS

Understanding the ways in which climate variability is influencing food environments and riverine livelihoods can help to identify ways to support climate change adaptation strategies, including regulations, that protect communities' access to nutrient-rich food sources. Future work should focus on identifying levers for strategies that increase food environment resilience within the context of increased climate variability.

BRIDGING KNOWLEDGE SYSTEMS: A COMMUNITY-BASED PARTICIPATORY FOOD SYSTEMS APPROACH TO INDIGENOUS FOOD SECURITY AND FOOD SOVEREIGNTY

Shannon Udy[1, 2]; Treena Delormier[1, 2]; Kaylia Marquis[3]; Derek Montour[4]; Vivienne Walz[5]; Alexis Shackleton[6]
[1]School of Human Nutrition, Centre for Indigenous Peoples' Nutrition and Environment, McGill University - Macdonald Campus, Sainte-Anne-de-Bellevue, Canada; [2]Research Team, Kahnawake Schools Diabetes Prevention Program, Kahnawake, Canada; [3]Community Advisory Board, Kahnawake Schools Diabetes Prevention Program, Kahnawake, Canada; [4]Executive Director, Kahnawake Shakotiia'takehnhas Community Services, Kahnawake, Canada; [5]Community Health Plan Liason, Onkwata'karitáhtshera Secretariat, Kahnawake, Canada; [6]Director of Client Based Services, Mohawk Council of Kahnawake, Kahnawake, Canada

BACKGROUND AND OBJECTIVES

This study aimed to co-design a participatory process to create a shared vision and understanding of a community food system to promote Indigenous food security, nutrition, and well-being. This study arose to support community-driven efforts for food security and food sovereignty in one Indigenous community in Canada. The innovation of this research lies in its bridging of Indigenous and Western research approaches, ensuring that Indigenous knowledge systems and practices are central to food security planning.

METHODS

The research proposes a Community-Based Participatory Food Systems Approach that aligns Indigenous and Western research methodologies, including community-based participatory research and system dynamics. This approach fosters collaborative engagement through participatory visioning and group model building workshops. Community members work together to explore their hoped future for their food system, develop a causal loop diagram centred on a priority food system issue, and identify strategies for food system change. Workshop data are analyzed qualitatively to develop themes characterizing participants' shared vision and understanding of their food system.

RESULTS

The participatory process resulted in a community food system vision emphasizing local values and priorities such as food production and access to land. The food system model developed highlighted the interconnectedness of food security, land management, social and cultural dimensions, and community participation, illustrating the many factors and dynamics shaping food security and food sovereignty at the community level. This shared, systemic perspective provided a framework for participants to identify impactful actions for the future. The findings and the dedicated engagement of community members demonstrate the value of aligning Indigenous and Western research approaches to address complex food system challenges.

CONCLUSIONS

This study contributes a new approach to Indigenous food security and food sovereignty research and planning by bringing together distinct knowledge systems in a way that prioritizes Indigenous values and cultural practices. It fosters self-determination by providing a framework for developing actionable strategies to promote food security and systemic change. The research offers a model for future community-based research and practice that honours and respects Indigenous knowledge while advancing community-driven food sovereignty initiatives.

GREENING SCHOOL LUNCH: A PATH TO SUSTAINABLE NUTRITION IN EDUCATION

Piyanit Churak[1]; Kitti Sranacharoenpong[2]
[1]Institute of Geography, University of Erlangen-Nuremberg, Erlangen, Germany; [2]ASEAN Institute for Health Development, Mahidol University, Nakhon Pathom, Thailand

BACKGROUND AND OBJECTIVES

The intersection of climate change and sustainability with school nutrition programs is a critical, yet underexplored area of research. This study investigates the challenges and opportunities within school meal systems in Thailand, with particular emphases on the fostering of sustainable practices and climate resilience. Schools in both urban and rural settings share the responsibility of providing nutritious meals, but schools individually face different challenges of small budgets, unpredictable food sources, and reliance on conventional modes of agriculture production that hasten environmental degradation.

METHODS

The methodology included qualitative interviews with educators, school directors, and stakeholders combined with an analysis of food procurement practices, menu planning processes, and the integration of sustainability into meal programs.

RESULTS

The findings reveal that while many schools try to include local ingredients, logistical and financial barriers often limit their efforts. Hydroponic gardening and partnerships with local farmers have been at the pilot stage but remain fragmented. A key gap identified is the underutilization of local, organic, and sustainably sourced produce in school meals despite growing awareness of the health and environmental benefits. While urban schools have limited space and personnel to engage in agricultural activities, rural schools have a lack of infrastructure and difficulty accessing sustainable suppliers. This disparity in conditions between urban and rural areas highlights the need for systemic approaches that align local agricultural production with school nutrition needs.The findings also point out the potential of school meal programs to serve as platforms for the promotion of sustainability. Sourcing local and seasonal produce will reduce the carbon footprint of schools, adding value to regional economies. Educating students through meal programs can further instill lifelong habits of environmental stewardship and food security.

CONCLUSIONS

To achieve these goals, the study recommends policy interventions to provide incentives for local farmers to supply schools and invest in training and infrastructure that enables the implementation of sustainable food. Successful models can be taken to scale through effective collaboration of schools, local governments, and agricultural cooperatives. This research underlines the potential that school meal programs play in transforming the dual challenges of climate change and nutrition. As schools adapt to climate-related challenges, integrating sustainability into food systems is not just an opportunity but an imperative.

LINKING CLIMATE CHANGE AND MALNUTRITION INDICATORS IN CHILDREN UNDER FIVE

Cecília Klapka[1]; Arthur Ramalho Magalhães[2]; Brena Barreto Barbosa[3]; Estela Barici Pereira[4]; Ana Luiza Gomes Domingos[5]; Antônio Augusto Ferreira Carioca[3]; Aline Carvalho[5]
[1] Nutrition and Public Health Department, University of São Paulo, São Paulo, Brazil; [2]Department of Botany, Biosciences Center, Federal University of Pernambuco, Recife, Brazil; [3]Health Sciences Center, UNIVERSITY OF FORTALEZ, Fortaleza, Ce, Brazil; [4]Nutrition Departament, UNIFESP, São Paulo, Brazil; [5]Nutrition and Public Health Department, University of São Paulo, São Paulo, Brazil

BACKGROUND AND OBJECTIVES

Climate change, driven by natural or human-induced factors, involves long-term shifts in climate, including rising temperatures and extreme events such as droughts. These changes disproportionately affect vulnerable populations, particularly children under five years of age, due to their rapid growth, heightened nutritional needs and dependence on caregivers for adequate food. Additionally, food security, and consequently malnutrition, is likely to be impacted by climate change, as extreme weather events disrupt food production, access and affordability, particularly in low-and middle-income countries. Thus, the objective is to investigate the relationship between climate change and malnutrition in children under five in Brazil.

METHODS

Data were collected from SISVAN, WorldClim and DATASUS to create a database linking malnutrition and climate change across all Brazilian municipalities from 2008 to 2019. Children's nutritional status was assessed using height-for-age, weight-for-height, and BMI-for-age indices. Mean climate anomalies were calculated from WorldClim precipitation and temperature data, measuring how much annual observations for each municipality deviate from the 1970-2000 historical average. We included the Standardized Precipitation-Evapotranspiration Index (SPEI), a measure combining precipitation and potential evapotranspiration to assess drought severity. We used generalized additive models to test the non-linear relationship between climate change (temperature, precipitation, and SPEI anomalies) and malnutrition in children. Linear regression analyses were conducted using the ‘mgcv’ package from R software.

RESULTS

Our study revealed significant associations between the SPEI and critical markers of undernutrition in children under five years of age. Thinness was associated with a Mean Coefficient of -0.41 (adjusted $R^2 = 10\%$), low weight-for-height, reflecting acute weight deficit, with a Mean Coefficient of -0.43 (adjusted $R^2 = 8\%$) and very low height-for-age, a marker of chronic undernutrition, with a Mean Coefficient of -0.23 (adjusted $R^2 = 6\%$). These findings highlight an impact of drought conditions on child nutritional outcomes, demonstrating that municipalities experiencing intensified and prolonged droughts, likely driven by climate change, face a heightened risk of undernutrition among children.

CONCLUSIONS

The study links climate change, particularly drought intensity, to a significant, though subtle, increases in malnutrition among Brazilian children.

OAP14_09

ASSESSING THE ACCEPTABILITY AND HEALTH IMPACTS OF A HEALTHY AND SUSTAINABLE DIETARY PATTERN (MED_EAT-IT): FINDINGS FROM THE INSTEAD STUDY

Massimiliano Tucci[1]; Daniela Martini[1]; Cristian Del Bo'[1]; Iolanda Cioffi[1]; Ellis Bianchi[1]; Alessandro Meneghini[1]; Patrizia Riso[1]
[1]Department of Food, Environmental and Nutritional Sciences (DeFENS), University of Milan, Milano, Italy

BACKGROUND AND OBJECTIVES

The transition to sustainable diets that are healthy, culturally acceptable, affordable, and environmentally friendly is crucial to tackling the pressing challenges of global food and nutrition security. However, defining dietary patterns that meet these criteria remains complex and validation data from interventional studies are still scarce [1]. The INSTEAD study, part of the OnFoods project [2], aims at exploring the feasibility, acceptability, and health impacts of the MED_EAT-IT dietary pattern, an adaptation of the Planetary Health Diet tailored to the Italian context and optimized based on several initial assessments [3-6].

METHODS

A crossover, single-blind, randomized controlled trial has been implemented to assess the effect of this dietary pattern in a group of apparently healthy adults, and the intervention was recently concluded. Participants followed either the MED_EAT-IT diet or a Control diet based on the Italian food-based dietary guidelines for 8 weeks, separated by a washout period. Study outcomes include compliance, perceived acceptability (through a validated questionnaire [7]), dietary intake, nutritional status, body composition, physiological and metabolic function, including proteomic and metabolomic analyses.

RESULTS

Of the 121 screened individuals, 72 were randomized, and 53 completed the study (39 females, 14 males; mean age 44 ± 14 years). Acceptability of the MED_EAT-IT dietary pattern was rated as 6 (median, Q1-Q3 = 5-6) on a score ranging from 1 (completely unacceptable) to 7 (extremely acceptable). Also, no significant differences in terms of effort or feasibility were observed between the MED_EAT-IT and Control diets. Currently available health markers indicates that the MED_EAT-IT intervention led to a significant reduction in LDL cholesterol (between-group difference: -7.7 mg/dL; 95% CI: -13.9, -1.4; $p < 0.05$). Significant within-group modifications ($p < 0.05$) included improvements in fasting glucose (Δ = -2.9 mg/dL; 95% CI: -5.0, -0.9), triglycerides (Δ = -10.8 mg/dL; 95% CI: -17.1, -4.5), total cholesterol (Δ = -14.7 mg/dL; 95% CI: -20.4, -9.0), but also a reduction of ferritin (Δ = -4.4 µg/L; 95% CI: -8.3, -0.5), and hemoglobin (Δ = -0.2 g/dL; 95% CI: -0.4, -0.1).

CONCLUSIONS

Currently available findings suggest that the sustainable MED_EAT-IT dietary pattern can be considered feasible and well-accepted and with potential health benefits. However, observed reductions in iron status markers highlight the need for additional investigation. Further analysis and particularly, metabolomic and proteomic data will help elucidate individual responses and support personalized dietary strategies for specific target populations.

OAP 07 - CLIMATE CHANGE, SUSTAINABILITY AND NUTRITION

OAP7_01

SPECIES RICHNESS OF FRUIT AND VEGETABLES AND DIET QUALITY OF ITALIAN ADULTS

Aliki Kalmpourtzidou[1]; Sara Boussetta[1]; Beatrice Maccarini[1]; Ghanya Al-Naqeb[1]; Rachele De Giuseppe[1]; Laura D'addezio[2]; Lorenza Mistura[2]; Hellas Cena[1]
[1]Department of Public Health, Experimental and Forensic Medicine, Università Degli Studi di Pavia - Scientific Center, Pavia, Italy; [2]Research Centre for Food and Nutrition, Council for Agricultural Research and Economics (CREA), Rome, Italy

BACKGROUND AND OBJECTIVES

Dietary species richness (DSR) is key to food security and nutrient adequacy. Fruit and vegetable consumption could contribute significantly to the food biodiversity of diets, however, studies about their DSR in comparison to diet quality are mostly not available. This is the first analysis evaluating the DSR of fruit and vegetables in comparison to the diet quality of Italian adults using nationally representative data.

METHODS

Data from the Italian dietary survey (IV SCAI study 2018-2020) was used, including 726 adults (346 male, 380 female), aged from 18 to 64 years old. Dietary assessment was conducted based on the EU Menu methodology of EFSA with the use of two 24-hour recalls. DSR of fruit and vegetable was calculated for both days per individual by counting and summing the total number of unique species consumed. Diet quality was assessed using the global diet quality score (GDQS). Total GDQS was calculated based on 25 food groups (score 0-49), and sub-indices GDQS+ (16 food groups; score 0-32) and GDQS- (7 food groups; score 0-17) were calculated according to the consumption of healthy and unhealthy foods, respectively. Total GDQS cut-off is defined as high risk for poor diet quality as of <15, while for low risk ≥23. A mean score for both days was calculated per individual. After testing for the normal distribution of the variables, Spearman's rho test for non-normally distributed variables was used to evaluate potential correlations between the DSR of fruit and vegetables and the diet quality indices for the total population and per gender.

RESULTS

The mean of total fruit and vegetable DSR summed for two days was 9 per individual. The mean of total GDQS was 18.95, which RESULTS in a moderate diet quality, but not a low risk of poor diet quality, while the mean GDQS+ and GDQS- were 7.77 and 11.18, respectively. Higher DSR of fruit and vegetable in total was positively correlated with higher total GDQS (better total diet quality) [rs=0.20; p= <0.001], GDQS+ (higher consumption healthy foods) [rs=0.20; p= <0.001] and GDQS- (lower consumption of unhealthy foods) [rs=0.07; p= 0.046]. When the correlations were tested per gender, positive correlations were found for total GDQS and GDQS+ both in males and females.

CONCLUSIONS

Based on this analysis, higher DSR of fruit and vegetables could result in higher diet quality in Italian adults, however further research in Europe regarding DSR and food biodiversity indexes is required. Varieties of fruit and vegetable species may have different nutrient profiles, but the use of 24-hour recalls cannot provide this information in most cases.

LINKING DIETARY PATTERNS TO FOOD WASTE MANAGEMENT: INSIGHTS FROM MALAYSIAN ONLINE SURVEY

Janice Ee Fang Tay[1]; Satvinder Kaur Nachatar Singh[2]; Amierah Amer[3]; Nur Atiqah Hasbullah[3]; Veronika Forstmeier[3]; Chitra Devi Gopalakrishnan,[3]
[1]Food Science and Nutrition, UCSI University, Kuala Lumpur, Malaysia; [2]Food Science and Nutrition , UCSI University, Kuala Lumpur, Malaysia; [3]Food Footprint Pillar, Marine Programme, WWF-Malaysia, Petaling Jaya, Malaysia

BACKGROUND AND OBJECTIVES

Dietary preferences are hypothesized to influence what and how much of food is discarded, suggesting a relationship between food choices and waste generation. By focusing on how dietary patterns shape waste behaviors, we can identify strategies to promote more sustainable consumption practices and food waste prevention. This study aimed to identify food consumption patterns that explain their role in food waste management behaviour among Malaysian adults.

METHODS

An online survey was conducted among 1,061 Malaysian adults aged 18 years and above between December 2020 and January 2021. Data were collected through a self-administrative online questionnaire covering sociodemographic characteristics, dietary choices, and food waste management practices. Factor analysis using principal component analysis (PCA) with equamax rotation was used to identify different dietary patterns based on similar characteristics of dietary choices. Generalized Estimating Equation (GEE) analysis was used to associate emerging dietary patterns with food waste management behaviours. The analysis controlled for potential confounders such as age, sex, ethnicity, household size, and combined household income.

RESULTS

Factor analysis identified three dietary patterns accounting for 55.2% of variance in food choices: animal-based diet, health-food/sustainable-driven diet, and convenient food. Poorer food waste management was reported out-of-home (mean score: 69.9%) compared to inside-of-home (mean score: 74.4%). Individuals with health-food/sustainable-driven diets (aOR [95%CI] = 2.04 [1.78, 2.34]; $p<0.001$) and convenient food patterns (aOR [95%CI] = 1.29 [1.16, 1.44]; $p<0.001$) were more likely to manage food waste well, whereas those with animal-based diets (aOR [95%CI] = 0.83 [0.73, 0.94]; $p<0.001$) were more likely to exhibit poor food waste management.

CONCLUSIONS

These findings suggest that dietary patterns may influence food waste practices. Notably, health-food/sustainable-driven dietary patterns, which emphasize the consumption of edible portions, could potentially contribute to lesser food waste as compared to animal-based diet. Future research is warranted to further explore the components and edible portions of Malaysian dietary preferences in relation to their food waste habits.

EFFECTS OF WILDFIRES BURNED AREA ON CONSUMER FOOD PRICE WORLDWIDE: A CONSEQUENCE OF CLIMATE CHANGE

Haris Majeed[1]; Shyon Baumann[2]; Hamnah Majeed[3]; Daniyal Zuberi,[4]
[1]Factor-Inwentash Faculty of Social Work, University of Toronto, Toronto, Canada; [2]Sociology, University of Toronto, Toronto, Canada; [3]Faculty of Medicine and Health Sciences, McGill University, Montreal, Canada; [4]Factor-Inwentash Faculty of Social Work and Munk School of Global Affairs and Public Policy, University of Toronto, Toronto, Canada

BACKGROUND AND OBJECTIVES

The past two decades have seen unprecedented wildfires worldwide, which has caused large areas of damage to agricultural land. This damage can be highly disruptive to different sectors of the economy. While most studies report negative economic effects with increasing wildfires, the literature does not offer conclusive evidence regarding its risk on consumer food price index (the cost of a fixed basket of goods and services purchased by consumers). Preliminary analyses pertaining to the effects of wildfires on nutrition and economic indicators have focused solely on a single country, yet there is a need to understand the effects of wildfire damage on consumer food prices worldwide.

METHODS

A cross-sectional global analysis from 2002-2022 incorporating 160 countries [North America (16 regions), South America (12 regions), Europe (37 regions), Asia (45 regions), Africa (44 regions), Oceania (6 regions)] assessed the annual associations between burned forest area, burned crop land, and consumer food price index using Poisson regression. Forest and crop burned area data was obtained from the Global Wildfire Information System, whereas consumer food price index (measured with 2015 base prices) data obtained from Food and Agriculture Organization of the United Nations. Models controlled for crude oil prices, GDP, unemployment, gold prices, region, and trend. All models were interpreted as a rate ratio (RR).

RESULTS

From 2002-2022, consumer food prices experienced a significant ($P<0.001$) rise in each of the six continents, where Africa experienced the greatest increase (8.2% per year, $P<0.001$) and Oceania experienced the slowest rise (2.7% per year, $P<0.001$). Overall, adjusted models showed that for every 100,000 hectares of forest area burned, regions in South America, Europe, Asia, and Africa experienced a decrease in consumer food prices (RR 0.99, $P<0.001$). In contrast, for every 100,000 hectares of crop area burned, regions in North America, South America, and Africa experienced an increase in consumer price index (RR 1.001, $P=0.01$). Gold prices were the most significant predictor of consumer food prices.

CONCLUSIONS

These findings of this research suggest that the type of burned land can have different consequences on consumer food prices, including variations between regions in each continent. Future climate change may exacerbate such relationships and increase wildfires, possibly having important consequences for food costs.

TRANSITION TOWARDS HEALTHIER AND MORE SUSTAINABLE FOOD HABITS: WHAT IS THE ACTUAL COST FOR PARENTS FACING FINANCIAL HARDSHIP?

Basile Verdeau[1]; Qhadira Kissangou Chumo[1]; Sandrine Monnery-Patris[1]
[1]INRAE - AlimH, Centre des Sciences du Goût et de l'Alimentation (CSGA), Dijon, France

BACKGROUND AND OBJECTIVES

Transitioning towards more plant-based diets is needed to protect the environment and improve public health. However, little is known about the determinants of this transition for low-income consumers, who already tend to have diets of poorer nutritional quality. Although sustainable diets would be less expensive than current diets, the acceptability of such changes still may be challenging. The aim of this study is to understand how financial scarcity could act as a barrier to the adoption of more sustainable diets, focusing on parents of children aged 3 to 11 as parenthood implies additional constraints on food choices.

METHODS

A mixed-method approach was used. First, fourteen semi-structured interviews were conducted with parents living in a deprived neighbourhood in France and reporting financial hardship. Sorting tasks were performed with 17 cards representing different food groups to explore perception of prices, food frequency consumption and willingness to adopt plant-based habits. A thematic analysis was carried out based on the transcribed interviews. Second, a representative sample of 500 parents in France completed an online questionnaire. The questionnaire was designed according to the scarcity theory and explored sustainable choice intentions, choice motives, perceived cost of a dietary change, feeling of powerlessness and perceived prices. Regression analyses will be conducted to identify the link between financial hardship and psychological constructs.

RESULTS

Qualitative analysis: Most parents reported a daily consumption of meat and/or fish and a low consumption of fruits, vegetables, pulses, nuts and whole grains. A healthy diet was automatically associated with higher costs, but the perception of price appeared to imply multiple rationales. Different costs were identified beyond the financial cost: the transition towards sustainable diets represented a cognitive, cultural, social and hedonic cost. Food choices were based on monthly routines, in which meat played a central role, favoured by trade-offs that limit its cost to the detriment of healthy foods.

Quantitative analysis: The RESULTS of the survey will be available by May 2025.

CONCLUSIONS

Food choices made by parents in financial hardship are rooted in stable habits which hinder the possibility of considering a change towards a more sustainable diet. Promoting sustainable food habits in this population should encourage the exposure to healthy plant-based foods at no additional financial cost, but also at no additional cognitive cost.

WHAT ALTERNATIVE PROTEINS ARE EXPECTED BY CONSUMERS IN 7 NORTHERN EUROPEAN MEMBER STATES? A BRADLEY-TERRY MODEL

Federico Perez-Cueto[1]; Arturo Turillazzi[1]; Eva Palmquist[1]
[1]Research Group Sustainable Food Transitions, Department of Food, Nutrition & Culinary Science, University of Umea, Umea, Sweden

BACKGROUND AND OBJECTIVES

Given the current climate emergency, shifting diets to more sustainable sources has been advocated for environmental and health perspectives [1, 2]. Such societal shift requires active involvement by citizens and their adoption of proposed alternatives[3]. In Northern Europe, meat and dairy consumption remains far above recommendations[4–6]. Therefore, the objective of this communication is to identify what kind of alternative proteins were preferred and expected by consumers by the end of 2024.

METHODS

Data Collection: A cross-sectional survey was conducted online by *Enkätfabriken* AB between November and December, 2024 in DE, EE, FI, LT, NO, PL and SE (n=5250, 50% women). The questionnaire included sociodemographic characteristics and ranking of consumer expectations toward alternative protein sources.

Data analysis: A Bradley-Terry model was fitted to evaluate consumer preferences for following alternative protein sources: fermented plant-based foods, cultivated proteins, fungi, algae, extruded plant-based proteins, and insects. Fermented plant-based products were used as the reference category. Analyses were perfomed with R version 4.4.2 (2024-10-31), using package BradleyTerry 2. A p-value <0.05 was considered significant.

RESULTS

All alternative protein categories were significantly less preferred compared to fermented plant-based products ($p<0.001$). Cultivated proteins were 32% less likely to be ranked as first, followed by extruded plant-based foods (47% less likely). Algae- and fungi-based products also showed lower preference, being 78% and 59% less likely to be ranked first, respectively. The least preferred protein source was insects with a log-odds estimate of -2.44 ($p < 0.001$). The model exhibited strong fit, with a residual deviance of 4.54e-13 and an AIC of 122.33.

CONCLUSIONS

Fermented plant-based foods are significantly preferred over other alternative proteins, with insect-based foods being the least favored option.

ADVANCING COURAGEOUS LEADERSHIP PRACTICES TO TACKLE POWER IMBALANCES AND ACCELERATE CHANGE IN NUTRITION AND FOOD SYSTEMS: THE CASE OF THE NEXT GEN(D)ERATION LEADERSHIP COLLECTIVE

Isabel Pemjean[1]; Juliana Miraldi,[2]; Rajji, Lea Al[3]; Hala Ghattas[4, 5]; Ana Clara Duran[6]; Camila Corvalán[1]
[1]CIAPEC, Institute of Nutrition and Food Technology, University of Chile, Santiago, Chile; [2]Núcleo de Estudos e Pesquisa em Alimentação (NEPA), UNICAMP Universidade Estadual de Campinas, São Paulo, Brazil; [3]American University of Beirut, Department of Health Management and Policy, Beirut, Lebanon; [4]Arnold School of Public Health, University of South Carolina, Columbia, United States of America; [5]Center for Research on Population and Health, American University of Beirut, Beirut, Lebanon; [6]Center for Food Studies and Research, UNICAMP Universidade Estadual de Campinas, Campinas, Brazil

BACKGROUND AND OBJECTIVES

The current food system fails to provide equitable access to nutritious food, exacerbating inequalities, environmental degradation and climate change. Addressing power imbalances in leadership can increase the effectiveness, equity, and resilience of food systems. This requires the unique perspectives and innovative practices of marginalized people, particularly women, who play a vital role in food systems but face substantial inequalities exacerbated by intersectionality. The Next Gen(D)eration Leadership Collective (NGLC) is a global innovative initiative that addresses these issues through interventions, like Forums and Pods which have engaged nearly 700 women since 2021. These online activities are based on the NGCL's 8 leadership practices (Manifesto) and Theory of Change (ToC) (Collective support- collective efficacy- collective agency- mobilizing coalition- collective action- redressing power imbalances). This study evaluates NGLC's activities (2021-2024) to identify strengths and weaknesses, informing its contribution to accelerating food system transformation.

METHODS

We conducted a process and impact evaluation of the NGLC's activities using a mixed-METHODS approach based on quantitative data on activities and participants and 27 semi-structured interviews with activities´ participants. We ran descriptive statistical RESULTS for quantitative data and deductive content analyses (based on the ToC) using the interviews.

RESULTS

The NGLC Forums engaged 473 participants and Pods, 123. Participants viewed the Forums as reflective spaces for discussing challenges and barriers to teamwork in food systems, addressing the two first steps (collective support and collective efficacy) of the NGLC ToC, recognizing the experiences of others and reinforcing supportive leadership. This raised awareness of structural barriers (gender and intersectionality), aiming to redress power imbalances in leadership. However, challenges arose in maintaining relevance post-pandemic. Participants noted the Forums' multiplier effect relied on individual capacities to implement discussed leadership values. The global character of the initiative was valued, but power inequalities were seen as territory specific. Participants valued the Pods but reported that they required significant commitment. They focused on collective support and, along with the Forums, addressed the 8 leadership practices outlined in the NGLC's Manifesto.

CONCLUSIONS

While challenges persist, the NGLC's approach has shown promise in accelerating food system transformation: it has contributed to raising awareness of structural barriers (gender and intersectionality), promoting collective work, and providing soft skills to exercise power.

Co-benefits and trade-offs between environmental impact and diet quality: RESULTS from a population-based cohort

Elinor Hallström[1]; Niclas Håkansson,[2]; Ulf Sonesson,[3]; Agneta ÅKesson,[2]; Alicia Wolk,[2]
[1]Nutrition Sustainability and Health Promotion, National Food Institute (DTU), Kongens Lyngby, Denmark; [2]Institute of Environmental Medicine, Karolinska Institute, Stockholm, Sweden; [3]Food and Agriculture, Rise Research Institutes Of Sweden, Gothenburg, Sweden

BACKGROUND AND OBJECTIVES

Dietary changes can reduce environmental impact and improve health outcomes, but trade-offs between these aspects may occur. In particular, concern has been raised for an increased risk of inadequate nutrient intake in environmentally adapted diets with lower amounts of animal-based foods. This study aims to identify potential co-benefits and trade-offs between environmental and nutritional perspectives by assessing the nutritional adequacy of self-reported diets varying in environmental impact.

METHODS

Dietary intake was based on data of 30 000 individuals (aged 56-70) within two population-based Swedish cohorts, who completed a food questionnaire in 2009 (1). Environmental impact was assessed based on life cycle assessment data using an aggregated score based on six environmental indicators (greenhouse gas emissions, cropland use, nitrogen application, phosphorus application, consumptive water use, extinction rate) (2). Linear regression analyses examined associations between dietary environmental impact and energy standardized nutrient intake across quintiles of aggregated environmental impact. Nutritional adequacy was assessed by comparing the mean nutrient intake in men and women to gender and age specific reference values (average requirements and recommended intake) of the Nordic Nutrition Recommendations 2023.

RESULTS

Diets with lower environmental impact were associated with *higher* intake of total carbohydrates, fibre, whole grains, sucrose (women), polyunsaturated fatty acids, linoleic acid and α-linolenic acid, but *lower* intake of protein, total fat, saturated fatty acids, monosaturated fatty acids, EPA, DPA, DHA, total n-3 fatty acids and alcohol. Diets with lower environmental impact were moreover associated to *lower* intake of most vitamins and minerals, except for potassium, and magnesium. Diets with lowest compared to highest environmental impact had higher adherence to some recommendations for macronutrients and met reference intake levels of all micronutrients except for selenium and vitamin D (women).

CONCLUSIONS

Self-reported diets with a lower impact on multiple environmental indicators had both positive and negative effects on diet quality. While low-impact diets had a lower intake of most vitamins and minerals, adherence to macronutrient recommendations was generally higher, and micronutrient intake was adequate, except for selenium and vitamin D.

OAP25_02

DETERMINANTS AND COMPARISON OF WILLINGNESS TO TRY PLANT-BASED FERMENTED FOODS FROM DIFFERENT TECHNOLOGIES IN 9 EU COUNTRIES

Jean-Paul Garin[1]; Helene Reinbach[2]; Maxime Michaud[3]; Federico Perez-Cueto[1]
[1]Research Group Sustainable Food Transitions, Department of Food, Nutrition & Culinary Science, University of Umea, Umea, Sweden; [2]Department of Food Science, University of Copenhagen, Copenhagen, Denmark; [3]Research Center, Lyfe Institut, Écully, France

BACKGROUND AND OBJECTIVES

Traditional fermentation techniques are valued for improving shelf-life, digestibility, flavour and texture of food (1). New technologies like biomass and precision fermentation offer solutions to efficiently manufacture value-added protein-rich products (2) and to produce specific bioactive ingredients (3). Fermentation technologies provide solutions to the nutritional and sensory challenges of the PBF category (4). Willingness to try (WTT) shows the consumer's level of acceptance of these technologies by providing strategic information on how to promote, market and make PB alternatives the new default. The objective of this study is to identify and compare the determinants of willingness to try for different fermentation technologies in 9 EU countries.

METHODS

A cross-sectional survey (December 2023/February 2024 in BE, CH, DE, DK, FI, FR, IT, RO, SE) to investigate consumer perceptions towards PB fermented foods (5). The questionnaire included sociodemographic characteristics, dietary lifestyle and WTT. Linear regression was performed with the 3 statements "I would be willing to try a product that is prepared through Precision/Traditional/Biomass Fermentation" as dependents and sociodemographic characteristics as explanatory variables. A p-value below 0.05 was considered significant.

RESULTS

In total, 7812 responses were collected; 50% females equally divided in five age groups. About 60% of the respondents are willing to try traditionally fermented foods compared to 50% willing to try foods made from biomass and precision fermentation. Across technologies, negative associations were found between WTT and being a female, and with age. Positive associations were found for WTT and education, financial situation and locality of residence. The coefficients associating WTT with diet show that moving towards a more plant-based dietary lifestyle increases the WTT by around 25-30%. The country of residence was not influencing WTT.

CONCLUSIONS

The more educated, well-off and PB-eating people are, the more willing they are to try a product made from Precision/Traditional/Biomass Fermentation in 9 EU countries. Older people, men and those living in rural areas are more reluctant to try such products. These aspects should be considered for promoting and supporting a sustainable, healthy and tasty dietary transition.

SOUTH AUSTRALIAN GOVERNMENT FOOD, AGRICULTURE AND ENVIRONMENTAL POLICIES AND THE EXTENT TO WHICH THEY HELP OR HINDER THE DEVELOPMENT OF A HEALTHY, SUSTAINABLE AND EQUITABLE FOOD SYSTEM

Amanda Hayes[1]; Kim Anastasiou[1]; Matt Fisher[1]; Dora Marinova[2]; Fran Baum[1]
[1]Stretton Health Equity, The University of Adelaide, Adelaide, Australia; [2]Curtin University Sustainability Policy Institute, Curtin University, Bentley, Australia

BACKGROUND AND OBJECTIVES

Food systems are made up of a complex web of interconnected and intersecting policies and activities from production to consumption. In high-income countries, like Australia, food systems are much less healthy for humans than they might be and contribute to degradation of the environment. This paper reports on the first stages of a study examining South Australian government food-related strategic policies and analyses the extent to which they help or hinder the development of a healthy, sustainable and equitable food system.

METHODS

South Australian government websites were searched to identify food-related strategic policies in the agriculture, environment, food processing, manufacturing, and marketing sectors. Agreed inclusion and exclusion criteria were followed resulting in a data set of 15 policy documents. We analysed these documents using NVivo 13 Software employing a detailed pre-defined qualitative coding framework to determine the types of policy actions engaged in (e.g. educational intervention), and the outcomes (e.g. health, sustainability, economic) these policy actions purported to achieve. The extent to which the policies recognised evidence and proposed action on social and commercial determinants of health and health inequities was also identified.

RESULTS

Our preliminary findings indicate that food-related policy in South Australia does not prioritise health or environmental sustainability. Environmental and agricultural policies favour adaption and resilience over mitigation, and sustainability outcomes, when articulated, were predominantly non-specific. We also found a strong focus on economic outcomes, such as attracting investment into “climate smart” businesses. Several policies did mention equity, but strategies often employed feeble language (e.g. “giving weight to equity considerations”). Our analysis indicates that some cooperation between government departments exists in policy formulation but more opportunities to enhance intersectoral collaboration are evident. In addition, silences were noticeable in several policies integral to the food system such as landscape management strategies.

CONCLUSIONS

Our research highlights the need for robust food policies in South Australia that act on evidence concerning the contribution of the food system to population health, environmental degradation and health inequities. While economic considerations are important our study suggests they dominant over efforts to create a healthy, sustainable, and equitable food system that benefits all South Australians.

OAP25_04

DIETARY INTAKE OF PLANT-BASED MEAT CONSUMERS VERSUS NON-CONSUMERS IN UK NATIONAL DIET & NUTRITION SURVEY

Nicole Neufingerl[1]; Laurine Ballintijn[2]; Sander Biesbroek[2]; Anne Wanders[3]
[1]Nutrition and Health, Unilever Foods Innovation Centre - Hive, Wageningen, Netherlands; [2]Division of Human Nutrition and Health, Wageningen University & Research, Wageningen, Netherlands; [3]Diet and Health, Unilever Foods Innovation Centre - Hive, Wageningen, Netherlands

BACKGROUND AND OBJECTIVES

Current knowledge on the influence of plant-based meat (PBM) on dietary intakes is mainly based on theoretical modelling studies, while evidence from actual consumption data of PBM consumers is scarce, preventing health authorities from developing clear guidelines on PBM consumption. Therefore, this study aimed to investigated dietary intakes of PBM consumers and compare them to those of non-PBM consumers and to dietary reference values.

METHODS

Cross-sectional dietary intake data of 18–64-year-old PBM consumers (n=101) and non-PBM consumers (n=1845), based on 4-day food diaries, from the UK National Diet & Nutrition Survey Rolling Program (2014-19) were used for the analysis. Independent student t-tests were performed to test for significant differences in food and nutrient intakes between PBM consumers and non-PBM consumers. Average nutrient intakes were compared to the estimated average requirements (EAR), or in case no EAR is established to reference average population intakes (AI), reference nutrient intakes (RNI) or upper limits (UL).

RESULTS

Average intake of PBM among PBM consumers was 36.5 ± 30.3 g/d. PBM consumers had a higher intake of fruit (+54%, $p<0.001$), vegetables (+49%, $p<0.001$), pulses (+42%, $p=0.04$) and non-alcoholic drinks (+13%, $p=0.008$), and a lower animal meat intake (-62%, $p<0.001$) than non-consumers. Nutrient intakes of PBM consumers were more in line with dietary reference values, with higher intakes of fibre (83% vs 62% of AI, $p<0.001$), polyunsaturated fatty acids (105% vs 96% of AI, $p=0.005$) and most micronutrients than non-consumers, a lower but adequate intake of protein (180% vs 191% of EAR, $p=0.001$), and no differences in saturated fatty acid (SFA) (both 122% of UL, $p=0.82$) and sodium intakes (89% vs 86% of UL, $p=0.49$). In both groups inadequate intakes of fibre, vitamin D, vitamin E, selenium, and potassium and too high intakes of SFA were found.

CONCLUSIONS

PBM consumers had more favourable food and nutrient intakes than non-consumers, suggesting that PBM can support the transition to a heathier plant-based diet. However, more dietary changes are required to ensure adequate intakes of all nutrients.

CONFLICTS OF INTERESTS

NN and AW are employees of Unilever, a company that produces and markets foods and beverages including plant-based meat alternatives. The other authors report no conflict of interest.

OAP25_05

THE TRUE PRICE OF FATTY FISH: ENVIRONMENTAL EXTERNALITIES AND HEALTH IMPACTS IN THE PRODUCTION AND CONSUMPTION OF WILD-CAUGHT AND FARMED FISH IN THE NETHERLANDS

L. Jacky Florencio[1]; Jeljer Hoekstra[1]; Elisabeth Temme[1]; G. Ardine De Wit[1]
[1]Centre for Prevention, Lifestyle and Health, National Institute for Public Health and Environment (RIVM), Bilthoven, Netherlands

BACKGROUND AND OBJECTIVES
The true price of fish, which reflects both its health benefits and potential risks, alongside the environmental impact of its production, is still under-studied. While fish consumption, particularly fatty fish, is associated with health benefits (e.g. cardiovascular diseases), contaminants in fish can pose risks to human health. Additionally, the METHODS of fish production, whether through wild capture or aquaculture, significantly affect biodiversity and present environmental challenges. The objective of this study was to calculate the true price of fatty fish by internalising the environmental and health costs associated with its consumption in the Netherlands.
METHODS

Nationally representative fatty fish consumption data were retrieved from the Dutch National Food Consumption Survey 2019-2021. Fish products were classified by species and fishery type. The cost-of-illness (COI) method was applied to determine the direct and indirect health costs of ischemic stroke, ischemic heart disease and intracerebral haemorrhage, taking into account the Population Attributable Fraction (PAF) to assess the proportion of these diseases associated with insufficient fish consumption. Environmental impacts were assessed for global warming, terrestrial acidification, freshwater eutrophication, marine eutrophication, land use, and water consumption using the Dutch Life Cycle Assessment Food Database Environmental prices from CE Delft 2023 were applied to monetise these impacts. A premium or discount reflecting the combined environmental and health impacts was applied to baseline Dutch food retail prices.

RESULTS

Majority of the Dutch population consume less fish than recommended by the dietary guidelines for sufficient fish consumption, resulting in €12,16 per capita and €159 million total external healthcare costs from this deficiency. The health discount for fatty fishes is -€2.38. Environmental costs vary by fish species and fishery type, with the highest price being for cultivated salmon and lowest for wild-caught mackerel. The true price reflect a percentage change ranging from -31% to +6% compared to current market prices (prelimnary resuts).

CONCLUSIONS

This study suggests that current fatty fish market for some fish species are below their true societal costs. The true pricing method provides a valuable tool to support the transition to sustainable production and consumption in the food system by internalising positive and negative externalities.

NUTRITIONAL-ECOLOGICAL FACTORS AND THEIR RELATIONSHIPS IN SUSTAINABLE FOOD SYSTEMS - QUALITIATIVE MODELLING

Eleonore Heil[1, 2]; Fröba Anna[3]; Vanessa Vohland[1]
[1]WG Nutrition Ecology, Justus Liebig University, Gießen, Germany; [2]Center of Sustainable Food Systems, Justus Liebig University, Giessen, Germany; [3]WG Nutrition Ecology, Justus Liebig University, Giessen, Germany

BACKGROUND AND OBJECTIVES

Food systems are complex and include production, processing, packaging, storage, transport and distribution. With a growing global population and an increase in diet-related non-communicable diseases, it is essential to address food systems in the context of planetary health. This includes consideration of the impact of climate change on the environment, ecosystems and human well-being, making it essential to integrate multiple dimensions into research and decision-making.

METHODS

A qualitative model of sustainable food systems was developed using the Nutrition-Ecological Modelling (NutriMod) method. A two-round Delphi study was conducted with 54 experts from different disciplines and countries to reach consensus on the model. All factors and relationships were graphically represented in a hyperlinked model, defined and supported by scientific literature. A total of 389 scientific papers were analysed.

RESULTS

The model is highly aggregated to reflect the complex reality of sustainable food systems. The many determinants relevant to sustainable food systems have been summarised in 60 factors, grouped into 15 thematic clusters and defined using evidence-based criteria based on the scientific literature. Different forms of relationships between the factors were visualised. The relationships can be further differentiated according to their direction, type and the inclusion, number and thematic cluster of the factors involved. The following effects can be distinguished Effects between factors within a thematic cluster; Effects between factors of different thematic clusters; Retroactive effects; Effects involving several factors. In addition, individual effects merge into effect chains and feedback loops that illustrate complex interrelationships and dependencies and lead to the final complex model of a sustainable food system. For example, livestock production leads to the formation of greenhouse gases, which affect the climate and accelerate global warming. Global warming has a number of effects on crop farming, such as land degradation and lower crop yields, which reduces food security. The interactive hyperlink model ensures that all factors and relationships are explained and that the sources used can be verified.

CONCLUSIONS

The model depicts the complex and multidimensional interrelatedness, promotes a common understanding of the topic by actors from different disciplines and thereby contributes to a transformation towards sustainable food system by supporting integrative problem-solving.

OAP25_07

GRASSHOPPER-BASED DIM SUM: A SUSTAINABLE AMINO ACID-RICH FOOD SOLUTION FOR PRESCHOOLERS

Anny Nila Syauqiyyah[1]; Eny Palupi[1]; Budi Setiawan[1]; Reisi Nurdiani[1]
[1]Nutrition Science, IPB University, Dramaga, Indonesia

BACKGROUND AND OBJECTIVES

Preschoolers (60–72 months) require high-quality protein for growth and cognitive development. With increasing global demand for sustainable nutrition, grasshoppers (*Valanga nigricornis*) emerge as a promising protein alternative due to their rich nutritional profile and lower environmental impact than livestock. This study explores grasshopper-based dim sum's amino acid composition and nutritional potential as a sustainable solution for supporting preschoolers' dietary needs.

METHODS

A controlled experimental design was employed, utilizing a Completely Randomized Design (CRD) approach to analyze the amino acid profile, proximate composition, and mineral content of grasshopper-based dim sum (F1: 25% grasshopper, 75% mackerel) compared to a control (F0: 100% mackerel). Amino acid content was quantified using UPLC and HPLC, with RESULTS evaluated against FAO/WHO guidelines. Nutrient adequacy was assessed using the Nutrient Adequacy Levels (NAL) for preschoolers.

RESULTS

The F1 formulation exhibited an amino acid score of 122, reflecting superior protein quality. Essential amino acids such as lysine (10,400.20 mg/kg) and tryptophan (1,028.26 mg/kg) significantly exceeded FAO/WHO requirements. Glutamic acid, present at 20,176.64 mg/kg, enhanced the nutritional impact and sensory acceptance. Additionally, F1 contributed to 56.1% of the protein and notable amounts of essential minerals, such as calcium and zinc, needed for growth and cognitive development.

% Amino acid contribution in children aged 4-6 years based on ANU/WHO 2007		
Lisin	176.4	297.1
Sulfur amino acids (Methionine+cystine)	61.1	122 (100+)
Threonine	251.7	356
Tryptophan	133.8	214.2

CONCLUSIONS

Grasshopper-based dim sum represents an innovative, eco-friendly, and nutrient-dense alternative to conventional protein sources. Its exceptional amino acid profile and contribution to preschoolers' nutrient needs underscore its potential to address protein malnutrition sustainably. Future research should explore long-term health impacts and consumer acceptance.

DEATHS ATTRIBUTABLE TO DIET- AND WEIGHT-RELATED RISK FACTORS IN CITIES: A GLOBAL MODELLING STUDY

Olivia Auclair[1]; Jack Rawden,[2]; Sebastiano Caleffi[2]; Marco Springmann,[1, 2]
[1]Environmental Change Institute, School of Geography and the Environment, University of Oxford, London, United Kingdom; [2]Institute for Global Health, University College London, London, United Kingdom

BACKGROUND AND OBJECTIVES

Diets are a leading cause of global mortality from non-communicable diseases. While existing studies have conducted health risk assessments for regions, there is potential for targeted polices aimed at addressing public health at the city level. Our objective was to estimate deaths attributable to diet- and weight-related risk factors in cities.

METHODS

We used a comparative risk assessment framework to estimate attributable deaths from diet- and weight-related risk factors for adults living in cities with agglomerations of 300,000 individuals or more. The underlying data for intake of diet-related risk factors (vegetables, fruits, legumes, nuts and seeds, red meat) were based on proxies generated by combining waste-adjusted food availability data with sociodemographic trends from dietary surveys and estimates of energy intake for weight-related risk factors (underweight, overweight, obesity) inferred from anthropometric measures. We then used the age and sex distribution within populations from city-level data from WorldPop and World Urbanisation Prospects 2018 to infer dietary intakes and energy intakes.

RESULTS

Nearly half of global attributable deaths occurred in cities (3.9 million v. 8.7 million for countries). Cities with the highest proportion of deaths attributable to diet- and weight-related were typically from Eastern Europe (Ukraine, Belarus, Uzbekistan) and Russia (35-40%). Deaths from diet-related risk factors were highest for Ulaanbaatar (Mongolia) (25%), which was largely attributable to their consumption of diets high in red meat and low in fruits (each contributing 8% to total deaths). The proportion of deaths from weight-related risk factors was greatest for cities of countries in the Middle East (Iraq, Syria, Egypt, Bahrain) and Port of Spain (Trinidad and Tobago) (25%). Obesity was responsible for the greatest proportion of deaths from coronary heart disease (CHD) and type 2 diabetes (T2D) for cities in the Middle East and the USA (CHD: each 30%; T2D: 60% for Egypt, 55% for USA), and alongside diets low in vegetables for cities in the Democratic Republic of the Congo, contributed most to cancer deaths for cities in Egypt (each 17%). Diets low in fruits contributed most to deaths from stroke in Banjul (Gambia) (35%) and underweight to deaths from respiratory disease for cities in Ethiopia (28%).

CONCLUSIONS

Given that only one-third of the global adult population reside in cities but account for half of diet- and weight-related attributable deaths, our findings highlight the need for policy action at the city level to facilitate the transition to healthy and sustainable diets.

A VISUAL TOOL FOR ASSESSING THE HEALTH AND ENVIRONMENTAL IMPACTS OF FOOD CHOICES

Joan Sabate[1]; Ujué Fresán[2]
[1]Center for Nutrition, Healthy Lifestyle, and Disease Prevention, Loma Linda University School of Public Health, Loma Linda, United States of America; [2]Sustainable diets, ISGlobal, Barcelona, Spain

BACKGROUND AND OBJECTIVES

The environmental and health impacts of food production and consumption are receiving increasing attention, yet studies often address these impacts separately. Additionally, existing visualizations of this information are often complex, limiting their accessibility to non-experts. This study aims to create a simplified, two-dimensional visual tool that connects a broad range of food groups to both human health outcomes and environmental sustainability, making this information more accessible to a wider audience and promoting healthier, more sustainable food choices.

METHODS

We conducted a comprehensive analysis of recent meta-analyses and reviews to evaluate the health and environmental impacts of 30 different food groups. Foods were classified according to their effects on human health (favorable, neutral, or unfavorable) based on mortality and morbidity outcomes for chronic diseases. Environmental impacts were assessed by their carbon footprint and classified as low, medium, or high. The interrelationship between health effects and carbon footprint is represented in a color-coded 3x3 matrix, allowing for clear visual comparison.

RESULTS

Our analysis supports the well-established understanding that plant-based foods are beneficial for both human health and the environment, while meat and some processed foods tend to have negative effects. However, not all plant-based foods provide the same level of benefit, and the impacts of animal-based foods vary widely. The matrix visualization allows for an easy comparison of these tradeoffs, helping to highlight the complexity of food choices in a clear and digestible format.

CONCLUSIONS

The 3x3 matrix provides an effective, simplified means of presenting the health and environmental impacts of many food groups. By making this information accessible to a broader audience, including non-experts, we hope to encourage more informed decision-making that can improve both individual health outcomes and environmental sustainability.

LOW-CARBON DIETS IN PRACTICE: BALANCING HEALTH AND SUSTAINABILITY THROUGH MEAL SERVICE STRATEGIES

Ke-Yu Chang[1]
[1]Department of Nutrition & Dietetics of Healthcare system , Changhua Christian Hospital, Changhua, Changhua County, Taiwan, Taiwan

BACKGROUND AND OBJECTIVES

As climate change accelerates, dietary carbon emissions have become a critical concern for environmental sustainability. Food production contributes approximately 26% of global greenhouse gas emissions, with animal-based foods, such as meat and dairy, being major contributors. This study examines the composition of VIP meals provided in hospitals, which are often associated with larger portions of animal protein. These meals present a valuable opportunity to integrate sustainable dietary concepts. By analyzing the carbon footprint of these meals and revising their composition, the goal is to align meal offerings with low-carbon dietary standards.

METHODS

The original meals consisted of 100 g of animal protein (chicken, pork, or fish), 200 g of vegetables, 50 g of tuber-based sides, 80 g of white rice, and 30 g of soybean oil. Based on data from *Our World in Data*, the carbon footprint per meal ranged from 1.03 to 1.13 kg CO_2e. A revised 28-cycle menu was implemented with the following adjustments: (1) altering protein sources to a 7:3 ratio of animal- to plant-based proteins; (2) reducing soybean oil usage from 30 g to 20 g per meal; and (3) increasing the proportion of whole grains in the starch component to achieve a refined carbohydrate-to-whole grain ratio of 1:1.

RESULTS

The carbon footprint of the original meals was 1.13 kg CO_2e (chicken), 1.23 kg CO_2e (pork), and 1.03 kg CO_2e (fish). After revisions, the footprints decreased to 0.66 kg CO_2e, 0.73 kg CO_2e, and 0.80 kg CO_2e, respectively, meeting the ≤1 kg CO_2e standard for low-carbon diets. Additionally, each revised meal included approximately 140 g of fruit and achieved a balanced macronutrient distribution, with carbohydrates accounting for 45–65%, protein for 15–25%, and fat approximately 30%. A post-meal satisfaction survey reported satisfaction rates of 93–95%, demonstrating the revised meal plans' success in achieving both sustainability and nutritional balance.

CONCLUSIONS

The carbon footprint of the original meals exceeded the low-carbon threshold. By incorporating plant-based proteins, increasing vegetable portions, and substituting refined grains with whole grains, carbon emissions were significantly reduced. The implementation of these revised menu guidelines provides a practical pathway for achieving sustainable dietary practices while maintaining high levels of consumer satisfaction.

ENVIRONMENTAL IMPACT AND PRICE OF NUTRIENT ADEQUATE DIETS; INSIGHTS FROM OPTIMISATION MODELLING USING THE IOTA MODEL®

Mahya Tavan; Nick Smith; Andrew Fletcher; Jeremy Hill; Warren Mcnabb,

BACKGROUND AND OBJECTIVES

Over the past decade, there has been an increasing interest in the environmental sustainability of diets, but little attention has been paid to the nutrient adequacy, consumer acceptability and cost of such diets. The iOTA Model® is designed to fill this gap by offering an accessible and customisable platform for optimising diets. This study showcases the capabilitues of this model in simulation of a diverse range of dietary scenarios to reach nutrient adequacy at a national level, using New Zealand as an example.

METHODS

The iOTA Model® was constructed using mixed integer linear programming by integrating country-specific dietary data to generate nutrient adequate diets for adult males and females. The data was obtained from various open-access sources including but not limited to food composition (adjusted for protein and amino acid digestibility for more accuracy), dietary greenhouse gas emissions (GHGE), national nutrition surveys and food prices. Optimisation was performed by minimising deviation from sex-specific baseline diets as an objective function and sex- and age-specific nutrient targets as constraints.

RESULTS

The RESULTS demonstrated that making minimal adjustments to the current diets of both male and female New Zealanders to achieve nutrient adequacy can reduce both dietary GHGE and price. For example, when optimising diets of the 19-30 year old males, weekly GHGE and price of the diet dropped by 30% and 26%, respectively. These optimised diets showed higher intake of nutrient-dense foods such as green leafy vegetables, legumes and pulses, and offal while reducing the intake of discretionary foods, root vegetables, ruminant meat, pork and seafood. The lowest dietary GHGE achieved was 6 kg CO2-eq per week, a 79.4% reduction for 19-30 year old females, with the diet showing greatest deviation from the baseline dietary pattern. Despite all nutrient targets being met, this low impact diet had very limited food variety and a heavy reliance on fortified foods.

CONCLUSIONS

This study shows that adhering to dietary guidelines alone may provide reductions in dietary GHGE without making drastic shifts in the current diets of New Zealanders. The iOTA Model® is a powerful tool for simulating nutrient adequate diets enabling users to customise simulations based on their own preferences and access in-depth knowledge about nutritional composition, environmental impact and price of optimised diets. The iOTA Model® is publicly accessible and expandable to other regions across the globe.

CONFLICTS OF INTERESTS

Development of the model was performed by researchers of the Sustainable Nutrition Initiative® at the Riddet Institute, Massey University, and supported by the Global Dairy Platform.

TRUE ILEAL AMINO ACID DIGESTIBILITY OF TENEBRIO MOLITOR LARVAE DETERMINED BY THE DUAL STABLE-ISOTOPE TRACER METHOD IN YOUNG WOMEN

Laila Hammer[1]; Roshni M Pasanna[2]; Rajashekhar Reddy[2]; Alida Melse-Boonstra[3]; Christophe Zeder[4]; Lotti Egger[5]; Reto Portmann[5]; Sarita Devi[6]; Anura V Kurpad; Diego Moretti[1, 7]
[1]Departement of Research, Nutrition, Fernfachhochschule Schweiz (FFHS) - Hochschulcampus Gleisarena, Zürich, Switzerland, Zurich, Switzerland; [2]Division of Nutrition, St.John's Research Institute, Bengaluru, India; [3]Division of Human Nutrition and Health, Wageningen University & Research, Wageningen, Netherlands; [4]Laboratory of Nutritional and Metabolic Epigenetics, Institute of Food Nutrition and Health, Zürich, Switzerland; [5]Biochemistry of milk and microorganisms, Agroscope, Bern, Switzerland; [6]Division of Nutrition, St. John's Research Institute, Bengaluru, India; [7]FFHS, SUPSI - Scuola universitaria professionale della Svizzera italiana, Manno, Switzerland

BACKGROUND AND OBJECTIVES

Meeting human protein requirements in sufficient quantity and quality, while keeping production within the planetary boundaries, demands a transition to more sustainable protein sources. Edible insects, such as *Tenebrio molitor* (TM) larvae are rich in protein and indispensable amino acids (IAAs) and can be produced with a lower environmental footprint compared to conventional animal source proteins, but no human studies have been conducted on protein digestibility till date.

METHODS

We reared TM on (2H)-labelled maize and yeast. TM were freeze dried and administered with vegetable soup to 5 healthy women (18-45y, normal BMI) using a plateau-feeding protocol The meal was divided into 10-mini meals and administered hourly, from 8:00 to 16:00 following a priming meal composed of 3 combined mini meals. We assessed true ileal digestibility of the IAAs; methionine, phenylalanine, threonine, lysine, leucine, iso-leucine, and valin by comparing the plasma appearance of individual IAA from intrinsically (2H)-labelled TM relative to a crystalline 13C-algal amino acid mixture as a reference.

RESULTS

All participants completed the feeding protocol. The mean (SD) protein digestibility (n=5) for the IAAs was 83.7 (0.5)%. For comparison, previously reported values for digestibility using the same methodology are 60.0 (8.0) % for chickpeas, 61.2 (9.1) % for mung beans, 89.4 (4.5)% for whole boiled eggs, and 92.0 (2.9)% for chicken meat. This suggests TM digestibility to be in a similar range than conventional animal protein.

CONCLUSIONS

The high protein digestibility of TM demonstrates its potential as an excellent protein source for human nutrition.

ADHERENCE OF THE SWISS DIET TO THE EAT-LANCET PLANETARY HEALTH DIET AND ITS RELATED SUSTAINABILITY IMPACTS

Flurina Suter[1]; Anita Frehner[2]; Adrian Muller[2]; Diego Moretti[3]; Sabine Rohrmann[1]; Giulia Pestoni[3, 1]
[1]Division of Chronic Disease Epidemiology, Epidemiology, Biostatistics and Prevention Institute (EBPI), University of Zurich, Zurich, Switzerland; [2]Department of Food System Sciences, FiBL - Research Institute of Organic Agriculture, Frick, Switzerland; [3]Nutrition group, Swiss Distance University of Applied Sciences (FFHS), University of Applied Sciences and Arts of Southern Switzerland (SUPSI), Zurich, Switzerland

BACKGROUND AND OBJECTIVES

Low quality diets are a key risk factor for global morbidity and mortality as well as for environmental deterioration. In 2019, the EAT-Lancet commission proposed the planetary health diet (PHD), a healthy and environmentally friendly reference diet encouraging the consumption of plant-based foods and limiting the intake of animal-source foods, refined grains, saturated fats, and sugars. We aimed to compare the average Swiss diet to the PHD and assess its sustainability impact. The Swiss diet was examined overall, and by sex, language region, and the four main Swiss dietary patterns.

METHODS

We used data of the cross-sectional population-based National Nutrition Survey menuCH (2014-2015, n=2057, 18-75 years). Food consumption was assessed with two 24-hours dietary recalls and food avoidance was collected with a self-administered questionnaire. Using the Multiple Source Method, the habitual food intake of the participants was calculated. The environmental and socio-economic impacts of the Swiss diet were examined by determining Greenhouse Gas (GHG) emissions, total land and grassland use, the Social Hotspots Index (SHI), and the diet's costs. Adherence to the PHD and sustainability impacts of the Swiss diet were analyzed descriptively.

RESULTS

Compared to the PHD, the menuCH study population, representative for Switzerland, consumed on average less legumes (2.1% of the recommended amount), whole grains (8.9%), nuts (11.7%), unsaturated fats (27.9%), and vegetables (68.1%) and more red meat (509.2%), dairy products (231.5%), and sugars (151.4%). Closer adherence to the PHD was observed for females and for the Prudent dietary pattern. None or few participants adhered to the recommendations on whole grains, legumes, and nuts, whereas nearly all adhered to the recommendations on tubers and starchy vegetables and saturated fats. The sustainability impacts were generally similar among subgroups, but relevant trade-offs were identified between social impacts, costs, GHG emissions, and healthy diets. Overall, diets low in animal-source foods tended to have reduced GHG emissions and land use, whereas diets high in fruits and vegetables tended to have higher costs and risks of adverse social impacts.

CONCLUSIONS

A dietary shift towards increased consumption of regionally produced plant-based foods and decreased consumption of animal-source foods would lead to higher diet quality and lower environmental footprint of the average Swiss diet and should be encouraged by future public health measures.

CONFLICTS OF INTERESTS
The authors have no conflict of interest.

A 10-MONTH CLUSTER-RANDOMIZED TRIAL TO SHIFT TOWARDS PLANT-FORWARD MEALS IN EARLY CHILDHOOD EDUCATION AND CARE CENTERS – EFFECTS ON BONE AND MINERAL METABOLISM IN FINNISH CHILDREN

Suvi Itkonen[1]; Jelena Meinilä[1]; Henna Vepsäläinen[1]; Liisa Korkalo[1]; Sari Niinistö[2]; Susanna Raulio[2]; Mari ÅKerlund[2]; Tuuli Korhonen[2]; Leena Forma[3]; Merja Saarinen[4]; Suvi Virtanen[2, 5, 6]; Maijaliisa Erkkola[1]
[1]Department of Food and Nutrition, University of Helsinki, Helsinki, Finland; [2]Nutrition Team, Finnish Institute for Health and Welfare, Helsinki, Finland; [3]Department of Health and Social Management, University of Eastern Finland, Kuopio, Finland; [4]-, Natural Resources Institute, Helsinki, Finland; [5]Faculty of Social Sciences, Tampere University, Tampere, Finland; [6]Centre for Child Health Research and Wellbeing Services County of Pirkanmaa, Tampere University Hospital, Tampere, Finland

BACKGROUND AND OBJECTIVES

A shift towards predominantly plant-based diets is emphasized for health and environmental sustainability. This transition may affect nutrient adequacy. We investigated how a change towards plant-forward meals in Finnish early childhood education and care (ECEC) centers affects bone and mineral metabolism and intakes of bone-related nutrients in 3-5-year-old children.

METHODS

ECEC centers were cluster-randomized into 11 intervention and 12 control ECEC centers. During the 10-month intervention, more plant-based products and less red meat was served at ECEC centers. A moderation in milk consumption was also encouraged. We also provided the intervention ECEC centers with food education materials tailored to support the menu change. The control ECEC centers maintained their regular meals. Blood samples (both before and after the intervention) were available from 18 children in the intervention arm and 28 children in the control arm. Differences in bone and mineral metabolism markers (serum tartrate-resistant acid phosphatase 5b [TRAP5b], total and bone-specific alkaline phosphatase (ALP; BAP), 25-hydroxyvitamin D, calcium, phosphate, and plasma parathyroid hormone) between the groups were analyzed using analysis of covariance (adjusted for baseline, sex, and height).

RESULTS

Preliminary analysis showed that bone resorption marker TRAP5b, bone formation marker BAP, and ALP concentrations were higher in the intervention arm compared to the control arm ($P<0.05$). No other differences were observed ($P>0.05$).

CONCLUSIONS

The RESULTS suggest increased bone turnover when transitioning to plant-forward meals, indicated by higher bone resorption and bone formation marker concentrations. This may raise concerns about long-term bone health since the shift of bone turnover during childhood should be towards bone formation. However, the small dataset limits the generalizability. Further analysis of nutrient intakes may reveal the underlying causes.

BACKGROUND AND OBJECTIVES

In Madagascar, to meet the growing demand of rice, the staple food , its rain-fed cultivation on the hills has developed despite their poor soils. Innovative agroecological practices on upland rice cultivation, including earthworms and their capability in producing nutrient-rich fertilizers (vermicompost) were developed in a collaborative research project with local farmers. The aim of this study was to understand the nutritional repercussions of this innovative fertilization at several levels: the nutritional composition of rice, the nutritional quality of rainfed rice dishes and the overall diet quality.

METHODS

The Chhomrong Dhan rice (*Oryza sativa*) variety was cultivated with traditional and innovative practices by 11 farmers spread across 5 villages in the district of Imerintsiatosika. Nutritional components (proteins, minerals, B1 vitamin) were determined after decortication and polishing. Feeding practices involved the monitoring of 5 traditional rice recipes and 8 accompanying dishes (n=3 for each dish combination), with 24 families among the project farmers. 42 farmers responded to the Malagasy Diet Quality Questionnaire (DQQ).

RESULTS

Innovative fertilization had no significative impact on rainfed rice nutritional composition, compared to traditional practices, for both whole-grain and semi-husked rice as consumed locally. The nutritional quality of the 8 rice-based dishes showed low Individual Nutritional Recommendations Adequacy Score (SAIN) (4.2 ± 1,4 % for 100 kcal) and low Score of compounds to be nutritionally limited (2.6 ± 1,3 % for 100g), showing a global poor diet. Concomitantly, the energy contribution of 100g of rice dishes to nutritional requirements of proteins and lipids was only 12.2 and 12 % respectively as recommended, while that of carbohydrates was 76%, linked to a high mean rice consumption, 540 to 782 g per dish portion, instead of 45-50 %. According to the DQQ, the Food Group Diversity Score (FGDS) was shown to be adequate for 62% of farmers, and only 67 % of people have an adequate All-5 indicator, including the main five food groups of dietary guidelines (starchy food, vegetables, fruits, pulses and nut, animal-source foods).

CONCLUSIONS

Despite minor beneficial effects of agroecological practices on the nutritional quality of upland rice, the overall diet of rural inhabitant could be improved by increasing consumption of food groups other than starchy foods, locally available grown or raised.

DAIRY TRENDS IN THE UNITED KINGDOM: A COMPREHENSIVE ANALYSIS OF DIET, NUTRIENT, AND ENVIRONMENTAL IMPACTS USING THE NATIONAL DIET AND NUTRITION SURVEY

Alexander Vonderschmidt[1, 2]; Ricki Runions[1]; Kaela Connors[1, 2]; Hemione Brandt[3]; Joe Kennedy[1]; Sarah Frank[1]; Lindsay Jaacks[1]; Cristina Stewart[4]; Rosemary Green[5]; Peter Alexander[1, 2]; Alexandra Bellows[1]
[1]Global Academy of Agriculture and Food Systems, The University of Edinburgh, Edinburgh, United Kingdom; [2]School of GeoSciences, The University of Edinburgh, Edinburgh, United Kingdom; [3]Dietetics, National Health Service Foundation Trust, Salisbur, United Kingdom; [4]MRC/CSO Social and Public Health Sciences Unit, School of Health and Wellbeing, University of Glasgow, Glasgow, United Kingdom; [5]Centre on Climate Change and Planetary Health, London School of Hygiene & Tropical Medicine, London, United Kingdom

BACKGROUND AND OBJECTIVES

Dairy provides key nutrients but has mixed associations with chronic disease, depending on dairy type and fat content. The UK's Climate Change Committee recommends a 20% reduction in dairy consumption by 2030 to meet Net Zero greenhouse gas emissions. However, previous trend analyses have primarily focused on total dairy or certain categories like milk, without disaggregating dairy content within composite foods (e.g., lasagne). A recent Scottish analysis found that failing to disaggregate dairy from composite dishes underestimates dairy intake. Therefore, understanding trends in specific dairy types and fat content groups is critical to inform effective sustainable diet strategies. We aim to (1) disaggregate dairy from composite foods; (2) assess trends in dairy consumption and dairy's contribution to nutrient intake; and (3) estimate dairy's environmental impact.

METHODS

We analyse 11 rounds of the UK National Diet and Nutrition Survey (2008/09 to 2018/2019). Using the UK Nutrient Databank (NDB) and Food Standards Agency Recipes Database, we disaggregate dairy in composite dishes and classify by type (milk, yogurt, cheese, butter, cream) and fat content (skimmed, semi-skimmed, whole). We estimate mean daily intake (g/day) per 2-year cycle with generalized linear regression models. Environmental indicators are linked to the NDB via foodDB, a UK grocery database with life cycle assessment data.

RESULTS

Total dairy consumption remains stable over the 11-year period, at 256.0g/day in 2008/09 and 237.4g/day in 2018/19 (P=0.11). Milk intake decreases by 11.9% (-24.7g/day, from 207.0 to 182.3, P<0.05), with no change in fat content groups. Yogurt consumption increases by 23.8% (+4.5g/day, from 18.9 to 23.4, P<0.05), with a 34.6% increase in skimmed yogurt (+0.9g/day, from 2.6 to 3.5, P<0.05). Cheese intake overall remains unchanged (P=0.61); however, cheddar cheese decreases by 12.0% (-1.4g/day, from 11.7 to 10.3, P<0.05), offset by a 17.9% increase in "other" cheese (+1.4g/day, from 7.8 to 9.2, P<0.05). Cream consumption sees no change (P=0.23). Butter intake rises by 35.7% (+2.0g/day, from 5.6 to 7.6, P<0.05).

CONCLUSIONS

These findings reveal nuanced shifts in UK dairy consumption over the past decade. The slight rise in butter consumption will increase saturated fat intake, while the growth in yogurt consumption, particularly skimmed varieties, aligns with positive, health-oriented dietary shifts. Future analyses will integrate nutrient profiles and environmental indicators to provide a fuller picture of dairy's role in a sustainable and healthful diet.

ASSESSING DIETARY GREENHOUSE GAS EMISSIONS IN KOREA IMPLICATIONS FOR SUSTAINABLE NUTRITION AND CLIMATE CHANGE MITIGATION

JeeYeon Hong[1]; Mi Kyung Kim[1]
[1]Department of Preventive Medicine, College of Medicine, Hanyang University, Seoul, Korea, Republic of

BACKGROUND AND OBJECTIVES

The food industry is a major contributor to greenhouse gas (GHG) emissions, accounting for about half of human-generated emissions. These emissions stem from diverse sources, including agricultural practices, deforestation, transportation, food processing, and waste. With climate change causing significant environmental and societal impacts, it is crucial to assess and mitigate GHG emissions associated with dietary patterns and food systems. This study examines dietary GHG emissions among Koreans and evaluates the environmental impact of dietary recommendations.

METHODS

Data from the 7th Korea National Health and Nutrition Examination Survey (KNHANES, 2016–2018) was analyzed, including dietary recall data from 21,271 participants aged 1–80 years. GHG emissions were calculated using food systems-related greenhouse gas emission factor database. Demographic characteristics such as region, income, and education were analyzed for their impact on dietary emissions. Statistical analyses were conducted using SAS 9.4.

RESULTS

On average, Koreans emit 5.08 kgCO2eq/day from their diet. Emissions were highest for "Meats" and "Beverages," followed by "Alcoholic beverages" and "Fish and Shellfish." Men and individuals in their 20s to 40s emitted more GHGs than other groups. Urban residents, particularly in medium-sized cities, showed higher emissions than rural populations. Higher income and education levels were also associated with increased dietary emissions. Dietary recommendations advocating two daily servings of dairy were found to align with lower GHG emissions, averaging 5.04 kgCO2eq/day.

CONCLUSIONS

Dietary choices significantly impact GHG emissions, with meats and beverages being major contributors. Addressing these emissions through sustainable dietary practices and policies is vital for climate change mitigation. Aligning dietary guidelines with environmental goals can reduce emissions while supporting health and nutrition.

REPLACING MEAT AND DAIRY WITH PLANT-BASED OPTIONS IN SPAIN COULD REDUCE ENVIRONMENTAL HUMAN HEALTH DAMAGE BY A THIRD WHILE PROMOTING MORE NUTRITIONALLY ADEQUATE DIETS

Ujué Fresán[1]; Montserrat Núñez,[2]; Inés Valls[1]; Ralph Rosenbaum[2]
[1]Sustainable diets, ISGlobal, Barcelona, Spain; [2]Sustainability in Biosystems, IRTA Torre Marimon, Caldes de Montbui, Spain

BACKGROUND AND OBJECTIVES

The shift from traditional plant-based Mediterranean diets to Western dietary patterns in Spain has exacerbated chronic diseases and increased environmental degradation. The human health damage derived from this environmental degradation has received less attention so far. This study quantifies the human health burden linked to the environmental impacts of Spain's food demand, assessing the potential benefits of reducing meat and dairy consumption and food waste.

METHODS

Using the IMPACT World+ v2.0.1 Life Cycle Impact Assessment method, the environmental health impacts of food consumption and waste in Spain during 2022 were evaluated. ReCiPe 2016 v1.1 was used as sensitivity analysis. Scenarios involving the reduction or replacement of meat and dairy with plant-based options and the mitigation of food waste were analyzed for environmental human health and nutritional outcomes.

RESULTS

Meat and fish were the food groups with higher environmental human health impact, both on a weigh and protein content basis. Meat, fish, and dairy contributed 56% of dietary environmental human health damage, with total food demand resulting in 228,156 DALYs. Replacing 100% of meat and dairy with plant-based alternatives could reduce this burden by 32.4%, while eliminating food waste could lower it by 4.6%. Combined interventions may prevent 37% of DALYs. Nutritional analyses demonstrated that these dietary changes would result in diets more closely aligned with WHO guidelines, promoting improved adherence to recommended nutrient intakes.

CONCLUSIONS

Transitioning towards plant-based diets and reducing food waste can significantly decrease environmental human health damages while fostering healthier, nutritious, and sustainable dietary practices in Spain. Policymakers should integrate these strategies into public health initiatives to mitigate planetary and health crises.

DIET QUALITY PATTERNS AMONG SETTLED FULANI HOUSEHOLDS IN TCHAOUROU, NORTHERN BENIN: A SEASONAL ASSESSMENT

Mahounakpon Wilfried Tossou[1, 2]; Carole Nadia Adjouavi Sossa-Vihotogbé[1]; Daniel Mörlein[2]
[1]Departement de Nutrition et Sciences des Aliments, Université de Parakou, Parakou, Benin; [2]Quality of Animal Products, University of Göttingen, Göttingen, Germany

BACKGROUND AND OBJECTIVES

In low- and middle-income countries, the livestock sector is crucial, contributing significantly to agricultural Gross Domestic Product [1,2] and supporting livelihoods, nutrition, especially among pastoralist groups like the Fulani in West Africa [3,4]. However, climate change, resource depletion, and land use changes threaten their nomadic way of life, prompting a transition to sedentary lifestyles [5-7]. This study aims to address gaps in knowledge by providing insights into dietary quality among Fulani communities, often excluded in nutrition surveys in Benin.

METHODS

The study, conducted in two settled Fulani villages in Tchaourou, northern Benin, monitored 79 households from October 2023 to September 2024. Diet quality patterns were evaluated using a longitudinal food survey with a pictogram-based questionnaire, recording seven days of monthly household food consumption [8]. Informed and clear consent was obtained from all relevant parties involved in the study. Statistical analyses included the Kruskal-Wallis test and Dwass-Steel-Critchlow-Fligner test for mean and seasonal comparisons.

RESULTS

The average household size was 8.6 members (SD = 4). Fulani households demonstrated stable dietary diversity scores (M = 7.9, SD = 4) over time, though diversity declined significantly in June and July 2024. Food consumption scores (FCS) also fell within the acceptable range (FCS > 35), with an average of 66.5 (SD = 18.2), but showed marked decreases during the dry season (January–March 2024). Diets were dominated by unprocessed cereals, consumed consistently throughout the year (M = 6.9 times per week), while processed cereals (1.7 times), roots, tubers, and pulses (3.7 times) varied seasonally ($p < .001$). Frequency of fruit consumption (2.2 times) was also seasonal, with vitamin A-rich fruits like mangoes and papayas peaking in April and May (4 times weekly). Dairy consumption (3.8 times) varied seasonally, decreasing during the dry season and peaking during the rainy season (May–August 2024), when milk production increases.

CONCLUSIONS

Fulani households in Tchaourou demonstrated good dietary diversity and acceptable food consumption scores. However, their diet is characterised by seasonal variations in staple foods, fruits, and animal-source foods, particularly dairy, which is heavily influenced by climatic cycles.

THE INTEGRATION OF GENDER EQUALITY, DISABILITY AND SOCIAL INCLUSION (GEDSI) PRINCIPLES IN FOOD AND CLIMATE POLICY IN INDONESIA

Hesti Arini[1, 2]; Syefira Salsabila,[1]; Sujarwoto Sujarwoto[3]; Briar Mckenzie[4]; Julia Novrita[1]; Anna Palagyi[4]
[1]Nutrition and Health Department, The Habibie Center, Jakarta, Indonesia; [2]Institute for Physical Activity and Nutrition, School of Exercise and Nutrition Sciences, Deakin University, Geelong, Australia; [3]Department of Public Administration, Faculty of Administrative Science, University of Brawijaya, Malang, Indonesia; [4]The George Institute for Global Health, University of New South Wales, Sydney, Australia

BACKGROUND AND OBJECTIVES

Little is known about how Indonesian policies target the most food-insecure and climate-vulnerable members of the community, particularly in terms of gendered and social inequities. This policy review aimed to examine the intersectionality and inclusion gaps in Indonesian food and climate policies.

METHODS

Active policy documents regulating food security and climate change were searched on national, provincial, and local government websites in November 2023. A gender equality, disability and social inclusion (GEDSI) analysis was conducted by assessing the inclusion of GEDSI considerations in existing policy directives and examining how evidence of gender, race, age, sex and sexuality, socio-economic background, geographical location, and disability status had been incorporated in policy design.

RESULTS

Following the screening process, 36 policy documents published from 2009 to 2023 were included in the review. Food-climate intersectionality was addressed in 16 (44%) documents, and GEDSI components were mentioned in 25 (69%) documents. The use of scientific evidence in food and climate policies was rare: some food policies referred to national food and nutrition surveys while climate policies were founded on government-led climate and environmental analyses. GEDSI was incorporated within policies in diverse ways, with women and children being commonly addressed considering their higher risks of undernutrition. People with disabilities were only mentioned in two documents. No policy discussed the inclusion of community voices in the policy development process.

CONCLUSIONS

The review highlighted variations in Indonesia's attempt to incorporate GEDSI in policy directives intended to address food and climate issues. Future policies need to better incorporate GEDSI principles by clearly defining the targeted social groups, planning sustainable support actions, accounting for relevant evidence, and engaging community and diverse perspectives in the policy development process to reduce inequalities.

DIETS OPTIMIZED FOR ENVIRONMENTAL SUSTAINABILITY AND HEALTH: IMPLICATIONS FOR DIET COSTS ACROSS SOCIO-ECONOMIC POSITIONS FOR DUTCH ADULTS

Reina Vellinga[1]; Samantha Heerschop[2]; Sander Biesbroek[2]; Pieter Van 'T Veer[2]; Jose Drijvers[1]; Marieke Van Bakel[1]; Anne Hollander[1]; Liesbeth Temme[1]
[1]Health and Sustainable Nutrition, National institute for public health and the environment (RIVM), Bilthoven, Netherlands; [2]Global Nutrition, Wageningen University & Research, Wageningen, Netherlands

BACKGROUND AND OBJECTIVES

Universal access to healthy, safe, environmentally sustainable, and affordable diets is imperative for individuals across all socio-economic positions. The objective of this modelling study was to investigate how dietary patterns can be improved among Dutch adults with different socioeconomic backgrounds, and how these changes affect the costs of their diets.

METHODS

Food consumption data for 1747 adults were derived from the Dutch National Food Consumption Survey 2019–2021. Participants were categorized according to their highest attained educational level (low, intermediate, high) as proxy for socio-economic position. For each individual the diet was minimized for greenhouse gas (GHG) emissions and maximized for diet quality according to the Dutch Healthy Diet 2015 (DHD15) index. Optimized diets were made using a benchmark approach, involving linear combinations of current diets, either within or across the three educational subgroups (i.e. peer groups). Constraints limited individual dietary changes to within 33% of current consumption, except for less commonly consumed food groups. Diet costs were compared between current and optimized diets. Secondary outcomes included nutritional aspects and additional environmental impact indicators.

RESULTS

For all educational subgroups, the optimized diets had on average a 19-24% lower GHG emission and a 52-56% improvement in diet quality (DHD15 index) compared to current diets, and the median diet costs remained similar. Depending on the educational subgroup, selected optimal diets contained more vegetables (6%), fruits (8-16%), nuts (37-89%), legumes (100-133%), and fish (59-66%), and less grains (-8-5%), dairy (-17-12%), meat (-27-25%), cheese (-11-6%), soft drinks (-45-42%), and juices (-56%-18%). More pronounced improvements were found when the optimization was not stratified by educational level.

CONCLUSIONS

Across all socio-economic subgroups modest dietary changes can improve healthiness and environmental impacts of diets, without affecting diet costs. Furthermore, socio-economic disparities in diet quality can be reduced without additional diet costs, provided these educational subgroups are willing and facilitated to adopt diets divergent from their peer group.

OAP56_06

DIETARY ENVIRONMENTAL IMPACT AND ITS ASSOCIATION TO THE DEVELOPMENT OF OVERWEIGHT AND OBESITY IN YOUNG CHILDREN: THE GECKO DRENTHE COHORT

Junyang Zou[1]; Elise de Boer[1]; Reina Vellinga[2]; Eva Corpeleijn[1]
[1]Epidemiology, University Medical Center Groningen, Groningen, Netherlands; [2]National Institute for Public Health and the Environment, Rijksinstituut voor Volksgezondheid en Milieu (RIVM), Bilthoven, Netherlands

BACKGROUND AND OBJECTIVES

The growing global population demands a shift towards sustainable diets that are healthy, environmentally friendly, acceptable, and affordable. Shifting towards more plant-based diets may have consequences for food and nutrient intake, but are generally considered more healthy. In this study, we explore the environmental sustainability of diets in young children and relate this to the development of overweight.

METHODS

In the GECKO Drenthe birth cohort, dietary intake was derived from a validated 71-item food frequency questionnaire designed for children aged 2-12 years, filled in by parents, when children were 3 years old. Diet-induced Greenhouse Gas Emissions (GHGE) and Blue Water Consumption (BWC) were calculated using Lifecycle Assessment data by the Dutch Institute for Public Health and the Environment and adjusted for the total amount of food consumed, for total, solid food consumption and liquid food consumption. BMI Z-score, the change in BMI Z-score between 3 and 10/11 years old, and weight status (overweight/obesity by IOTF criteria) were derived from height and weight measured by trained nurses.

RESULTS

The final analysis included 893 children (50.2% male). After excluding 73 children with overweight and obesity at 3 years, 820 children (50.6% male) were included for the analyses of overweight/obesity, of which 107 (13%) developed overweight/obesity at 10/11 (10.6±0.4) years old. The mean GHGE from solid foods and liquid foods were 1.88±0.58 (mean±SD) kg CO2eq./day and 0.57±0.29 kg CO2eq./day, respectively. The mean BWC from solid foods and liquid foods were 27±8 liter/day and 15±14 liter/day, respectively. GHGE and BWC from grains, fruits, meats, dairy products, sugary snacks, and sugar-sweetened beverages contributed most to total GHGE and total BWC. After adjusting for potential confounders, GHGE per kg of solid foods in the highest tertile was associated with a higher BMI Z-score (β=0.159 (95% CI 0.001, 0.318)) and a higher weight gain (delta BMI-Z, β=0.21 (0.06, 0.35)) at 10/11 years old, compared with the lowest tertile. Both GHGE per kg of solid foods in the highest tertile (OR=1.83 (1.06, 3.16)) and BWC per kg of solid foods in the highest tertile (OR=1.69 (1.01, 2.84)) were related to a higher risk of developing overweight/obesity at 10/11 years old, compared with the lowest tertile.

CONCLUSIONS

A less sustainable diet among young children was associated with a higher risk of developing overweight and obesity in later childhood. Promoting sustainable dietary habits may bring benefits to young children in preventing overweight and obesity.

OAP56_07

ONE HEALTH CONCEPTUALISATION OF SUSTAINABLE DIETS IN LOW- AND MIDDLE-INCOME SETTINGS: A SYSTEMATIC REVIEW

Edith Monica Esievo[1, 2]; Whatford Louise[2]; Sarah Nájera Espinosa[1]; Abraham Awulu Oche[2]; Nuhu Ahmed Aliyu[3]; Kris Murray[3]; Zakari Ali[4]
[1]Population Health, London School of Hygiene & Tropical Medicine, London, United Kingdom; [2]Pathobiology and Population Sciences, Royal Veterinary College, Hertford, United Kingdom; [3]Nutrition and Planetary Health, MRC Unit The Gambia at LSHTM, Serrekunda, Gambia, Republic of the; [4]Nutrition and Planetary Health Theme, MRC Unit The Gambia at LSHTM, Serrekunda, Gambia, Republic of the

BACKGROUND AND OBJECTIVES

Average diets fail to meet basic health and environmental needs. They are proven risk factors for non-communicable diseases and mortality, diminish natural resources, and contribute to climate change. This is particularly challenging in low- and middle-income countries (LMICs) with a fast-growing population concurrently compounded by multiple burdens of malnutrition and increasing climate change impacts exacerbating food/nutrition insecurity and livelihoods. Sustainable diets protective of One Health (human, animal, plant and environmental health) promises to address this challenge, yet LMICs are often underrepresented in global studies on sustainable diets. The objective of this review was to conceptualise dietary sustainability in LMICs integrating the One Health approach.

METHODS

Using the preferred reporting items of systematic reviews and meta-analyses (PRISMA) guidelines and the checklist for one health epidemiological reporting of evidence (COHERE) standards, four bibliographical databases were searched (Embase, Global Health, Web of Science, and Scopus) between 1947 and June 2023. Dietary sustainability was assessed in LMICs by evaluating coverage across the four One Health pillars (human, animal, plant and environmental health) and five dietary sustainability dimensions (diet/nutrition, health, environment, economic and social). Data were extracted and analysed qualitatively.

RESULTS

The database searches yielded 3122 studies. After removing duplicates and screening for eligibility, 35 studies were selected for inclusion. Most studies were from upper (77%) and lower (20%) middle-income countries. While 19 studies assessed human and environmental health, none assessed plant or animal health, nor all four One Health pillars combined. No study assessed all five dietary sustainability dimensions. Most studies assessed two (54%) or three (34%) dimensions, and the most frequently assessed dimension was the environment (71%). Overall, the assessment of the 35 studies found that LMICs' diets are unsustainable due to low quality, low diversity, and high environmental effects, with associated inequities.

CONCLUSIONS

The underrepresentation of LMICs, particularly, low-income countries, in this review is a wake-up call urging the generation of more country-specific data incorporating more dietary sustainability dimensions and One Health pillars (especially plant and animal health considerations) for progress and monitoring towards attaining global dietary sustainability.

ADHERENCE TO THE EAT-LANCET DIET AND THE INCIDENCE OF MAJOR DEPRESSIVE DISORDER: FINDINGS FROM THE SWISS COLAUS|PSYCOLAUS COHORT STUDY

Laís Bhering Martins; Setareh Ranjbar,[1]; Marie-Pierre F. Strippoli,[1]; Aurelie M. Lasserre,[2]; Pedro Marques-Vidal,[3]; Séverine Vuilleumier,; Martin Preisig,; Angeline Chatelan[4]
[1]Department of Psychiatry, Lausanne University Hospital (CHUV) and University of Lausanne, Lausanne, Switzerland; [2]Addiction Medicine, Lausanne University Hospital (CHUV) and University of Lausanne, Lausanne, Switzerland; [3]Department of Medicine, Internal Medicine, Lausanne University Hospital (CHUV) and University of Lausanne, Lausanne, Switzerland; [4]Department of Nutrition and Dietetics, Geneva School of Health Sciences, HES-SO, Geneva, Switzerland

BACKGROUND AND OBJECTIVES

The EAT-Lancet diet, a flexitarian dietary pattern recommended to promote health and preserve environmental resources, has demonstrated benefits in preventing cardiometabolic diseases and cancers. Emerging evidence suggests that a healthy diet may also play a role in preventing Major Depressive Disorder (MDD). However, the relationship between adherence to the EAT-Lancet diet and psychiatric disorders, including MDD, remains largely unexplored. The objective of this study is to investigate the association between adherence to the EAT-Lancet diet and the incidence of MDD in a Swiss population cohort.

METHODS

Data from 1,966 participants (mean age: 58.8 ± 10.8 years, 47% female) of the CoLaus|PsyCoLaus study were analyzed. Dietary intake was assessed using a validated semi-quantitative food-frequency questionnaire. Adherence to the EAT-Lancet diet was scored based on recommended intake levels of 12 food groups, ranging from 0 to 39 points. Participants were categorized into low-, medium-, and high-adherence groups based on tertiles of the score. MDD was assessed at baseline and follow-up visits using the Diagnostic Interview for Genetic Studies (DIGS). Cox proportional hazards models were employed to evaluate the association between EAT-Lancet diet adherence and the incidence of a first diagnosis of MDD, adjusting for sociodemographic characteristics, behavioral factors, psychiatric comorbidities, and total energy intake.

RESULTS

Over a mean follow-up period of 9.2 years (SD ±3.4), 224 individuals received a first-time diagnosis of MDD. Higher adherence to the EAT-Lancet diet was associated with a non-significant reduction in MDD risk (medium adherence: HR 0.80, 95% CI: 0.59–1.11; high adherence: HR 0.74, 95% CI: 0.53–1.05, P for trend: 0.08) in the fully adjusted model.

CONCLUSIONS

In a Swiss population-based cohort, higher adherence to the EAT-Lancet diet showed a potential association with a lower hazard of MDD incidence. However, the findings were not statistically significant, highlighting the need for further studies with larger sample sizes to confirm this trend.

SHAPING SUSTAINABLE FOOD CHOICES IN YOUTH: INSIGHTS FROM A COM-B MODEL SYSTEMATIC REVIEW

Soraya van Etten[1]; Marijn Stok[2]; Lonneke Jansen[2]; Brian Dermody[3]; John De Wit[2]; Michèlle Bal[2]
[1]Dept. of Interdisciplinary Social Science , Utrecht University, Utrecht, Netherlands; [2]Dept. of Interdisciplinary Social Science, Utrecht University, Utrecht, Netherlands; [3]Copernicus Institute of Sustainable Development, Utrecht University, Utrecht, Netherlands

BACKGROUND AND OBJECTIVES

The present-day food system is a key driver of climate change and non-communicable diseases, making it imperative for populations to shift towards more sustainable and healthy food behaviours. Involving youth in this transition is vital as dietary habits are shaped during this period in life and will have long-lasting impacts. This systematic review explores the associations of capabilities, opportunities and motivations – derived from the COM-B model - with sustainable food behaviours among youth, identifying dominant factors and their interrelations.

METHODS

Four databases were searched for studies exploring at least two of three COM-B elements associated with sustainable food behaviours in individuals under 18. Sustainable behaviours included adopting a plant-forward diet, consuming local and seasonal foods, and minimizing food waste.

RESULTS

Twenty-three eligible studies were reviewed. Food preference emerged as the primary criterion for food choice, with cost also identified as an important factor. Familiarity and prior experiences with specific foods, influenced by social environments, shaped adolescents' food preferences. Parents were pivotal in introducing familiar foods, while schools expanded food exposure. This underscores the dynamic interplay between personal food preferences and external influences, emphasizing the significance of the social environment. Adolescents demonstrated basic skills and knowledge about general food behaviours but lacked the specific skills, knowledge, and awareness necessary to engage with sustainable and healthy food practices. Although animal welfare was mentioned—particularly by vegetarians—as a motivator for plant-based eating, sustainability was rarely cited, and awareness of sustainability issues was generally low. Knowledge and awareness did not consistently translate into sustainable eating behaviours, though some studies linked greater understanding of sustainable practices to more positive attitudes and food choices. Despite knowledge gaps, adolescents expressed a willingness to learn more about sustainable eating practices, indicating that education could play a key role in fostering sustainable behaviours.

CONCLUSIONS

Effective interventions must address multiple factors within the COM-B model, rather than focusing on isolated factors, to support a meaningful transition to sustainable food practices among youth. The findings provide valuable guidance for future research and the development of practical strategies to drive lasting change.

DEMAND-SIDE FOOD POLICY STRATEGIES: THE EFFECT ON ENVIRONMENTAL SUSTAINABILITY, AND PROTEIN INTAKE IN ELEVEN EUROPEAN COUNTRIES

Reina Vellinga[1]; Matthijs Sam[2]; Gerda Van Donkersgoed[2]; Jacob Klaveren Van[2]; U Blaznik; E Rauscher-Gabernigc[3]; Darja Sokolic[4]; B Hamborg Jensen[5]; A Crepet[6]; Liesbeth Temme[1]
[1]Health and Sustainable Nutrition, National institute for public health and the environment (RIVM), Bilthoven, Netherlands; [2]Chemical food safety, National institute for public health and the environment (RIVM), Bilthoven, Netherlands; [3]AGES, Austrian Agency for Health and Food Safety, vienn, Austria; [4]HAPIH, Croatian Agency for Agriculture and Food, Osijeik, Croatia; [5]National Food institute, Technical University of Denmark, Kongens Lyngby, Denmark; [6]Risk assessment, French agency for food, environmental and occupational health and safety, maisons-alfort, France

BACKGROUND AND OBJECTIVES

Improving human and planetary health is one of the most important goals of current century. Demand-side food policy strategies can be implemented to improve human and planetary health. To develop and implement policy measures effectively, it is essential to conduct upfront analyses that demonstrate the potential impact of such measures. The objective of this study was to study the environmental impact of EU diets and investigate the potential of food policies focusing on simultaneously improve human and planetary health.

METHODS

Individual food consumption data from 11 European countries were used to assess the potential impact of demand-side food policy scenarios reflecting health and sustainability objectives. Dutch life-cycle assessment data were used to estimate six environmental impact indicators. Food composition data was used to estimate protein intake. Food consumption, dietary environmental impact and protein intake were estimated using the Monte-Carlo Risk Assessment software for baseline and established scenarios and comparisons were made for each country.

RESULTS

All countries showed potentially large reductions up to -55% in GHG emissions, land use, usage of blue water, and animal protein, and up to -70% for fresh and marine water eutrophication, acidification, when limiting meat intake and/or replacement with legumes or meat substitutes. Strategies such as replacing dairy with dairy substitutes, replacing soft drinks with water and limiting discretionary foods had less pronounced effects on environmental indicators ranging between -1 and -11%. Strategies increasing fruit and vegetable consumption negatively impact the environment impact up to 7%, and up to 14% for usage of blue water.

CONCLUSIONS

Demand-side food policy strategies can potentially simultaneously improve human and planetary health. The most promising benefits can be achieved by the reduction and substitution of meat with plant-based foods. This requires the implementation of a coherent set of measures with both forceful and soft strategies.

IMPACT OF REPLACING FOODS WITHIN DISH CATEGORIES OF JAPANESE FOOD-BASED DIETARY GUIDELINES ON NUTRITIONAL QUALITY, GREENHOUSE GAS EMISSIONS, AND DIETARY COST

Mariko Takano[1]; Fumi Hayashi[1]; Yukari Takemi[1]
[1]Nutrition Ecology, Kagawa Nutrition University, Sakado, Saitama, Japan

BACKGROUND AND OBJECTIVES

The Japanese food-based dietary guidelines (FBDG) define three main dish categories (grain, vegetable, and fish and meat), including foods with varying environmental impacts and prices. While guideline adherence is linked to better nutrient intake, it may not necessarily result in lower environmental impact or dietary costs. This study aimed to identify foods with higher nutrient density, lower greenhouse gas emissions (GHGE), and lower prices and examine the impact of replacing these foods within the main dish categories on nutritional quality, dietary GHGE, and dietary costs.

METHODS

The analyses were based on two-day dietary record data from 479 men and women aged 30–65 years who participated in the Saitama Prefecture Nutrition Survey 2017 and 599 foods consumed as home-cooked meals recorded in the dietary data. Based on the Japanese FBDG, the 599 foods were categorized into 14, 31, and 42 groups within grain, vegetable, and fish and meat dishes, respectively. These groups were further classified into three, four, and five clusters using hierarchical cluster analysis based on their Nutrient-Rich Food Index (NRF) 9.3 scores, GHGE, and price, respectively. Foods from clusters with lower NRF scores and higher GHGE and prices were replaced with those from clusters with higher NRF scores, lower GHGE, and lower prices at replacement levels of 25%, 50%, 75%, and 100% of the servings within each dish category. The impact of replacement was evaluated based on changes in the NRF 9.3 scores, GHGE, and dietary costs compared with baseline diets.

RESULTS

Cluster 1 of grain (rice), vegetable (potatoes, sweet potatoes, pulses other than soybeans, carrots, and cabbage), and fish and meat dishes (soybean products, eggs, sardines, and mackerel) was characterized by higher NRF 9.3 scores and lower GHGE and prices across all categories. The changes from the baseline diet, resulting from replacing foods with those from these clusters at 25%, 50%, 75%, and 100% of servings were as follows: NRF 9.3 scores increased by +5.9%, +11.8%, +17.4%, and +22.2%, GHGE decreased by -5.8%, -11.6%, -17.4%, and -23.2%, and dietary cost decreased by -5.2%, -10.3%, -15.5%, and -20.7%, respectively.

CONCLUSIONS

Foods with higher nutrient densities, lower GHGE, and lower prices were identified. Replacing foods within the three dish categories of the Japanese FBDG with these foods resulted in diets with improved nutritional quality, lower GHGE, and lower costs.

OAP59_02

POTENTIAL CLIMATE CHANGE IMPACTS ON THE MINERAL CONTENT OF FARMED ATLANTIC SALMON

Xin Zhan[1, 2]; Richard S. Cottrell[1, 3, 4]; Chris G. Carter[1, 5]; Beth Penrose[2, 6]; Louise R. Adams[1]
[1]Institute for Marine and Antarctic Studies, University of Tasmania, Hobart, Australia; [2]Tasmanian Institute of Agriculture, University of Tasmania, Hobart, Australia; [3]Centre for Marine Socioecology, University of Tasmania, Hobart, Australia; [4]Centre for Biodiversity and Conservation Science, School of the Environment, The University of Queensland, Brisbane, Australia; [5]Seafood and Marine Products, Blue Economy Cooperative Research Centre, Launceston, Australia; [6]Research Institute for Northern Agriculture, Charles Darwin University, Darwin, Australia

BACKGROUND AND OBJECTIVES

Global warming poses significant risks to marine food production including aquaculture systems (IPCC 2023). Atlantic salmon (*Salmo salar*) represents the largest farmed marine finfish sector globally, with strong consumer demand and prized for its nutritional benefits (FAO 2024). However, an increase in seawater temperatures above salmon's optimal growing conditions (16–18°C) can cause physical stress, which affects metabolism and consequently the nutritional composition of the fish (Siciliani et al. 2023). This paper aims to investigate the effect of projected increases in seawater temperatures on the mineral composition of Atlantic salmon and the knock-on effects on consumer nutritional intake.

METHODS

Combining experiments that quantify the effects of water temperatures (15°C vs 20 °C) on the mineral composition of Atlantic salmon tissues with projected changes in sea surface temperatures by the end of the 21st century, we explore potential risks from climate change on the future mineral delivery from farmed salmon to human consumers.

RESULTS

Salmon reared at 20°C showed statistically clear changes in fillet mineral composition compared to those at 15°C, with higher concentrations of magnesium (Mg), sodium (Na), phosphorus (P), selenium (Se), and zinc (Zn) and lower concentration of iodine (I) - all critical for human health. Notably, iodine concentration decreased by 81% in the fillet of salmon from 20 °C, meaning consumers would need to eat five servings (100 g/serve) of salmon from 20°C to achieve equal iodine provided by one serving size of salmon from 15°C. Projections indicate a key salmon farming regions in Norway, Canada, and Tasmania are likely to experience ocean temperatures exceeding 20°C by the end of the 21st century, meaning a reduction of iodine if management of the fish stays the same. Using Tasmanian Atlantic salmon farming as a case study, we highlight the potential consequences of warming oceans on the nutritional quality of farmed salmon and its implications for public health.

CONCLUSIONS

These findings underscore a broader concern: as ocean temperatures rise, the declining mineral content in salmon may exacerbate existing nutrient deficiencies, reduce the efficacy of salmon as a dietary source of essential micronutrients, and challenge global food and nutrition security. Adaptive strategies to maintain product quality in aquaculture, such as increasing mineral content in salmon and other aquaculture feeds, will likely be crucial to mitigating these impacts and ensuring sustainable human nutrition in the face of climate change.

COUPLED HEALTH, ENVIRONMENTAL, ECONOMIC, AND SOCIAL IMPACTS OF SHIFTING TO RECOMMENDED DIETS IN THE US

Brooke M Bell[1]; Frederick Cudhea[1]; Kyra Battaglia[1]; Alejandra S. Marquez[1]; Julia C. Nelson[1]; Edgar Rodriguez Huerta[2]; Beth Jackson[2]; Lu Wang[1]; Sean B. Cash[1]; Patrick Webb[1]; Fang Fang Zhang[1]; Nicole Tichenor Blackstone[1]
[1]Friedman School of Nutrition Science and Policy, Tufts University, Boston, United States of America; [2]Rights Lab, University of Nottingham, Nottingham, United Kingdom

BACKGROUND AND OBJECTIVES

Changes to federal nutrition guidelines have been proposed as an avenue to reduce the environmental impacts of diets while promoting population health. At the same time, sustainable healthy diets must also be affordable and ensure the well-being of workers and communities in food value chains (1). Previous research has examined the environmental impacts and costs of US recommended diets (2–4), but no research to date has analyzed impacts of dietary shifts across all four pillars of sustainability (5). The goal of this study was to estimate health, environmental, economic, and social impacts of shifting to four recommended dietary patterns in the US.

METHODS

Current dietary intake for US adults was estimated using two cycles of the National Health and Nutrition Examination Survey (2015–2016 and 2017–2018) (6,7). Recommended food patterns came from the 2020-2025 Dietary Guidelines for Americans (8) and the literature (9). Cardiometabolic (CMD)- and cancer-specific health outcomes associated with the intake of 18 food groups were calculated using a comparative risk assessment model. Environmental outcomes were assessed using life cycle impact assessment data and considered consumed, wasted, and inedible foods. Economic and social impacts were calculated using food cost and forced labor risk datasets, respectively.

RESULTS

Shifting to the four recommended patterns RESULTS in health benefits for both CMD and cancer, with the greatest reduction in adverse health outcomes for the Healthy Vegetarian (VEG) pattern, followed by the Healthy Vegan (VEGN) pattern. Concurrently, shifting to each of the four patterns RESULTS in increased water scarcity. Shifting to the Healthy-Mediterranean and Healthy-US Style patterns RESULTS in increased global warming potential (GWP), cumulative energy demand (CED), blue water use, food cost, and forced labor risk. However, shifting to the VEG and VEGN patterns result in reduced GWP, CED, and blue water use, as well as reduced cost and forced labor risk. The extent of change across outcomes is largely due to the underlying recommendations within each food group and the magnitude of difference between current and recommended intake.

CONCLUSIONS

This analysis highlights the benefits and tradeoffs of transitioning from current to recommended diets in the US based on a four-pillar framework of sustainability. Incorporating multiple dimensions of sustainability into the development of recommended diets can help achieve a transition to sustainable food systems.

WOMEN'S DIETARY DIVERSITY AMIDST CLIMATE VARIABILITY: A COMPARATIVE ANALYSIS ACROSS EIGHT LOW- AND MIDDLE-INCOME COUNTRIES

Bianca Carducci[1]; Rukundo Benedict[2]; John Corrigan[2]; Ben Mayala[2]; Sorrel Namaste[3]; Franco Bilotto[4]; Peiyu Cao[4]; Mario Herrero[4]; Zhe Guo[5]; Jessica Fanzo[1]
[1]Columbia Climate School, Columbia University, New York, United States of America; [2]Demographic and Health Surveys, ICF, Rockville, United States of America; [3]Health Sector Activity, Research Triangle Inter, Research Triangle Park, NC, USA, United States of America; [4]Global Development, Cornell, Ithaca, United States of America; [5]Foresight and Policy Modeling Unit, International Food Policy, Washington D, United States of America

BACKGROUND AND OBJECTIVES

It is widely anticipated that climate change and climate variability will threaten food and nutrition security through multiple pathways. Because of this, measuring and monitoring global diet quality is of growing relevance. However, there is a dearth of evidence on the relationship between climate variability and women's minimum dietary diversity (MDD-W), especially in low- and middle- income countries (LMICs).

METHODS

We conducted hierarchical statistical modeling, fitted within a Bayesian framework, to investigate the impacts of climate variability on MDD-W, of 142,484 non-pregnant women, aged 15-49 years, in eight LMICs (Burkina Faso, Cambodia, Côte d'Ivoire, Ghana, Kenya, Mozambique, Nepal and Tanzania). Driver covariates included variability and anomalies of daytime and nighttime land surface temperature and precipitation (NASA's Moderate Resolution Imaging Spectroradiometer; Climate Hazards center InfraRed Precipitation with Station), total population and nightlights; food production covariates included nutrient yield, growing season and enhanced vegetation index; and individual and household-level covariates from Demographic and Health Surveys (DHS-8, 2020-2022). All analyses were analyzed and adjusted for the weights and sample design (with strata and clusters) for each survey separately, as the relationships between variables vary across surveys.

RESULTS

Across the eight countries, the proportion of women achieving MDD-W the previous day ranged between 20.8% (Mozambique) to 57.3% (Cambodia). The full model RESULTS suggest that climate variables showed significant negative associations with MDD-W, except for long- term precipitation variability in Nepal (Odds Ratio (OR) 1.13, 95% Credible Interval (Cl): 1.01, 1.25) and Mozambique (OR 1.24, 95% CI: 1.05, 1.46) and long-term variability in daytime land surface temperature in Mozambique (OR 1.21, CI: 1.03, 1.43). Few food production variables were significantly associated with MDD-W across countries. Individual-level variables were significantly positively associated with MDD-W in almost all countries, including women's education, employment, media access and land ownership. Household wealth was consistently associated with MDD-W in all countries.

CONCLUSIONS

These findings suggest that safeguarding women's diet diversity requires adaptation efforts that target vulnerable households to ensure nutrition. Future research should explore the impact of climate variability on MDD-W across spatial and temporal scales, and greater inclusion of food system covariates.

NUTRITIONAL LABELLING TOWARDS HEALTHY AND SUSTAINABLE DIETS: AN ANALYSIS OF THE NUTRIENT PROFILING SYSTEMS PROPOSED AT GLOBAL LEVEL

Luca Muzzioli[1]; Francesco Frigerio[2, 1]; Viviana Morolli[1]; Eleonora Poggiogalle[1]
[1]Department of Experimental Medicine, Sapienza University of Rome, Roma, Italy; [2]Department of Human Sciences and Promotion of the Quality of Life, Università telematica San Raffaele, Roma, Italy

BACKGROUND AND OBJECTIVES

Nutrient Profiling Systems (NPSs) represent "the science of classifying foods based on their nutritional composition for the purpose of preventing disease and promoting health". These systems are quantitative algorithms to score food products based on the presence and/or the amount of nutrients or attributes classified as either beneficial or harmful: therefore, they have emerged as global, relevant tools for policymaking. In addition, to meet the urgent challenge of global warming and climate change, environmental labels have also been developed; however, environmental scores do not always overlap with nutritional ones, thus hampering consumer ability of making healthy food choices. Therefore, the aim of this study is to assess the correlation between different NPSs and environmental impact indicators, in order to understand to what extent NPSs agree with healthy and sustainable diets.

METHODS

Two databases were used in the study: the 2015–2016 What We Eat In America (WWEIA) NHANES survey based on 24-h dietary recalls and the Agribalyse 3.0, which comprises values of fifteen environmental indicators derived from Life Cycle Assessments. Products were further divided in twelve food categories. For each food item, a score was calculated using seven different NPSs: Food Compass Score, Health Star Rating, FSAm-NPS, Multiple Traffic Lights, Chilean Warning Label, Israeli labels, and NOVA classification. The Kendall's Tau test was used to determine the correlation of selected NPSs with environmental impact indicators of greenhouse gas emissions and use of resources by the agri-food system.

RESULTS

A sample of 775 food products was obtained by matching products from 8032 foods included in the WWEIA and the 2520 food items of the Agribalyse database. The majority of NPSs revealed negligible or weak correlations (i.e., Food Compass Score, Health Star Rating, and NOVA classification), while Chilean Warning labels showed a moderate correlation with Land Use only (τbLU=0.370, $p<0.001$). On the contrary, Multiple Traffic Light (τbGWP=0.262, $p<0.001$; τbLU=0.370, $p<0.001$), FSAm-NPS (τbGWP=0.296, $p<0.001$; τbLU=0.322, $p<0.001$), and Israeli labels (τbGWP=0.281, $p<0.001$; τbLU=0.300, $p<0.001$) displayed a moderate correlation with GWP100 and Land Use. As for the Water use indicator, all NPSs showed weak or negligible correlations.

CONCLUSIONS

The investigated NPSs revealed significant but moderate or weak associations with environmental indicators. Further research should focus on how to combine dimensions of health and sustainability into a unique NPS.

EVALUATION OF THE KNOWLEDGE LEVELS OF ADULT INDIVIDUALS ON SUSTAINABLE NUTRITION

Nazli Nur Aslan Çin[1]; Nursena Ersoy Söke[2]
[1]Nutrition and Dietetics, Karadeniz Teknik Üniversitesi, Trabzon, Türkiye; [2]Nutrition and Dietetics, Ankara University, Ankara, Türkiye

BACKGROUND AND OBJECTIVES

Despite the rapid increase in the world population, the limited food resources lead societies to take measures for sustainable nutrition. For this reason, it is important for society to be aware of sustainable nutrition, which is defined as a diet that is sensitive to environmental effects and contributes to healthy nutrition today and in the future. The aim of this study is to evaluate the knowledge level of adults on sustainable nutrition.

METHODS

The study was conducted with 400 adult individuals between the ages of 19 and 64 years living in Ankara. The data were collected with a questionnaire form using the face-to-face interview technique. The questionnaire includes sociodemographic characteristics, nutritional habits, information questions about sustainable nutrition, and anthropometric measurements. In order to determine the level of knowledge on sustainable nutrition, a questionnaire consisting of 30 questions was prepared by reviewing the literature. The research data were evaluated in the SPSS package program by making appropriate analyses.

RESULTS

Participants in the study comprised 63.0% (n = 252) women and 37.0% (n = 148) men, with a mean age of 29.2 ± 11.6 years. 90.0% of the individuals stated that they buy fruits and vegetables according to the season for sustainable nutrition; 77.3% of them use processes such as freezing or drying for use in the following seasons. 70.6% of women and 29.4% of men have heard of the concept of sustainable nutrition before, and there is a statistically significant difference between genders ($p<0.05$). 63.9% of women and 45.3% of men reported that sustainable nutrition is important for a healthy world ($p<0.05$). 93.8% of the participants stated that they have heard of the concept of climate change and that climate change can cause famine, drought, and natural disasters. 48.6% of men and 61.1% of women stated that herbal nutrition is important for sustainability, and the difference is statistically significant ($p<0.05$). It was determined that nearly half of the participants knew the definitions of water footprint (40.0%) and carbon footprint (52.5%), and there was a statistically significant difference according to gender ($p<0.05$).

CONCLUSIONS

This study found that especially male individuals had lower knowledge about sustainable nutrition. It is essential for strategies and policies to be developed to increase the knowledge and behaviors about sustainable nutrition in society with the initiatives to be made on the subject.

REPLACING RED AND PROCESSED MEAT, POULTRY, OR FISH WITH LEGUMES AND THE RISK OF GALLBLADDER DISEASES IN A LARGE BRITISH COHORT

Fie Langmann[1]; Daniel B. Ibsen[1]; Luke Johnston[2]; Aurora Perez-Cornago[3]; Christina C. Dahm[1]
[1]Department of Public Health, Aarhus University, Aarhus, Denmark; [2]Steno Diabetes Center Aarhus, Steno Diabetes Center Aarhus, Aarhus, Denmark; [3]Joint Research Centre, European Commission, Joint Research Centre (JRC), Ispra, Italy

BACKGROUND AND OBJECTIVES

Legumes are promoted as a source of environmentally sustainable and healthful proteins. This study examined the association between substituting red and processed meats, poultry, or fish with equivalent amounts of legumes and the risk of gallbladder disease.

METHODS

Participants from the UK Biobank Cohort who had completed at least two 24-hour dietary assessments and provided complete covariate data were included. Data on age, sex, socioeconomic status, and lifestyle factors were collected at baseline, while dietary intake was assessed through repeated 24-hour dietary assessments. Incident gallbladder disease (including cholelithiasis, cholecystectomy, or cholecystitis) was identified through health registry records using ICD10 diagnosis and operative procedure codes. Cox Proportional Hazards regression models, adjusted for potential confounders, were used to estimate the hazard rate of gallbladder disease associated with replacing red and processed meats, poultry, or fish with legumes.

RESULTS

Over a median follow-up of 10.5 years (interquartile range: 10.4-10.9), 121,593 participants contributed 1,246,913 person-years, with 3,772 cases of gallbladder disease recorded. Substituting 80 grams per week of red and processed meat with legumes was associated with a slightly reduced rate of gallbladder disease (HR: 0.97, 95% CI: 0.95; 0.98, $p<0.001$). No significant associations were observed when replacing poultry or fish with legumes. Adjustments for BMI did not alter these findings.

CONCLUSIONS

Replacing red and processed meat with legumes was associated with a lower rate of gallbladder disease. Further studies in populations with higher legume consumption are needed to validate these RESULTS.

PROFILES OF EIGHT-YEAR TRAJECTORIES OF DIET-RELATED ENVIRONMENTAL PRESSURES

Elie Perraud[1]; Aurélien Chayre[2]; Sylvaine Berger[2]; Annabelle Richard[2]; Justine Berlivet[1]; Benjamin Allès[1]; Denis Lairon[3]; Philippe Pointereau[2]; François Mariotti[4]; Julia Baudry[1]; Christian Couturier[2]; Emmanuelle Kesse-Guyot[1]
[1]Équipe de Recherche en Épidémiologie Nutritionnelle (EREN), Sorbonne Paris Nord University, Inserm, CNAM, INRAE, Bobigny, France; [2]Solagro, Solagro, Toulouse, France; [3]C2VN, AixMarseille Université, Inserm, INRAE, Marseille, France; [4]AlimH, Université Paris-Saclay, AgroParisTech, INRAE, UMR PNCA, Palaiseau, France

BACKGROUND AND OBJECTIVES

Few studies have described the evolution of diet-related environmental pressures at the individual level, with greenhouse gas emissions (GHGe) and land occupation (LO) dominating the scientific literature. The present study aims to evaluate trajectories of the environmental pressures of diets over 8 years, a recent period in which awareness of the environmental crisis has increased.

METHODS

Dietary data were collected using a food frequency questionnaire distinguishing between organic and conventional foods in a sample that completed the questionnaire three times (2014, 2018, 2022). Environmental indicators at the farm perimeter were estimated for organic and conventional farming using a multi-source approach. Latent class models were used to identify trends in pressures related to food production, as well as in a synthetic Environmental Pressure Indicator (EPI) comprising standardized values for GHGe, LO, energy demand, agroecological infrastructure, water withdrawal, and pesticide footprint. Indicator trajectories were modeled using mixed models adjusted for energy intake and gender.

RESULTS

Over the study period (2014-2022), in the whole sample (n=8,905) environmental pressures, except for water withdrawal, decreased by 8-12%, with the EPI decreasing by 9.1%. Two to four distinct trajectory profiles were identified for individual indicator, with most participants showing stable or declining trends in pressures, except for water withdrawal, where two main profiles showed either increasing or decreasing trends over time. Globally, 4 different trajectories were identified for EPI. Dietary changes driving EPI variations included increased meat consumption among participants with rising EPI over time and increased plant-based consumption alongside reduced meat consumption among those with declining EPI over time.

CONCLUSIONS

This study highlights that, despite growing awareness of sustainable diets, most individuals maintained stable diet-related environmental pressures, with only a minority showing significant increases or decreases over the 8-year period. These findings emphasize the need for strong and urgent targeted public policies and communication strategies to promote sustainable dietary shifts, particularly by addressing sociocultural, economic and commercial barriers to environmentally sustainable diets.

SUSTAINABLE DIMENSIONS OF DIETS WITH VARYING LEVELS OF FOOD BIODIVERSITY IN A LARGE COHORT STUDY

Justine Berlivet[1]; Bernard Srour[1]; Benjamin Allès[1]; Philippe Pointereau[2]; Cédric Agaësse[1]; Denis Lairon[3]; Mathilde Touvier[1]; Jeroen Berden[4, 5]; Carl Lachat[5]; Inge Huybrechts[4]; Julia Baudry,[1]; Emmanuelle Kesse-Guyot[1]
[1]Centre of Research in Epidemiology and Statistics, Nutritional Epidemiology Research Team (EREN), Université Sorbonne Paris Nord and Université Paris Cité, INSERM, INRAE, CNAM, Bobigny, France; [2]Solagro, Solagro, Toulouse, France; [3]Aix Marseille Université, Inserm, INRAE, C2VN, Marseille, France; [4]Nutrition and Metabolism branch, IARC - International Agency for Research on Cancer, Lyon, France; [5]Department of Food Technology, Safety and Health, Faculty of Bioscience Engineering, Ghent University, Ghent, Belgium

BACKGROUND AND OBJECTIVES

Dietary diversity has been associated with some health benefits. However, the concept of food biodiversity and its associations with different sustainability dimensions require further attention. We aimed to estimate the associations between dietary species richness (DSR), defined as the number of unique species consumed in individual diets, and various environmental pressures, dietary quality indicators and monetary cost.

METHODS

This study was carried out among 29,173 participants of a large cohort who filled in a 264-item food frequency questionnaire. ANOVA and ANCOVA models were used to evaluate the associations of overall, plant, and animal DSR (modelled as both quintiles (Q) and continuous variables) with environmental pressures (greenhouse gases emissions (GHGe, kg eqCO2/day), cumulative energy demand (MJ/day), and land use (LU, m2/day)), dietary quality indicators (the cDQI, reflecting the share of unhealthy and healthy animal and plant-based food in the diet, and the sPNNS-GS2, reflecting the level of adherence of national dietary guidelines) and monetary cost (€/day). The main model was adjusted for age, sex, and alcohol-free energy intake.

RESULTS

After adjustment, higher overall DSR was associated with reduced environmental pressures (GHGe, Q5 vs. Q1: -12.8%; energy demand, Q5 vs. Q1: -11.0%; LU, Q5 vs. Q1: -7.7%), and higher overall dietary quality (cDQI: Q5 vs. Q1: +29.1%; sPNNS-GS2, Q5 vs. Q1: +44.8%), while monetary cost of diets remained stable across quintiles. After further adjustment for animal DSR, higher plant DSR was related to lower GHGe, energy demand and LU (GHGe, Q5 vs. Q1: -25.8%; energy demand, Q5 vs. Q1: -17.1%; LU, Q5 vs. Q1: -20.7%), higher overall dietary quality (cDQI: Q5 vs. Q1: +13.6%; sPNNS-GS2, Q5 vs. Q1: +103.2%), and increased monetary cost (Q5 vs. Q1: +6.9%). On the other hand, after adjustment for plant DSR, animal DSR was associated with higher environmental pressures, lower dietary quality, and reduced monetary cost. Additionally, the share of organic food in the diet was positively associated with plant DSR and inversely associated with animal DSR.

CONCLUSIONS

Increasing DSR, and especially plant DSR, was associated with lower overall environmental impacts and better dietary quality, but led to increased monetary cost. The concept of food biodiversity is recent and its associations with various sustainability dimensions warrant further investigations in other settings.

DO FOODS DISPLAYING SUSTAINABILITY LABELS ACTUALLY HAVE A LOWER ENVIRONMENTAL IMPACT? PREVALENCE AND ACCURACY OF SUSTAINABILITY LABELLING ON PACKAGED FOOD

Mariel Keaney[1]; Eden Barrett[2, 1]; Alexandra Jones[1]
[1]The George Institute for Global Health, UNSW, Sydney, Australia; [2]School of Health Sciences, Faculty of Medicine and Health, UNSW, Sydney, Australia

BACKGROUND AND OBJECTIVES

International guidance on packaged foods emphasises that labels should not mislead consumers. Consumer interest in the sustainability of their diets has seen a growth in the use of voluntary sustainability labels. However, concerns of 'greenwashing' have been raised worldwide, given many of these labels are unverifiable. The aim of this study was to analyse whether food products carrying sustainability labels were actually more sustainable than their non-label carrying counterparts using product-specific greenhouse gas emissions (GHGe) estimates.

METHODS

Labelling data on packaged food were collected at five Australian supermarkets. We determined whether each product displayed a sustainability label anywhere on pack. For all products, we calculated a 'Planetary Health Rating' (PHR), which summarises the estimated GHGe of a product through a rating between 0.5 (highest emitting products) to 5 (lowest emitting products). We then analysed whether products displaying a sustainability label had a higher PHR than their non-label carrying counterparts, overall and by product category.

RESULTS

In our sample of >27,000 products, around 1/3 displayed ≥1 sustainability label. There were 30 unique sustainability labels identified. Overall, products displaying sustainability labels had a higher mean PHR compared to unlabelled products (2.51 vs 2.09). By product category, the mean difference in PHR was the highest for meat and meat alternatives, and dairy product categories. For these categories, the mean PHR was higher for products displaying a sustainability label, driven by vegan labels displayed on plant-based alternatives in these categories. However, for the majority of product categories, the mean difference in PHR for labelled vs unlabelled products was indiscernible.

CONCLUSIONS

Products carrying sustainability labels may not be considerably more sustainable than their unlabelled counterparts. Given the limited regulation in this area, there is a risk unverified claims may mislead consumers. The wide variety of unique labels may also limit consumers ability to compare different products. Adopting lessons from nutrition labelling, a standardised government-led sustainability label may improve consumer trust and comparability across products as part of comprehensive policies to promote and healthy and sustainable food systems.

ORGANIC VERSUS CONVENTIONAL CONSUMPTION OF FRUIT AND VEGETABLES IN RELATION TO CANCER RISK: FINDINGS FROM A LARGE COHORT STUDY

Justine Berlivet[1]; Benjamin Allès[1]; Denis Lairon[2]; Emma Meyer[1]; Bernard Srour[1]; Serge Hercberg[1]; Mathilde Touvier[1]; Julia Baudry,[1]; Emmanuelle Kesse-Guyot[1]
[1]Centre of Research in Epidemiology and Statistics, Nutritional Epidemiology Research Team (EREN), Université Sorbonne Paris Nord and Université Paris Cité, INSERM, INRAE, CNAM, Bobigny, France; [2]C2VN, Aix Marseille Université, Inserm, INRAE, Marseille, France

BACKGROUND AND OBJECTIVES

A regular consumption of fruit and vegetables (F&V) has been associated with health benefits, including lower risk of certain cancers. F&V consumption is also one of the main source of pesticide exposure in the general population. While higher organic food consumption has been related to lower pesticide exposure, it remains unclear if cancer risk varies with higher consumption of organic F&V compared to conventional F&V.

METHODS

This study aims to examine the association between the substitution of conventional F&V by organic F&V and cancer risk, in a large sample of adults, using detailed data on F&V consumption from a food frequency questionnaire distinguishing production METHODS. Using a residual methodological approach, the association between the substitution of conventional F&V by organic F&V, at fixed total F&V consumption, and cancer risk (overall and by location), was examined with Cox proportional hazards models for 100g replacement of conventional by organic F&V and for quintiles of replacement. In the main models, data were weighted for the national 2009 census data, and a large set of sensitivity analyses were conducted to improve causal inference.

RESULTS

A total of 30,981 participants were included in the analyses. During follow-up (mean (SD)=6.5 years (2.9)), 1,194 incident cancer cases were registered over 207,750 person-years. After confounder-adjustments (including anthropometrics, socio-demographics, family history of cancer, diet quality, lifestyle and total F&V consumption), substitution of conventional F&V by organic F&V was associated with lower risk of overall, colorectal and skin cancer, with HR (95%CI)=0.93 (0.90-0.96), 0.87 (0.79-0.96) and 0.90 (0.83-0.99) respectively, for an increment of 100g. After further adjustment for women-related risk factors, the substitution was also associated with a marked lower risk of postmenopausal breast cancer, with HR=0.76 (0.66-0.87) for the same increment. No association was detected for prostate, bladder, and lung cancer. Findings remained consistent after adjustment for the amount of ultra-processed food in the diet, or for the share of organic food in the diet, and considering another diet quality measure, or after removing early cases. The use of marginal structural model and inverse probability weighting METHODS did not substantially modify the findings. With unweighted data, substitution of conventional F&V by organic F&V was associated with a lower risk of postmenopausal breast cancer only.

CONCLUSIONS

The role of replacing conventional by organic F&V should be investigated in other settings.

CONFLICTS OF INTERESTS

DOSE-RESPONSE RELATIONSHIPS FOR ESTIMATING HEALTH IMPACTS OF DIETARY RISK FACTORS – AN UPDATE AND EVIDENCE SELECTION FROM THE NORDIC NUTRITION RECOMMENDATIONS 2023

Anna E. Jacob[1]; Claire Dénos[2, 3, 4]; Marianne Uhre Jakobsen[1]; Stefanie Vandevijvere,[4]; Sara M. Pires[1]; Lea Sletting Jakobsen[1]
[1]National Food Institute, Technical University of Denmark, Kongens Lyngby, Denmark; [2]STEN, Universiteit Gent - Campus Coupure, Gent, Belgium; [3]SONYA, Usquare.brussels (VUB - ULB), Ixelles, Belgium; [4]Department of Epidemiology and Public Health, Sciensano, Brussels, Belgium

BACKGROUND AND OBJECTIVES

Dietary health impact assessment modelling is a valuable tool to provide decision-support evidence for population-wide dietary shifts, including sustainable diet transitions. These assessments rely on epidemiological evidence to estimate associations between exposure to dietary risk factors and disease incidence for a given dietary pattern. However, selecting evidence can be challenging for several reasons including a lack of systematic approaches to risk-outcome pair selection and ability to extract dose-response data from scientific papers. An aligned approach would allow for more robust assessments, better comparability, and increased harmonisation in the field. This work aimed to update the Nordic Nutrition Recommendations 2023 (NNR2023) evidence base, construct a database of extracted dose-response relationships, and highlight challenges of evidence selection.

METHODS

An update of the NNR2023 evidence was conducted by replicating the scoping review methodology provided in the NNR2023 background papers. Dose-response relationships were selected according to NNR2023 selection criteria (the commissioning body criteria was omitted) and certainty of the evidence. Non-linear relationships were replicated following a novel approach that used an online graphing tool (WebPlotDigitiser) to extract data points and then applying piecewise linear functions to the extracted points.

RESULTS

Eighteen new studies were added to the evidence base following the updated searches. From included studies (original NNR2023 and newly identified studies), 88 individual risk-outcome pairs were included, 22 of which were non-linear relationships. Linear functions and piecewise functions for non-linear relationships were compiled to create a dietary risk-factor database. When there was conflicting data for the same risk factor, a critical comparison was conducted to select the strongest evidence. Time and resource availability meant that replicating RESULTS of meta-analyses was not usually possible which led to the development of a standard piecewise function approach. There were also discrepancies between the NNR2023 and Global Burden of Disease Study; a comparison highlighting differences in food group designation and methodologies was constructed.

CONCLUSIONS

Selection and extraction of data to be used in dietary health impact modelling is an ongoing challenge for risk assessors. The constructed database and methodology applied to extract dose-response relationships aims to increase transparency and provide a standard approach for data selection in impact assessment, including sustainable diet investigations.

OAP 11 - FOOD SCIENCE, GASTRONOMY AND LIFE QUALITY

OAP11_01

The Effect of Different Cooking METHODS and Fat Types on the Estimated Glycemic Index Value of Potatoes

Feyza Kaya Özçavdar[1]; M. Merve Tengilimoğlu-Metin[2]; Berat Aytül Hamzalıoğlu[3]
[1]Department of Nutrition and Dietetics, Başkent University, Ankara, Türkiye; [2]Department of Nutrition and Dietetics, Hacettepe University, Ankara, Türkiye; [3]Food Quality and Safety (FoQuS) Research Group, Department of Food Engineering, Hacettepe University, Ankara, Türkiye

BACKGROUND AND OBJECTIVES
The glycemic index (GI) concept is a beneficial tool for selecting carbohydrate-containing foods in achieving glycemic control. The GI value of foods is affected by different preparation METHODS as well as the botanical origin of the food. Also, heat-processed forms of potatoes, such as French fries, may pose health concerns due to high levels of fat and carcinogenic compounds. This study aimed to investigate the effect of different alternatives to deep-frying cooking METHODS and different fat types on the eGI value of potatoes.
METHODS

Potatoes were prepared by deep-fat frying (12 min, 190°C, 275 ml oil/100 g potatoes), air-frying (30 min, 200°C, 5 ml oil/100 g potatoes), and baking (30 min, 180°C, 5 ml oil/100 g potatoes), using sunflower oil (SO), canola oil (CO), olive oil (OO), and butter (B) (butter was only not used in the deep-fat fried samples). The proximity, starch fractions (rapidly digestible starch (RDS), slowly digestible starch (SDS), total digestible starch (TDS), resistant starch (RS), total starch (TS)) and according to glucose estimated GI (eGI(glucose)) of cooked potatoes were evaluated.

RESULTS
A comparison of the eGI values of the test foods revealed that potatoes air-fried with the addition of SO exhibited the lowest value (eGI(glucose)= 59.51). In contrast, potatoes baked with the addition of B demonstrated the highest value (eGI(glucose)= 74.96). The findings of this study indicate that the cooking method and type of oil used to prepare fried potatoes can influence the eGI of fried potatoes by up to approximately 15 units. It was determined that the potatoes prepared using SO exhibited a lower eGI value than other oil types in the air-fried and baked samples (for the air-fried and baked samples p=0,009 and p=0,000, respectively). When SO, OO, and B were used, air-frying resulted in lower eGI values than other cooking METHODS (p=0,023, p=0,038, p=0,003 respectively). This study also found a significant strong negative correlation between linoleic acid concentration of SO in fried potatoes and RDS and eGI (-0.61 $p<0.05$ and -0.77 $p<0.01$, respectively).
CONCLUSIONS
Since deep-frying may result in foods with a high-fat content, alternative METHODS such as baking or air-frying with the oil addition can be used instead. This study demonstrated that the eGI of air-fried and oven-baked potatoes was lower and similar, respectively, than that of deep-fried potatoes. In addition, the use of SO may be more appropriate for alternative METHODS of cooking potatoes, as it has a lower starch digestibility than other oils. The RESULTS may be important for individuals aiming to control postprandial glycemia.

ASSOCIATION OF RED AND PROCESSED MEAT CONSUMPTION WITH DIABETES IN A REPRESENTATIVE SAMPLE OF U.S. ADULTS (NHANES 2003-2016)

Djibril Ba[1]; Yue Zhang[2]; Tian Qiu[1]; Nazia Raja-Khan[3]; Muscat Joshua[1]; Vernon Chinchilli[1]
[1]Public Health Sciences, Penn State College of Medicine, Hershey, United States of America; [2]Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, United States of America; [3]Department of Medicine, Penn State College of Medicine, Hershey, United States of America

BACKGROUND AND OBJECTIVES

Greater consumption of red and processed meat has been associated with a higher risk of mortality and major chronic diseases including diabetes. The association between red and processed intake and diabetes remains unclear using a nationally representative sample of US adult population. This study aimed to examine the associations between red/processed meat intakes and diabetes among US adults.

METHODS

A total of 34,222 adult participants (mean (SE) age of 45.8 (0.3) years) of the National Health and Nutrition Examination Survey (NHANES) 2003-2016 were included. Total red meat intake included red meat and processed meat items such as beef, veal, pork, lamb, and cured meat and was estimated using 24-hour dietary recalls. Diagnosed diabetes was defined using any of the following criteria: self-report of diabetes diagnosis by a physician or other health professional, having a fasting plasma glucose level of 126 mg/dL or more, an HbA1c level of 6.5% or more, or use of anti-diabetic drugs. Multivariable surveylogistic regression models were used to examine the associations of total red meat, unprocessed red meat, and processed meat intake with diabetes, adjusting for potential confounders such as demographics, lifestyle, total calories, and other dietary factors. RESULTS were presented as adjusted odds ratio (aOR) and 95 % confidence intervals (CIs).

RESULTS

More than one-half of the participants (67.7%) were Non-Hispanic White, 52.4% women, and 14% were food insecure. After adjustment for sociodemographic factors, and other lifestyle and dietary risk factors including total calories, compared with the lowest quintile, highest quintile of total red meat, processed, and unprocessed red meats were positively associated with higher odds of diabetes with aORs of 1.78 (95% CI, 1.46-2.18), and 1.64 (95% CI, 1.31-2.05), and 1.34 (95% CI, 1.15-1.56), respectively (*P* trend for all <0.001). Substitutions of one serving of plant-based proteins, fish, eggs, and dairy per day for one serving of red meat per day were associated with a 12–16% lower odds of diabetes.

CONCLUSIONS

This study provides more evidence about the health hazards of red meat intake in relation with diabetes using nationally representative of the US adult population. Compared with red meat intake, other dietary components, such as plant-based proteins, dairy products, fish, and eggs, were associated with lower odds of diabetes.

SUPPRESSIVE EFFECT OF CEREAL ALBUMIN ON POSTPRANDIAL BLOOD GLUCOSE ELEVATION AND ITS PHYSICOCHEMICAL PROPERTIES

Kazumi Ninomiya[1]; Shigenobu Ina[2]; Norikazu Ogino[1]; Miho Otsuka[1]; Yusuke Yamaguchi[2]; Hitoshi Kumagai[3]; Yusuke Inoue[1]; Hitomi Kumagai[2]
[1]Graduate School of Science and Technology, Gunma University, Gunma, Japan; [2]College of Bioresource Sciences, Nihon University, Kanagawa, Japan; [3]Department of Food Science and Nutrition, Kyoritsu Women's University, Tokyo, Japan

BACKGROUND AND OBJECTIVES

Diabetes mellitus is one of the most serious diseases in the world because it leads to various complications. Most cases of diabetes are classified as type 2, and it is important for patients to control the elevation of postprandial blood glucose level by taking an appropriate diet. Wheat albumin is known to suppress postprandial hyperglycaemia due to its inhibitory effect on mammalian α-amylase. However, the functions of proteins from other cereals have not fully understood yet. In this study, albumins were extracted from cereals and their postprandial glycaemic effect and physicochemical properties were investigated to evaluate their potential application in functional foods.

METHODS

Albumins were extracted from cereals such as buckwheat, wheat, rice, barley, and rye. Then, these extracts were further purified by ammonium precipitation and dialysed against water. The inhibitory activity against α-amylase was evaluated by measuring the absorbance of chloro-nitrophenol at 405 nm produced from the cleavage of 2-chloro-4-nitropnenyl α-D-maltotrioside by α-amylase. The digestibility of cereal albumin was evaluated by SDS-PAGE and the retained α-amylase inhibitory activity after *in vitro* digestion. The thermal stability was determined by the retained α-amylase inhibitory activity after heating. Then, cereal albumins were administered to rats together with starch, and blood glucose levels were measured.

RESULTS

Buckwheat, wheat, barley and rye albumins inhibited mammalian α-amylase. On the other hand, rice albumin only inhibited the activity of insect α-amylase. Buckwheat and wheat albumin retained their high α-amylase inhibitory activity after heating. Buckwheat albumin was hydrolysed to peptides by digestive enzymes but retained its inhibitory activity even after digestion. The oral administration of buckwheat or wheat together with starch suppressed the postprandial blood glucose elevation in rats.

CONCLUSIONS

Buckwheat albumin suppressed postprandial hyperglycaemia after starch loading by inhibiting α-amylase activity. The high thermal stability of buckwheat albumin suggests its potential use in processed foods for which sterilization is required. Therefore, buckwheat albumin can be used in a variety of functional foods including bread and cakes to suppress blood glucose elevation.

"OPTIMIZATION OF STAPLE CEREALS WITH NUTRI-CEREALS TO ENHANCE NUTRITIONAL VALUE AND SENSORY APPEAL USING A D-OPTIMAL MIXTURE DESIGN: A FOOD-TO-FOOD FORTIFICATION APPROACH"

Shally Vishnoi[1]; Sangita Thenarangam[1]; Shrunga Shree S[1]; Pavithra R C[1]; Prasanthi P S[1]; Srinivas E[1]; Prathyusha Vasireddy,[1]; Brinda S A[1]; Ravindranadh P[2]; R Naveen Kumar[3]; Radhika Madhari[1]
[1]Department of Dietetics, ICMR - National Institute of Nutrition, Hyderabad, India; [2]Drug Safety, National institute of nutrition, Hyderabad, Telangana, India, India; [3]Microbiology Division, ICMR - National Institute of Nutrition, Hyderabad, India

BACKGROUND AND OBJECTIVES

Micronutrient deficiencies affect over two billion people globally, including a significant population in India, due to cereal-based diets lacking diversity and nutrients. Millets are rich in micronutrients, fiber, and bioactive compounds and thrive in diverse agro-ecological conditions, offering a promising alternative. This study aims to optimize a staple flour with nutri-cereals to improve nutrient intake, focusing on women of reproductive age (WRA).

METHODS

The grain-based blended flour formulations were designed using Design-Expert software (version 13, Stat-Ease Inc., USA), generating 19 formulations within specified constraints (10–80% for whole wheat flour (WF), finger (FM) and pearl millet (PM)). Four responses-Iron (Fe), Zinc (Zn), Calcium (Ca) and Overall Acceptability (OA)-were optimized to align with 15–20% of the Estimated Average Requirement (EAR) for WRA of India. Each response underwent statistical analysis to determine the optimal model, assessing the goodness of fit (R^2), and ensure adequate precision for design exploration. The sensory test was conducted in the 15 semi-trained panellists on the product Indian Flat Bread (*Paratha*) prepared using the blended flours. Multiple regression techniques were used with model mixture designs incorporating various mathematical models. Mineral content and sensory scores were analysed using Tukey's post-hoc test in SPSS (version 23, IBM, USA).

RESULTS

The mineral analysis of 19 formulated flours showed that higher FM and PM proportions significantly ($p < 0.05$) increased Fe and Ca levels. The Fe, Ca, and Zn content showed high significance in the linear model, with a $p < 0.0001$ and an R^2 of 0.98 while for OA it was represented by reduced cubic model. The optimized solution included 23.65 g of WF, 42.66 g of FM, and 33.69 g of PM. This optimized flour resulted in a measured Fe content of 4.20 ± 0.05 mg/100g, Zn content of 2.46 ± 0.05 mg/100g, Ca content of 158.14 ± 2.41 mg/100g, and an OA score of 7.04 ± 0.07 fulfilling 19-20% of the EAR for WRA.

CONCLUSIONS

The incorporation of staple flour with nutri-cereals resulted in a nutrient-dense flour that met 15-20% of the EAR for WRA, providing essential micronutrients like Fe, Ca, and Zn. This optimized product offers an affordable solution to combat micronutrient deficiencies and was well-accepted in the sensory evaluation. It has a potential of supporting growth and development as a local alternative to expensive commercial foods, particularly in resource-limited settings.

OAP11_07

UNVEILING THE POTENTIAL OF MORINGA LEAVES (MORINGA OLEIFERA): NUTRITIONAL PROFILING, RECIPE STANDARDIZATION AND SENSORY EVALUATION OF AN UNDERUTILIZED GREEN LEAFY VEGETABLE

Pavithra R C[1]; Srinivas E[1]; Prasanthi P S[1]; Shrunga Shree S[1]; Shally Vishnoi[1]; Sangita Thenarangam[1]; Raghavendra Rao Ch[2]; Prathyusha Vasireddy[1]; Brinda S A[1]; Radhika Madhari[1]
[1]Department of Dietetics, ICMR - National Institute of Nutrition, Hyderabad, India; [2]Clinical Division (MCHN), ICMR - National Institute of Nutrition, Hyderabad, India

BACKGROUND AND OBJECTIVES

Moringa oleifera provides versatile products year-round, with its leaves being especially rich in protein, minerals and vitamins. While moringa leaf concentrates are popular as supplements and nutraceuticals, there is limited research done on incorporating moringa leaves in regular diets. Furthermore, the potential of using nutrient-rich moringa leaves for food-to-food fortification has not been fully explored. Therefore, this study aims to develop and standardize recipes using moringa leaves, analyse their key nutrients such as calcium (Ca), iron (Fe) and Vitamin A (Vit-A), their contribution to % Daily Value (%DV) and to evaluate their sensory acceptability among healthy adults.

METHODS

Moringa leaf samples were procured from five different local markets within the study area. The samples were pooled, washed, air-dried and were taken for nutritional profiling (proximates, iron, calcium and beta-carotene). Further, a few traditional Indian recipes were selected and substituted with Moringa leaves (fresh and dried forms) and standardised. A total of 12 recipes were prepared alongside their leafy and non-leafy control products. Affective sensory evaluation was conducted using a 9-point hedonic scale by 20 semi-trained institutional panel members. A score of >7 was indicative of a highly acceptable recipe. Descriptive statistics and one way ANOVA using post-hoc Tukey's test were performed for the sensory evaluation using IBM-SPSS software (version 23).

RESULTS

The nutritional profile of Moringa-based recipes was superior to their respective controls. The %DV for 100 g of the Moringa recipes ranged from 4.7 (Moringa Adai Dosa) to 38.1 (Dried Moringa Leaf Podi) for Ca; 6.1 (Moringa Pulao) to 78.4 (Dried Moringa Podi) for Fe and 35.6 (Moringa Adai Dosa) to 300.6 (Dried Moringa Leaf Podi) for Vit-A. The %DV of most of the recipes fall under ‘good to excellent’ source category (USFDA). The overall palatability score from the sensory evaluation ranged from 7.05±1.1 (Moringa Adai) to 8.2±0.7 (Moringa Rice) which indicates strong acceptance by the panel. Statistical analysis showed no significant difference, indicating equal acceptance of Moringa-incorporated recipes and their controls.

CONCLUSIONS

The findings suggest that incorporating Moringa leaves into traditional Indian recipes could serve as an effective strategy to enhance the nutritional quality of everyday meals while also offering potential for food fortification. Further exploration into the broader applications of moringa leaves in food-to-food fortification is recommended to optimize its health benefits.

HARNESSING WASTE HEAT FOR GRAIN STORAGE: INSIGHTS INTO WHEAT QUALITY PRESERVATION OPTIMIZING WHEAT STORAGE WITH RECOVERED WASTE HEAT: A QUALITY ANALYSIS

Shravani Gadge[1]; Menon Kavitha[1]; Usman Mohd.[2]
[1]Nutrition and Dietetics, Symbiosis School of Culinary Arts and Nutritional Sciences, Pune, India; [2]Community Medicine, Symbiosis Medical College for Women, Pune, India

BACKGROUND AND OBJECTIVES

Climate change has intensified food loss, impacting farmers' incomes and food security. To tackle this, the innovative 'Hot and Cold Storage' system repurposes waste heat from cold storage for grain storage in a 'Hot Storage' room. The study evaluated its effectiveness of preserving grain quality and reducing insect damage.

METHODS

The study compared wheat stored in gunny bags of hot storage (Experimental-compartments I &II) and a room having ambient conditions (control). Freshly harvested wheat bought from the market was used for the study. The wheat was divided into one-kilogram gunny bags and was stored in three compartments for a year. Half of these bags were artificially spiked with 20 adults per kg of *Sitophilus oryzae* and *Ryzopertha dominica* each. Eighteen stored gunny bags were taken out every three months for analysis. A reading at 45th day was also included. A total of 93 samples were analyzed for parameters such as refractions, physiological weight loss, bulk density, hundred-kernel weight, weevilled grains, healthy grains, proximate composition, sugars, gluten, germination, fat acidity, and alcoholic acidity. Analyses were done in triplicates, and data were statistically evaluated using Kruskal-Wallis and Mann-Whitney U tests to study the effectiveness, and a 5% level of significance was considered for all the differences.

RESULTS

Samples were compared among the storage conditions and the 0th day reading at each time point. Hot storage showed significant ($P < 0.05$) changes in alcoholic acidity (0.10–0.12%), crude fiber (1.83–2.26%), and gluten (10.13%), all were within Indian food safety standards. Elevated temperatures reduced ($P < 0.05$) moisture (48.92%) and physiological weight (1.94–3.63%). Fat content increased ($P < 0.05$) in 90th- and 180th-day non-spiked samples but decreased ($P < 0.05$) in 270th-day spiked samples. In Ambient storage, infestation significantly ($P < 0.05$) impacted quantitative parameters, germination, weevilled grains, frass, crude fiber, alcoholic acidity, and moisture, even in non-spiked samples. Spiked samples showed additional ($P < 0.05$) significant changes in fat acidity, refractions, healthy grain count, and hundred-kernel weight, many exceeding permissible limits. Fat and protein changes were notable ($P < 0.05$) in some non-spiked ambient samples.

CONCLUSIONS

Hot storage shows potential to effectively resist insect damage and preserves grain quality better than ambient conditions over time.

ESTIMATING NUTRIENTS INTAKE IN EQUATORIAL GUINEA: ELABORATION OF A NUTRIENTS CONVERSION TABLE

Marina Prieto-Bercianos,[1]; Rocio Martin-Cañavate,[1]; Estefania Custodio,[1, 2]
[1]Centro Nacional de Medicina Tropical, Carlos III Health Institute, Madrid, Spain; [2]CIBER INFEC, Carlos III Health Institute, Madrid, Spain

BACKGROUND AND OBJECTIVES

Estimating nutrient intake is essential for assessing the general nutritional status of a population, particularly in countries where malnutrition or inadequate food intake may be prevalent. In the case of Equatorial Guinea, this analysis is especially important as no prior studies or published data on nutrients consumption exist. The objective of this study was to elaborate a Nutrients Conversion Table to allow estimation of nutrients intake from food consumption surveys.

METHODS

The Nutrients Conversion Table was designed following FAO and World Bank guidelines. A food list was created based on a nationally representative 24 hours recall survey among children under 5 years old. Nutrients composition was determined using eight Food Composition Tables (FCT) and Databases (FCDB) from culturally and geographically related countries, sourced via INFOODS for quality assurance. For foods without direct matches, average values were calculated, and specific attributes in some items required further averaging. Additionally, cooking METHODS were considered by applying refuse factors to adjust for nutrient changes during preparation. Foods were matched to their corresponding cooked forms in the FCT/FDBs, and retention factors were applied in specific cases to ensure accuracy. To enhance compatibility, FoodEx2 codes from European Food Safety Authority were assigned to each food item, enabling easier database matching and comparison with other NCTs. Six traditional recipes were also analyzed, broken into their ingredients using national sources and bibliographic references. Missing nutrient data was filled by cross-referencing similar items within the same FCT/FCDB or by consulting the same food in another FCT/FCDB from the previously utilized sources.

RESULTS

The resulting Equatorial Guinea NCT includes 213 foods, each with detailed information on energy and macronutrients, as well as on 29 micronutrients including vitamins, minerals, and other bioactive compounds. The first application of this NCT involved analyzing quantitative 24-hour dietary recall data from children under five. The analysis calculated average macro- and micronutrient intakes per child, offering valuable insights into dietary quality and highlighting potential nutritional deficiencies within this population.

CONCLUSIONS

This tool supports the development of public policies tailored to the nutritional needs of diverse population groups in Equatorial Guinea.

"Barley Beta-Glucans Under the Lens: A Systematic Investigation of Beta-Glucan Variability in Barley Across Processed Forms and Indian Cooking METHODS "

Shrunga Shree S[1]; Prasanthi P S[1]; Sangita Thenarangam[1]; Shally Vishnoi[1]; Pavithra R C[1]; Vinay Kumar Soma[2]; Raghavendra Rao Ch[3]; Srinivas E[1]; Prathyusha Vasireddy,[1]; Radhika Madhari[1]
[1]Department of Dietetics, ICMR - National Institute of Nutrition, Hyderabad, India; [2]Clinical Epidemiology Division, ICMR - National Institute of Nutrition, Hyderabad, India; [3]Clinical Division (MCHN), ICMR - National Institute of Nutrition, Hyderabad, India

BACKGROUND AND OBJECTIVES
Barley, often termed the "poor man's crop," thrives in extreme climates, making it a resilient grain. Recently, barley has gained attention for its exceptional nutritional benefits, particularly beta-glucan—a soluble fiber that enhances satiety, regulates blood glucose, and improves insulin sensitivity. Recognized by EFSA for its health benefits, changes in beta-glucan content during barley processing remains poorly understood. This study aims to examine the beta-glucan content in pearl barley and its processed forms available in Indian markets and assess the changes in beta-glucan levels influenced by traditional Indian cooking METHODS.
METHODS
Pearl barley (PB) and processed forms like Barley Grits (BG), Barley Flour (BF), Barley Flakes (BFL), and Barley Puffs (BP) were sourced from nine sample points across three zones of Hyderabad, Telangana (India). All dried and powdered samples were analysed for macronutrients and Phytic acid content. Further, PB, BG, and BF samples underwent soaking and non-soaking pre-treatments. These were then subjected to four household cooking METHODS: Pressure Cooking (PC), Microwave Cooking (MC), Boiling (B), and Roasting (R). The raw forms and dried samples (after processing) were analysed for beta-glucan content, with statistical evaluation performed using one way ANOVA using post hoc Tukey's b test on IBM SPSS software (version 23).
RESULTS
The beta-glucan content of raw samples obtained from local markets ranged between 3.8 to 4.8 g/100 g (dwb), PB had lower value (3.87 ± 0.25) while BFL and BG had significantly higher levels (4.55 ± 0.08, 4.81 ± 0.81). After pre-processing and cooking METHODS, all three barley types demonstrated significant differences in beta-glucan content depending on the cooking method. The mean beta-glucan content after cooking was: PB: 5.13 ± 0.31 g/100 g, BG: 4.94 ± 0.41 g/100 g, BF: 4.50 ± 0.26 g/100 g which indicate increase from their raw counterparts. Among cooking METHODS, pressure cooking retained the highest beta-glucan content (5.07 ± 0.52), while roasting resulted in the lowest levels (4.68 ± 0.45). The ranking of beta-glucan values across cooking processing is as follows: Pressure cooking>Boiling>Microwave cooking>Roasting.
CONCLUSIONS

Beta-glucan is a functional nutrient that plays a vital role in blood glucose and diabetes management Identifying cooking techniques that preserve or enhance its content can contribute to preventive healthcare initiatives and help reduce the global burden of diabetes.

IRON SPECIES AND SPATIAL DISTRIBUTION ASSESSMENT IN MICROALGAE FOR IRON DEFICIENCY ANEMIA PREVENTION AND TREATMENT

Agon Besimi[1]; Fengzheng Gao[2]; Ferdinand Von Meyenn[3]; Alexander Mathys[4]
[1]Health Sciences And Technology - Institute of Food,Nutrition and Health, ETH Zürich, Zürich, Switzerland; [2]Department of Health Sciences and Technology, ETH Zürich, Zürich, Switzerland; [3]Department of Health Sciences and Technology, ETH Zurich, Zürich, Switzerland; [4]Sustainable Food Processing Laboratory, ETH Zurich, Zürich, Switzerland

BACKGROUND AND OBJECTIVES

Iron deficiency (ID) is the most prevalent micronutrient deficiency, affecting 24.3% of the global population, particularly women of reproductive age and children up to the school age(1,2). Prolonged ID RESULTS in iron deficiency anemia (IDA), with major health consequences and currently affects 16.4% of the world population. Dietary ID accounts for ~66% of IDA cases (2). The bioavailability of dietary ferrous (Fe2+) iron is higher compared to the ferric (Fe3+) form. Chelation with polyphenols and phytates reduce, whereas ascorbic acid enhances the iron bioavailability (3). New approaches are needed to mitigate the burden of ID and IDA. Microalgae are rich in minerals, particularly iron (could contain up to 100 times more than beef), and integration of microalgae in food products or usage as supplements is an alternative to reduce ID in affected populations (4). Iron is stored as Fe2+ or Fe3+ in microalgae, depending on species and bioassimilation (5). The objective of this study is to characterize iron species in *Arthrospira platensis (A. platensis)*, *Chlorella vulgaris (C. vulgaris)*, and *Galdieria sulphuraria (G. sulphuraria),* and analyze iron bioavailability from the microalgal biomass *in-vitro.*

METHODS

Mineral content is characterized by inductively coupled plasma – mass spectrometry(6). Iron speciation (Fe2+, Fe3+, complexation with ligands) and the distribution of iron will be (beamline time allocated in January 2025) analyzed by X-ray near edge spectroscopy (XANES) at the Diamond Light Source synchrotron (UK) (7). Ascorbic acid is quantified by high performance liquid chromatography (8). Polyphenols are analyzed with the bicinchoninic acid (BCA) method (9). Iron bioaccessibility was measured by INFOGEST 2.0 (10).

RESULTS

Iron content in *A. platensis*, *C. vulgaris, G. sulphuraria* was found to be 570.7 ± 15.9 mg/kg, 1137.7 ± 22.5 mg/kg, 1485.4 ± 29.2 mg/kg, respectively. Iron bioaccessibility for *A. platensis* was 19.3%, for *C. vulgaris* 4.4%, and for *G. sulphuraria* 9.0%. Polyphenol content is shown as quercetin equivalents (QE) and is 124.0 QE mg/L *for A platensis*, 129.6 QE mg/L for *C. vulgaris* and 94.5 QE mg/L for *G. sulphuraria*.

CONCLUSIONS

This work adds to the evidence of the potential microalgae as a novel source of iron for ID and IDA treatment and prevention. Furthermore, it provides evidence for future animal and human trials.

A STUDY ON THE ASSOCIATION BETWEEN FOOD ADDICTION AND ULTRA-PROCESSED FOOD INTAKE AMONG CHINESE UNIVERSITY STUDENTS: THE MEDIATING ROLE OF MENTAL HEALTH STATUS

Liu Wenjun[1]; Liu Yangling[1]; Xu Wenting[1]; Almab Zainab[1]; MUHAMMAD JAMAL KHAN[1]; Lin Qian[1]
[1]Xiangya School of Public Health, Central South University, Changsha, China

BACKGROUND AND OBJECTIVES

This study aimed to investigate the prevalence of food addiction (FA) and its association with the intake of ultra-processed foods (UPFs) among Chinese university students, and to further analyse the mediating roles of anxiety, depression, and sleep conditions in it.

METHODS

Between September and December 2023, we collected general demographic information on 1866 study participants among college students in Chinese universities via electronic questionnaires; food addiction was assessed using the Yale Food Addiction Scale (YFAS) 2.0; intake of ultra-processed foods was investigated by the Food Frequency Questionnaire (FFQ); and anxiety, depression, and sleep status were assessed by the Generalised Anxiety Disorder Scale (GAD-7), the Patient Health Questionnaire (PHQ-9) and Pittsburgh Sleep Quality Index (PSQI) questionnaires, respectively. The relationship between demographic characteristics and food addiction was analysed by the $\chi 2$ test, and the U test was used to compare differences in daily intake of various types of ultra-processed foods between food-addicted and non-food-addicted groups, and to explore the mediating roles of anxiety, depression, and sleep in the daily amount of food addiction and ultra-processed food intake.

RESULTS

(1) Food addictions accounted for 8% of the college students surveyed, with 1.7%, 2.8%, and 3.5% having mild, moderate, and severe food addictions, respectively. (2) Grade level, major, ethnicity, anxiety, depression, sleep, and time spent on electronic screens were significantly associated with food addiction. (3) Daily intake of confectionery snacks ($P = 0.023$), puffed foods ($P = 0.038$), candied and dried fruits ($P = 0.025$), fast foods ($P = 0.013$), and refined cereals ($P = 0.042$) differed significantly between the food addiction and non-food addiction groups. (4) Anxiety and depressed mood had partially mediated effects in food addiction and fast food intake, with mediation shares of 25.2% and 27.3%, respectively; anxiety had fully mediated effects in food addiction and refined grain-based food intake. No mediating effect of sleep was found in food addiction and ultra-processed food intake.

CONCLUSIONS

Food addiction was significantly associated with ultra-processed food intake among Chinese university students, and anxiety and depression mediated the association between food addiction and specific ultra-processed food intake. The RESULTS of this study emphasise the importance of food addiction prevention and intervention in university student populations and suggest the role of mental health factors in nutritional interventions.

HOW TO LIMIT GLYCEMIC RESPONSE OF CEREAL BASED FOODS

Sophie Vinoy[1]; Agnès Demangeat[1]; Alexandra Meynier[1]
[1]Nutrition Research, Mondelez R&D, Paris Saclay Tech Centre, Saclay, France

BACKGROUND AND OBJECTIVES

Carbohydrate-rich foods are the main contributors to postprandial glycemic excursions. The objective of the work was to limit glycemic and insulin responses by modulating the nutritional composition of cereal-based foods by increasing the slowly digestible starch (by controlling the food processes), or protein and fibers, or the lipid content.

METHODS

The data were obtained from four clinical trials which followed the same design to measure glycemic and insulin indexes (GI; II) on 12 healthy normal-weight subjects. Product portions provided 50g of available carbohydrates. *For the processing condition*, six cereal-based products were made twice with the same raw ingredients using three different food processes: rotary molding, dry bread making and extrusion. The main difference was on starch digestibility determined by the content of slowly digestible starch (SDS) (range from 1 to 15g/portion). *For improved nutritional profile* with higher protein and fibers contents, three commercial products were selected on their protein and fiber contents (from 6 to 29 and from 9 to 28, respectively). *For increased lipid content*, six extruded products were made with the same raw ingredients and only the lipid content was modulated from 1 to 7 g/portion.

RESULTS

The GI and II values for all the products ranged from 38 to 77% and 54 to 79%, respectively. For the different process conditions, the modulations of GI and II were from 41 to 70% and 54 to 79% respectively, with the lowest GI and II with both rotary molded products which had the highest SDS content. For the improved nutritional profile with higher protein and fibers content, the modulations of GI and II were from 38 to 59% and 68 to 75%, respectively, with the lowest GI and II for the cereal based product containing the highest protein and fiber content. For the increased lipid content, the modulations of GI and II were from 53 to 77% and 59 to 75%, respectively with the lowest GI for the cereal based product containing the highest fat content.

CONCLUSIONS

We demonstrated that several ways can be applied to decrease GI and II of cereal-based products. Indeed, maintaining high SDS content, increasing protein and fiber content or even increasing lipid content have been shown to limit postprandial metabolic excursions. Combining multiple approaches could be useful to modulate postprandial metabolism of cereal-based products including improved nutritional profile of these products.

COMPREHENSIVE EXPLORATION OF THE ROLE OF DIETARY CAROTENOIDS INTAKES IN SARCOPENIA AND SARCOPENIA OBESITY

Ying Cai[1]; Yuanjie Lin[1]; Hengyu Zhou[1]; Ao Shen[1]; Dezhong Guo[1]; Jie Tang[1]
[1]School of nursing, Chongqing Medical University, Chongqing, China

BACKGROUND AND OBJECTIVES

Sarcopenia, causing physical function and mobility decline and higher risk of adverse outcomes, has been receiving increasing attention[1-2]. This study is designed to explore the role of carotenoids intakes in sarcopenia and sarcopenia obesity.

METHODS

A cross-sectional study was performed utilizing the 2011-2014 National Health and Nutrition Examination Survey. Participants included 5,122 adults whose carotenoids intakes were assessed by two 24-hour dietary review interviews. Low muscle mass measured by dual-energy X-ray absorptiometry was defined as sarcopenia with appendicular skeletal muscle mass/body mass index (ASM/BMI) based on National Foundation for Health Research[3]. Sarcopenia obesity (SO) was considered as BMI≥30 kg/m2 on the basis of sarcopenia[4]. Weighted logistic regression and weighted linear regression were quantified the relationship, multivariate cox regression and Kaplan-Meier curves were assessed mortality risk, and restricted cubic spline stratification was visualized the effect of carotenoids on mortality.

RESULTS

Total carotenoids, α-carotene, β-carotene, β-cryptoxanthin, lycopene, lutein/zeaxanthin intakes were all positively correlated with ASM and ASM/BMI, while all other carotenoids except lycopene were negatively correlated with fat mass index (FMI) ($P<0.05$). Carotenoids could affect body composition by increasing muscle mass and reducing fat. Meanwhile, total carotenoids, α-carotene, β-carotene, zeaxanthin/lutein reduced the prevalence of SO, only β-carotene and zeaxanthin/lutein reduced the prevalence of non-sarcopenia obesity and obesity ($P<0.05$). For an increase of one unit in the natural logarithm of total carotenoids, β-carotene, zeaxanthin/lutein, the prevalence of SO decreased by 17.52%, 27.23%, and 38.73%, respectively ($P<0.05$). The survival rate with high intakes of total carotenoids and β-carotene were higher than those with low intakes. For an increase of one unit in the natural log-converted β-carotene, the risk of all-cause death was reduced by 19.2% ($P<0.05$). Dose-response diagrams were used to visualize the association between β-carotene and all-cause mortality ($P<0.001$). There was U-shaped association between β-carotene and all-cause mortality in sarcopenia. Non-linear relationship was shown between the natural logarithm of β-carotene and all-cause mortality in SO, increasing β-carotene at lower levels significantly reduced the risk of death, and further increases above the threshold of 6.4175 microgram had less effect on the risk of death.

CONCLUSIONS

Carotenoids, especially β-carotene could promote muscle health and reduce mortality.

BACKGROUND AND OBJECTIVES

Millets stand out for their remarkable environmental resilience and rich nutritional profile. They thrive in extreme temperatures with minimal water and fertilizer, leaving a low carbon footprint, making them a sustainable choice. Finger millet (Eleusine coracana. L.), or 'ragi' in India, is valued for its high content of complex carbohydrates, dietary fibre, phytonutrients, essential amino acids, and minerals. It aids in preventing malnutrition, non-communicable diseases, and various other health concerns. While processing techniques reduce anti-nutrients, their effects on dietary fibre and phytonutrient content—especially across different varieties—remain unknown. This research aims to fill that gap by evaluating how processing METHODS impact the nutritional qualities of these varieties. To evaluate the effect of germination and roasting on the nutritional quality of finger millet, focusing on dietary fibre and phytonutrient content. To compare nutrient variability across three varieties and to identify the best processing method to maximize nutrient retention

METHODS

Three finger millet varieties—GPU-28 (red), GPU-67 (brown), and VL-Mandua-376 (light-brown)—were selected from the leading states in finger millet production. The grains were procured from ICAR-IIMR, Hyderabad, India. They were subjected to roasting (120 ◦C, 5min), soaking (24h), germination (24h, 48h, 72h) and a combination of germination and roasting (24h, 48h, 72h). AOAC METHODS were used for nutrient analysis and linear regression for statistical analysis

RESULTS

The findings revealed significant effects of processing techniques on the nutritional composition of finger millet. ($P<0.05$) VL-Mandua-376 exhibited the highest protein (8.81±0.01g/100g) and dietary fibre (13.23±0.26g/100g) content. Germination enhanced dietary fibre across all varieties with an increase in germination time. GPU-28 had the highest phytonutrient content, TPC (1552.40±4.70mgGAE/100g), TFC (1651.39±5.36mgCEQ/100g and Antioxidant (76.74%). However, germination constantly reduced these levels. The 48-h germination and roasting treatment showed the highest phytonutrient retention.

CONCLUSIONS

The study showed that processing techniques significantly impact the nutritional quality of finger millet. These findings suggest that optimizing processing METHODS can enhance its nutritional value, benefiting health-conscious diets, food industry applications, agricultural practices, consumer awareness, and updates to nutrient databases.

OAP40_09

DETERMINANTS OF ADHERENCE TO THE MEDITERRANEAN DIET IN EUROPE: THE DELICIOUS PROJECT

Giuseppe Grosso,[1]; Justyna Godos[1]; Sabrina Castellano[2]; Fabio Galvano[1]; Pablo Busó[3]
[1]Biomedical and Biotechnological Sciences, University of Catania, Catania, Italy; [2]Department of Educational Sciences, University of Catania, Catania, Italy; [3]AIJU, Technological Institute for Children's Products & Leisure, Valencia, Spain

BACKGROUND AND OBJECTIVES

The Mediterranean diet is considered a healthy dietary pattern associated with substantial health benefits. Its main features are strongly eradicated into the cultural heritage of populations living in countries facing the Mediterranean basin, but its preservation among younger generations is rather complex due to an abandonment of its funding principles and overall historical lifestyles. The aim of this study was to assess major determinants of adherence to the Mediterranean diet in 5 Mediterranean countries participating in the EU-funded DELICIOUS project.

METHODS

A multi-domain analysis has been performed on data obtained from a survey involving 2011 parents of children and adolescents living in Italy, Spain, Portugal, Lebanon, and Egypt participating in the project. Data obtained through validated instruments concerning personal (i.e., dietary and eating habits, lifestyle behaviors), family (i.e., parents believes, nutrition knowledge, barriers and enablers), and societal domains (i.e., food security) was analyzed via logistic regression analyses to assess the factors associated with higher adherence to the Mediterranean diet (assessed through the KIDMED test) in children and adolescents.

RESULTS

The average adherence to the Mediterranean diet was similar across participating countries, showing a rather low level (if considered in the context of Mediterranean populations). Higher adherence was embedded within a clear pattern involving higher physical activity level, adequate sleep duration, and healthier eating habits (frequent breakfast, eating at schools and with parents, lower preference for unhealthy ultra-processed foods). Also, parents' education and family economic allowance showed an association with adherence to the Mediterranean diet. Parents believes, barriers and enablers, capacity to seek information, and nutrition knowledge were all significant determinants of their children dietary choices. Finally, food security, especially in developing countries, also resulted associated with adherence to the Mediterranean diet.

CONCLUSIONS

Adherence to the Mediterranean diet is a component of a much more complex construct that involves the overall lifestyle, determined by family factors and the societal environment. Public health interventions to improve diet quality in children and adolescents living in the Mediterranean area should aim a comprehensive involvement of various targets in order to reach the desired goals.

THE ASSOCIATION BETWEEN FLAVONOID INTAKE AND PREVALENCE OF SARCOPENIA

yuanjie lin[1]; Ying Cai[1]; Hengyu Zhou[1]; Ao Shen[1]; Dezhong Guo[1]; Jie Tang[1]
[1]School of nursing, Chongqing Medical University, Chongqing, China

BACKGROUND AND OBJECTIVES

Chronic low - grade inflammation is one of the important pathogenesis of sarcopenia. It promotes muscle atrophy, stimulates protein catabolism and inhibits muscle synthesis. Flavonoids, which are widely present in plants, fruits and vegetables, have multiple benefits such as anti - inflammation and anti - oxidation. However, no study has clearly established the impact of flavonoid intake on sarcopenia. This study will be based on the NHANES and FNDDS databases to deeply analyze the relationship between flavonoid intake and sarcopenia, and reveal the potential role of flavonoids in the treatment of sarcopenia.

METHODS

This study uses the data from the National Health and Nutrition Examination Survey (NHANES) during 2017 - 2018. The participants include 1,998 adults, and the intake of flavonoids is evaluated through two 24 - hour dietary recall interviews. Weighted logistic regression and weighted linear regression are used to quantify whether the intake of flavonoids affects sarcopenia by changing muscle and fat in overweight and non - overweight populations. The Cox regression model and the Kaplan - Meier (KM) curve are used to evaluate the impact of flavonoid intake on survival rates under different disease states. In addition, the Weighted Quantile Sum (WQS) model is used to visualize the weights of the impact of flavonoids on sarcopenia. Missing variables are processed by multiple imputation METHODS.

RESULTS

1,998 participants (mean age 38)mean daily total flavonoid intake was 169.266 mg, lower in sarcopenia cases. Mean BMI was 28.915 kg/m², showing an overweight cohort.Weighted logistic regression showed flavones and flavonols affected sarcopenia risk. In overweight people, apigenin, luteolin and quercetin reduced risk; in non - overweight, luteolin and isorhamnetin did. Most sub - classes increased muscle mass ($P < 0.05$), and only apigenin and luteolin reduced fat mass after adjustment.Flavonoid intake cut death risk by 22.3% per unit increase ($P < 0.05$). In diabetes and diabetes - hypertension cases, higher kaempferol intake meant higher survival; in hyperlipidemia, higher luteolin intake did.The WQS model showed apigenin and kaempferol most influenced sarcopenia. These findings offer insights into flavonoids' role in sarcopenia.

CONCLUSIONS

Flavonoids can reduce the incidence of sarcopenia, especially apigenin.

OAP4_02

FROM ADVOCACY TO ACTION: CIVIL SOCIETY AND DEVELOPMENT AGENCIES ENGAGING PRIVATE SECTOR ACTORS FOR NUTRITION

Navneet Mittal[1]; Kudzai Mukumbi[2]; Fiona Wallace[3]
[1]School of Agriculture, Policy and Development , University of Reading, Reading, United Kingdom; [2]Department of Agricultural Sciences, Africa University, Mutare, Zimbabwe; [3]Research and Development, Nutrition Opportunities Worldwide, Toronto, Canada

BACKGROUND AND OBJECTIVES

Private sector companies actions can affect the food security and nutritional status of populations. A number of civil society organizations are creating initiatives to influence private sector actions to improve nutrition at national, regional, and international levels, particularly in countries with triple burden of malnutrition. The objectives of this study were a) to identify and describe civil society led initiatives aiming to influence private sector action on nutrition (CSI-PSANs) b) to classify the initiatives based on the organizations approach towards engaging the private sector c) to understand their successes and challenges.

METHODS

CSI-PSANs were identified through an online search, supplemented with authors knowledge. Included: CSI-PSANs with International and/or Africa presence, focused on food manufacturers or retailers, led by NGOs or UN agencies, focused on increasing nutrition and food security through either Convening and Collaboration (CC) with the private sector, Capacity Building (CB) support to the private sector and/or Commitments and Monitoring (CM) of private sector nutrition commitments. Excluded: initiatives led by private sector, or primarily focused on agriculture or emergency. Publicly available information for these initiatives was reviewed, and a database identifying and describing CSI-PSANs was created. Semi-structured interviews with select CSI-PSANs were conducted to gain insights into their successes and challenges

RESULTS

48 CSI-PSANs were identified, of which 11 met the inclusion criteria. These initiatives were primarily focused on CC and CM (82%) and CB (63%). Key informants from 9 CSI-PSANs were interviewed. The successes of these initiatives varied, however all identified limited resources and short time frames to affect change as a constraint. Key recommendations were to design initiatives with an appropriate structure and right private sector partners, ensuring an aligned vision between partners, having a business case, ensuring governance processes, and regular communication with stakeholders to ensure transparency.

CONCLUSIONS

CSI-PSANs are increasing in number and operate through different approaches to influence private sector actions. This study is the first to identify, describe civil society initiatives focused primarily on nutrition and fills a knowledge gap on successes and challenges of civil society led initiatives engaging the private sector for improved nutrition.

FEASIBILITY OF A MORE PLANT-BASED WEIGHT LOSS DIET IN OBESE OLDER ADULTS: THE 2EAT PILOT STUDY

Susanne Wildemast[1]; Marije Putker[1]; Annelies Rotteveel[2]; Amely Verreijen[3]; Peter Weijs[1, 4]; Sjors Verlaan,[1, 5]
[1]Department of Nutrition and Dietetics, Faculty of Health, Sport and Physical Activity, Amsterdam University of Applied Sciences, Amsterdam, Netherlands; [2]Department of Nutrition and Dietetics, Faculty of Health, Nutrition and Sport, The Hague University of Applied Sciences, The Hague, Netherlands; [3]Nutrition & Health, HAS university of applied sciences, 's-Hertogenbosch, Netherlands; [4]Department of Nutrition and Dietetics, Amsterdam University Medical Centers, Vrije Universiteit, Amsterdam, Netherlands; [5]Department of Medical BioSciences, Radboud University Medical Center, Nijmegen, Netherlands

BACKGROUND AND OBJECTIVES

Older adults participating in weight loss interventions should ensure adequate protein intake to minimize the loss of muscle mass (1,2). Incorporating a more plant-based diet, in line with EAT-Lancet, into weight loss strategies may contribute to reduced environmental impact and lower risk of chronic diseases (3). However, plant-based foods have lower total protein content and quality compared to animal-based sources. The 2EAT pilot study aimed to assess the feasibility of implementing a protein-rich, more plant-based weight loss intervention for older adults with obesity.

METHODS

An 8-week pilot study evaluated the feasibility of the more plant-based weight loss intervention in older adults (55+ years) with obesity. Participants received nutritional counseling from experienced dieticians focused on 1) 500 kcal/d caloric deficit, 2) high protein diet (1.2 g/kg/d) and 3) 60% plant-based protein. Nutritional counseling included five counseling sessions, a cooking class and a recipe book. Feedback was collected through focus groups with participants and dieticians post-intervention. Values are expressed as mean (minimum-maximum).

RESULTS

Ten participants (63 years (55-71 y), BMI 34 kg/m2 (27-41 kg/m2)) completed the 8-week 2EAT pilot study. Energy intake decreased from 2008 kcal/d (1537-2680 kcal/d) with 20% to 1599 kcal/d (1145-1907 kcal/d), protein intake slightly reduced from 0.95 g/kg/d (0,6-1,2 g/kg/d) with 8% to 0.87 g/kg/d (0,5-1,2 g/kg/d) and the proportion of plant-based protein increased from 46% (31-65%) with 20% to 55% (34-76%). Participants experienced reductions in body weight from 96 kg (71-120 kg) with 2% to 94 kg (68-115 kg) and body fat percentage from 41% (27-56%) with 2% to 40% (28-55%). Both the participants and dieticians highlighted challenges in achieving a high protein intake while adhering to caloric restrictions. Social support was identified as a critical factor for participant success, and dieticians emphasized the need to prioritize behavioral changes within the intervention.

CONCLUSIONS

The 2EAT weight loss intervention based on a more plant-based diet appears feasible. However, high protein intake within an energy-restricted diet containing 60% plant-based protein remains a key challenge. The intensively supervised 2EAT intervention will be further optimized and evaluated in a randomized controlled trial, with a primary focus on 60% plant-based protein.

STREAMLINING FUNDING ACCESS FOR PRODUCERS: ENHANCING FOOD SYSTEMS, COMMUNITY NUTRITION EDUCATION, AND HEALTHY BEHAVIORS IN UNDERSERVED COMMUNITIES

Virginie Zoumenou[1]; Kritika Gupta[2]; Verona Mulgrave[3]; Dionne Ray[4]
[1]Extension/Human Ecology, University of Maryland Eastern Shore, Princess Anne, United States of America; [2]Institutional Research & Evaluation, University of California R, Riverside, United States of America; [3]Extension, Delaware State University, Dover, United States of America; [4]Extension, University of Maryland Eastern Shore, Princess Anne, United States of America

BACKGROUND AND OBJECTIVES

Despite their critical role in agriculture and food production, BIPOC (Black, Indigenous, and People of Color) producers face significant barriers when applying for federal funding, including complex application processes and insufficient technical support, which limit their ability to build sustainable businesses. These challenges restrict access to fresh, nutritious food in rural and underserved communities, exacerbating food insecurity and chronic health issues. Additionally, past community nutrition education efforts have struggled to achieve lasting behavior change, further hindering public health progress. This study explores these issues by identifying key obstacles through focus groups and interviews, highlighting proposed solutions such as youth engagement and community partnerships to improve funding access, and examining how integrating community nutrition education with farmer success and expanded food access can drive consumer behavior change and improve health outcomes.

METHODS

To uncover key themes related to barriers and proposed strategies, approximately 302 focus groups and semi-structured interviews were conducted with BIPOC producers across the U.S. and its territories, using an inductive approach for analysis (Thomas, 2006). Additionally, a literature review of published studies from 2010 to 2023 was performed to explore the impact of combining community nutrition education with improved food access on consumer behavior and the prevention of chronic diseases

RESULTS

The study identified several key barriers faced by BIPOC producers, including overly complex application processes, inadequate technical support, and limited awareness of funding opportunities. To address these challenges, farmers proposed solutions such as engaging youth, fostering community partnerships, and simplifying the application process to improve access. These strategies, combined with efforts to empower BIPOC producers and expand food access through targeted nutrition education and community engagement, have the potential to enhance dietary habits and reduce the prevalence of chronic diseases in underserved communities

CONCLUSIONS

Empowering BIPOC farmers and involving youth and communities can improve food access, promote healthier behavior, and build resilient, equitable food systems essential for food security and stability amid global challenges like climate change and inequality.

PROTEIN ADEQUACY IN EUROPE: ADJUSTING CRUDE INTAKES USING THE PROTEIN ADEQUACY AND QUALITY SCORE (PAQS)

Samantha N. Heerschop[1]; Sander Biesbroek[1]; Merel C. Daas[1]; Anneleen Kuijsten[1]; Mirjana Gurinović[2, 3]; Johanna M. Geleijnse[1]; Pieter Van 'T Veer[1]
[1]Division of Human Nutrition and Health, Wageningen University & Research, Wageningen, Netherlands; [2]Centre of Research Excellence in Nutrition and Metabolism, Institute for Medical Research, National Institute of Republic of Serbia, University of Belgrade, Belgrade, Serbia; [3]-, Capacity Development in Nutrition (CAPNUTRA), Belgrade, Serbia

BACKGROUND AND OBJECTIVES

Current mean crude protein intake in 20 European countries ranges from 0.8 to 1.25 g/kg/d (1). These intakes largely exceed the Estimated Average Requirement (EAR) for protein of 0.66 g protein per kg body weight per day. For European and other Western countries, a shift towards more sustainable diets would typically include more plant- and less animal-based foods, as the latter generally have higher environmental footprints (2, 3). As plant-based foods are also known for their lower protein quantity and quality (4), the diet shift necessitates careful evaluation of protein adequacy while considering protein quality. The aim of this study was to provide an overview of current protein intake and adequacy in European adults, based on crude or utilizable protein using individual-level food consumption data including information on meal moments.

METHODS

To assess the prevalence of inadequate protein intake in Europe, the Protein Adequacy and Quality Score (PAQS) was developed and applied to adults (18-64y) of 25 national dietary surveys obtained from the Comprehensive European Food Consumption Database of the European Food Safety Authority. The PAQS assesses protein adequacy as the ratio of daily utilizable protein intake to requirement, with utilizable protein calculated on a meal basis by considering protein digestibility, indispensable amino acid requirements, and crude protein intake. The inadequacy prevalence was estimated by applying the EAR cut-point method, adjusted for energy misreporting, within-subject variation, and non-normality, in SPADE.

RESULTS

The median crude protein intakes in Europe largely exceed the EAR (1.3-2.1 times higher). When applying the EAR cut point method after adjusting for energy misreporting, within-subject variation, and non-normality of the intake distribution, the maximum prevalence of crude protein inadequacy was 1.0% for women (United Kingdom) and 0.1% for men (Austria, Germany, and the United Kingdom). For utilizable protein, i.e. after applying the PAQS, inadequacy ranged from 0% (Spain) to 7% (Austria) in women, except for Germany (17%), and from 0% (Montenegro) to 6% (Germany) in men.

CONCLUSIONS

These findings suggest that with the current diet composition and quantity of protein intake there is no immediate cause for concern in the healthy adult European population, althought the inadequcies of women in Germany warrant closer investigation. The prevalence of protein inadequacy in more plant-based diets, remains uncertain. Therefore, protein quality must be carefully considered when evaluating protein adequacy of these future diets.

OAP4_06

WHAT IS THE OPPORTUNITY COST OF FUNDING READY-TO-USE SUPPLEMENTARY FOODS COMPARED TO COUNSELLING FOR MODERATE MALNUTRITION?

Eleanor Grieve,[1]; Hemshree Desai,[1]; Charlotte Margaret Wright[2]
[1]Institute of Health and Wellbeing, University of Glasgow, Glasgow, United Kingdom; [2]Human Nutrition, University of Glasgow, Glasgow, United Kingdom

BACKGROUND AND OBJECTIVES

Commercially produced ready to use food supplements (RUF) improve outcomes for moderate acute malnutrition (MAM; weight-for-height z-score<-2) compared to routine care, but their use in isolation does not address the underlying causes of undernutrition. Well-delivered counselling may be as effective as RUF but requires substantial staff time; pilot work in Kenya found that staff spent an average of only 10 minutes per month with each carer of a child with MAM. We aimed to estimate the cost to individual country health systems of purchasing RUF, relative to employing staff to provide more generous counselling time and model the cost effectiveness of RUF compared to counselling.

METHODS

This was a cost effectiveness modelling study using secondary data. We identified 37 countries with rates of MAM greater than 5% from UNICEF / WHO / World Bank Child Malnutrition Estimates. Salary costs for nurses in each country were drawn from the Salary Explorer website and the cost of RUF from UNICEF supply division website. Data on effectiveness was drawn from 2 systematic reviews (1,2). A decision tree, of the pathway of a child receiving RUF compared with counselling was constructed to model cost per recovery and survival and disability adjusted life year (DALY). Distributions were fitted to reflect the considerable uncertainty in recovery, costs and disability weights.

RESULTS

The estimated monthly cost of RUF (1 sachet per day) was $8.22. The median average cost of one hour of registered nursing time was $2.70 per hour, and was less than the monthly cost of RUF for 84% countries. A systematic review (2) suggests that RUF is more effective (1:29, CI 1.19-1.40) but would cost ~$33 more per recovery and $1600 more per survival compared to one hour's counselling. Modelling DALYs increases the cost-effectiveness of RUF to within generally accepted thresholds, but with extensive uncertainty in those weightings associated with recovery, versus no recovery or relapse.

CONCLUSIONS

RUF appears to have higher efficacy, but significantly greater cost and may not represent value for money when it comes to longer term health outcomes. Well-staffed trials of the efficacy of problem-oriented counselling interventions for MAM, including detailed economic evaluation and cost-effectiveness are required, before the widespread adoption of treatment with RUF.

FACTORS AFFECTING FOOD DIVERSITY, FREQUENCY, ADEQUACY AND GROWTH IN CHILDREN AGED 6-36 MONTHS IN CONFLICTED-AFFECTED MALI

Agarwal Vanshika[1]; Tian Mengke[1]; Evans Asamane Atiah[1]; Sidibe Cheick[2]; Sophie Budge[1]; Martin James[1]; Kai Yan[1]; Traore Lacina[1]; Chang Shi[1]; Toure Ousmane[2]; Semira Manaseki-Holland[1]; Weber Katinka[1]
[1]Department of Applied Health Sciences, University of Birmingham, Birmingham, United Kingdom; [2]Applied Health and Research, University of Science, Techniques and Technology Bamako, Bamako,, Mali

BACKGROUND AND OBJECTIVES
Child undernutrition remains a critical public health issue in West Africa, particularly in conflict-affected areas. In Mali, despite efforts to improve nutritional outcomes, undernutrition among under-5s remains very high, with data estimating 1 million children are at risk of acute undernutrition, and 200,000 of fatal outcomes. We assessed dietary quality via the achievement of the Minimum Acceptable Diet (MAD) and its components, Minimum Dietary Diversity (MDD) and Minimum Meal Frequency (MMF), and prevalence and risk factors for stunting, wasting, and underweight among 6-36 month-children in conflict-affected Mali. Qualitative data via focus group discussions (FGD) contextualized understanding and RESULTS.
METHODS

We analysed cross-sectional data from 6,440 children in 120 deprived communities, collected during a large RCT. Anthropometry used DHS methodology and data were transformed into z-scores with –2SD cut off for stunting/wasting. MAD, MDD and MFF were analysed according to WHO guidelines. Mixed-effects logistic regression explored risk factors spanning 27 child, maternal and household domains, including internal displacement, child disability, acute/chronic illness, sanitation/hygiene, vaccination and maternal empowerment. Topic guides for components of ~80 FGDs (mothers, grandmother, fathers, community elders) translated, transcribed, thematically coded included nutrition related context.

RESULTS
RESULTS revealed high rates of child undernutrition with 9% wasted, 22% stunted and 17% underweight. Only 26.4% (n=1,699) of children met MAD. Meeting MAD was not significantly related to growth. Factors improving MAD were maternal empowerment (OR=2; 95%CI: 1.4-2.9), urban residence, handwashing pre-feeding and older age (driven by MMF). Married to one husband and no acute disease were also associated with improved MMF, and soap with MDD. For wasting/stunting/undernutrition, negative factors were female sex, maternal empowerment, sanitation facilities (underweight/stunting only with a dramatic OR=0.19; 95% CI 0.05-0.69), and current breastfeeding (wasting only). Qualitative data (presented at conference) contextualised how some factors contributed to RESULTS.
CONCLUSIONS
RESULTS suggests that dietary practices alone do not sufficiently explain infant growth in this setting. Factors such as maternal empowerment, poor sanitation and risks with poor urban housing may play a more critical role in determining child nutritional status in this context, and which are not regularly a part of nutrition programmes.
CONFLICTS OF INTERESTS

LONGITUDINAL ASSOCIATION BETWEEN WOMEN'S AGENCY AND HOUSEHOLD INCOME ON WOMEN'S DIETS IN RURAL BANGLADESH

Gargi Wable Grandner[1]; Kathleen Maher Rasmussen[1]; Katherine Dickin,[2]; Purnima Menon[3]; Ravi Kanbur[4]; John Hoddinott[5]
[1]Division of Nutritional Sciences, Cornell University, Ithaca, United States of America; [2]Department of Public and Ecosystem Health, Cornell University, Ithaca, United States of America; [3]Food Policy and Nutrition, IFPRI, New Delhi, India; [4]Department of Economics, Cornell, Ithaca, United States of America; [5]Division of Nutritional Sciences, Cornell, Ithaca, United States of America

BACKGROUND AND OBJECTIVES

In South Asia, where women are known to eat last and least, determinants of women's diets and dimensions that constitute women's agency are poorly understood in the context of the region's socio-economic transition. Moreover, the assumption that women with greater agency have better nutrition outcomes for themselves has rarely been tested.

METHODS

Using two rounds of panel data from the 2011/12 and 2015 Bangladesh Integrated Household Survey (BIHS), we assessed the longitudinal associations of household income and women's agency on women's dietary quantity and quality and also examined effect modification between income and agency. We used single, multiple pass 24-hour recall data on a balanced sample of 3227 women of reproductive age (WRA) and assessed total energy intake to measure diet quantity, and women's dietary diversity score (WDDS) and consumption of animal source foods to measure diet quality. Household income was measured as per capita consumption expenditure and categorized into two groups, with fourth and fifth quintiles representing higher-income households. Because women's agency is a latent, multi-dimensional, context-specific construct, we used covariate-adjusted latent class analysis to identify latent, homogenous subgroups of women who manifested similar patterns of agency via self-determination, control over resources, decision-making agency, and freedom of movement. Fixed effects multivariable models were used to control for unobserved heterogeneity.

RESULTS

Latent class analysis revealed 3 classes of women's agency: women least likely to have any agency (class 1), women likely to have full agency in control over resources and some agency in other dimensions (class 2), and women with some agency in all dimensions except mobility (class 3). Across all outcomes, we did not find evidence for effect modification. Higher household income was independently and positively correlated with all three dietary outcomes, while agency class 2 had a significant but weak association with WDDS. Sensitivity analyses with uni-dimensional measures of agency and alternative measures of income also suggested greater influence of income on women's diets.

CONCLUSIONS

Our analyses demonstrates that compared to women's agency, improved household income has a stronger and broader influence on improving women's diets in rural Bangladesh. These findings suggest that efforts aimed at improving women's diets should address overall household income constraints and go beyond a sole focus on improving women's agency.

DISASTERS AND THE COVID-19 PANDEMIC MAY NEGATIVELY IMPACT ON NUTRIENT INTAKES: AN ECOLOGICAL STUDY

Taichi Inui[1]; Akiko Kuwabara,[2]
[1]HNC Innovation, dsm-firmenich Kaiseraugst, Kaiseraugst, Switzerland; [2]Department of Nutrition, Osaka Metropolitan University, Habikino, Japan

BACKGROUND AND OBJECTIVES

Previous research on the impact of disasters tends to focus on acute impacts and on low- and medium-income countries. Disasters may have a long-term impact on dietary intake patterns as part of the changes in the living conditions and environment. We investigated the long-term impacts of disasters and pandemics on nutrient intake using publicly available data from Japan.

METHODS

Nutrient intake data were obtained from Family Income and Expenditure Survey by Statistics Bureau of Japan. Meteorological data, namely the number of earthquakes, days over maximum wind of 10m/s and total rain, were retrieved from Japan Meteorological Agency. Data from 2007 to 2023 were curated for 47 prefecture capitals in order to match the data from both agencies. We defined 2020 as the onset of COVID-19. Expenditure data were converted to food and nutrient intake using food composition table published as a part of National Health and Nutrition Survey 2018 by Ministry of Health Labor and Welfare of Japan. A multiple regression analysis was performed to evaluate the cumulative impact of disaster on nutrient density in each city between 2009 and 2023. The output is expressed as a relationship between the nutrient intake per 2000 kcal energy intake and the cumulative frequency of disasters over the preceeding three years.

RESULTS

Analysis of individual nutrient intake levels revealed that COVID-19 and total rainfall impacted negatively affected nine and eight nutrients, respectively. The analysis also revealed that larger cities had higher nutrient intake compared to the smaller counterparts. Potassium, calcium and magnesium intake decreased with higher total rainfall, whereas zinc intake was inversely associated with earthquake. Sodium intake was reduced with COVID-19 and disasters. Vitamin A intake decreased with COVD-19 and with a higher cumulative earthquake and max wind however increased with higher total rainfall. Although the intakes for vitamin C decreased with COVID-19 and higher total rain, it increased with higher number of total earthquake.

CONCLUSIONS

The present study suggested the long-term impacts of pandemic and disasters on nutrient intake in Japan. Our analysis indicated that the impact differs depending on the type of disaster and type of nutrients. Limitations include the lack of data on other disasters and data specific to the township where the disaster impacted the most. Further research should focus on the impact of other disasters such as floods and data from other countries.

THE ASSOCIATION BETWEEN FOOD BIODIVERSITY AND MICRONUTRIENT ADEQUACY AND QUALITY OF DUTCH DIETS

Celia Bannenberg[1]; Sander Biesbroek[1]; Corné van Dooren[1, 2]; Edith Feskens[1]
[1]Division of Human Nutrition and Health, Wageningen University & Research, P.O. Box 17, Wageningen, 6700 AA, Netherlands; [2]WWF-NL, 3708 JB, Zeist, Netherlands

BACKGROUND AND OBJECTIVES

To bend the curve of biodiversity loss, food production and consumption practices should be more sustainable (1). The latter includes shifting our diets to plant-forward, nutritious and potentially more biodiverse diets. Food biodiversity, referring to the diversity of food species consumed within food groups, has been gaining attention for its potential association with human and planetary health (2). This study aims to assess the association between food biodiversity and micronutrient adequacy and diet quality in the Netherlands.

METHODS

Individual-level food consumption data of the Dutch adult population is obtained from the 2019-2021 Dutch National Food Consumption Survey (3). Nutrient composition is based on the Dutch Food Composition Database (4). Food biodiversity is operationalized as Dietary Species Richness (DSR): the number of species consumed by each individual per day. Micronutrient intake (in)adequacy is estimated using the Dutch Dietary Reference Values. Diets are evaluated using the summary estimate Nutrient Rich Diet score (NRD 15.3). Descriptive analyses according to quartiles of number of consumed food species and micronutrient intake will be performed. Multiple linear regression analyses will be performed to estimate the association between DSR (quartiles and continuously) and NRD.

RESULTS

Descriptive RESULTS of this study will show the average species consumption per day as well as the mean intakes and adequacies of micronutrients in the population. Statistical RESULTS of this study will show the association between DSR and NRD, both per quartile and continuously. Moreover, the role of plant versus animal food species in this association will be examined. For this, DSR for food groups vegetables, fruits, and grains will be calculated. We hypothesize that a higher DSR is associated with a higher micronutrient intake and overall NRD, and that this association will be mainly due to the higher consumption of plant food species. We therefore also expect a higher DSR to be associated with an increase in micronutrients such as fibre that are present mostly in grains, vegetables, and fruits, as well as a potential decline in micronutrients such as iron, vitamin B12, calcium, and zinc, present mostly in animal-based products.

CONCLUSIONS

We expect to conclude that a higher food biodiversity is associated with higher micronutrient intakes and better diet quality with higher nutrient density. Furthermore, we expect to conclude that DSR is an adequate, relevant and additional indicator to assess diet quality in a high-income country such as the Netherlands.

OAP16_04

NUTRITIONAL ADEQUACY OF HEALTHY AND SUSTAINABLE DIETS AT GLOBAL, REGIONAL, NATIONAL LEVELS AND BY DEMOGRAPHIC GROUPS: A MODELLING STUDY

Sumati Bajaj[1]; Marco Springmann[1]
[1]Institute for Global Health, University College London, London, United Kingdom

BACKGROUND AND OBJECTIVES

Healthy and sustainable diets, like the planetary health diet (PHD)1 rich in plant-based foods with moderate amounts of animal products, are key to improving health while reducing the environmental impact of food systems. Given the high prevalence of nutrient deficiencies, particularly among women and children, meeting nutritional requirements from the PHD is critical. This study assessed the nutritional adequacy of adopting the PHD across regions, countries, and socio-demographic groups.

METHODS

We obtained current dietary intake data from a newly developed global dietary database with sociodemographic details2, and created a hypothetical PHD intake scenario by adjusting the current amount of foods consumed in line with the PHD. We also constructed an optimised-PHD intake scenario by introducing aquatic plants and further increasing the proportion of green leafy vegetables. We estimated nutrient intakes from these diets by the combining the dietary intake datasets with nutritional content from the Global Expanded Nutrient Supply (GENuS) model3, the Harvard Nutrient Database, FoodData Central4, and the Japanese food composition table. We accounted for changes in the bioavailability of iron and zinc based on the nutrient composition of the foods consumed in these diets5,6. To assess nutrient adequacy, we compared nutrient intakes from these diets against a harmonised set of average nutrient requirements7. We then calculated nutrient adequacy ratios (NAR) as the ratio of nutrient intake to nutrient requirements, capped at 1.

RESULTS

Globally, the PHD would provide adequate nutrient intake to meet nutritional requirements for most nutrients, except iodine (NAR=0.7) and vitamin B12 (NAR=0.8), while the optimised-PHD would provide nutritional adequacy for all nutrients and across all regions, age groups, and sexes (NAR=1). In high-income countries, intakes of some nutrients, such as vitamin B12 and B6, in the PHD would be lower than current levels but remain adequate. In low-income countries, the PHD would provide higher intakes of many key nutrients compared to current diets and achieve adequacy, including folate, vitamin A, vitamin C and zinc. While the PHD may not fully meet the additional needs of women and children for iron (NAR=0.97) and riboflavin (NAR=0.96), the optimised-PHD would address these shortfalls.

CONCLUSIONS

Adopting the PHD can improve nutrient intake and reduce nutrient deficiencies while reducing chronic diseases and environmental impacts. Few nutrient shortfalls for some populations may persist which can be addressed by dietary optimisation for additional needs.

ESTIMATION OF DIETARY SUGAR INTAKE USING SERUM CARBON ISOTOPE RATIO AS A BIOMARKER

Jananee Muralidharan[1]; Sumathi Swaminathan[2]; Roshni Pasanna[2]; Ayoob Fathima[2]; Tinku Thomas[3]; Sarita Devi[2]; Diane O'brien[4]; Cornelia Loechl[5]; Anura Kurpad[6]
[1]Internal Medicine, St. John's Medical College Hospital, Bengaluru, India; [2]Division of Nutrition, St. John's Research Institute, Bengaluru, India; [3]Biostatistics, St. John's Medical College, Bengaluru, India; [4]Biology and Wildlife, University of Alaska, Fairbanks, United States of America; [5]NAHU/NAHRES, IAEA, Vienna, Austria; [6]Physiology, St. John's Medical College, Bengaluru, India

BACKGROUND AND OBJECTIVES

Cane sugar has a high 13C content, and this may allow the latter's use as a biomarker of added cane sugar intake. The specific biomarker is the serum bulk 13C isotope ratio (CIR), or the specific enrichment of 13C-alanine (CIR-ala). This study therefore aimed to evaluate the serum CIR and CIR-ala isotopic abundance as an estimate of the dietary intake of cane sugar in adult Indians.

METHODS

Daily energy and sugar intakes were measured by four 24-hour dietary recalls conducted over 2 weeks in 76 weight-stable adults, along with records of demographic and physical activity data. A blood sample was drawn at the end of the month for measuring serum CIR, and CIR-ala (δ13C ‰), with external quality control of serum CIR executed through the analysis of horse serum samples from the University of Alaska. The estimation of dietary energy intake (EI, as a proxy for sugar) was validated by measurement of daily Energy Expenditure (EE) in 26 individuals, by an accurate isotopic method using the Double Labelled Water (DLW), as the daily EE would be expected to match the daily EI in weight stable individuals.

RESULTS

There were 35 men and 41 women with a mean BMI of 24.7±4 kg/m2. From these, 3 dropped out, while a further 16 had under-reported their energy intake considerably, as assessed by pre-defined EE cut-offs from predicted Basal Metabolic Rate and Physical Activity. In the remaining 57, the median (IQR) total sugar intake was 54(42) g/day; added sugar intake was 27(25) g/day, with 12(11) g/day from sugar sweetened beverages (SSB). The validation of energy intake recall showed a small mean difference between EE and EI of -88 kcal/day, with wide limits of agreement, but no pattern to this difference at different energy intakes. The CIR, but not CIR-ala, was identified to be a predictor for total sugar and added sugar intake, (Beta: 17.36 g/d (5.86,28.86) and 12.8 g/d (2.92,22.64); P<0.003 and 0.012 respectively) but not for SSB. CIR was also associated with animal protein, fish and poultry intake [Beta 0.028 (0.012,0.043), 0.0059 (0.0002, 0.0117) and 0.0046 (0.0008, 0.0085; P<.001, 0.01 and 0.01 respectively)].

CONCLUSIONS

Serum CIR is a biomarker of total and added sugar intake in India, where the latter is cane sugar. Per the present RESULTS, an increase of serum CIR by a unit δ13C indicates an increase of 13g of added sugar in the daily intake.

PERCEPTION OF PLANT-BASED MEAT SUBSTITUTES AMONG VEGANS

Isabelle Herter-Aeberli[1]; Diana Guerra[2]; Vanessa Keller[3]; Markus Keller[3]; Leonie Bogl[4]
[1]Departement of Health Sciences and Technology, ETH Zürich, Zürich, Switzerland; [2]HAFL, Bern University Of Applied Sciences, Bern, Switzerland; [3]Research Institute of Plant Based Nutrition, Research Institute of Plant Based Nutrition, Giessen, Germany; [4]Division of Nutrition and Dietetics, Bern University Of Applied Sciences, Bern, Switzerland

BACKGROUND AND OBJECTIVES

The rise in veganism has increased consumption of plant-based meat substitutes (PBMS). Although PBMS offer alternative protein sources, their classification as ultra-processed foods (UPFs) raises concerns about potential health impacts when replacing traditional plant-based proteins (TPBP). The perception of vegans towards PBMS consumption remains largely unexplored. The aim of this study was therefore to explore the motivation and attitudes of Swiss vegans towards PBMS consumption.

METHODS

In a first step, the 50 vegan participants of the Swiss arm of the VEGANScreener study were invited to complete a follow-up survey approximately 10 months after their original study visit. Through quantitative questions as well as qualitative thematic analysis, motivations and attitudes towards PBMS were explored. Data collection is currently ongoing in the four other VEGANScreener countries Germany, Spain, Czeck Republic, and Belgium and data will be available at the conference.

RESULTS

In Switzerland, 34 participants completed the survey. While all of them have tried PBMS, 23 reported a preference for TPBP and only one person preferred PBMS; 10 reported no preference. The mean frequency of PBMS consumption was 2.1 ± 3.2 portions per week, while the mean frequency of consumption of TPBP was 12.7 ± 7.4 portions per week. None of the participants aimed to increase the consumption of PBMS, while 23.5% thought about reducing it. Furthermore, the majority (76.5%) rated the nutritional quality of PBMS as somewhat worse or much worse compared to TPBP, but PBMS were easily available to 94.1%. As key motivators for the consumption of PBMS we identified nutritional benefits, taste, versatility, convenience, tradition, and satisfaction, while barriers included health concerns about processing, cost, taste, and environmental impact.

CONCLUSIONS

While PBMS are consumed by vegans, frequency of consumption is generally low and the majority prefers TPBP over PBMS. Concerns were raised about processing, healthiness, cost, and environmental impact. Addressing these issues through product improvements and transparent communication may enhance acceptance. These findings inform public health recommendations and support developing PBMS that align with vegans' nutritional needs and values.

Is habitual adherence to the planetary health diet associated with mortality and major chronic disease risk? RESULTS from the UK Biobank

Nena Karavasiloglou[1, 2, 3]; Flurina Suter[2, 3]; Alysha S. Thompson[4]; Giulia Pestoni[5]; Aedin Cassidy[4]; Tilman Kühn[4, 6, 7]; Sabine Rohrmann[3, 2]

[1]Nutrition and Food Innovation Unit, European Food Safety Authority, Parma, Italy; [2]Division of Chronic Disease Epidemiology, Epidemiology, Biostatistics and Prevention Institute (EBPI), University of Zurich, Zurich, Switzerland; [3]Cancer Registry Zurich, Zug, Schaffhausen, Schwyz, Pathology and Molecular Pathology Institute, University Hospital Zurich, Zurich, Switzerland; [4]Institute for Global Food Security & Co-Centre for Sustainable Food Systems, Queen's University Belfast, Belfast, United Kingdom; [5]Nutrition group, Swiss Distance University of Applied Sciences (FFHS), University of Applied Sciences and Arts of Southern Switzerland (SUPSI), Zurich, Switzerland; [6]Department of Nutritional Sciences, University of Vienna, Vienna, Austria; [7]Center for Public Health, Medical University of Vienna, Vienna, Austria

BACKGROUND AND OBJECTIVES

In 2019, the EAT Lancet commission proposed a globally applicable, sustainable, and healthy diet, the 'planetary-health diet' (PHD). The literature on the association between the PHD and the risk for health outcomes is sparse and diverse. With our study, we aim to add to the existing knowledge on the potential effects of the PHD on health outcomes by investigating the association between habitual adherence to the PHD and mortality and major chronic disease risk.

METHODS

Data of the large and population-based UK Biobank study cohort were used. A scoring system that reflects participants' habitual adherence to the PHD was defined based on the UK Biobank Oxford WebQ 24-hour dietary assessment data and by applying the Multiple Source Method (MSM; habitual dietary intake estimation)**.** Multivariate Cox proportional hazards regression models were fitted for the following health outcomes: all-cause mortality, cancer risk (all-cancer, female breast, colorectal, lung, and prostate cancer), and cardiovascular disease (CVD) risk (all-CVD, total stroke, ischemic stroke, myocardial infarction, and hemorrhagic stroke).

RESULTS

In our study, follow-up time ranged between 13.5 to 14.8 years depending on the outcome. Each 1-point increase in the PHD score was associated with a 3% lower risk of all-cause mortality (hazard ratio (HR) = 0.97; 95% confidence interval (CI): 0.96-0.99) and a 9% lower risk of lung cancer (0.91; 0.87-0.96). A trend between adherence to the PHD and all-cancer risk (0.99; 0.98-1.00) was also seen, while a null association between PHD adherence and CVD risk (0.99; 0.96-1.02) was found.

CONCLUSIONS

To the best of our knowledge, this is the first study estimating the association between habitual adherence to the PHD and mortality or chronic disease risk. Our RESULTS point towards an inverse association between habitual adherence to the PHD and all-cause mortality and cancer risk, although the associations with cancer depended on the cancer type. Our study provides additional evidence that sustainable diets can improve human health. Further studies are needed to investigate the link between PHD and chronic disease incidence and mortality in diverse populations.

BEEF INTAKE IS ASSOCIATED WITH LOWER DIVERSITY OF PLANT SPECIES CONSUMED BY THE BRAZILIAN POPULATION

Fernanda Helena Marrocos-Leite[1]; Euridice Martinez Steele[1]; Giovanna Andrade[1]; Neha Khandpur[2, 1, 3]; Renata Bertazzi Levy[1, 4]; Carlos Augusto Monteiro[1]

[1]Center for Epidemiological Research in Nutrition and Health (NUPENS/USP), School of Public Health, University of Sao Paulo, São Paulo, Brazil; [2]Division of Human Nutrition and Health , Wageningen University & Research, Wageningen, Netherlands; [3]Department of Nutrition, Harvard T.H. Chan School of Public Health, Bosto, United States of America; [4]Preventive Medicine, School of Medical Sciences, University of Sao Paulo, São Paulo, Brazil

BACKGROUND AND OBJECTIVES

Food biodiversity plays a crucial role in promoting healthy diets and improving human and planetary health1,2. The diversity of species in diets has been positively associated with adequate micronutrient intake3 and negatively associated with all-cause mortality4. Diets rich in fresh plant-sourced foods has also been linked to lower risks of chronic conditions (e.g. cardiovascular diseases)5. Given the increasing homogenization of global diets, this study aimed to evaluate the association between beef intake and the diversity of plant species from Nova Group 1 (unprocessed and minimally processed foods) consumed by Brazilian households.

METHODS

Data from the 2017-18 Household Budget Survey were used to identify all foods and beverages purchased by household strata (n=575). Food items were classified according to the Nova classification system into: 1) unprocessed or minimally processed foods, 2) processed culinary ingredients, 3) processed foods, 4) ultra-processed foods. Food items were identified at the species level by using taxonomical classification. Species richness (SR) was used to assess the diversity of plant species from Nova group 1. Linear regression models adjusted for area, region and income were used to evaluate the association between the quintiles of the share of beef to total food acquisition (% of total kilograms/person/year) and the SR of plant species from Nova group 1. Test of linear trend was used to investigate the effect of beef quintiles as a single continuous variable.

RESULTS

A mean number of 60 (SD: ±0.96) plant species from Nova group 1 were consumed by the Brazilian population in 2017-18. The mean amount of beef acquisition was 13.7 kg/person/year (5.4% of total food acquisition), and the mean share of beef to total food acquisition varied between 3.2% (min: 0.0%; max: 3.8%) and 8.6% (min: 6.9%; max: 24.7%) in the first and fifth quintiles, respectively. The mean SR decreased linearly across quintiles of the share of beef to total food acquisition (coefficient: -1.19; 95% CI -2.09 to -0.28; *p* value for linear trend <0.05), decreasing from 61 in the first quintile to 57 in the fifth quintile.

CONCLUSIONS

Our findings demonstrate that beef consumption may play a key role in decreasing the number of plant species from Nova group 1 consumed by the Brazilian population. Such RESULTS reinforce the need of implementing policies to reduce excessive beef consumption in the Brazilian context in order to improve human health and biodiversity outcomes.

A SYSTEMATIC REVIEW/META-ANALYSIS OF XENOBIOTICS IN APPLE AND APPLE-BASED PRODUCTS REVEALS LACK OF COMPLIANCE WITH EUROPEAN FOOD SAFETY AUTHORITY REGULATION

Alexis Noel[1, 2]; Rosa-Maria Guéant-Rodriguez[2, 1]; Olivier Cachard[3]; Sandra El Kouche[1]; Paul-Henri Graindorge[1]; Nadine El Wanny[1]; David H Alpers[4]; Nathalie Grova*[1, 5]; Jean-Louis Guéant*[1, 2]
[1]Inserm UMRS 1256 NGERE, Université de Lorraine, Vandoeuvre-lès-Nancy, France; [2]Deparment of biochemistry-Molecular Biology and Nutrition, FHU ARRIMAGE, Nancy, France; [3]Institut François Geny - Pôle SJPEG, Université de Lorraine, Nancy, France; [4]Department of Internal Medicine, Washington University School of Medicine, Saint Louis, MO, United States of America; [5]Department of Infection and Immunity - Immune Endocrine Epigenetics Research Group, Luxembourg Insitute of Health, Vandoeuvre-lès-Nancy, France

BACKGROUND AND OBJECTIVES

Apple is an iconic and widely studied example of food-safety issues, resulting from the globalization of the fruit agro-food market. Many of the issues associated with xenobiotics used in the production of this fruit can be transposed to the most consumed fruit types in the world. The presence of xenobiotics in apples deserves a great keen interest in food toxicology, including published data on Maximum Residue Limits (MRLs).

Our data raises questions about the compliance with production regulation requirements and the effectiveness of controls. According to the criteria that define MRLs, we also wonder about the significant public health problems caused by the high rate of non-compliance.

METHODS

By using a systematic search in the Pubmed, Web of Science and Embase databases, we extracted 1374 publications on pesticides, mycotoxins, and heavy-metal contents in apple products, which represented 44%, 48%, and 26% respectively, of publications among the 4 most consumed fruits in the world. The publications were included in the review if they met 2 criteria: i) the presence of accessible quantitative data to be used in a common database, ii) the analysis of raw apples or any processed product in which apples are the main ingredient to limit cross-contamination. We selected 90 articles in which we were able to assess compliance with the European Food Safety Authority's (EFSA) regulations

RESULTS

We observed 42.8% overall rate of checks exceeding the MRL, 51.6% rate for pesticides, 42.6% for heavy metals and 40.2% for mycotoxins. Over 60% of the 92 pesticides considered were banned by the European Union. The rate of non-compliance was much higher in the Middle East (65.2%), Africa (50%), Asia (43.9%), Europe (37.5%) and South America (33.3%), than in North America (12.5%). We observed an influence of the climate Köppen classification and the 2024 Human Development Index (HDI) on the rate of exceeding MRLs.

CONCLUSIONS

The high frequency of abnormal levels of contaminants in apples and apple-products raises numerous questions applicable to other fruits, concerning compliance with production requirements, compliance with established rules, controls by national agencies and potential consequences for public health. Apples can be a vector of exposure for all age categories, as shown by analyses of apple-based products intended for young children.

A NEWLY DEVELOPED NATURAL HOG CASING REDUCES THE SALT CONTENT AND THE OXIDATION OF CURED FERMENTED MEAT PRODUCTS

Eduardo Lopez-Huertas[1]; José Rubí[1]; Ana M. Haro[2]; Piedad Pérez-Polaino[3]; Ismael Heras-Jiménez[3]; Isabel Seiquer[2]
[1]ANTIOXIDANTS AND FREE RADICALS IN FOOD AND AGRICULTURE, CSIC-Consejo Superior de Investigaciones Científicas, Estación Experimental Zaidín, Granada, Spain; [2]Animal Nutrition, Consejo Superior de Investigaciones Científicas, Estación Experimental Zaidín, Granada, Spain; [3]Research and Development, United Caro, Granada, Spain

BACKGROUND AND OBJECTIVES

The plan to reduce salt consumption through food intake is one of the main challenges posed by the different EU Member States. In the case of Spain, in 2008 the Spanish Food Safety and Nutrition Agency (AESAN) started a plan to reduce salt intake by 15%. Cured meat products are among the categories of foodstuffs identified as contributing the most to salt intake through the diet. The natural casings which preserve the cured and fermented meats are made from animal intestines. They are conserved in brine and although they are partially desalted prior to use, their salt content is very high. Other problems associated with the use of natural casings are unpleasant odours and excess rancidity. To try to overcome these problems, we developed a new type of natural casings (NNC) and we tested their effects in cured fermented sausages, compared with controls.

METHODS

We developed a NNC consisting of several layers of (manually) defatted intestine which were thoroughly desalted and dried (Especta®, United Caro). Traditional Spanish cured sausage ("salchichón") is a highly consumed sausage made with lean pork, pork fat, spices and salt. We investigated the effects of the NNC on the salt content and markers of fat oxidation of "salchichon" during the ripening process, compared with traditional hog casing controls (cular). For this, a production was carried out, using both types of casings, in a well-established factory of traditional "salchichón" (Splendid Foods, Seva, Barcelona, Spain).

RESULTS

The NNC contained 25 times less sodium than the traditional casing. The concentration of malondialdehyde (MDA) and the peroxide index (markers of fat oxidation) were 90% lower (0.72 ± 0.06 vs. 1.70 ± 0.09 mg MDA per Kg of fresh weight, FW) and 60% lower (1.98 ± 0.75 vs. 25.8 ± 1.88 mEq O2/Kg FW) in the NNC compared with the traditional casing, respectively. The cured fermented Spanish sausages produced with NNC significantly ($P<0.05$) reduced their concentration of MDA by 65% (0.46 ± 0.09 vs. 1.35 ± 0.31) and the peroxide index by 50% (6.21 ± 2.95 vs. 12.60± 2.75) compared with traditional casing. In addition, the salchichón made with NNC contained 16% less salt than the one made with traditional casing (4.20 ± 0.27 vs. 4.82± 0.27 g salt/100 FW).

CONCLUSIONS

The use of the newly developed natural hog casing for the production of cured fermented meat products reduced oxidation of the meat and could be useful for the reduction of salt intake in consumers.

BACKGROUND AND OBJECTIVES

Severe acute malnutrition (SAM) affects 17 million children worldwide. Uncomplicated SAM cases are treated in outpatient programs with varying recovery rates. The TISA trial in northern Senegal assessed whether adding a Water Sanitation and Hygiene (WASH) component to standard SAM treatment could improve recovery rates. To complement clinical findings, a community restitution was conducted in Linguère and Podor to gather feedback from institutional partners, community actors, and caregivers. Participants shared their perceptions on the WASH kit's impact, acceptability, costs, logistical challenges, and potential national integration.

METHODS

A predefined protocol guided the restitution sessions, using structured discussion guides. Participants, selected via purposive sampling, included mothers of enrolled children, nurses, health workers, community volunteers, local authorities, health representatives, and trial staff. Two sessions were held in Podor and Linguère. Institutional actors discussed RESULTS in French, followed by group work on four themes: water quality, diarrhoea reduction, SAM treatment outcomes, and WASH kit scalability. For caregivers and community health actors, discussions were conducted in Pulaar and Wolof, facilitated by a translator who recorded and transcribed exchanges. Two researchers conducted textual analysis triangulated by a third.

RESULTS

The WASH component was widely perceived as beneficial. Mothers reported reduced diarrheal prevalence, improved water quality, and better hygiene practices, particularly handwashing. Institutional and community actors noted behavioral changes and improved water conservation. However, limiting factors were identified: insufficient kit quantities for larger households, stock-outs, prolonged consultations, and storage constraints. The high cost of the kit was a concern, as institutional actors questioned its cost-effectiveness given the lack of significant impact on SAM recovery rates. Participants suggested increasing kit components, improving material quality (e.g., adding filters), extending the intervention duration, strengthening logistical support for community volunteers and broadening sensitization target by including religious leaders. Investment in permanent WASH infrastructure was also recommended.

CONCLUSIONS

The restitution highlighted the importance of community engagement in interpreting RESULTS and addressing operational challenges. It fostered local ownership, generated actionable insights, and informed policy discussions for potential national adoption.

COMPREHENSIVELY MEASURING FOOD ENVIRONMENTS TO INFORM INTERVENTION DEVELOPMENT: PILOTING THE FOOD ENVIRONMENT TOOLBOX IN INDIA AND CAMBODIA

Shauna Downs[1]; W. Staromiejska,[1]; Selena Ahmed[2]; Nyda Chhinh,[3]; Elizabeth Fox,[4]; Anna Herforth,[5]; Serey Sok,[6]; Suparna Ghosh-Jerath[7]
[1]Department of Health Behavior, Society and Policy, Rutgers School of Public Health, Newark, United States of America; [2]Periodic Table of Food Initiative, American Heart Association, Inc, Dallas, United States of America; [3]Department of Economic Development, Royal University of Phnom Penh, Phnom Penh, Cambodia; [4]Department of Public & Ecosystem Health, Cornell University College of Veterinary Medicine, Ithaca, United States of America; [5]Global Health and Population, Harvard T.H. Chan School of Public Health, Boston, United States of America; [6]Research Office, Royal University of Phnom Penh, Phnom Penh, United States of America; [7]Nutrition and Food Systems, The George Institute for Global Health India, New Delhi, India

BACKGROUND AND OBJECTIVES

Food environments (FEs) drive consumers' decisions about what to eat. Characterizing the different domains (i.e., personal and external) and dimensions (i.e., accessibility, availability, affordability, convenience, quality, etc.) of FEs can facilitate better understanding of where people access food from and why, informing the design of interventions and policies tailored to the local context and people's lived experiences. The Food Environment Toolbox includes a suite of modified and refined tools designed to comprehensively assess diverse FEs in low- and middle-income countries. This study describes updates to tools, findings from the pilot of the FE Toolbox in India and Cambodia, and how findings can be used to monitor FEs and inform interventions and policies.

METHODS

The FE Toolbox includes seven tools to measure FEs in diverse LMIC settings: Participatory Mapping, Seasonal Food Availability Calendar, Food Environment Perceptions Survey (FEPS), Community Food Environment Mapping, Market Mapping, In-Depth Vendor Assessment, and a Cost of a Healthy Diet data collection protocol. We pilot-tested the tools in four communities, across an urbanicity gradient, in both India and Cambodia. The FEPS, which was designed to capture peoples' perceptions and experiences of their FEs (i.e., personal FE), was piloted with 60 participants in Cambodia and 44 in India. We also used a combination of tools to map the dimensions of the built FE (i.e., vendor type and hygiene, food availability, quality, promotions, prices) in each setting.

RESULTS

Based on our piloting findings from the FEPS tool, we found that the number of FE types accessed was significantly higher in rural (mean 2 ± 0.85 in Cambodia; mean 3.95 ± 0.92 in India) as compared to peri-urban (mean 1.7 ± 0.81 in Cambodia; mean 2.6 ± 0.97 in India) and urban (mean 1.2 ± 0.43 in Cambodia; mean 2.08 ± 0.76 in India) settings (p-value < 0.001 in India; p-value $= 0.02$ in Cambodia). Assessments of the built FE found differences in the foods sold across study settings as well as their quality (e.g., spoilage), relative affordability, and promotions. Promotions were observed in all FEs in Cambodia, particularly for alcohol, while promotions for ultra-processed foods were mostly observed in urban India.

CONCLUSIONS

The FE Toolbox provided insights into the different dimensions of FEs across settings and can lead to identification of context-specific points for intervening in the FE (e.g., alcohol promotion restrictions in Cambodia; strengthening market infrastructure in India) to improve the availability, affordability, and acceptability of healthy and nutritious food.

OAP33_05

THE IMPACTS OF VITAMIN A DEGRADATION ON THE EFFECTIVENESS AND COST-EFFECTIVENESS OF FOOD FORTIFICATION PROGRAMS: MODELED EVIDENCE FROM NIGERIA

Stephen Vosti[1]; Reina Engle-Stone,[1]; Michael Jarvis,[1]; Lauren Thompson,[1]; Katherine Adams,[1]
[1]Institute for Global Nutrition, University of California, Davis, Davis, United States of America

BACKGROUND AND OBJECTIVES

Vitamin A (VA) dietary inadequacy remains a serious public health problem, especially among young children. Large-scale food and condiment fortification programs are in place in many countries, but the potential for degradation of VA when exposed light, heat, and humidity may reduce the quantity of VA that reaches consumers. We modeled the impacts of different levels of VA degradation in three fortified products (wheat flour, sugar, and bouillon cubes) on program effectiveness and cost-effectiveness in the context of Nigeria.

METHODS

We used 2018-2018 Nigerian Living Standards Survey data to estimate apparent VA intake and prevalence of inadequacy among young children (6-59 months of age). We then predicted the potential reductions in VA inadequacy attributable to programs at varying hypothetical levels of VA degradation (zero loss to 80% loss). The Lives Saved Tool (LiST) was used to estimate child-lives saved based on changes in VA adequacy. Program costs were estimated using activity-based spreadsheet models.

RESULTS

Programs differed in their impacts on VA inadequacy: assuming zero VA losses, fortification of sugar (7.5 mg/kg), wheat flour (2mg/kg), and bouillon cubes (96 mg/kg) would reduce inadequacies among children by 3.3, 3.3, and 20.6 percentage points, respectively. VA degradation had negative, non-linear impacts on all programs: at 80% VA losses, these programs reduced inadequacies by 0.7 (sugar), 0.7 (wheat flour), and 9.6 (bouillon) percentage points. Over the zero-80% VA loss range, average annual child-lives saved over the 10-year model simulation period ranged from 3,984-769 (sugar), 3,036-739 (wheat flour), and 15,301-7,153 (bouillon cubes); estimated cost/child-life saved ranged from $550-$2,848 (sugar), $1,039-$4,271 (wheat flour), and $944-$2,018 (bouillon cubes).

CONCLUSIONS

VA degradation could reduce the effectiveness and cost-effectiveness of food and condiment fortification programs, perhaps undermining public policy efforts to address VA inadequacies where fortification programs are expected to contribute substantially to VA intakes. Fortificant selection, technological innovations in fortificants, and/or changes in premix handling and storage could help reduce degradation; all of these options would increase food program costs, but all merit consideration; some might be more cost-effective than others.

DOES THE AVAILABLE OBSERVATIONAL EVIDENCE SUPPORT A RELATIONSHIP BETWEEN ADHERENCE TO SUSTAINABLE DIETARY PATTERNS AND MENTAL HEALTH IN ADULTS? A SYSTEMATIC REVIEW

Rubén Fernández-Rodríguez[1, 2]; Bruno Bizzozero-Peroni[3]; Valentina Díaz-Goñi[3]; Miriam Garrido-Miguel[3]; Anna Boronat[4]; Miguel López-Moreno[5]; J. Martín-Olmedo Juan[1, 6]; Felice Jacka[2]; Ujué Fresán[7]

BACKGROUND AND OBJECTIVES

The rising burden of mental health disorders and planetary health are in the spotlight.1 Nutritional Psychiatry should advocate for dietary patterns that promote mental well-being while minimising environmental damage.2,3 Our systematic review aimed to explore how adherence to sustainable and healthy dietary patterns (e.g., Mediterranean diet [MedDiet], DASH, MIND, Eat-Lancet diet, Plant-based diet [PBD], Healthy Eating Index [HEI]) are related to common mental health disorders.

METHODS

We conducted a systematic search on 4 databases from database inception until Sept 2024. We followed the PRISMA and MOOSE recommendations for observational studies. We included prospective cohort studies that explored the longitudinal association between adherence to healthy low-environmental impact diets and depression, anxiety, cognitive decline or dementia among adults (≥18 y). When publications referred to the same cohort and the same exposure and outcome, we selected the most recent publication with the longest follow-up and the largest sample size.

RESULTS

A total of 40 studies involving 1,102,836 adults (mean age range: 34.4–80.7 y, 54.1% female) were included from 30 different cohorts. The mean follow-up was 10.3 y (range: 3–27 y). 24 studies explored MedDiet, 10 PBD, 7 DASH, MIND, and HEI, and 2 Eat-Lancet diet. The most explored outcome was incident depression (17 studies), followed by dementia (15 studies), cognitive impairment/decline (12 studies) and anxiety (2 studies). We broadly found that the highest adherence to these dietary patterns was related to a lower risk of mental health disorders.

CONCLUSIONS

Higher adherence to healthy and sustainable dietary patterns might be associated with a lower risk of common mental disorders. However, further research is needed to determine the effects of the latest diet indexes with the lowest environmental impacts according to evidence such as the Eat-Lancet diet to address public health strategies regarding mental health and planetary boundaries.

RELATIVE VALIDITY OF INTERVIEWER-ADMINISTERED 24-HOUR RECALLS COLLECTED BY PHONE AND IN-PERSON VERSUS WEIGHED FOOD RECORDS IN RURAL SRI LANKA

Caroline A. Joyce[1]; Christine P. Stewart,[2]; Charles D. Arnold,[3]; Hasara Sitisekara[4]; Bess L. Caswell[5]; Amy Margolies[6]; Thushanthi Perera[4]; Thilanka Ranathunga[4]; Sonja Y. Hess[7]; Deanna Olney[6]; Renuka Silva[4]; Aulo Gelli[8]

BACKGROUND AND OBJECTIVES

Quantitative dietary assessment is hindered by cost, time, and logistical burdens. Collecting 24-hour recall (24HR) dietary data by phone may be particularly advantageous in rural areas. We assessed the validity and costs of phone versus face-to-face (FTF) 24HR compared to standard observed weighed food records (WFR), a gold standard dietary assessment method.

METHODS

We used a randomized crossover design to collect one phone and one FTF 24HR from 103 rural Sri Lankan adults. Each 24HR was matched to a WFR collected on the reference day. We compared mean differences in log-transformed nutrient intakes (energy, 3 macronutrients, and 11 micronutrients) between 24HR and WFR using equivalence testing with a priori 15% error bounds. The same procedure was used to compare the relative error of the two 24HR METHODS. We also assessed agreement using concordance correlation coefficients (CCC) and Bland-Altman plots. Memory and portion size estimation errors were examined using descriptive statistics. Incremental financial and economic costs of phone and FTF 24HR recalls were estimated using activity-based costing, combining financial expenditure data with micro-costing.

RESULTS

Respondents underreported energy intake by 263 kcal (12.6%) and 229 kcal (10.9%) compared to WFR by phone and FTF 24HR, respectively. Mean intakes of protein, calcium, iron, zinc, riboflavin, niacin, and folate were equivalent between phone 24HR and WFRs. No nutrients were equivalent for the FTF 24HR. The CCCs between phone 24HR and WFR were higher than FTF 24HR for energy and all nutrients except calcium, riboflavin, folate, and vitamin B12. Memory error was lower in FTF 24HR. Portion sizes were underestimated in both recall METHODS. Costs per respondent were $337 for the phone 24HR and $498 for FTF.

CONCLUSIONS

Among rural Sri Lankan adults, phone-based 24HR were comparable to FTF 24HR in estimating nutrient intakes, although both METHODS underestimated true intakes. Phone-based 24HR dietary assessment performed at least as accurately as those conducted in-person and were notably less expensive. Further research is warranted to evaluate METHODS to improve food and portion size recall and accuracy of portion size estimation over the phone, in addition to validation of phone-based 24HR in other contexts.

INTEGRATION OF A WASH COMPONENT IN THE STANDARD NATIONAL PROTOCOL FOR TREATMENT OF SEVERE ACUTE MALNUTRITION IN CHILDREN AGED 6-59 MONTHS IN NORTHERN SENEGAL – A COSTING STUDY

Bibata Wassonguema[1]; Maily Lê-Lacanette[2]; Laura Braun[3]; Matar Ba[4]; Francoise Siroma[4]; Emile Cabo[4]; Antonio Vargas Brizuela[5]; Moustapha Seye[6]; Lapegue Jean[7]; Alexandre Devort[8]; Oliver Cumming[3]; Dieynaba Ndiaye[9]

BACKGROUND AND OBJECTIVES

Severe acute malnutrition (SAM) affects 17 million children worldwide. Integrating a water, sanitation and hygiene (WASH) kit in outpatient SAM treatment has been shown to improve recovery rates, but its cost implications at scale is unknown. The study, conducted as part of the TISA trial, estimates the cost of integrating a WASH component into Senegal's national protocol for treating uncomplicated SAM.

METHODS

This costing study was nested within the TISA randomised controlled trial, which evaluated the additional benefit of a WASH component to standard SAM treatment for children aged 6-59 months. Data related to WASH costing were collected from 660 participants enrolled between December 2020 and December 2021. A societal perspective and micro-costing approach were used to estimate direct medical, non-medical (e.g. transportation) and indirect costs of SAM treatment.

RESULTS

The WASH component added a $105 additional cost per child treated, with the WASH kit, transportation and management representing $33. Sensitisation to hygiene and water treatment cost $13.4 at health posts and $30 for two at-home visits. Human resources were the main cost driver for the WASH component, exceeding the human resources for standard SAM treatment. However, this WASH component did not generate any additional out-of-pocket expenses to households. The cost for standard SAM treatment was evaluated at $233 per child treated (for an average of 6.4 consultations), with the main expense being Ready-to-Use-Therapeutic Food (RUTF) ($154). Household out-of-pockets cost amounted $43, corresponding to non-medical costs as treatment for malnutrition is included in Senegal's universal health protection. It also incurred $13.4 of opportunity costs for the caregiver. The absence of additional costs for households induced by the WASH component is encouraging, as suggest that is will not be an obstacle to care seeking or integration into the national protocol.

CONCLUSIONS

This study provides a comprehensive cost estimate for integrating a WASH kit and hygiene promotion into Senegal's SAM treatment protocol. While this increased the treatment cost by 45%, it remained lower than estimates from a previous study. These findings are critical for informing SAM management budget planning, supporting future cost-effectiveness evaluation, and guiding or preventing the integration of WASH interventions into SAM interventions in similar settings.

DICHOTOMOUS HEALTHY DIET INDICATORS TO REFLECT WHO DIETARY GUIDANCE

Anna Herforth[1, 2]; Doris Wiesmann[3]; Lucrezia Bertoni[4]; Giovanna Andrade[5]; Alexandra Bellows[6]; Kaela Connors[6]; Euridice Martinez Steele[7]; Sonia Rodriguez Ramirez[8]; Zhiyong Zou[9]
[1]Global Health and Population, Harvard T.H. Chan School of Public Health, Boston, United States of America; [2]Division of Human Nutrition and Health, Wageningen University & Research, Wageningen, Netherlands; [3]N/A, Independent, Singen, Germany; [4]Epidemiology and Data Science, Amsterdam UMC, locatie AMC, Amsterdam, Netherlands; [5]Nutrition, Faculdade de Saúde Pública USP, São Paulo, Brazil; [6]Global Academy of Agriculture and Food Systems, The University of Edinburgh, Edinburgh, United Kingdom; [7]NUPENS, University of São Paulo, São Paulo, Brazil; [8]Department of Food, Culture, and Environment, National Institute of Public Health, Cuernavaca, Mexico; [9]Institute of Child and Adolescent Health, School of Public Health, Peking University, Beijing, China

BACKGROUND AND OBJECTIVES

Monitoring indicators of healthy diets, including those aspects of diets related to noncommunicable diseases (NCDs), is critical for public health to monitor trends and inform advocacy, policy and interventions. The World Health Organization (WHO) has published guidelines, recommendations, and evidence reviews on dietary risk factors for NCDs. The aim of this study was to develop and validate dichotomous food group-based indicators that reflect WHO dietary guidance.

METHODS

National quantitative dietary intake data from 8 countries (Bangladesh, Brazil, China, Mexico, Netherlands, Switzerland, United Kingdom, United States) were analyzed by classifying each food or beverage item consumed into 29 food groups used in the Diet Quality Questionnaire (DQQ). Candidate indicators were drafted from these food groups. Associations between food groups / candidate indicators and WHO recommendations were tested using odds ratios, correlations, and sensitivity and specificity analyses. Additionally, the sodium and free sugar content of salty and sugary food and beverage food groups were identified using the USDA branded foods database.

RESULTS

Indicators with significantly higher odds of meeting the WHO recommendations included the Protective Foods Indicator (PFI), associated with meeting the WHO recommendations for vegetables, fruits, whole grains, pulses, and fiber; and the Dietary Moderation Indicator (DMI), associated with meeting recommendations on free sugar, sodium, saturated fat, and processed meat. Sub-indicators on sugary foods and beverages and salty processed foods were associated with the WHO guidelines on free sugar and salt, respectively. An aggregate Healthy Diet Indicator is associated with meeting all the WHO recommendations.

CONCLUSIONS

These novel indicators are valid food group-based proxy indicators of adherence to WHO dietary recommendations. By measuring aspects of diet quality related to prevention of NCDs, they complement the minimum dietary diversity for women (MDD-W), a food group-based proxy indicator of nutrient adequacy. They are feasible to monitor at low cost using food group-level data. Using the DQQ, a 5-minute questionnaire, data suitable for calculating these indicators have been collected in 94 countries.

PROTEIN-RICH PLANT-BASED DIETS: PERSPECTIVES OF ACTIVE OLDER ADULTS

Sophie van Oppenraaij[1, 2]; Marije Putker[1]; Peter Weijs[1, 3]; Sjors Verlaan[1, 4]
[1]Department of Nutrition and Dietetics, Faculty of Health, Sport and Physical Activity, Amsterdam University of Applied Sciences, Amsterdam, Netherlands; [2]Aging and Later Life, Amsterdam Public Health Research Institute, Amsterdam, Netherlands; [3]Department of Nutrition and Dietetics, Amsterdam University Medical Centers, Vrije Universiteit, Amsterdam, Netherlands; [4]Department of Medical BioSciences, Radboud University Medical Center, Nijmegen, Netherlands

BACKGROUND AND OBJECTIVES

Older adults may require an increased protein intake to preserve muscle mass. A predominantly plant-based diet is beneficial for the climate and may lower the risk of certain non-communicable diseases. However, it may also lead to protein intakes below recommendations among older adults. This study seeks to elucidate facilitators and barriers in older adults adopting a diet that is both predominantly plant-based and provides sufficient protein to preserve muscle mass.

METHODS

Three focus groups were conducted with 30 active Dutch adults, aged 55-74 years. The focus groups explored participants' views on protein-rich, plant-based diets. Three researchers independently thematically analysed the data and facilitators and barriers were mapped to the Capability (C), Opportunity (O), Motivation (M) – Behaviour (B) model.

RESULTS

Health effects and taste were both the most dominant motivations regarding transition towards a protein-rich and more plant-based diet. Knowledge (C) and social influences (O) were important factors that influence dietary choices regarding the other COM-B model components. Environmental benefits (M) and animal welfare (M) were mentioned as additional benefits rather than as main facilitator. Participants expressed a clear need for enhanced knowledge and tools about the health and environmental benefits of protein-rich, plant-based diets.

CONCLUSIONS

This qualitative study revealed that health effects and taste were dominant drivers for active, older adults in the transition towards a protein-rich and more plant-based diet. According to their recommendations, targeted messaging on health benefits is essential. Additionally, improving taste perceptions offers an opportunity to foster more positive associations with plant-based diets.

DUTCH STUDENTS OF SECONDARY VOCATIONAL EDUCATION AND PLANT-BASED EATING

Marloes vanderHorst[1]; Yassir Sefu,[1]; Willemijn Vermeer,[2]; Martinette Streppel[3]; Mathijs Sijperda[4]; Korrie Hoekstra[5]; Antien Zuidberg[6]; Esther Veen[1]; Patricia Bulsing[7]
[1]Urban Food Issues, Aeres University of Applied Science, Almere, Netherlands; [2]Psychology for Sustainable Cities, Amsterdam University of Applied Science, Amsterda, Netherlands; [3]Department of Nutrition and Dietetics, Faculty of Health, Sprt and Physical Activity, Amsterdam University of Applied Science, Amsterdam, Netherlands; [4]Nutrition and Dietetics, Hanze University of Applied Science, Groningen, Netherlands; [5]Environmental Science, Van Hall Larenstein, University of Applied Science, Leeuwarden, Netherlands; [6]Design METHODS in Food, HAS Green Academy, 's-Hertogenbosch, Netherlands; [7]Purposeful Marketing, The Hague University of Applied Science, The Hague, Netherlands

BACKGROUND AND OBJECTIVES

The transition to a plant-based diet is globally recognized as critical for combatingclimate change and improving public health (Willett, 2019). Secondary vocationaleducation students are a key demographic due to their adaptable eating habits (Story,2002). However, limited knowledge, skills, cost, and social influences often hinderplant-based choices (Rickerby, 2024). This study examines the eating habits, knowledge,motivations, barriers, and attitudes of Dutch secondary vocational education students towards plant-based eating.

METHODS

A consortium of researchers, educators, and public health professionals carried out this study. Based on the COM-B model (Michie 2011), semi-structured interviews were conducted amongst 156 students. A thematic analysis was applied to identify patterns.

RESULTS

Most respondents eat three main meals daily, with breakfast at home and lunch and dinner varying by location. Many live with their parents, who handle most grocery shopping and cooking. Dinners of potatoes, vegetables, and meat are common, with Italian and Asian cuisines also popular. A majority (83.7%) identify as omnivores, with smaller proportions as flexitarian or vegetarian; no respondents are vegan. Plant-based eating is most common in snacks (26.1%) and least in desserts (3.3%), with modest adoption for lunch (5.2%) and dinner (7.2%).

A third of students bring lunch from home, while others buy meals at school or supermarkets, favoring sandwiches and snacks. Only 11.8% consciously engage with plant-based nutrition, and 49% find it unimportant. Barriers include costs, limited options, and unappealing taste, though cheaper and better-tasting products might help.

Friends and family influence the eating habits of half the students, regardless of engagement with plant-based eating. While health and environmental benefits are recognized, fewer than half associate plant-based options with these advantages. Students more engaged in plant-based eating show higher motivation and are more likely to link it to positive outcomes in health, taste, and sustainability.

CONCLUSIONS

Plant-based eating holds little importance for most students interviewed. We found little evidence of resistance to the protein transition but also little interest. Most respondents eat what their parents cook and pay little attention to their diet's health or environmental impact. Interventions targeting parents and normalizing plant-based choices could increase adoption among this population.

OAP50_03

GLOBAL VARIATION IN TAX POLICIES, SUGAR CONTENT, AND ANNUAL SALES VOLUME OF SUGAR-SWEETENED BEVERAGES

Daniel Zaltz[1]; Anusha Ramesh[1]; Emily Ziraldo[1]; Mary L'abbe[1]
[1]Nutritional Sciences, University of Toronto, Toronto, Canada

BACKGROUND AND OBJECTIVES

Sugar-sweetened beverages (SSBs) are a leading source of added sugars in the global diet. High consumption of added sugars increases risks of chronic diseases including type 2 diabetes, obesity, and cardiovascular disease. Public health policies including taxes and nutrient warnings may improve national food systems by reducing sugar content of SSBs, thereby passively decreasing population-level intake of this nutrient of concern. However, there are no current studies of global variations of sugar content in SSBs, nor are there studies to combine these data with contemporaneous estimates of sales volumes, which are required to accurately compare average nutrient contents across national and regional food systems. The purpose of this study is to compare global differences in sugar content of specific SSBs and sales-weighted averages between 2019 – 2023.

METHODS

We collected data on sugar content (grams/100mL) and annual sales volume (million litres) for all available SSB categories between 2019-2023 within the Euromonitor International Passport (EIP) database, a third-party data aggregation platform used in similar studies. We calculated per-year per-country means and 95% confidence intervals of sugar content for each beverage category. Then, we calculated sales-weighted average sugar content in each country's respective SSB market. Finally, in forthcoming analyses completed prior to this conference, we will estimate differences between countries with respect to sugar content comparing those that do and do not have SSB taxes and front-of-pack nutrition labelling.

RESULTS

Regular colas contain the highest sugar content across all global markets, with a mean (95% CI) content of 33.3 (33.1-33.5) grams per 335mL serving. Energy drinks and orange carbonates contain similarly high levels of added sugars per serving, with significant regional variation. Overall sales-weighted average sugar content within SSB markets differed considerably, with Japan and the United Kingdom having less than 10 grams/335mL serving compared to India and the United Arab Emirates having more than 25 grams/335mL.

CONCLUSIONS

Significant regional variation of sugar content points to key global markets for public health intervention. High sugar content in regular colas, energy drinks, and orange carbonates highlights the importance of targeting these beverages for reformulation. Forthcoming analyses of the correlation between sugar content and relevant policies may further elucidate the need to improve interventions like SSB taxes to encourage industry reformulation.

ASSOCIATION BETWEEN ANEMIA AND SOYBEAN AND BAOBAB USE AMONG RURAL WOMEN IN NORTHERN GHANA: CROSS-SECTIONAL STUDY

Brenda Abu[1]; Wilna Oldewage-Theron[2, 3]
[1]Wegmans School of Health and Nutrition, Rochester Institute of Technology, Rochester, United States of America; [2]Nutritional Sciences, Texas Tech University, Lubbock, United States of America; [3]Department of Sustainable Food Systems & Development, University of the Free State, Bloemfontein, South Africa

BACKGROUND AND OBJECTIVES

Baobab, an abundant wild tree crop in Ghana is a good vitamin C source. Soybean has high iron content and is the only plant-based complete protein available in Ghana. Women in rural smallholder farming communities have an increased risk of anemia related to food insecurity and inadequate dietary quality. The study objective was to assess the effects of soybean and baobab consumption on hemoglobin levels among rural women in Ghana.

METHODS

In this cross-sectional study, in-person interviews were conducted with questions on 1) demographic data, 2) 7-day recall of the 10-item food group scale used for dietary diversity, and 3) soybean and baobab-related knowledge, access, use, and recipes. 4) Food security using the Household Food Insecurity Access Scale, and 5) Hemocue to assess hemoglobin levels. Means, standard deviation, chi-square analysis, and linear regression were computed using IBM SPSS, version 29. A market surveillance was done to identify baobab and soybean-related products at three main markets.

RESULTS

Of the 150 mothers, 95 (62.5%) had no formal education, 22 (14.5%) had completed primary education and the remaining 33 (22.0%) had completed senior high school/tertiary education. The mean hemoglobin level was 11.2 ± 1.8 g/L for women. A third (n=53; 34.9%) of the mothers were non-anemic, while the remaining 90 (60.0%) had mild to moderate anemia. In almost all households 148 (97.4%) in the sample had access to a baobab tree, and 78 (51.3%) farmed soybeans. Soy kebab and soy ice cream were the most common soy products identified by market surveillance. Soymilk and yogurt were however the most popular in households and markets. In the one week before the study, 28 (18.4%) had consumed baobab pulp juice, 107 (70.0%) had used baobab leaves for soup and 68 (44.7%) had consumed soy kebab. Controlling for food security status, the use of soybeans one week before the study was significantly related to anemia status (p=0.035). However, access to a baobab tree, farming soybeans, reported use of baobab, and intake were not associated with anemia status. Few mothers reported their knowledge of soybean and baobab as “good for general health”, while others reported that, they used the pulp as a laxative, used pulp as animal feed, disposed of it, or did not know the health benefits.

CONCLUSIONS

Soybean intake but not baobab was significantly associated with anemia status. Baobab and soybean were available but minimally used at household levels. Larger-scale intervention studies are needed to determine their benefits in food-based anemia prevention strategies.

NAVIGATING ANTAGONISTIC OUTPUTS IN A LONG-TERM MULTI-INSTITUTION AND MULTILINGUAL NUTRITION RESEARCH PARTNERSHIP

Silondile Luthuli[1, 2]; J. Hope Corbin[2]; Marguerite Daniel[2]
[1]Center for Rural Health, University of KwaZulu-Natal, Durban, South Africa; [2]Department of Health Promotion and Development, University of Bergen, Bergen, Norway

BACKGROUND AND OBJECTIVES

International nutrition research partnerships, which involve diverse linguistic and institutional contexts, face complex collaborative challenges. This study examines a four-way partnership between institutions in both the global North and South that offer a graduate nutrition research program. It specifically explores how partners navigate and learn from contested outputs of the program within the partnership.

METHODS
Using the Bergen Model of Collaborative Functioning (BMCF), we conducted a formative evaluation employing a Participatory Action Research (PAR) approach. We used purposive sampling to recruit members of the partnership for participation. Data collection METHODS included cognitive mapping and restorative justice group exercises, which were analyzed through inductive thematic network analysis using NVivo v15.
RESULTS

The key challenges identified by the partners included issues surrounding supervision, roles and accountability, and sustainability. Supervision was found to be critical, significantly influencing research quality and student outcomes. Problems included miscommunication, varying supervision models, and language barriers between supervisors and students. Institutional role ambiguity, hierarchical structures, and uneven decision-making processes further complicate the effectiveness of the partnership, leading to delays and a lack of accountability. Concerns regarding sustainability highlighted the need for alternative funding mechanisms after initial partnership funding has ended. However, embedded within these challenges are long-standing tensions in communication and differences in contexts of the different institutions that had the overall impact on productivity and expected outcomes of the partnership.

CONCLUSIONS

The findings emphasize the significant influence of communication and contextual differences on the functioning and outcomes of global health research and nutrition research partnerships. Addressing these challenges with targeted strategies can enhance collaboration, ensure sustainability, and improve research outcomes for future partnerships.

INFORMALITY IN THE FOOD ENVIRONMENT: A REVIEW OF NUTRITION, LIVELIHOOD, AND SOCIO-POLITICAL CONTEXT AND IMPLICATIONS FOR FOOD POLICY

Ramya Ambikapathi[1]; Elizabeth Fox,[2]; Swetha Manohar[3]; Erick Muriungi,[4]; Jacob Blizzard,[4]; Bezner Kerr Rachel[5]; Simon Kimenju,[6]; Mason-Dcroz Daniel[4]; Mario Herrero[7]; Nilupa Gunaratna,[8]; Stella Nordhagen[9]
[1]Food Environment and Consumer Behavior, International Center for Tropical Agriculture, Cali, Colombia; [2]Department of Public & Ecosystem Health, Cornell University College of Veterinary Medicine, Ithaca, United States of America; [3]PHND, International Food Policy Research Institute, Washington, United States of America; [4]Global Development, Cornell University, Ithaca, United States of America; [5]Department of Global Development, Cornell University, Ithaca, United States of America; [6]Kula Vyema Centre of Food Economics, Kula Vyema Centre of Food Economics, Ruiru, Kenya; [7]Global Development, Cornell, Ithaca, United States of America; [8]Public Health, Purdue, West Laf, United States of America; [9]Knowledge Leadership Team, GAIN, Genève, Switzerland

BACKGROUND AND OBJECTIVES

Over one billion people in low- and middle-income countries (LMIC) work in the "informal" food system. Street and mobile vendors are often part of the informal sector and contribute to food environments critical for the food security, safety, and resilience of low-income populations. Despite the role that informality plays in the food environment in LMIC, there is little systematic research on how informality in the food environment impacts nutrition livelihoods, given various socio-political context. This scoping review addresses these gaps.

METHODS

We undertook a scoping review (OSF registration:https://doi.org/10.17605/OSF.IO/YMK3T) that addressed three key questions about informality: 1) How is informality in the food environment defined and studied? 2) What factors in the informal food environment influence consumer food choices, diets, and nutrition outcomes? 3) How do socio-political factors, such as bribes, personal safety, regulations, and governance affect informal food vendors? A search strategy was developed in July 2023. We included English-language studies published after 2000 on informal food environments in LMIC with outcomes related to nutrition, or livelihoods, or socio-political contexts.

RESULTS

The search yielded 23,250 records, with 12,294 remaining. From these, 1,870 records were selected for full-text screening. A total of 358 records were included for data extraction and analysis after applying the inclusion/exclusion criteria, with over 95% being peer-reviewed articles. The studies covered 56 countries, with clusters in South Africa, Kenya, India, and China. Most research was conducted in urban or capital city settings (73%); less than 10% focused on peri-urban areas, and fewer than 7% on rural or secondary cities.

Preliminary RESULTS show that a quarter of the papers studied all three outcomes (nutrition, livelihood, and socio-political context), with less than 15% focusing on nutrition. Commonly studied commodities included prepared foods, vegetables, and meat; commonly studied socio-political factors included governance, gender, water, sanitation, and public space use. Livelihoods focused on business challenges and vendors' working hours. Most common FE dimensions included vendor characteristics and food availability, convenience, and prices.
CONCLUSIONS

Informal food environments are essential for LMIC countries, though their importance is often overlooked. These environments serve as critical nutritional and economic hubs in urban areas, shaped by socio-political contexts and rooted in economic histories.

DISPARITIES IN MICRONUTRIENT DEFICIENCIES, INFLAMMATION, AND THEIR CO-OCCURRENCE IN RELATION TO ADVERSE BIRTH OUTCOMES: THE BRINDA PROJECT

Jiaxi Geng[1]; Hanqi Luo[2]; Rochelle Werner[2]; Ramakrishnan Usha[2]; Phuong Nguyen[3]; Parmi Suchdev[4, 2]; Melissa Young[2]; Yi-An Ko[1]

[1]Department of Biostatistics and Bioinformatics, Rollins School of Public Health, Emory University, Atlanta, United States of America; [2]Hubert Department of Global Health, Rollins School of Public Health, Emory University, Atlanta, United States of America; [3]Nutrition, Diets, and Health Unit, International Food Policy Research Institute, Washington D.C., United States of America; [4]Department of Pediatrics, School of Medicine, Emory University, Atlanta, United States of America

BACKGROUND AND OBJECTIVES

Maternal micronutrient deficiencies (MNDs) and inflammation contribute to adverse birth outcomes (ABOs). The consequence of co-occurrence of MNDs remains unclear. Identification of factors associated with higher prevalence of MNDs and inflammation can also help improve maternal health care. The study examined disparities in maternal MNDs and inflammation, as well as associations of 1) single MND and inflammation and 2) co-occurring MNDs with ABOs.

METHODS

Data from 9,567 pregnant women across 8 datasets from 7 countries were assessed for baseline prevalence of MNDs (including iron, vitamin A, zinc, serum folate, vitamin D, and vitamin B12), inflammation (c-reactive protein >5 mg/L or α-(1)-acid glycoprotein > 1g/L). Associations with maternal demographics (age, height, body mass index [BMI], education, socioeconomic status [SES]) using chi-square. Associations of 1) single MNDs and inflammation and 2) co-occurring MNDs (2 deficiencies at a time) with low birth weight (LBW, < 2500 g), preterm birth (PTB, < 37 wks), and small-for-gestational age (SGA, < 10th percentile for gestational age), were examined using modified Poisson regression to estimate Relative Risk (RR), adjusting for age, SES, and dataset.

RESULTS

Younger age and shorter height were associated with up to 10% and 25% higher prevalence of MND and inflammation. Maternal underweight was associated with lower inflammation (23.9% vs 35.5%), while lower education (64.6% vs 41.5%) and lower SES (56.1% vs 47.7%) were associated with B12 deficiency. Focusing on the effects of single MND, folate deficiency was associated with LBW (RR [95% CI]: 1.21 [1.06, 1.39]), and inflammation was associated with SGA (1.15 [1.03, 1.29]). Looking at the effect of co-occurring MNDs, women with folate deficiency, but not iron (1.37 [1.13, 1.67]) or vitamin B12 deficiency (1.66 [1.08, 2.54]), exhibited a higher risk of LBW comparing with those with neither of the deficiencies. Iron deficiency without vitamin B12 deficiency was associated with a lower risk of LBW (0.42 [0.27, 0.67]). No significant differences were observed among women with two MNDs compared to those with neither deficiency.

CONCLUSIONS

Certain maternal characteristics were associated with MNDs and inflammation, potentially contributing to adverse birth outcomes. A better understanding of the unexpected effect of co-occurring MNDs and complex underlying nutrient interactions may be useful to improve birth outcomes.

Dietary pattern analyses: a comparison of different clustering METHODS

Esther Kok[1]; Kim Maasen[1]; Ming-Jie Duan[1]; Elise Talsma[1]; Phuong Nguyen[2]; Gabriela Fretes[2]; Mai T. Truong[3]; Rock Zagre[2]; Nga T. Hoang[3]; Marie Ruel[2]; Jef Leroy[2]; Inge Brouwer[2, 1]
[1]Human Nutrition and Health - Global Nutrition, Wageningen University and Research, Wageningen, Netherlands; [2]Nutrition, Diets & Health, International Food Policy Research Institute, Washington, United States of America; [3]Nutrition, National Institute of Nutrition, Hanoi, Vietnam

BACKGROUND AND OBJECTIVES
Understanding dietary patterns and their determinants is necessary to identify leverage points in food systems transformation that can help achieve sustainable healthy diets. Several METHODS exist to analyse dietary patterns, but it remains unclear which method is better at capturing the variation in food consumption among individuals and at clustering consumers with similar dietary patterns in a population. This study compares dietary patterns identified using two METHODS in the same population.
METHODS

Under the CGIAR initiative Sustainable Healthy Diets Through Food System Transformation (SHiFT), dietary intake data were collected using a multi-pass quantitative 24-hour recall in adolescents 11 to 19 years in low- to middle- income areas in small-town, peri-urban, and urban North Vietnam (n=2861). We compared dietary patterns identified using Latent Class Analysis (LCA) with patterns identified using Agglomerative Hierarchical Clustering (AHC). Healthiness of dietary patterns was evaluated as Global Diet Quality Score (GDQS-Healthy and GDQS-Unhealthy components; a higher score reflecting higher diet quality).

RESULTS

Using LCA, we identified five dietary patterns consumed by 26, 24, 20, 15 and 15% of the population. Pattern 5 had lowest consumption of healthy foods (GDQS-Healthy 5 out of 32; GDQS unhealthy 12 out of 17), and mainly consisted of rice and poultry. Pattern 3 had the highest consumption of unhealthy foods, with high intakes of soft drinks and sweets. Pattern 4 had high intakes of both healthy and unhealthy food groups (GDQS-Healthy 11, GDQS-Unhealthy 12), characterized by intakes of fish, eggs, and liquid oil. AHC also identified five patterns, consumed by 41, 30, 14, 8, and 7% of the population. Pattern 3 was the least healthy, both in its low intake of healthy and high intake of unhealthy food groups (GDQS Healthy 7, GDQS Unhealthy 9). Main food groups consumed were soft drinks, deep fried foods, and sweets. Pattern 4 was the healthiest (GDQS-Healthy 8, GDQS-Unhealthy 12), with high intakes of fruits, leafy vegetables, cruciferous vegetables, whole grains, and dairy.

CONCLUSIONS
The dietary patterns identified differed in cluster size, healthiness and food intake. With AHC, one pattern had poor diet quality based on both low intake of healthy foods and high intake of unhealthy foods, whereas with LCA these scores were divided over two distinct patterns. When analysing dietary patterns, RESULTS from data exploration guides method choices. We found comparing METHODS and understanding the consequences of underlying algorithms valuable to check their robustness before drawing CONCLUSIONS.

CURATIVE EFFECT OF ZINC-SELENIUM TEA ON RAT'S CARDIOTOXICITY INDUCED BY LONG-TERM EXPOSURE TO NONYLPHENOL

Jie Yu[1]; Jie Xu[1]
[1]School of Public Health, Zunyi Medical University, Zunyi, China

BACKGROUND AND OBJECTIVES

This study aimed to explore whether zinc-selenium tea has an curative effect on the cardiotoxicity induced by environmental endocrine disruptors-nonylphenol (NP), and to compare the effect of zinc-selenium tea and green tea.

METHODS

The rats were randomly divided into 4 groups (each group of 10): control group (C, corn oil), NP group (40 mg/kg), NP (40 mg/kg) + green tea group (1 g/kg) /d), NP (40 mg/kg) + zinc-selenium tea group (1g/kg/d). Rats were gavaged on an empty stomach once a day at 8:00, with a volume of 5ml/kg. All dose groups were gavaged with corn oil or drugs for 180 days.

RESULTS

After drinking of zinc-selenium tea or green tea, compared with the control group, the left ventricular anterior wall became thinner, and the left ventricular end-diastolic diameter increased, the anterior wall of the left ventricle became thin at the end of diastole in the NP group. The serum myocardial enzymes aspartate aminotransferase (AST), serum creatine kinase (CK), serum creatine kinase isoenzyme (CK-MB), lactate dehydrogenase (LDH) and α-hydroxybutyrate dehydrogenase (α-HBDH) in the NP group were significantly increased, and the serum myocardial enzymes were significantly decreased after the intervention of zinc-selenium tea. Proteins and mRNA expressions of CollagenI and Colagen III in the tea groups were lower than those in the NP group. In the green tea and zinc-selenium tea intervention groups, the disorder and degree of myocardial fiber were alleviated to varying degrees. The disturbance, breakage and inflammatory cell infiltration of myocardial fibers in zinc-selenium tea and green tea groups were less than that of NP group. After tea intervention, collagen I and collagenIII in the myocardium decreased. The intervention effect of zinc-selenium tea was better than that of green tea.

CONCLUSIONS

Zinc-selenium tea and green tea could interfere with the cardiotoxicity indued by NP, which would alleviate the myocardial fibrosis by reducing expressions of collagen I and collagen III. Moreover, the curative effect of zinc-selenium tea was better than that of green tea.

ASSOCIATIONS OF CIRCADIAN BEHAVIOUR INDEX WITH PLASMA GLYCEMIC PARAMETERS AND CONTINUOUS GLUCOSE MONITORING MEASURES AMONG PREGNANT WOMEN

Yu-En Chen[1]; Chee Wai Ku[2, 3]; Ruther Teo Zheng[4]; Jerry Kok Yen Chan[2, 3]; Fabian Yap[5, 4]; See Ling Loy[2, 3]; Ling-Wei Chen[1, 6]

[1]Institute of Epidemiology and Preventive Medicine, National Taiwan University College of Public Health, Taipei, Taiwan; [2]Department of Reproductive Medicine, KK Women's and Children's Hospital, Singapore, Singapore; [3]Academic Clinical Program, Duke-NUS Medical School, Singapore, Singapore; [4]Department of Paediatrics, KK Women's and Children's Hospital, Singapore, Singapore; [5]Lee Kong Chian School of Medicine, Nanyang Technological University (NTU), Singapore, Singapore; [6]Master of Public Health Program, National Taiwan University College of Public Health, Taipei, Taiwan

BACKGROUND AND OBJECTIVES

Disruptions in the alignment of food intake, exercise, sleep, and light exposure timing with the endogenous circadian clock are associated with metabolic disturbances[1]. This study examined the combined effects of these factors on glycemic regulation during pregnancy.

METHODS

In this prospective cohort study, 279 healthy pregnant women at 18-24 weeks' gestation completed 4-day food diaries and questionnaires assessing sleep, exercise, and media use. Glycemic outcomes included fasting, 1-hour and 2-hour plasma glucose levels, gestational diabetes mellitus (GDM) diagnosis via a 75-g oral glucose tolerance test at 24–28 weeks, and continuous glucose monitoring (CGM) metrics at 18–24 weeks. Skewed outcomes were log-transformed. The Circadian Behaviour Index (CBI) quantified temporal behaviour disruptions by assigning one point each for the following: night-eating (>50% of total daily energy intake after 7 P.M.)[2], eating jetlag (>1-hour difference in weekday-weekend first or last meal time)[3], short or excessive sleep (<7 or >9 hours)[4], social jetlag (>2-hour difference in weekday-weekend sleep midpoint)[5], excessive electronic media use before bedtime after 7 P.M. (≥ 3 hours)[6] and physical activity after 7 P.M. (≥10 minutes of any type of activities)[7]. Higher CBI scores (range: 0-6) indicated greater temporal behaviour disruptions. Multivariable linear and logistic regressions, respectively, assessed associations between CBI and continuous and binary glycemic outcomes.

RESULTS

The mean [standard deviation (SD)] CBI score was 1.82 (1.11), with 10% of participants scoring >3. After adjusting for covariates, each one-point increase in the CBI was associated with higher fasting glucose (FG) [geometric mean ratio (95% confidence intervals): 1.02 (1.01, 1.03)], 1-hour glucose [1.03 (1.00, 1.06)], and CGM metrics, including mean glucose (MG) [1.02 (1.00, 1.04)], glucose management indicator (GMI) [1.01(1.00, 1.03)], J-index [1.05 (1.01, 1.09)], and SD [1.04 (1.01, 1.08)]. No significant association was observed for GDM. When comparing extreme categories, women with CBI score >3 (vs. <1) had higher FG [1.06 (1.01, 1.11)], 1-h glucose [1.13 (1.01, 1.27)], MG [1.10 (1.01, 1.19)], GMI [1.06 (1.01, 1.12)], J-index [1.27 (1.05, 1.53)], %time>7.8 mmol/L [1.64 (1.07, 2.53)], and SD [1.26 (1.03, 1.54)].

CONCLUSIONS

Higher CBI scores were associated with a poorer glycemic profile during pregnancy, suggesting the importance of addressing rhythm-disruptive behaviours to optimize maternal glucose control.

EVALUATION AND COMPARISON OF THE AVAILABILITY AND HEALTHINESS OF BREADS, YOGURTS AND BREAKFAST CEREALS ACCORDING TO THEIR DEGREE OF PROCESSING IN THE USA AND FRANCE

Thais da Silva Marques; Ana Giulia Forjaz Grassi; Juliana Maria Goncalves Julio; Renata Bertazzi Levy; Fernanda Rauber

BACKGROUND AND OBJECTIVES

The increase in the consumption of ultraprocessed foods (UPFs) over recent decades has become a growing public health concern (Baker et al., 2020). Foods such as oats, natural yogurts, and simple breads have long histories of consumption across various culinary traditions, however, technological advancements have enabled the development of ultra-processed versions. The availability of less processed foods varies significantly across countries with differing cultural and regulatory contexts, such as France and the United States (US).This study aims to evaluate and compare the availability and the nutritional quality of ultra-processed breads, yogurts, and breakfast cereals with their less-processed versions in the US and French markets.

METHODS

Cross-sectional study using the Open Food Facts platform as a data source to obtain the list of food products. Data on breads, yogurts, and breakfast cereals registered on the Open Food Facts platform for United States and France through July 2024 were extracted. Eligible products had a unique code and available information on Nova classification, Nutri-Score score, nutritional composition and food additives. Data were expressed as absolute or relative frequencies for categorical variables, and continuous variables were presented as median and interquartile range (IQR).

RESULTS

The final sample included 28,490 products: 14,662 from the USA and 13,828 from France. Among them, 5,365 were breakfast cereals, 9,831 were yogurts, and 13,294 were breads. Most breakfast cereals and yogurts belonged to group 4, but less processed options were also present in both countries. For breads, group 4 dominated, though group 3 had significant representation, especially in France. Nutritional quality varied by Nova group. Over 90% of group 1 cereals received high Nutri-Score ratings (A or B), while over 70% of group 4 cereals fell into lower categories (C, D, E). Group 1 yogurts had high scores in both countries (92.3% USA, 70.5% France). Breads showed diversity: 62.1% of group 3 scored A or B in the USA versus 47.5% in France, while 59% of group 4 breads were A or B in both countries.

CONCLUSIONS

Based on the 28,490 products assessed, a significant proportion of these were found to be UPFs, especially in the USA. However, less processed alternatives were also present in both countries, particularly in France. These RESULTS highlight the importance of promoting less processed options to improve the nutritional quality of the diet.

IMPACT OF SERUM FOLATE CONCENTRATIONS DURING PREGNANCY ON OFFSPRING FOLATE STATUS: A PROSPECTIVE LONGITUDINAL STUDY

Marly Augusto Cardoso[1]
[1]Department of Nutrition, Universidade de São Paulo, São Paulo, Brazil

BACKGROUND AND OBJECTIVES

Folic acid supplementation (FAS) before conception and throughout pregnancy is widely used in prenatal care to prevent neural tube defects and gestational anemia. However, there is limited longitudinal data on maternal folate levels during pregnancy, and emerging evidence suggests that excessive folate during pregnancy may influence long-term health outcomes for both mothers (1) and offspring (2,3). This study examines the serum folate levels in pregnant women and their children in a cohort with mandatory folic acid flour fortification and FAS distribution through prenatal care.

METHODS

We enrolled pregnant women (mean age 24.7 years) and collected data on lifestyle factors, including FAS use (5 mg/day), and serum folate concentrations during the second and third trimesters, as well as at 1- and 2-year follow-ups for their offspring. Folate levels were measured using high-performance liquid chromatography. Folate deficiency was defined as serum folate < 4.4 ng/mL(4), and high folate concentrations as serum folate ≥ 21 ng/mL

RESULTS

Among the 497 women with available data, 372 (74.8%) reported FAS use, while 90 (15.3%) did not provide this information. Median (interquartile ranges, IQR) serum folate concentrations were higher among FAS users during the second (12.8 ng/mL, IQR 9.3-18.8) and third (10.1 ng/mL, IQR 7.3-14.2) trimesters compared to non-users (10.1 ng/mL, IQR 7.4-15.1; 8.6 ng/mL, IQR 6.1-12.9). FAS use was not associated with gestational morbidities, maternal anemia at delivery, or newborn birth weight. At the 1-year (n=225) and 2-year (n=211) follow-ups, only 2 and 1 children exhibited folate deficiency, while 23 (10%) and 40 (19%) children had high serum folate concentrations, respectively.

CONCLUSIONS

Mandatory folic acid fortification and supplementation significantly increase serum folate levels in both pregnant women and their children. However, the potential long-term effects of high folate concentrations on child health warrant further monitoring in longitudinal studies. These findings will help guide future recommendations for folic acid supplementation during pregnancy to optimize health benefits while minimizing risks of excessive folate exposure.

EFFECTS OF A HYPOCALORIC TIME-RESTRICTED FEEDING DIET PROGRAM ON SLEEP QUALITY, QUALITY OF LIFE, AND PERCEIVED STRESS IN INDIVIDUALS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE: A SECONDARY ANALYSIS OF A RANDOMIZED CONTROLLED TRIAL

Sofia Tsitsou[1]; Kalliopi-Anna Poulia[1]; Evangelos Cholongitas[2]; Emilia Papakonstantinou[1]
[1]Food Science and Human Nutrition, Agricultural University of Athens, Athina, Greece; [2]First Department of Internal Medicine, Laiko General Hospital of Athens, Medical School, National and Kapodistrian University of Athens, Athens, Greece

BACKGROUND AND OBJECTIVES

Time-restricted feeding (TRF) seems to have favorable effects on cardiometabolic risk factors in individuals with metabolic dysfunction-associated steatotic liver disease (MASLD); however, its effects on lifestyle parameters have not been studied yet in this population. This study aimed to investigate the impact of a hypocaloric TRF diet program on sleep quality, quality of life, and perceived stress in MASLD patients.

METHODS

This is a secondary analysis of a 12-week randomized controlled trial in MASLD individuals with overweight/obesity consisted of three groups, all following a hypocaloric Mediterranean-type diet: control (without any time restriction in feeding), early 14:10 (14 hours of fasting) TRF (eTRF, eating between 08:00-18:00), and late 14:10 TRF (lTRF, eating between 12:00-22:00). All participants filled out the Pittsburgh Sleep Quality Index (PSQI), the Chronic Liver Disease Questionnaire (CLDQ), and the 14-item Perceived Stress Scale (PSS) at baseline and 12 weeks.

RESULTS

Fifty-nine MASLD individuals (27 males, 45.8%; mean age 52.9 years; BMI 32.1 kg/m2) participated in the analysis (control, *n*=19; eTRF, *n*=20; lTRF, *n*=20). All groups achieved significant 12-week improvements in body weight and liver steatosis, but only the eTRF group improved glucose metabolism. The 3 groups did not differ in PSQI, CLDQ, and PSS scores at 12 weeks. The C improved the total CLDQ score and the sub-scores of abdominal symptoms, fatigue, and worry. The eTRF improved the total CLDQ score and the sub-scores of systemic symptoms and worry. The lTRF improved the score of systemic symptoms of the CLDQ; however, in this group, the PSQI score, also, improved at 12 weeks. Finally, in the lTRF, there was a positive correlation between the 0-12 weeks difference in 0-60 min area under the curve for glucose and the differences in sleep quality and PSS score. The lTRF had a higher difference of 0.302 units in sleep quality compared to the control.

CONCLUSIONS

A Mediterranean-type diet may lead to improvements in the quality of life in MASLD patients, with or without time restrictions in feeding. However, a later TRF protocol seems to have favorable effects on sleep quality.

EFFECT OF INTEGRATING HOUSEHOLD WATER TREATMENT AND HYGIENE PROMOTION INTO THE NATIONAL PROTOCOL FOR MANAGEMENT OF ACUTE MALNUTRITION OF SENEGAL – A CLUSTER-RANDOMISED CONTROLLED TRIAL

Laura Braun[1]; Matar Ba[2]; Emile Cabo[2]; Joseph Wells[1]; Francoise Siroma[2]; Yahya Gnokane[2]; Lapegue Jean[3]; Antonio Brizuela[4]; Charles Opondo[1]; Moustapha Seye[5]; Dieynaba Ndiaye[3]; Oliver Cumming[1]
[1]Disease Control, London School of Hygiene & Tropical Medicine, London, United Kingdom; [2]ACF, ACF Senegal, Dakar, Senegal; [3]ACF, ACF France, Paris, France; [4]ACF, Accion con, Madrid, Spain; [5]LARTES-IFAN, UCAD, Dakar, Senegal

BACKGROUND AND OBJECTIVES

Severe acute malnutrition (SAM) affects approximately 17 million children globally, increasing their susceptibility to disease and risk of mortality. The WHO recommends that uncomplicated SAM cases receive outpatient treatment under the Community-based Management of Acute Malnutrition (CMAM) approach. CMAM has reduced cost of treatment, increased coverage and improved outcomes, but recovery rates vary significantly across settings.

METHODS

The TISA study was a cluster-randomised trial to assess the effectiveness of combining a scalable water, sanitation and hygiene (WASH) kit within the standard CMAM protocol for uncomplicated SAM cases aged 6-59 months, in northern Senegal. 86 health centres were randomly allocated to a control group receiving the national CMAM protocol or to an intervention group receiving a "WASH kit" in addition to the standard protocol. The WASH kit included a plastic storage vessel for drinking water, a supply of chlorine tablets, soap, and instruction on water treatment and hygiene practices. Outcomes included SAM recovery, weight gain, referral to inpatient care, diarrhoea, and all-cause mortality.

RESULTS

2411 children diagnosed with uncomplicated SAM were enrolled. The proportion of children recovering from SAM was similar in the control (39.3%) and intervention groups (39.7%) and we found no evidence for a difference between arms (aOR 0.98, 95% CIs 0.66 – 1.45). Nurse-recorded recovery was higher in the intervention arm (60.0%) than the control arm (54.1%) but with no evidence for a difference (aOR: 1.08; 95%CIs: 0.72-1.64). Weight gain was greater in the intervention arm (4.38 g/kg/d) than the control arm (4.06 grams per kg per day [g/kg/d]) with no evidence of a difference between arms (difference in means 0.24; 95%CIs: -0.40 - 0.88). There was no evidence for a difference in mortality between arms. Caregiver-reported diarrhoea at 8-weeks follow-up was higher in in the control group (20.0%) than the intervention group (12.5%), with evidence for a difference between arms, accounting for between-group differences at baseline (aOR: 0.36; 95%CIs: 0.26 – 0.50).

CONCLUSIONS

The addition of a WASH kit and hygiene promotion to the CMAM protocol did not improve recovery nor related outcomes of weight gain and referral. The intervention did though reduce diarrhoea progressively at 4 and 8 weeks of follow-up. Our RESULTS suggest that the addition of a WASH kit to the standard protocol would not improve SAM outcomes in this setting but would potentially reduce the burden of diarrhoea among this vulnerable group.

BACKGROUND AND OBJECTIVES

Sedentary behaviours, such as excessive screen time, are associated with negative health outcomes in children. Adherence to the Mediterranean Diet (MD) is recognized for its protective role against cardiometabolic risk factors, but its relationship with sedentary behaviours in preschool children remains unclear. This study aimed to evaluate the association between adherence to the MD and sedentary behaviours in preschool children.

METHODS

This study included 1,414 preschool children from the CORALS cohort, a multicenter prospective study conducted in seven Spanish cities. Sedentary behaviour was defined as exceeding 60 minutes of daily screen time. It was assessed based on time spent watching television and using mobile devices or tablets, as reported by parents through a questionnaire. This threshold was established according to the World Health Organization (WHO) recommendations for preschool children, which advise less than one hour per day. Adherence to the MD was assessed using the MED4CHILD questionnaire, recently validated for preschool-aged children, with higher scores indicating greater adherence. Logistic regression models were used to evaluate the association between MD adherence score and sedentary behaviour, adjusting for age and maternal education. Separate analyses were conducted for boys and girls. All the statistical analyses were carried out using the SPSS statistical package (version 25.0, SPSS Inc., Chicago, IL, USA).

RESULTS

Higher adherence to the MD was associated with a reduced likelihood of sedentary behaviour in both boys and girls. Among boys, a one-unit increase in the MED4CHILD score was associated with an 18.3% reduction in the odds of being sedentary (OR = 0.827; 95% CI: 0.773–0.884; $p < 0.001$). Among girls, the reduction was 15.3% (OR = 0.847; 95% CI: 0.794–0.899; $p < 0.001$). Age was positively associated with sedentary behaviour in both groups, with older children exhibiting higher odds of being sedentary (boys: OR = 1.528; 95% CI: 1.291–1.808; girls: OR = 1.616; 95% CI: 1.375–1.899; $p < 0.001$). Maternal education was significantly associated with sedentary behaviour. Boys and girls with mothers having medium or high education exhibited higher odds of being sedentary compared to those with mothers having low education, with ORs ranging from 1.95 to 2.53 ($p < 0.001$).

CONCLUSIONS

https://doi.org/10.1017/jns.2026.10126 Published online by Cambridge University Press

Adherence to the MD is inversely associated with sedentary behaviours in preschool children, with similar effects observed in boys and girls. These findings highlight the importance of promoting healthy dietary patterns and limiting screen time from an early age.

EFFECTS OF EGG AS AN EARLY COMPLEMENTARY FOOD ON GROWTH AND DEVELOPMENT, MORBIDITY, ALLERGY AND NUTRITIONAL STATUS BIOMARKERS OF 6 TO 9-MONTH-OLD INFANTS: A RANDOMISED CONTROLLED TRIAL

Marius Smuts[1]; Linda Malan[1]; Hannah Ricci[2]; Regina Nakiranda[1]; Cristian Ricci[2]; Arista Nienaber,[1]; Herculina Salome Kruger[1]; Mieke Faber[1]
[1]Centre of Excellence for Nutrition, North-West University, Potchefstroom, South Africa; [2]Africa Unit for Transdisciplinary Health Research, North-West University, Potchefstroom, South Africa

BACKGROUND AND OBJECTIVES

Effects of egg as an early complementary food on growth and development, morbidity, allergy and nutritional status biomarkers of 6 to 9-month-old infants: A randomised controlled trial

METHODS

In a randomised controlled trial, we investigated the effects of daily egg provision (n=250) compared to no egg provision (n=250) among infants aged 6 to 9 months from a low socioeconomic community for 6 months during 2021 on linear growth and other growth parameters, gross motor milestones development, anaemia and iron status, incidence and duration of morbidity including COVID-19, allergic sensitisation and symptoms to eggs and other common allergenic foods.

RESULTS

Baseline prevalence of stunting, underweight, wasting, overweight and anaemia was 23.8%, 9.8%, 1.2%, 13.8%, and 29.2%, respectively, and did not differ between groups. There was no intervention effect on length-for-age, weight-for-age, weight-for length Z-scores, gross motor milestone development, anaemia, iron status or COVID-19 infection. There was a significant reduction in fibroblast growth factor 21 (FGF21) concentration in the intervention group (B=−0.132; 95% CI −0.255, −0.010; p=0.035). Baseline levels of fibroblast growth factor 21 (FGF21) and intestinal fatty acid-binding protein (I-FABP) were inversely associated with endpoint growth indicators. Gastrointestinal morbidity without fever tended to be 1.4 times higher in the intervention group (OR: 1.43, 95% CI: 1.03, 1.93; P=0.058) and 4 times higher with fever (OR: 4.07, 95% CI: 0.86, 19.23; P=0.077). At endpoint, egg sensitisation was observed in 1.9% of the egg intervention group and 2.0% of the control group (adjusted odds ratio [aOR]: 0.936; 95% CI: 0.229–3.822; p=0.926). Sensitisation to all foods occurred in 7.5% of the egg intervention group and 12.9% of the control group (aOR: 0.515; 95% CI: 0.264–1.005; p=0.052). The incidence of allergic disease during the study was 7.5% in the egg intervention group compared to 13.4% in the control group (p=0.069).

CONCLUSIONS

Complementary feeding with eggs did not improve linear growth and may increase gastrointestinal morbidity. However, the egg intervention reduced growth hormone resistance and decreased allergic sensitisation to common allergenic foods, suggesting it could be a promising approach if implemented carefully, accompanied by ongoing caregiver training on hygiene practices. It may also contribute to enhancing dietary diversity in these populations.

OAP3_01

ASSOCIATION OF CORD BLOOD VITAMIN D AND VDR/VDBP GENETIC POLYMORPHISMS WITH CHILDHOOD ALLERGY IN SHANGHAI, CHINA: A PROSPECTIVE COHORT STUDY

Xirui Wang[1]; Xiaodan Yu[1]
[1]Department of Developmental and Behavioral Pediatrics, Shanghai Children's Medical Center, Shanghai Jiao Tong University School of Medicine, Shanghai, China

BACKGROUND AND OBJECTIVES

The influence of early-life vitamin D on the development of childhood allergies remains a subject of debate. Polymorphisms in genes associated with the vitamin D pathway, specifically the VDR and VDBP genes, are hypothesized to modulate the effects of vitamin D in vivo. In our prior study, we observed that the concentration of 25-hydroxyvitamin D [25(OH)D] in cord blood was, on average, 9.2 ng/mL lower, representing an approximate 50% reduction compared to maternal levels. This study aims to investigate the associations between vitamin D exposure and genetic interactions pertaining to the VDR/ VDBP genes in the context of childhood allergy development.

METHODS

In a population-based cohort study comprising 826 participants, we examined the relationship between cord blood serum levels of 25(OH)D and the incidence of allergies at 6 months, 1 year, and 2 years of age. The concentrations of 25(OH)D were quantified using liquid chromatography-tandem mass spectrometry. The analyses were stratified according to genotypes of the vitamin D receptor (VDR) genes [rs1544410 (BsmI), rs731236 (TaqI), rs7975232 (ApaI)] and the vitamin D binding protein (VDBP) genes (rs4588 and rs7041).

RESULTS

A U-shaped relationship was observed between cord blood serum25(OH)D levels and the risk of developing childhood allergies. In infants with 25(OH)D levels below 15 ng/mL, the risk of total allergy status at two years of age increased as 25(OH)D levels decreased (Odds Ratio [OR] 1.50; 95% Confidence Interval [CI]: 0.99-2.34), particularly among those carrying the rs4588 CC genotype (OR 5.00; 95% CI: 1.20-20.83). Conversely, in infants with 25(OH)D levels exceeding 25 ng/mL, the risk of allergy increased with higher 25(OH)D levels (OR 1.78; 95% CI: 1.19-2.67), notably among those with the rs4588 AA genotype and the rs7041 TT genotype.

CONCLUSIONS

Both deficient and excessive vitamin D status during early life are associated with an increased risk of childhood allergies. Polymorphisms that influence vitamin D-binding protein (VDBP) levels modify the relationship between serum 25(OH)D concentrations and childhood allergy, suggesting enhanced vitamin D bioavailability in individuals with lower VDBP levels. This finding supports the biological plausibility of vitamin D's involvement in the pathogenesis of allergies.

NUTRITIONAL STATUS IS ASSOCIATED WITH COGNITION AND GRIP STRENGTH AMONG OLDER ADULTS: A 10 YEAR LONGITUDINAL STUDY IN GHANA AND SOUTH AFRICA

Karen Charlton[1]; Barbara Corso[2]; Kofi Awuviry-Newton[3]; Christopher Seth Appia[4]; Daniel Doh,[5]; Paul Kowal,[6]
[1]School of Medical, Indigenous and Health Sciences, University of Wollongong, Wollongong, Australia; [2]Neuroscience Institute, National Research Council, Padua, Italy; [3]Institute for Health and Sport, Victoria University, Melbourne, Australia; [4]Department of Sociology and Social Work, Kwame Nkrumah University of Science and Technology, Accra, Ghana; [5]School of Allied Health, University of Western Australia, Perth, Australia; [6]Australian National University, Centre for Health Workforce Studies, Canberra, Australia

BACKGROUND AND OBJECTIVES

A large body of works exists on the associations between nutritional status, cognition and grip strength globally. However, there is limited understanding of the nature of these associations among older African populations. The current study examines the association between nutritional status – and changes in cognition and grip strength among Ghanaian and South African older adults over time by using three waves of data from the WHO Study on global AGEing and adult health (SAGE).

METHODS

In total 6,242 and 3,623 adults aged 60+years were assessed from Ghanaian and South African datasets, respectively, extracted from the three waves of the SAGE study, conducted between 2007 and 2019. The 6-item Mini Nutritional Assessment – Short Form questionnaire – was used to evaluate nutritional status. The five cognitive performance tests comprising immediate and delayed verbal recall, forward and backward digit span and verbal fluency were used to compute cognitive status. Handgrip strength was evaluated by dynamometer performed twice for each hand. The baseline covariates included age, gender, marital status, education, location of residence, living conditions, alcohol use, tobacco use, dietary habits, physical activity, gait speed and chronic health conditions. Data were analyzed by one-way ANOVA and linear mixed models.

RESULTS

After adjusting for all significant covariates, participants at risk of malnutrition (Ghana 3.08 (SE=0.54), $p<0.0001$; South Africa 3.94 (SE=1.54), $p<0.0001$) and those with adequate nutritional status (Ghana 6.42 (SE=0.57), $p<0.0001$; South Africa 8.45 (SE=1.52), $p<0.0001$) had significantly higher cognitive scores compared to malnourished participants. In Ghana, significantly higher handgrip strength was measured in participants either classified as at-risk of malnutrition (1.46 (SE=0.47), $p=0.002$) or with adequate nutritional status (2.16 (SE=0.52), $p<0.0001$), compared to participants classified as malnourished. In South Africa, only those with adequate nutritional status had a higher handgrip strength (9.76 (SE=1.97), $p<0.0001$).

CONCLUSIONS

The study has confirmed a positive longitudinal association between nutritional status and both cognitive function and hand grip strength for older adults in Ghana and South Africa. These findings highlight the importance of nutritional interventions to promote access to adequate, nutritious diets as people in low and middle income countries age.

ASSOCIATION BETWEEN GUT MICROBIOTA DURING PREGNANCY AND THE DEVELOPMENT OF GESTATIONAL DIABETES MELLITUS

Xiaoyu Wang[1]; Yujie Xu[1]; Jingyuan Xiong[2]; Guo Cheng[1]
[1]Maternal & Child Nutrition Center, West China Woman's and Children's Hospital, Sichuan University, Chengdu, China; [2]West China School of Public Health and West China Fourth Hospital, Sichuan University, Chengdu, China

BACKGROUND AND OBJECTIVES

Gut microbiota plays an important role in regulating physiological functions of the host. However, the longitudinal association between the gut microbiome during pregnancy and gestational diabetes mellitus (GDM) remains unclear.

METHODS

Pregnant women who registered between 12 and 14 gestational weeks at a hospital in China between February 2022 and October 2023 were included. Stool samples were collected in each trimester and analyzed for 16s rRNA sequencing. Serum glucose, HbA1c, insulin were retrieved from the records in the Medica Birth Registry. GDM was defined by plasma glucose and OGTT test at 24-28 weeks of gestation using criteria recommended by the International Association of Diabetes and Pregnancy Study Groups. We used MaAsLin2 and linear mixed models to investigate the longitudinal association between gut microbiota abundance and host phenotypes, and employed generalized linear models to examine the role of gut microbiome changes during pregnancy on concurrent host phenotypes changes.

RESULTS

This study included 652 singleton pregnant women with an average age of 32.0 years, and the prevalence of GDM was 21.3%. Pregnant woman with GDM experienced a gradually reduction in microbiome diversity during pregnancy. After adjustment for maternal age, pre-pregnancy BMI and parity, an increase in abundance of *Nitrospirota*, *Nitrospiria*, *Nitrospira*, *Methylomirabilia*, and *Rokubacteriales* were associated with decreased HbA1c levels in mid-pregnancy (all $p<0.05$). Increased relative abundance of *Oscillospirales*, *Ruminococcaceae* and *Faecalibacterium* from early to mid-pregnancy was found to associate with decreased blood glucose levels at 1h of the OGTT in mid-pregnancy ($p<0.05$).

CONCLUSIONS

This study found that the microbial structure and transition during pregnancy was associated with glucose metabolism, which could provide a new strategy for early prevention of GDM.

BACKGROUND AND OBJECTIVES

Edible insects have been proposed as a novel and sustainable source of protein and other essential nutrients for human consumption but nutrient absorption efficiency is still uncertain. We investigated zinc absorption from house crickets (*Acheta domesticus*) in a single-center and single-blinded cross-over study with children aged 24-36 months old in Kenya from September-November 2021.

METHODS

Children were randomized to consume two different experimental meals labeled with stable isotopes of zinc (Zn) at two different days, separated by a wash-out period of one month. Primary endpoints were the differences in amount of absorbed zinc (AZ) from maize-based meals enriched with intrinsically 67Zn-labeled house crickets (2.61 mg Zn, n= 28) in comparison with meals enriched with 68Zn (low-enriched: 0.90 mg Zn, n= 29) ; high-enriched: 3.24 mg Zn, n= 28) or with intrinsically 67Zn-labeled low-chitin cricket flour (2.51 mg Zn, n= 25), whereas the secondary endpoints were the differences in fractional zinc absorption.

RESULTS

We found that AZ from meals with whole crickets (geometric mean: 0.36 mg; 95%CI: 0.30, 0.43) was 2.6 times higher than from low-enriched maize meals (0.14 mg; 0.11, 0.16; $P<0.001$), while it was not different from low-chitin cricket flour meals. Absorbed zinc from both cricket meals was higher than that from high-enriched meals. No severe adverse side events were reported.

CONCLUSIONS

We conclude that edible house crickets are a good source of well-absorbable zinc, and their increased consumption could contribute to the alleviation of zinc deficiency. This trial was registered at the Pan African Clinical Trials Registry as PACTR202104533831364.

EFFECTS OF FRONT-OF-PACKAGE LABELS FOR ADDED SUGARS AND NON-SUGAR SWEETENERS (NSS) ON PARENTS' PERCEPTIONS AND SELECTION OF FOODS AND BEVERAGES FOR THEIR CHILDREN

Allison Sylvetsky[1]; Mariana Fagundes Grilo[1]; James W. Krieger,[2]; Sydney Pryor[1]; Lindsey Smith Taillie[3]
[1]Department of Exercise and Nutrition Sciences, The George Washington University, Washington, United States of America; [2]School of Public Health, University of Washington, Seattle, United States of America; [3]Department of Nutrition, University of North Carolina in Chapel Hill, Chapel Hill, United States of America

BACKGROUND AND OBJECTIVES

Many countries have adopted FOPLs for added sugars, potentially increasing the use and selection of NSS-containing products. The U.S. Food and Drug Administration is considering FOPLs for added sugars but has yet to address NSS. This study aimed to evaluate effects of FOPLs for added sugars and NSS on U.S. parents' selection of foods and beverages for their children and their perceptions of products' healthfulness for children.

METHODS

Parents (n= 2,896) of children 2-12 years old from across the U.S. completed an online survey and were randomized to one of three treatment arms: control (n = 990), FOPL for added sugars (n = 949), or FOPLs for both added sugars and NSS (n = 957). Participants were shown four fruit drinks and four yogurts. For each set, one was unsweetened, one was sweetened with added sugars only, one with NSS only, and one with added sugars and NSS. Products in each set were shown in random order and had FOPLs per the participants' assigned treatment arm. Participants selected which product they would buy and which they considered the healthiest. Group differences were analyzed using proportions with 95% confidence intervals (CIs) for each treatment arm.

RESULTS

Participants exposed to both added sugar and NSS FOPLs were significantly more likely to choose the unsweetened fruit drink (58%, CI: 55–61) compared to the added sugar FOPL group (40%, CI: 36–43) and the control group (32%, CI: 29–35). For yogurt, 60% (CI: 57–64) of participants in the added sugar and NSS FOPL condition selected the unsweetened option, compared to 29% (CI: 26–32) in the added sugar FOPL group and 14% (CI: 12–17) in the control group. Additionally, participants in the added sugar and NSS FOPL condition were most likely to identify unsweetened products as the healthiest for fruit drinks (70%, CI: 67–73), compared to the added sugar FOPL group (46%, CI: 42–49) and the control group (37%, CI: 34–40). Similarly, for yogurts, participants in the added sugar and NSS FOPL condition identified the unsweetened option as the healthiest (76%, CI: 73–79), compared to the added sugar FOPL group (49%, CI: 46–52) and the control group (33%, CI: 30–36).

CONCLUSIONS

FOPLs for both added sugars and NSS resulted in a higher likelihood of identifying unsweetened products as the healthiest option and choosing them for their children, compared with either a FOPL for only added sugar or no FOPL. These findings are particularly relevant for countries adopting FOPLs, as they demonstrate that labeling both added sugars and NSS can encourage parents to choose healthier, unsweetened options for their children.

ADHERENCE TO FRENCH DIETARY GUIDELINES AND HYPERTENSION: INTERACTIONS WITH OTHER LIFESTYLE FACTORS IN THE E3N FRENCH PROSPECTIVE COHORT

Marques Chloé[1]; Frenoy Pauline[2]; Xuan Ren[2]; Severi Gianluca[2]; Francesca Romana Mancini[2]
[1]Université Paris-Saclay, UVSQ, Inserm, Gustave Roussy, CESP, Villejuif, France; [2]Université Paris-Saclay, UVSQ, Inserm, Gustave Roussy, Inserm, Villejuif, France

BACKGROUND AND OBJECTIVES

Diet is a modifiable risk factor of hypertension, such as other lifestyle factors (BMI, physical activity, or smoking). French dietary guidelines offer advice for a healthier diet. We aimed to study the association between adherence to these dietary guidelines and hypertension in the E3N (Etude Epidémiologique auprès de femmes de l'Education Nationale) French cohort, and to analyse interactions between adherence to these guidelines and other lifestyle factors.

METHODS

We studied 45 251 women of the E3N prospective cohort who completed a questionnaire on food consumption, BMI, physical activity, and smoking status in 1993. Adherence to French dietary guidelines was estimated using the simplified "Programme National Nutrition Santé - guidelines score 2" (sPNNS-GS2). We estimated the association between sPNNS-GS2 and hypertension using Cox proportional hazard models. We also studied interactions (on both additive and multiplicative scales) between sPNNS-GS2 and BMI, physical activity, and smoking status in relation to hypertension risk.

RESULTS

During follow-up (1993-2014), we identified 13 623 hypertension cases. We found a linear inverse association between sPNNS-GS2 and hypertension (HRoneSD [95%CI]: 0.92 [0.89; 0.95]). We observed a statistically significant multiplicative interaction between sPNNS-GS2 and BMI (pinteraction=0.026), and no statistically significant multiplicative interaction with physical activity and smoking status. We didn't observe statistically significant additive interactions with BMI, physical activity, and smoking status. When studying the combined variable of sPNNS-GS2 and BMI (both in two categories split along their median) in relation to hypertension, a high BMI (irrespective of sPNNS-GS2) was associated with a higher risk of hypertension than a low BMI (even with a low sPNNS-GS2): HRlowBMI/highsPNNS-GS2 as reference, HRlowBMI/lowsPNNS-GS2 [95%CI]: 1.08 [1.02; 1.14], HRhighBMI/highsPNNS-GS2 [95%CI]: 1.41 [1.34; 1.48], and HRhighBMI/lowsPNNS-GS2 [95%CI]: 1.50 [1.43; 1.59]. We also highlighted that a low sPNNS-GS2, compared to a high sPNNS-GS2, was more strongly associated with a higher risk of hypertension among current smokers (HRlowsPNNS-GS2 vs highsPNNS-GS2 [95%CI]: 1.14 [1.04; 1.25]) than among no of former smokers (HRlowsPNNS-GS2 vs highsPNNS-GS2 [95%CI]: 1.07 [1.02; 1.11]).

CONCLUSIONS

This study suggests that higher adherence to French dietary guidelines is associated with a reduced risk of hypertension and discusses the complex interactions between adherence to French dietary guidelines and other lifestyle factors in their relation with hypertension.

EXAMINING THE RELATIONSHIP BETWEEN MEDITERRANEAN DIET AND INFERTILITY AMONG US WOMEN: AN INVESTIGATION OF THE US NHANES

Angelina Baric[1]; Annika Bauer[1]; Anthea Christoforou[1]
[1]Kinesiology, McMaster University, Hamilton, Canada

BACKGROUND AND OBJECTIVES

Infertility, the inability to achieve pregnancy after 12 months or more of trying to conceive, affects 20-30% of women of reproductive age (1). Fertility is not only a key indicator of reproductive health but is also independently associated with increased psychological distress, economic strain, marital discord, and later-onset adult diseases. Reproductive outcomes can be influenced by lifestyle factors, including smoking, physical activity, and diet (2). There has been limited investigation which considers the role of dietary patterns on infertility. Previous investigations in the US has implicated the "fertility diet", high in healthy fats, vegetable protein, dairy, iron, and supplements, in lower odds of infertility (3). Similarly, adherence to a Mediterranean Diet (MD), a diet high in whole foods and healthy fats, and low in processed foods, dairy, and refined carbohydrates, was associated with improved fertility among Spanish women (4). This relationship has not yet been investigated in Western contexts. The primary aim of this study was to examine the association between MD adherence and infertility among a nationally representative sample of US women.

METHODS

Our study draws on data from the 2013/14 and 2015/16 National Health and Examination Survey, a nationally representative cross-sectional health survey of Americans. Dietary data collected by 24-hour dietary recall will be scored based on adherence to MD, using a literature-based scoring system. Participants were grouped into quartiles based on MD scores. Multivariable logistic regression analyses assessed the association between MD quartile and self-reported infertility, adjusting for age, race, income, education, smoking, birth control use, female hormone use, age at menarche, history of pelvic inflammatory disease (PID), body mass index (BMI), physical activity (PA), and total energy intake.

RESULTS

We found that infertility affected 13.15% of American women and was significantly associated with being older, married, higher income, history of PID, and less PA. Mean MD score among infertile women was 5.23, significantly lower than fertile women who scored a mean MD score of 5.46. In the fully adjusted model, being in the highest MD quartile compared to the lowest was significantly associated with lower odds of infertility (OR: 0.408; 95%CI: 0.209, 0.798).

CONCLUSIONS

This work highlights key, modifiable lifestyle factors contributing to reproductive health among women, providing important perspectives to inform current food policies as well as improve consumer guidance.

ASSOCIATION BETWEEN IRON DEFICIENCY ANEMIA AND GUT MICROBIOME COMPOSITION IN POSTPARTUM, MALNOURISHED LACTATING WOMEN IN PAKISTAN

Naveed Iqbal[1, 2]; Aneela Pasha[1]; Khan Waqasuddin; Amjid Umar[1]; Nisar Imran[1]; Fyezah Jehan[1]
[1]Paediatrics and Child Health, Aga Khan University, Karachi, Pakistan; [2]Biotechnology and Inforatics, FLS&I, BUITEMS, BUITEMS, Quetta, Pakistan

BACKGROUND AND OBJECTIVES

Anemia remains the most prevalent nutrition-related disorder among pregnant women in developing countries, significantly affecting maternal and child health. However, postpartum anemia, particularly in low-resource settings, remains underexplored despite its association with impaired quality of life, reduced cognitive function, emotional instability, depression, and other significant health challenges in women of reproductive age. This study investigates the impact of postpartum anemia on the gut microbial ecology of lactating women from a peri-urban setting in Pakistan.

METHODS

Stool samples from 150 lactating women were collected as part of the Mumta Lactating Women (LW) Trial. Microbiome profiling was conducted using shotgun metagenomic sequencing. Bray-Curtis dissimilarity quantified pairwise differences between microbiome samples, while PCoA reduced dimensionality to highlight distinguishing microbial features between healthy and anemic cohorts. Generalized linear models (GLM) identified associations between anemia and microbial taxa and pathways. Random Forest (RF) machine learning was applied to uncover microbiome predictors of postpartum anemia.

RESULTS

Stool samples from 144/150 women (healthy: 36, anemic: 108) passed QC. Shannon diversity analysis showed significantly reduced microbial diversity in anemic mothers ($p = 0.0063$), reflecting taxonomic dysbiosis with decreased richness and evenness. Prevotella copri was the most abundant species across cohorts, with higher relative abundance in healthy mothers. Bray-Curtis dissimilarity and PERMANOVA revealed moderate ecological disruptions in anemic microbiomes (beta-diversity, $p = 0.083$). Escherichia coli and Bifidobacterium longum were key contributors to microbial community structure. Differential analysis identified ~15 species enriched in healthy mothers, including Acetatifactor spp., Olsenella spp., and Parabacteroides distasonis, while these taxa were diminished in anemic mothers. RF modelling highlighted Acetatifactor spp., Prevotella spp., and Olsenella spp. as top predictors of postpartum anemia (AUC = 0.814).

CONCLUSIONS

Postpartum iron deficiency anemia in malnourished LW is associated with microbial dysbiosis, reduced diversity, and compositional shifts in the gut microbiome. Key microbial signatures, including *Acetatifactor spp.*, *Prevotella spp.*, and *Olsenella spp.*, show potential as predictive biomarkers for anemia. These findings underscore the need for microbiome-targeted therapeutic interventions to address anemia in low-resource settings.

THE USE OF FOOD FREQUENCY QUESTIONNAIRE DATA IN SUBSTITUTION MODELLING: QUESTIONABLE VALIDITY OF FINDINGS

Jimmy Chun Yu Louie[1]; Jahar Bhowmik[2]
[1]Department of Allied Health, Swinburne University of Technology, Hawthorn, Australia; [2]Department of Biomedical, Health and Exercise Sciences, Swinburne University of Technology, Hawthorn, Australia

BACKGROUND AND OBJECTIVES

Food Frequency Questionnaires (FFQs) are widely utilized in large-scale cohort studies for their practicality in assessing long-term dietary intake. However, FFQs have notable limitations, including recall bias, imprecise portion size estimation, and systematic errors in nutrient reporting. These issues raise concerns about the validity of FFQ data when used in substitution modelling, a method that estimates the effects of hypothetically replacing one food or nutrient with another. We critically examined the appropriateness of using FFQ data in substitution modelling and aim to highlight the potential statistical challenges and inaccuracies that may arise from this practice.

METHODS

We analyzed the statistical challenges associated with FFQ measurement errors, including violations of parametric assumptions, distortions in dose-response relationships, and inaccuracies in estimating individual dietary intake. A literature search of studies published between January 2018 and September 2023 using the search terms ("food frequency questionnaire" OR "FFQ") AND "substitution". A simulated example was used to demonstrate the impact of these errors on substitution analysis outcomes, specifically examining how FFQ data with moderate correlation to true intake influences the detection of significant associations.

RESULTS

The literature search identified 63 studies. After screening, 51 studies were confirmed to have used FFQ data in substitution modelling, with 35.3% and 52.9% published in Science Citation Index (SCI)-Q1 and Q2 journals, respectively. The validity of the FFQs in most of these studies was generally fair to moderate, with over half focusing on substitution variables that were not properly validated. The simulation revealed that FFQ data, even when moderately correlated with true dietary intake, could fail to identify significant associations in substitution analysis.

CONCLUSIONS

Our finding suggests that using FFQ data in substitution modelling can lead to incorrect CONCLUSIONS, potentially compromising the validity of research outcomes that inform dietary guidelines. It is crucial to interpret the RESULTS of such studies with caution. We recommend a re-evaluation of existing literature that relies on FFQ-based substitution models and suggest that future research prioritize quantifying the extent of errors associated with FFQ data to improve the reliability of nutritional research.

DOES BODY COMPOSITION IMPACT ESTIMATION OF RESTING METABOLIC RATE IN OLDER ADULTS?

Judi Porter[1]; Leigh Ward; Kay Nguo[2]; Zoe Davidson[2]; Simone Gibson[2]; Ross Prentice[3]; Marian L Neuhouser[3]; Helen Truby[4]
[1]Institute for Physical Activity and Nutrition, Deakin University, Melbourne, Australia; [2]Department of Nutrition, Dietetics and Food, Monash University, Clayton, Australia; [3]Division of Public Health Sciences, Fred Hutchinson Cancer Center, Seattle, United States of America; [4]School of Human Movement and Nutrition Sciences, University of Queensland, Brisbane, Australia

BACKGROUND AND OBJECTIVES

As body composition changes during ageing, the inclusion of body composition measures as a variable within predictive equations for resting metabolic rate (RMR) may improve predictive accuracy. This analysis aimed to develop new RMR equations for adults (≥65 years) incorporating variables for body composition, to predict performance and accuracy of these equations.

METHODS

Using an international dataset (n=1238), including WHI and CLEVER studies, RMR was predicted from potential predictive variables using stepwise multiple regression. Predictive performance of the final model was assessed using double cross validation and compared with published equations from similar populations. Direct associations between the determined predictor variables and RMR with indirect effects mediated via fat free mass (FFM) was examined using mediation (or pathway) analysis.

RESULTS

The new equations performed similarly to some published anthropometric-based prediction equations. Predictors using FFM performed marginally better than those using lean body weight (LBW). All variables had significant direct effects upon RMR and significant indirect effects for sex, weight and height ($p<0.001$).

RMR = 8.645 * Height (cm) + 23.684 * Weight (kg) - 29.717 * Age (y) + 38.213 * FFM (kg) + 209.637 * Sex (M=1, F=0) + 2693.223

RMR = -30.570 * Age (y) + 80.736 * LBW (kg) - 186.825 * Sex (M=1, F=0) + 3956.822

CONCLUSIONS

Both equations predict RMR at the population level with minimal bias, however the difference in performance with anthropometry-based equations was minimal. This may be explained by the contribution of FFM to weight, whereby equations that include weight already account for FFM.

METABOLIC DYSFUNCTION IN INDIAN ADOLESCENTS AND ITS ASSOCIATION WITH BODY FAT AND HEPATIC ADIPOSITY

Shalini Hegde[1]; Shreyas Reddy[2]; Babu Phillip[2]; C Roopashree[3]; Anura Kurpad[4]; Pratibha Dwarkanath[3]
[1]Pediatric Surgery, St John's Medical College Hospital chapel, Bengaluru, India; [2]Radiology, St. John's Medical College Hospital, Bengaluru, India; [3]Nutrition, St. John's Research Institute, Bengaluru, India; [4]Department of Physiology, St. John's Medical College, Bengaluru, India

BACKGROUND AND OBJECTIVES

India has a high burden of metabolic disease in adulthood, attributed to a higher body fat percentage for a given BMI compared to the Western populations, and also to increased liver fat. While a high number (about 50%) of Indian children aged 5-19 years have recently been shown to have ≥1 biomarker (high plasma glucose, cholesterol, triglycerides and high blood pressure) of chronic disease risk at all BMI ranges, possibly due to increased body fat, it is unclear if there is simultaneous hepatic adiposity at young age as well. This study aimed to determine whether Indian adolescents develop increased liver and body fat simultaneously with biomarkers of metabolic dysfunction.

METHODS

Detailed anthropometry was performed in otherwise healthy adolescents along with the measurement of seated blood pressure. Measurements of metabolic dysfunction (fasting glucose, lipid profile and liver function tests) were made in a fasting blood sample. Hepatic fat was measured by MRI proton density fat fraction (PDFF) using a 3.0 T system (GE Signa Architect) and a 3D volumetric, <16sec breath hold sequence as well as by Ultrasound Guided Attenuated Parameter (UGAP) using LOGIQ E10 ultrasound system (GE Healthcare). Body fat was measured by DXA.

RESULTS

Forty adolescents (26 boys, 14 girls) were recruited with a mean age of 14.3 ± 1.5 years. 25% were overweight with a BMI-for-age >90th percentile. At least one biomarker of metabolic dysfunction was seen in 55% of the children; 10% had a waist-to-height ratio of >0.5, while 22.5 % had an HDL ≤ 40 mg/dl, 12.5% a TG ≥ 130 mg/dl and 17.5% had impaired fasting glucose. All children were normotensive with a BP < 130/80 mmHg. Their average body fat percentage was 22.7 ± 3.1 % (Range 19.2 – 29.0%), while the prevalence of fatty liver, as detected by MRI-PDFF and UGAP imaging, was 5%. The latter was present in the participants without an increase in blood biomarkers of metabolic dysfunction. There was no relation between BMI, percent body fat or liver fat.

CONCLUSIONS

While there is a high prevalence of metabolic dysfunction in Indian adolescents, as found in an earlier national Indian survey, this is not explained by total body or hepatic adiposity. Conversely, high liver or body fat is not accompanied with biomarkers of metabolic risk. Unlike in adults, anthropometric measures and metabolic biomarkers show no clear linkage at this age.

SIMULATION OF THE IMPACT OF FERMENTATION DURING INJERA PREPARATION ON ESTIMATION OF FOLATE AND COBALAMIN ADEQUACY IN THE ETHIOPIAN CONTEXT AND ITS CONSEQUENCES

Eric Verger[1]; Sonia Fortin[2]; Aynadis Tamene[3]; Henok Ashagrie[2]; Claire Mouquet-Rivier[2]; Christele Humblot,[2]
[1]Moisa, Institut de Recherche pour le Développement (IRD), Montpellier, France; [2]UMR QualiSud, Equipe 6 - Aliments, Nutrition et Santé, Institut de Recherche pour le Développement (IRD), Montpellier, France; [3]Center for Food Science and Nutrition, College of Natural and Computational Sciences, Addis Ababa University, Addis Ababa, Ethiopia

BACKGROUND AND OBJECTIVES

B-vitamin content of plant-based foods can be deeply modified by fermentation, especially for active cobalamin form. In many food composition tables, cobalamin values are likely to be considered zero by default, even in fermented products of plant origin, which may lead to overestimating the prevalence of inadequate intakes in contexts where fermented products are consumed as staple foods. Injera is a fermented flatbread widely consumed in Ethiopia, and the production of the active form of cobalamin through fermentation have been demonstrated at laboratory scale. The aim of this study was to measure the difference between estimates of folate and cobalamin intake adequacy depending on whether or not the impact of fermentation during injera preparation is considered.

METHODS

This was done using secondary quantitative 24-hour recall data from a survey on 164 non-pregnant and 159 pregnant women in Ethiopia and measures of folate and cobalamin content from the literature (1-3). The usual intake distribution of folate and cobalamin was estimated using the multiple source method and the EAR-cut-point method was used to estimate the prevalence of inadequate intakes of folate and cobalamin among the participants.

RESULTS

The observed dietary pattern was characterized by a plant-based diet, and the average consumption of injera was 170 g/d among the total sample and 442 g/d among the consumers only (38% of the total sample). The observed diet was associated with high prevalence of inadequacy in pregnant and non-pregnant women for folate (99.4% and 86.6%, respectively) and cobalamin (97.5% and 98.8%, respectively). In our simulations, we showed that increasing folate concentrations can reduce inadequacy estimates to 67% in non-pregnant women but not in pregnant women, while increasing cobalamin concentrations can reduce inadequacy estimates to 64% in non-pregnant women and 54% in pregnant women.

CONCLUSIONS

Considering the impact of fermentation during injera preparation had major consequences on estimates of folate and cobalamin adequacy in the Ethiopian context, which should be extended to other contexts where fermented foods are consumed as staple foods.

ASSESSING THE LEVELS OF NUTRIENT OF CONCERN IN COMMERCIALLY PRODUCED COMPLEMENTARY FOOD FOR INFANTS AND YOUNG CHILDREN ACROSS SIX WEST AFRICAN COUNTRIES

Aïcha Diongue[1]; Olouwafemi Mistourath Mama[1]; Mane Hélène Faye[1]; Adama Diouf[1]; Nicole Idohou-Dossou[1]; Arnaud Laillou[2]; Simeon Nanama[2]
[1]Laboratoire de Recherche en Nutrition et Alimentation Humaine, Faculté Sciences et Techniques, Universite Cheikh Anta Diop (UCAD), Dakar, Senegal; [2]Nutrition Section, UNICEF West and Central Africa Regional Office, Dakar, Senegal

BACKGROUND AND OBJECTIVES

Complementary foods for infants and young children (IYC) must provide essential nutrients in adequate quantities to support their development and well-being. However, commercially produced complementary foods (CPCFs) are increasingly preferred over home-prepared foods, due to their convenience and apparent safety, despite concerns about their nutritional quality. This study aimed to assess the nutritional quality of CPCFs sold in West African countries.

METHODS

This cross-sectional, descriptive study was conducted from August to October 2023 on CPCFs available in Benin, Mali, Mauritania, Niger, Senegal, and Togo. An exhaustive inventory of CPCFs was carried out in 315 sales outlets in these 6 countries. The levels of nutrients of concern (sugar, fat, and sodium) were recorded based on the information available on the product labels and compared with the European Nutrient and Promotional Profile Model (NPPM) recommendations. In addition, an interview survey was conducted among 736 mothers/caregivers enrolled at the exit of some of these outlets to determine whether nutritional information on product labels influenced their purchasing decisions.

RESULTS

A total of 659 products were identified, of which 77.7% were imported. Cereals (37.7%) and purees (25.9%) were the most common product categories, while snacks accounted for only 3.9%. Of the total of products collected, 6.5%, 17%, and 23.4% did not mention the total sugar, fat, and sodium content, respectively, on their labels. Compared to NPPM guidelines, 44.3% and 19.3% of products exceeded the recommended maximum thresholds for sodium and fats, respectively. Additionally, 41.6% exceeded the maximum recommended percentage of energy from sugars, and 33.7% contained added sugar. The interview RESULTS showed that only 13.8% of purchasers chose products on the basis of nutritional value, compared with 42.2% who do on personal preference and 31% on price.

CONCLUSIONS

This study highlights significant concerns regarding the nutritional quality of commercially produced complementary foods. It also shows that mothers/caregivers do not necessarily prioritize nutritional content when purchasing these products, despite their concerning nutritional profiles.

EARLY EFFECTS OF A SUGAR-SWEETENED BEVERAGE TAX ON CONSUMER BEHAVIOUR AND PUBLIC PERCEPTIONS: EVIDENCE FROM A NATIONAL SURVEY

Akua Tandoh[1]; Gideon Amevinya[2]; Annabel Yeboah-Nkrumah[1]; Silver Nanema[1]; Alice Sallar Adams[1]; Alex Kombat[3]; Daniel Nuer[4]; Emma Ofori Agyemang[5]; Percy Agyekum[6]; Mary Mpereh[7]; Sebastian Sandaare[8]; Amos Laar[1]

[1]Department of Population, Family and Reproductive Health. School of Public Health, University of Ghana, Accra, Ghana; [2]UMR MoISA , Research and Development Institute IRD Montpellier, Montpellier, France; [3]Research and Policy, Ghana Revenue Authority, Accra, Ghana; [4]Tax Policy Unit, Ministry of Finance, Accra, Ghana; [5]Policy, Planning, Monitoring and Evaluation, Ministry of Health, Accra, Ghana; [6]Food Evaluation and Registration Department, Food and Drugs Authority, Accra, Ghana; [7]Gender, Population and Social Policy, National Development Planning Commission, Accra, Ghana; [8]CAPHA, Coalition of Actors for Public Health Advocacy, Accra, Ghana

BACKGROUND AND OBJECTIVES

In 2023, Ghana, a sub-Saharan African country implemented a 20% excise duty tax on the price of sugar-sweetened beverages (SSBs) as part of wider efforts to reduce the purchase and consumption of such beverages and address the increasing burden of diet-related non-communicable diseases. This study assesses the early effects of this fiscal intervention on consumer purchasing and consumption behaviour and public perceptions of the tax.

METHODS

A cross-sectional survey using face-to-face interviews was conducted with a nationally representative sample (n= 2468; 18 years and above) in September 2024. Data were collected and analysed on SSB consumption patterns, awareness of associated health consequences, awareness of the SSB tax, and consumer reactions to price changes, including purchasing habits and beverage choices.

RESULTS

Most respondents (42.5%) reported consuming SSBs one to two times a week, with fewer (5.6%) consuming them daily. The study also found a high level of awareness among respondents (82.9%) regarding the health consequences associated with excessive SSB consumption. Overall, 84.4% had noticed an increase in the price of SSBs since April 2023 when the tax was implemented. In response to the tax's effect on product prices, 49.6% of respondents reported reducing their SSB purchases, and 31.3% reported switching to water or fresh fruits. While there was an almost even split in awareness among respondents of the SSB tax itself (47.1% aware vs. 52.9% unaware), majority of respondents (71.2%) still believed the tax was a good measure to improve public health.

CONCLUSIONS

The findings suggest that the SSB tax is influencing consumer behaviour and is broadly supported as a public health measure. To maximise the long-term influence of the tax on SSB purchase, consumption and related health outcomes, continued monitoring and public education campaigns are essential. The findings highlight the potential of SSB taxation to promote public health and may inform similar fiscal interventions in other low-to-middle-income country settings.

CAN NUTRIENT ICONS AND EMOTICONS ON FRONT-OF-PACK NUTRITION LABELS (FOPNLS) FACILITATE THE SELECTION OF HEALTHIER PACKAGED FOODS AMONG CONSUMERS WITH LIMITED EDUCATION?

RICHA PANDE[1]; G. Bhanuprakash Reddy[2]; Subbarao M Gavaravarapu[3]; Bharati Kulkarni[4]
[1]MATERNAL AND CHILD HEALTH, NUTRITION, ICMR - National Institute of Nutrition, Hyderabad, India; [2]BIOCHEMISTRY DIVISION, ICMR - National Institute of Nutrition, Hyderabad, India; [3]NUTRITION INFORMATION, COMMUNICATION & HEALTH EDUCATION (NICHE), ICMR - National Institute of Nutrition, Hyderabad, India; [4]Reproductive, Child Health & Nutrition (RCN), Division, Indian Council of Medical Research Headquarters, New Delhi, India

BACKGROUND AND OBJECTIVES

FOPNLs are considered an important nutrition education tool globally to educate consumers and reduce the consumption of unhealthy packaged foods.Many FOPNLs are aimed at literate individuals, limiting their accessibility to disadvantaged population groups. This research aims to evaluate whether using nutrient icons and emoticons can make FOPNLs accessible for individuals with minimal or no formal education.

METHODS

The study was conducted in Rangareddy District, Telangana.It compared the Food Safety and Standards Authority of India-proposed FOPNL,featuring red and white blocks to indicate high and normal nutrient levels, to two other developed formats: Format 2 with nutrient icons in each block, and Format 3, in which red and white blocks were replaced with emoticons. Nutrient profiling of locally available packaged foods was conducted using the WHO SEARO Profiling Model to develop FOPNLs. Participants were randomly assigned an FOPNL format and made food selections based on the assigned format. In Activities 1 and 2, they chose one product out of five in each category-first without and then with instructions to select the healthier option. Activity 3 required identifying products with excessive content of a specific nutrient. For identification of healthy products each time, participants were awarded +10 score. All the participants also rated the three FOPNLs based on how simple they were to underdtand.The total quiz scores of all the three activities were compared using ANOVA post-hoc tests with Tukey-Kramer adjustment on IBM SPSS.

RESULTS

In total, 148 individuals participated in the study: Group1(n=59), Group2(n=45), and Group3(n=44).FOPNL 3 with emoticons was rated as easiest to understand by two groups (group2=57%;groupt3=58%), but activity-wise total scores indicate Format 2 was most effective in assisting the participants for choosing healthier foods (group 1 total quiz score =41.69±15.8; group 2 total quiz score =71.5±16.6; and group 3 total quiz score =53.41±18.0) [all p-values <0.001].

CONCLUSIONS

The research demonstrates effectiveness of modified FOPNLs on packaged foods for assisting individuals with limited education in making healthy food choices.

ASSOCIATIONS BETWEEN NUTRITION KNOWLEDGE, HOUSEHOLD FOOD INSECURITY AND DIET QUALITY AMONG ADOLESCENTS IN URBAN AND RURAL FOOD ENVIRONMENT IN KENYA

Nicanor Odongo[1, 2]; Irmgard Jordan,[1]; Francis Oduor[1]; Tosin Akingbemisilu[1]; Irene Induli[1]; Sam Bodjrenou[3]; Kiio Juliana,[4]; Teuber Ramona,[2]; Céline Termote,[1]
[1]Food environment and consumer behaviour, Alliance of Bioversity Interntaional and CIAT, Nairobi, Kenya; [2]Institute of Agricultural Policy and Market Research, Justus-Liebig-Universität Giessen, Giessen, Germany; [3]Food Environment and Consumer Behavior Department, Alliance of Bioversity international and CIAT, Cotonou, Benin; [4]Department of Food, Nutrition and Dietetics, Kenyatta University, Nairobi, Kenya

BACKGROUND AND OBJECTIVES

The prevalence of overweight and obesity among adolescents has been rising globally, increasing their vulnerability to non-communicable diseases (NCDs). A nutrition transition towards nutrient-poor, energy-dense diets has fuelled this trend. In sub-Sahara Africa, limited research exists on adolescents' diet quality (DQ) and its determinants in rural and urban areas. This study assessed the association between adolescents' nutrition knowledge (NK), food insecurity (FI) and DQ across Kenya's urban and rural food environments (FE).

METHODS

A cross-sectional survey was conducted among 210 and 610 Kenyan adolescents in rural and FE respectively. Interviews assessed the adolescents' NK, focussing on foods that contribute to or protect against NCD risk. Household FI was assessed using the Food Insecurity Experience Scale. Diet quality was assessed through a 24-hour repeated dietary recall, analysed based on Global Diet Quality Scores (GDQS). The computation included Overall GDQS, GDQS+ and GDQS- representing overall DQ, healthy food consumption and unhealthy food consumption, respectively. Associations were tested using linear regression in R.

RESULTS

The overall GDQS was significantly higher among rural adolescents (RA) (rural: 19.02±3.13; urban: 16.05±3.54, $p < 0.001$). Similarly, GDQS+ was significantly higher among RA (rural: 7.00±2.71; urban: 5.73±2.98, $p<0.001$). Urban adolescents (UA) consumed more unhealthy foods, as indicated by significantly low GDQS- scores (rural: 12.01±1.49; urban: 10.32±1.75, $p<0.001$). Urban adolescents had significantly ($p<0.001$) higher nutrition knowledge than RA. Among RA, knowledge of foods contributing to NCD risk showed a positive association with the overall GDQS ($\beta = 0.4330$, $p<0.001$) and GDQS+ ($\beta = 0.3325$, $p<0.001$). However, there was no significant association with GDQS-. Knowledge about vitamins and minerals relevant for nutritional health among RA showed no significant associations with consumed diet. Knowledge of foods contributing to NCD risk showed a negative association with GDQS- score (β=-01190, $p<0.0.05$). Food insecurity had a negative association with the GDQS+ score among UA (β= -0.1033, $p<0.001$).

CONCLUSIONS

Adolescent diets, particularly in urban areas, are of low quality. Therefore, targeted policy interventions are needed to improve DQ and promote adolescent health. Knowledge of foods contributing to NCD risks showed a significant association with DQ and could enhance nutrition advocacy messaging aimed at improving DQ among adolescents.

ASSOCIATION AND LONGITUDINAL EFFECTS OF DIET QUALITY ON HEALTHY AGING - FOCUS ON CARDIOMETABOLIC HEALTH - FINDINGS FROM THE CANADIAN LONGITUDINAL STUDY ON AGING (CLSA)

Farhad Vahid[1]; Piotr Wilk[2]; Torsten Bohn[1]
[1]Department of Precision Health, Luxembourg Institute of Health, Strassen, Luxembourg; [2]Department of Epidemiology and Biostatistics, Western University, London, Canada

BACKGROUND AND OBJECTIVES

Healthy aging is a pressing public health issue, with diet playing a critical role in mitigating health outcomes, including cardiometabolic diseases such as hypertension (1-3). This study investigated the longitudinal association between diet quality and healthy aging, using data from the Canadian Longitudinal Study on Aging (CLSA) (4, 5), a database comprising >50,000 participants from all parts of Canada. We hypothesized that especially a higher Mediterranean Diet Score (MDS) would be associated with improved blood pressure measurement (BPMs) over time.

METHODS

CLSA participants aged 45-85 years at baseline were followed for up to nine years. MDS (6) was based on responses to the Short Diet Questionnaire (SDQ), a validated tool that provided an overview of individual dietary habits (7). Systolic/diastolic blood pressures (SBP/DBP) were measured, and Mean Arterial Pressure (MAP) was calculated as DP + 1/3(SP – DP) (8) at three-time points: baseline (2010), follow-up 1 (2015), and follow-up 2 (2018). Linear mixed models (LMMs) and latent change score models (LCSMs) were employed to examine the association and longitudinal effect of MDS on MAP, adjusting for age and sex, among others. The latent variables MDS_change1 and MDS_change2 represent the changes in the MDS at follow-up 1 and follow-up 2, respectively, while MAP1 and MAP2 represent the MAP at the same time points. These latent variables were scaled to 1, i.e., their variances were fixed as reference points to allow estimating changes in MDS and MAP over time.

RESULTS

25,377 participants completed all three waves and were included. A 1-unit increase at baseline in MDS (out of a maximum of 50) was associated with a 0.065 mmHg reduction in MAP (coefficient = -0.065); older age was linked to a 0.048 mmHg increase in MAP/year (coefficient = 0.048), and male sex was associated with 3.999 mmHg higher MAP vs. females. For MAP1, sex remained a significant predictor, but changes in MDS and age at follow-up 1 were not. For MAP2, a significant negative association was found between changes in MDS and MAP, with each 1-unit increase in MDS_change2 linked with a reduction in MAP by 0.039 mmHg. Similar significant RESULTS were found for DBP and SBP.

CONCLUSIONS

Higher adherence to the MD was associated with lower BPMs over time, even after controlling for confounding variables. The study highlights the importance of diet quality in promoting healthy aging and mitigating cardiometabolic risk, emphasizing the benefits of dietary interventions for reducing the burden of chronic diseases in aging populations.

TRAQQ: AN INNOVATIVE ECOLOGICAL MOMENTARY DIETARY ASSESSMENT APP; A POTENTIAL NEW TOOL FOR CROSS-COUNTRY DIETARY DATA COLLECTION

Desiree Lucassen[1]; Hanne De Jong[1]; Michelle Van Alst[2]; Edith Feskens[1]
[1]Division of Human Nutrition and Health, Wageningen University & Research, Wageningen, Netherlands;
[2]Human Nutrition and Health, Wageningen University & Research, Wageningen, Netherlands

BACKGROUND AND OBJECTIVES
Current dietary assessment METHODS are prone to memory-related bias and heavily burden respondents. To address these limitations, we developed Traqq, an innovative ecological momentary dietary assessment (EMDA) smartphone app that enables (near) real-time dietary assessment. Specifically, we implemented a 2-hour recall (2hR) methodology to reduce reliance on memory and lower respondent burden. This work focuses on validating the 2hR method against traditional 24-hour recalls (24hRs) and objective biomarkers. As Traqq's flexible design also allows customization for diverse research objectives, including adaptation to different countries. We also propose a standardized approach to adapt Traqq for use in different countries, including a usability evaluation.
METHODS

The 2hRs were validated in 215 Dutch adults on 6 randomly selected non-consecutive days (i.e., 3 2hR-days and 3 24hRs) during a 4-week period. Sixty-three participants provided 4 24-h urine samples, to assess urinary nitrogen and potassium concentrations. In addition, a standardized process was applied, in consultation with local nutrition experts, encompassing: 1) development of country-specific food lists, 2) creation of country-specific portion size suggestions, 3) translation of the app, and 4) integration, pilot testing, and refinement. System usability scale (SUS) was used to assess usability of each version.

RESULTS

Intake estimates of energy (2052±503 kcal vs. 1976±483 kcal) and nutrients (e.g., protein: 78±23 g vs. 71±19 g; fat: 84±30 g vs. 79±26 g; carbohydrates: 220±60 g vs. 216±60 g) were slightly higher with 2hR-days than with 24hRs. Comparing self-reported protein with urinary protein indicated a slightly higher accuracy of 2hR-days than 24hRs (−14% vs. −18%). The adaptation process resulted in the development of Traqq versions for Austria, Belgium (Flanders), Denmark, Finland, Germany, Greece, Norway, Poland, Spain, Sweden, and Switzerland (German). User evaluation showed an above-average usability for most versions (SUS>68).

CONCLUSIONS

Comparing 2hR-days with 24hRs showed a relatively similar group-level bias for energy, most nutrients, and food groups, with differences primarily driven by higher intake estimates from 2hR-days. Biomarker comparisons showed less underestimation by 2hR-days compared to 24hRs, suggesting that 2hR-days are a valid approach. The EMDA app, Traqq, offers an alternative to traditional 24-hour recalls, providing more accurate dietary intake data, reducing respondent burden, and simplifying cross-country dietary intake comparisons.

VITAMIN A, D, AND E INTAKES, SERUM CONCENTRATIONS, AND BREASTMILK STATUS IN BREASTFEEDING WOMEN IN IRELAND

Malak Ali[1]; Fiona O'dwyer[1]; Sharleen O'reilly[1]; Aifric O'sullivan,[1]
[1]UCD Institute of Food and Health, School of Agriculture and Food Science, University College Dublin, Dublin, Ireland

BACKGROUND AND OBJECTIVES

Breastfeeding is universally recommended as it delivers the best combination of nutrients and bioactives for infants. However, maternal diet and nutrition status impacts concentrations of some nutrients in breastmilk such as the fat soluble vitamins A, D, and E. Given the limited evidence and the high degree of inter-individual variation, it is important to understand the relationship between dietary intakes, vitamin status in serum and breastmilk, and health outcomes. This understanding can help improve targeted nutritional interventions that promote maternal and infant health and well-being.

METHODS

Demographics, dietary intake data, serum and breastmilk were collected in a 4-week randomised control trial from lactating women in the first 2 months post-partum (LS-23-07-OSullivan). Participant vitamin intakes were assessed using FoodBook24 self-completed 24-hour recalls. Vitamin A, D and E concentrations were quantified using LC-MS/MS in serum and breastmilk. Data was analysed using IBM SPSS Statistics (version 27).

RESULTS

Data from 44 participants indicated that maternal vitamin A, D and E intakes are low. Only 9%, 4% and 52% of participants were meeting intake recommendations for vitamins A, D, and E, respectively. Mean serum concentrations were sufficient at 58.9±20.7nmol/L, 2.1±0.4µmol/L, and 45.2 ±9.7µmol/L. Concentrations of breastmilk were low at 0.5 ±0.2µmol/L and 15.3 ±7.4µmol/L for vitamins A and E, and below the detection limit for vitamin D.

CONCLUSIONS

Intakes of vitamins A, D and E are poor, and it appears habitual diet alone is insufficient to achieve the daily vitamin D requirements, even when supplements are consumed. Despite sufficient serum status, concentrations in breastmilk are low and warrant further investigation. A combination of approaches including nutrition education, supplementation strategies, and the introduction of food fortification policies may be a feasible method for improving intakes and status across the population.

A Mixed-METHODS Investigation of Infant and Young Child Feeding Practices in Rural Ethiopia: Integrating Insights from Surveys, Direct Observations, and Qualitative Research

Amanda Ojeda[1]; Ibsa Ahmed[2]; Crystal Slanzi[3]; Chhavi Tiwari[4]; Jemal Yousuf[5]; Arie Havelaar[6]; Sarah Mckune[4]
[1]Microbiology & Cell Science, University of Florida, Gainesville, United States of America; [2]College of Public Health and Health Professions Department of Environmental & Global Health, University of Florida, Gainesville, United States of America; [3]Psychology, California State University, Los Angeles, Los Angeles, United States of America; [4]Department of Environmental and Global Health, University of Florida, Gainesville, United States of America; [5]Administration, Haramaya University, Haramaya, Ethiopia; [6]Emerging Pathogens, University of Florida, Gainesville, United States of America

BACKGROUND AND OBJECTIVES

Optimal infant and young child feeding (IYCF) practices are fundamental to child survival and development. While self-reported data form the basis for most IYCF assessments, their reliability, and underlying sociocultural determinants remain poorly understood in resource-limited settings. This study employed a multi-method approach to assess IYCF practices and elucidate contextual factors influencing feeding behaviors in rural Ethiopia.

METHODS

We conducted a prospective cohort study of 106 mother-infant dyads (December 2020–June 2022), combining monthly surveys with standardized 10-hour feeding observations of 79 infants. Qualitative inquiry comprised 26 semi-structured interviews and five focus group discussions with mothers, grandmothers, and community leaders (January–February 2024). Statistical analyses evaluated practice concordance, while thematic analysis identified behavioral determinants.

RESULTS

Self-reported surveys revealed colostrum consumption for 95% of infants and early breastfeeding initiation among 66%, yet 67% reported prelacteal feeding of their infant. Based on self-reported 24-hour recall data, 70% of mothers reported exclusive breastfeeding (EBF) of the infant during the first six months. However, using a stricter definition, which includes colostrum, the timing of breastfeeding initiation, and prelacteal feeding, the rate of EBF in this population fell to a significantly lower rate of 18% ($p=0.002$). Complementary feeding was timely among 55% of infants; of untimely introduction, 67% were introduced early (<6 months) and 33% late (>8 months). Direct observations showed 83% of infants <6 months receiving complementary foods. Among EXCAM infants under six months of age classified as EBF based on 24-hour recall data (n=39), 67% were observed receiving complementary foods. Qualitative findings revealed that prelacteal feeding was deeply rooted in cultural symbolism, endorsed by 67% of traditional healers and 50% of religious leaders, despite opposition from 40% of mothers. Economic pressures and entrenched cultural norms influenced early complementary feeding and deviations from recommended practices.

CONCLUSIONS

This study reveals substantial discordance in EBF rates when using refined definitions, emphasizing the need for standardized multi-method assessments. Future interventions must integrate cultural practices, particularly regarding prelacteal feeding, to effectively improve child nutrition outcomes.

EFFECTS OF MATERNAL PROBIOTICS AND OMEGA-3 FATTY ACIDS SUPPLEMENTATION DURING PREGNANCY THROUGH 6 MONTHS POSTPARTUM ON COVID-19 PREVALENCE AND NEUTRALIZING ANTIBODIES

Rina Agustina[1, 2]; Davrina Rianda[2]; Erfi Prafiantini,[1, 2]; Dyana Santika Sari[2]; Setyo Handryastuti,[3]; Ali Sungkar,[4]; Anuraj H. Shankar[5, 6, 2]

[1]Department of Nutrition, Faculty of Medicine, Universitas Indonesia – Dr. Cipto Mangunkusumo General Hospital, Jakarta, Indonesia; [2]Human Nutrition Research Center, Indonesian Medical Education and Research Institute (IMERI), Faculty of Medicine, Universitas Indonesia, Jakarta, Indonesia; [3]Department of Pediatrics, Faculty of Medicine, Universitas Indonesia – Dr. Cipto Mangunkusumo General Hospital, Jakarta, Indonesia; [4]Department of Obstetrics Gynecology, Faculty of Medicine, Universitas Indonesia – Dr. Cipto Mangunkusumo General Hospital, Jakarta, Indonesia; [5]Centre for Tropical Medicine and Global Health, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom; [6]Oxford University Clinical Research Unit Indonesia, Oxford University Clinical Research Unit Indonesia, Jakarta, Indonesia

BACKGROUND AND OBJECTIVES

Pregnant and lactating mothers are vulnerable to SARS-CoV-2 infection. Probiotics and omega-3 fatty acids (FAs) may act synergistically to improve immune responses among these populations. We evaluated the effects of maternal probiotics and omega-3 FAs supplementation during pregnancy through 6 months postpartum on COVID-19 prevalence and neutralizing antibodies among mothers.

METHODS

We conducted a double-blind, randomized controlled trial involving pregnant women at seven health centers in Jakarta, Indonesia. A total of 314 mothers in their second trimester of pregnancy were enrolled and randomly assigned to one of two intervention groups. The intervention groups received a daily probiotics [*Lactobacillus rhamnosus* GG, *Bifidobacterium animalis subsp. lactis* (BB-12), *L. acidophilus* (LA-5)] along with a higher-dose of omega-3 FAs (480 mg DHA, 720 mg EPA). The control group received a placebo with a standard-dose of omega-3 FAs (240 mg DHA, 360 mg EPA). During the intervention period, study physicians and local health centers recorded diagnoses of COVID-19 confirmed by PCR. We assessed neutralizing antibodies to SARS-CoV-2 in a subsample of 176 mothers before and after intervention. General linear models were used to determine the intervention's effects. We included potential confounders, such as socioeconomic and nutritional status, in the adjusted analyses if they had associations with $p<0.2$.

RESULTS

The mean age of mothers was 29.8 ± 5.16 yo in the intervention and 29.3 ± 5.45 yo in the control group, with 80.2% of participants in both groups having ≥ 9 years of education. The baseline characteristics were comparable between groups. Completion rates were 91.1% for the intervention and 84.1% for the control group. The COVID-19 prevalence in the intervention group was significantly 60% lower than the control group (11 vs. 22 cases; aOR 0.40, 95%CI 0.17 to 0.88; p=0.027). At the end of the intervention period, the intervention group exhibited a lower inhibition response to SARS-CoV-with a mean difference of -10.17 (95%CI -20.1 to -0.23; p=0.045) and a smaller change in induced responses from baseline to endline (-7.59, 95%CI -15.12 to -0.06; p= 0.048) compared to the control group.

CONCLUSIONS

Combined probiotics and omega-3 FAs supplementation protected pregnant and lactating mothers from COVID-19 in a community setting. The intervention led to a lower antibody response, indicating that its protective effect may not depend on enhancing antibody production.

Impact of targeting strategies for balanced energy protein supplementation in pregnancy on weight gain in pregnancy: RESULTS of a cluster randomized controlled trial in rural Bangladesh

Andrew Thorne-Lyman[1]; Towfida Siddiqua[2]; Hasmot Ali,[3]; Eleonor Zavala,[4]; Rezwanul Haque[2]; Kaniz Ayesha[2]; Lee Shu Fune Wu[2]; Hasan Mahmud Sujan[2]; Diwakar Mohan[4]; Daniel Erchick[5]; Kaosar Afsana[6]; Parul Christian[4]
[1]International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, United States of America; [2]JiVitA, Maternal and Child Health & Nutrition Research Project, Rangpur, Bangladesh; [3]JiVitA, Maternal and Child Health & Nutrition Research Project, Rangpur, Bangladesh, Rangpur, Bangladesh; [4]Center for Human Nutrition and Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States of America; [5]Center for Human Nutrition and Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, United States of America; [6]BRAC, James P Grant School of Public Health, BRAC University, Dhaka, Bangladesh

BACKGROUND AND OBJECTIVES

Balanced energy-protein (BEP) supplementation is recommended by WHO for pregnant women in undernourished populations to promote gestational weight gain and reduce low birth weight. BEP supplementation is known to result in modest weight gain in pregnancy but the effectiveness of targeted supplementation based on body mass index or weight gain in pregnancy has not been assessed. We aim to assess the effects of targeted and untargeted BEP supplementation compared to MMS on weight gain.

METHODS

A cluster-randomized controlled trial in rural Bangladesh compared different targeting approaches during pregnancy of daily fortified BEP supplementation (15 nutrients at 1 RDA; 500 mg calcium; ~400 kcal; ~15 g protein) vs. daily multiple micronutrient supplements (MMS) using the UNIMMAP formulation. Starting at 12 weeks of gestation until pregnancy outcome, pregnant women aged 15-35 years living within the study area were randomly assigned to receive (1) MMS (control), (2) BEP, (3) BEP for those with pre-pregnancy body mass index (BMI) < 18.5 kg/m2, while those with a pre-pregnancy BMI ≥ 18.5 kg/m2 received daily MMS or (4) BEP for those with pre-pregnancy BMI < 18.5 kg/m2, MMS for others, with a switch to BEP if inadequate gestational weight gain was identified. Weight gain in pregnancy was measured by community health workers during home-based visits scheduled at the 8 WHO-recommended ANC contacts. Inadequate weight gain was calculated using the INTERGROWTH-21st reference for women with normal pre-pregnancy BMI, and IOM standards for women with pre-pregnancy BMI<18.5 or >25 kg/m2. Weight gain will be analyzed across arms using linear regression and Relative risk ratios (RRR's) for the proportion with inadequate GWG, both using generalized estimating equations to account for cluster design.

RESULTS

In total 3390 pregnant women were enrolled in the trial (age 23.6±5.4 years, BMI 21.8 ± 3.7kg/m2, gestational age at enrollment 9.9±3.6 weeks) and baseline characteristics were balanced across groups. Pregnancy follow-up will conclude in March 2025. RESULTS of the impact of fortified BEP supplementation (both targeted and untargeted) vs. MMS will be presented.

CONCLUSIONS

Findings will examine the effectiveness of different targeting approaches of BEP supplementation on maternal weight gain in pregnancy, informing future programs and recommendations from WHO.

NUTRITIONAL INTAKE OF ADULTS LIVING IN FOOD INSECURITY IN DEVELOPED COUNTRIES: A SCOPING REVIEW PROTOCOL

Ana Karina Pastrana Polo[1]; Maria Waling[1]; Olsson Cecilia[1]
[1]Food and Nutrition, Umeå universitet, Umeå, Sweden

BACKGROUND AND OBJECTIVES

It is well known that diet quality plays an important role in growth, development and future health of children. However, some families with children face difficulties in meeting their nutritional needs due to financial constraints. As a result, these families are exposed to food insecurity, which is defined as "limited or uncertain availability of nutritionally adequate and safe foods or limited or uncertain ability to acquire acceptable foods in socially acceptable ways". Food Insecurity is a phenomenon that is rising not only in the Global South but also in the Global North. Despite this, there is limited literature exploring quality of diet in the context of food insecurity. This scoping review aims to examine the link between food insecurity and dietary quality among children residing in developed countries.

METHODS

The scoping review will follow the PRISMA-ScR guidelines for systematic reviews and will be supported by recommendations from the Joanna Briggs Institute (JBI). Our team will identify key terms relevant to the variables of food insecurity, dietary quality, and children, and will establish inclusion and exclusion criteria. The search strategy will primarily involve using three scientific databases, but will also include hand-searching and checking reference lists. EndNote will be used to capture all found articles during the preparation stage. Articles unrelated to developed countries, based on The World Bank classification of countries, will be removed, following the screening of titles and abstracts. We will focus on original articles written in English that assess and analyze food insecurity and dietary intake among children aged 5-18. The selected articles will then undergone full reading and a critical appraisal. The final list of selected articles will be exported to an Excel file for processing.

RESULTS

An information extraction sheet will be created from the final selected articles to capture all relevant details related to the research question. The findings will be presented in both narrative form and through diagrams and tables. The study population will be described based on the available research on the topic. Descriptive statistics will be used to report main characteristics of the RESULTS regarding diet quality and potential nutritional defficiencies that this population group faces due to food insecurity in daily life. This approach will help identify key needs, and gaps in research and suggest possible actions.

CONCLUSIONS

The findings will contribute to the discussion on inequalities and the rigth to food within the context of the Sustainable Development Goals, specifically for this vulnerable group, even in developed countries.

WEIGHT CHANGES OVER A 5-YEAR PERIOD IN THE NUTRINET BRASIL COHORT STUDY: DESCRIPTION AND ASSOCIATED FACTORS

Kamila Tiemann Gabe[1]; Laura Claro[2]; Amanda Jesus[3]; Juliana Jesus[3]; Rosane Augusto[4]; Maria Laura Da Costa Louzada,[5]
[1]Center for Epidemiological Research in Nutrition and Health of the University of São Paulo, Universidade de São Paulo, São Paulo, Brazil; [2]Departamento de Nutrição, Faculdade de Saúde Pública USP, São Paulo, Brazil; [3]Center for Edepimiological Research in Nutrition and Health of the University of São Paulo, School of Public Health, University of São Paulo, São Paulo, Brazil; [4]Center for Epidemiological Research in Nutrition and Health of the University of São Paulo, School of Public Health, University of São Paulo, São Pa, Brazil; [5]NUPENS, Center for Epidemiological Research in Nutrition and Health, São Paulo, Brazil

BACKGROUND AND OBJECTIVES

Ultra-processed foods (UPF) have been linked to several negative health outcomes, including weight gain. Behavioral interventions targeting UPF consumption may be an effective strategy for obesity prevention. The NutriNet Brazil Study, a web-based cohort launched in 2020, follows Brazilian adults to explore the association between local dietary patterns and chronic diseases. This cohort provides a unique opportunity to investigate the impact of behavior change interventions on weight through a nested randomized clinical trial, particularly targeting individuals with high UPF consumption and at higher risk of weight gain. This study aims to describe five-year weight changes and associated sociodemographic factors among NutriNet Brazil Cohort participants who present high intake of UPF.

METHODS

This analysis included adults (18 to 60 years old) who completed at least five years of follow-up, did not go through any pregnancy in this period, and consumed a percentage of calories from UPF above the median of the cohort;s consumption at baseline, based on the average of two self-completed 24-hour dietary recalls. Weight and height were self-reported at baseline, with weight updated every six months. Relative weight change was calculated as the difference between follow-up weight and baseline weight, divided by baseline weight, expressed as a percentage. Multivariate logistic regression was used to identify associations between a ≥5% weight gain and baseline body mass index (BMI), age, gender, ethnicity, and income.

RESULTS

Included participants (n = 4314) gained, on average, 2,4% (sd = 1,8) of their body weight over the five-year period, with 25,1% gaining 5% or more. The likelihood of gaining ≥5% of body weight was lower among people above 39 years old (OR = 0,52; CI95% 0,48 to 0,54; ref = 18 to 39 years old) and those with obesity at baseline (OR = 0,73; CI95% 0,61 to 0,87; ref = eutrophic), and higher among Black individuals (OR = 1,23; CI95% 1,06 to 1,43; ref = white). Gender and income were not significantly associated with weight gain in this cohort.

CONCLUSIONS

Younger adults (up to 39 years old) and those with a baseline BMI up to 29 kg/m² are at higher risk of weight gain in the NutriNet Brazil Cohort Study. Early adulthood is a critical window for obesity prevention, making it an ideal target group for behavioral interventions aimed at obesity prevention.

BACKGROUND AND OBJECTIVES

Adequate gestational weight gain is essential for fetal development; both inadequate gestational weight gain (I-GWG) and excessive gestational weight gain (E-GWG) can have significant adverse effects on fetal and birth outcomes. The literature for understanding factors linked to both I-GWG or E-GWG in low- and middle-income countries (LMICs) is limited. This study aims to identify risk factors for I-GWG and E-GWG.

METHODS

We analyzed data from the ongoing Pregnancy Risk and Infant Surveillance and Measurement Alliance (PRISMA) open cohort study in Ghana, Kenya, India, Pakistan, and Zambia. Early pregnancy Body Mass Index (BMI) was estimated by weight measure at or before nine weeks gestation, or imputed using a mixed-effects restricted cubic spline model for measures taken between 10 - 20 weeks gestation. The Institute of Medicine BMI-specific guidelines were used to determine weight gain adequacy. A multi-level multinomial model was used to assess the impact of demographic, clinical, and nutritional risk factors.

RESULTS

5,134 women with a pregnancy outcome were included. The median age was 26 years, mean gestational age at enrollment was 13±3.6 weeks, and mean early pregnancy BMI was 23.5 kg/m2. The prevalence of I-GWG and E-GWG were 37% and 33%, respectively. Women at an increased risk for I-GWG were aged 25-29 (RR 1.21 (95%CI 1.02, 1.45)) or 35+ (RR 1.50 (95%CI 1.19, 1.90)), HIV+ (RR 1.67 (95%CI 1.23, 2.26)), unmarried (RR 1.50 (95%CI 1.10, 2.04)), farmers (RR 1.75 (95%CI 1.17, 2.63)), had previously given birth >2 times(RR 1.27 (95%CI 1.07, 1.50)), had moderate anemia during the third trimester (RR 1.25 (95%CI 1.04, 1.49)), or had low ferritin during pregnancy (RR 1.24 (95%CI 1.02, 1.51)). Risk of E-GWG increased among women who were 20-24 years old (RR 1.41 (95%CI 1.01, 2.00)), unemployed (RR 1.32 (95%CI 1.02, 1.70), or in the highest wealth quintile (RR 1.67 (95%CI 1.18, 2.33).

CONCLUSIONS

Findings highlight that nutritional status related to anemia and iron deficiency is associated with I-GWG, in addition to advanced maternal age, multiparity, marital status and HIV status. On the other hand, maternal age, employment status, and higher wealth index is associated with E-GWG risk. Our findings suggest the need for targeted interventions for specific groups at risk of I-GWG or E-GWG. Nutrition counseling should focus on women who are older, multiparous, HIV+, and/or anemic. For those at risk of I-GWG, balanced energy and protein supplements should be an integral part of antenatal care.

IMPACT OF A TIMED AND TARGETED CARE FOR FAMILY (TTCF) PROGRAM ON MATERNAL AND CHILD NUTRITION AND HEALTH IN EASTERN VISAYAS, PHILIPPINES

Yunhee Kang[1]; Heunghee Kim[2]; Hee Sun Kim[2]; Ahreum Choi[3]; Sherlyn Mae Provido[2]; Heyeon Ji[4]; Jihwan Jeon[4]
[1]International Health Department, Johns Hopkins Bloomberg School of Public Health, Baltimore, United States of America; [2]Research Institute of Human Ecology, Seoul National University, Seoul, Korea, Republic of; [3]Department of Public Health, Seoul National University, Seoul, Korea, Republic of; [4]International Ministry Division, World Vision Korea, Seoul, Korea, Republic of

BACKGROUND AND OBJECTIVES

Timed and Targeted Care for Families (ttCF) is a contextualized, family-inclusive, and gender-transformative behavioral communication approach. Trained Barangay Health Workers (BHWs) delivered ttCF nutrition and health messages through home visits in Eastern Visayas, Philippines (2021–2025). This study evaluated the impact of the ttCF program on maternal and child health and nutrition outcomes during the first 1,000 days of life.

METHODS

A quasi-experimental design was used involving 12 municipalities (6 intervention and 6 comparison areas) with 1518 women (458 pregnant and 1050 postpartum mothers <12 mo. In the intervention areas, BHWs trained in ttCF conducted 12 household visits from pregnancy until 2 years of child age. In the comparison areas, only routine health services were provided. Linear regression analyses adjusted for baseline differences in outcomes and socio-economic covariates were used to estimate program impact. The primary outcomes included child minimum dietary diversity (MDD; consumption of ≥4 out of 7 food groups including breastfeeding), and the prevalence of stunting and wasting. Secondary outcomes were maternal MDD (≥5 out of 10 food groups), mid-upper arm circumference (MUAC)<23 cm, and depressive disorder [defined as Edinburgh Postnatal Depression Scale (EPDS)≥9].

RESULTS

Out of 1518 women, 1313 (655 in comparison and 658 in intervention) were followed up 12 months after enrollment. The number of home visits by BHWs was higher in the intervention vs. comparison areas between birth to 6 mo postpartum [mean=2.6 (sd 2.0) vs. 1.3 (1.4)] and >6 mo postpartum [2.3 (2.0) vs. 1.4 (1.5); all p<0.001]. In intention-to-treat analysis, no significant differences were found between the intervention and comparison areas for child MDD (23.2% vs. 24.9%; p=0.4 at follow-up only), and the prevalence of stunting [adjusted difference (adiff)=-2.6 percentage point (pp); 95%CI: -7.7, 2.5] or wasting (adiff=1.4 pp; 95%CI: -5.0, 7.4) among children between intervention and comparison groups. At maternal level, there was no difference between two areas in MDD (adiff =-6.1 pp; -12.8, 0.6) or MUAC<23 cm (adiff=-0.0 pp; 95%CI:-0.0, 0.0). However, ttCF home visits reduced the proportion of depressive disorder by 12.5% (95%CI: -19.4, -5.6) and EPDS by -1.2 score (95%CI: -1.9, -0.5), adjusting for enrollment differences in outcomes.

CONCLUSIONS

ttCF approach in the Eastern Visayas increased the number of home visits by BHWs and reduced maternal mental disorders. However, its impact on key maternal and child nutrition and health outcomes during the first 1000 days was limited.

THE TYPE OF FOOD SUPPLY ESTABLISHMENTS, A KEY FACTOR IN THE LEVEL OF PROCESSING OF PURCHASED FOODS AND BEVERAGES

Mauricio Hernandez Fernandez[1]; Sonia Hernández-Cordero,[1]; Wilfrido Gómez-Arias,[2]; Mariana Ramos-Flores,[1]; M. Arantxa Colchero,[3]
[1]EQUIDE, Universidad Iberoamericana Ciudad de México, Ciudad de México, Mexico; [2]INIAT, Universidad Iberoamericana Ciudad de México, Ciudad de México, Mexico; [3]CIEE, National Institute of Public Health, Ciudad de Mexico, Mexico

BACKGROUND AND OBJECTIVES

Several studies have examined the relationship between the availability of establishments in the modern food supply system and diet quality or purchases of these foods (1,2), but the impact of traditional food supply systems remains less understood (3). This study explores whether the association between traditional types of establishments (small grocery stores, specialized stores, bakeries, *tortillerias*, territorial and street markets) and household purchases of ultra-processed foods and beverages differs from that observed for modern establishments (supermarkets, discount stores, warehouse stores, convenience stores) in a representative sample of the population of a middle-upper-income country in 2020-2022.

METHODS

Food purchases were estimated based on the information from a nationally representative household income and expenditure survey (4). The densities for each type of establishments (density=#establishments/population) were calculated at the municipal level based on the national directory of economic units (5), except for territorial and street markets, which were estimated based on the municipal census. Two-part models (6) were used to test the associations between establishment densities and household purchases of ultra-processed foods, beverages, and fruits/vegetables, adjusting for sociodemographic factors.

RESULTS

The densities of convenience and discount stores were significantly associated with higher purchases of ultra-processed food (1.1 gr, $p<0.05$; 0.7 gr, $p<0.05$) and ultraprocessed sugar sweetened beverages (15.3 gr, $p<0.05$; 8.4 gr, $p<0.05$). Instead, specialized stores in animal origin food were significantly associated with less purchases of this products. On the other hand, the densities of convenience stores, discount stores and supermarkets were significantly associated with lower purchases of fruits and vegetables (-10.5 gr, $p<0.05$; -4.9 gr, $p<0.05$; -5.2 gr, $p<0.05$), while specialized stores in animal origin food, fruits/vegetables/seeds, other foods, and *tortillerias* were significantly associated with higher purchases of fruits and vegetables (5.5 gr, $p<0.05$; 7.5 gr, $p<0.05$; 8.2 gr, $p<0.05$, 1.6 gr, $p<0.05$). The RESULTS for warehouse clubs and small grocery stores were opposite to the common pattern of the other categories within the same modern/traditional types.

CONCLUSIONS

These findings suggest that greater availability of convenience and discount stores may encourage less healthy purchasing patterns, underscoring the need to revitalize the traditional food supply system, generally linked to healthier purchasing behaviours. Moreover, efforts should be made to improve the offerings of traditional small grocery stores.

INTERACTION BETWEEN THE ENUTRI DIET QUALITY SCORE AND APOLIPOPROTEIN E GENOTYPE ON CARDIOMETABOLIC DISEASE RISK MARKERS: A CROSS-SECTIONAL ANALYSIS IN UK ADULTS

Arife Yilmaz[1]; Michelle Weech[1]; Kim Jackson[1]; Julie Lovegrove[1]
[1]Hugh Sinclair Unit of Human Nutrition, Department of Food and Nutritional Sciences, University of Reading, Reading, United Kingdom

BACKGROUND AND OBJECTIVES

Evidence suggests that *APOLIPOPROTEIN (APO)E* genotype impacts on lipid responses to dietary fat manipulation [1-4], but its role in the relationship between diet quality and cardiometabolic disease (CMD) risk remains unclear. Therefore, this secondary data analysis aimed to explore the interaction between the *APOE* genotype and the eNutri diet quality score (DQS) on CMD risk markers in UK adults.

METHODS

Baseline data from four randomised controlled trials and one observational study conducted at the University of Reading in disease-free UK adults (n=621) aged 18-70 years were compiled. From weighed diet records, diet quality was assessed using the UK-based eNutri DQS consisting of 11 food and nutrient components (higher scores represent higher diet quality). *APOE* genotyping (rs429358, rs7412) was determined retrospectively, and participants were grouped according to *APOE* genotype group (*E2* carriers, wild-type *E3/E3* and *E4* carriers) for the main effect of genotype, and the *APOE* x eNutri-DQS interaction. Participants were first stratified into tertiles (T) of adherence to the eNutri-DQS before a general linear model was performed to assess the *APOE* x eNutri-DQS interaction on CMD risk factors, which included adjustment for confounding variables. If interactions were significant ($P<0.05$), pairwise comparisons with Bonferroni correction were conducted.

RESULTS

Significant *APOE**eNutri-DQS interactions were observed for waist circumference (WC), waist:height ratio (WHtR), waist:hip ratio (WHR) and fasting glucose ($P<0.05$). WC and WHtR were significantly lower in eNutri-DQS T3 versus T1 and T2 in *E4* carriers ($P=0.001$), and versus T2 only in *E2* carriers ($P=0.027$ and $P=0.036$, respectively). The WHR was lower in T3 compared with T1 and T2 in both *E2* ($P=0.003$) and *E4* carriers ($P=0.007$), and between T2 and T1 in the *E3/E3* group ($P=0.008$). In *E4* carriers, T3 had lower mean fasting glucose concentrations than T2 ($P=0.042$).

CONCLUSIONS

Our findings suggest that, in *E2* and *E4* carriers, higher diet quality was associated with lower central adiposity, estimates of body fat distribution and fasting glucose (*E4* carriers only), with little impact on CMD risk markers in the *E3/E3* group. Further research is warranted, employing a prospective genotyping approach to explore the underlying mechanisms and validate these observations.

OAP15_06

ASSOCIATIONS BETWEEN SERUM LIPID PROFILE AND COGNITIVE FUNCTION IN OLDER ADULTS FROM THE ENGLISH LONGITUDINAL STUDY OF AGEING (ELSA)

Alaa Elhoriny[1]; Christopher Long[1]; Sumanto Haldar[1]
[1]Faculty of Health and Social Sciences, Bournemouth university, Bournemouth, United Kingdom

BACKGROUND AND OBJECTIVES

Maintaining optimal cognitive function is an essential part of healthy ageing. Abnormal blood lipid profile such as elevated LDL-cholesterol (LDL-C), elevated triglycerides (TG) and reduced HDL-cholesterol (HDL-C) levels can lead to simultaneous increases in endothelial dysfunction and/or chronic inflammation, both of which are independent risk factors for cognitive impairment through reduction in neuronal plasticity and pathogenesis of cerebral microvascular diseases (1, 2). However, the associations to date between individual lipid profile components and various cognitive function measures have been equivocal, which warranted further investigation in large epidemiological cohorts.

METHODS

Using data from Wave 4 (2007-2008) of the English Longitudinal Study of Ageing (ELSA) study (3), 5642 individuals with complete data for serum lipid profile (Total cholesterol, LDL-C, HDL-C, TG) and cognitive function measures (memory performance, executive function, mental speed etc.) were included in the final analyses. Multiple linear regression analyses were used to explore associations between lipid profile and cognitive measures, controlling for key covariates such as HbA1c, physical activity, BMI, ethnicity and education.

RESULTS

Higher levels of HDL-C were consistently associated with better cognitive performance across multiple cognitive function domains including memory performance, executive function (both $p \leq 0.001$) and mental speed ($p \leq 0.01$). On the contrary higher level of TG were associated with diminished cognitive performance (both $p \leq 0.05$). The negative association of TG with various cognitive domains were particularly apparent in older females (≥70 years). Surprisingly, we also found positive associations between memory performance with both total and LDL-cholesterol (both $p \leq 0.05$) as well as positive association between executive function and LDL-cholesterol ($p \leq 0.05$).

CONCLUSIONS

This study has demonstrated consistent associations between various parameters of serum lipid profile with multiple cognitive function domains, with the relationships being modulated by both gender and age. This creates opportunities for developing stratified lifestyle interventions to modify lipid profile parameters and thereby improve cognitive function as part of healthy ageing. The positive associations between serum LDL-C and various cognitive function domains warrants further investigation.

CHANGE IN SUGAR-SWEETENED BEVERAGES AND NONESSENTIAL ENERGY-DENSE FOOD PURCHASES BY TYPE OF STORE, AFTER THE IMPLEMENTATION OF TAXES IN MEXICO

Claudia Gabriela Garcia Chavez[1]; Tonatiuh Barrientos Gutierrez[2]; Shu Wen Ng[3]; Juan Angel Rivera Dommarco[2]; M. Arantxa Colchero[4]
[1]Centro de Investigación en Nutrición y Salud, Instituto Nacional de Salud Pública, Cuernavaca, Mexico; [2]Centro de Investigación en Salud Poblacional, Instituto Nacional de Salud Pública, Cuernavaca, Mexico; [3]Department of Nutrition, University of North Carolina in Chapel Hill, Chapel Hill, United States of America; [4]Centro de Investigación en Sistemas de Salud, Instituto Nacional de Salud Pública, Cuernavaca, Mexico

BACKGROUND AND OBJECTIVES

In 2014, the Mexican government implemented a tax on sugar-sweetened beverages (SSB) of one peso per liter and an 8% tax on nonessential energy-dense foods (NEDF). Prior studies have evaluated these taxes on household purchases, but none have considered the potential heterogeneity by type of store with national survey data. We aimed to estimate the association of the taxes on purchases in Mexican households by store type.

METHODS

We analyzed the Mexican National Household Income and Expenditure Survey (ENIGH, for its Spanish acronym) from 2008 to 2018. To estimate changes in purchases overall and by store type, we used a two-part model to assess the probability of purchase and the amount purchased among purchasers, and we stratified the models by type of store to assess the potential effect modification.

RESULTS

After the implementation of the taxes, purchases of NEDF and SSB decreased by 7.0 and 4.4%, respectively. There was also a slight decrease in purchases of untaxed foods (-1.7%), while untaxed beverages rose by 10.9%. The largest reductions for taxed foods were found in “small neighborhood stores” (-19%; -7.6 g/capita/week). For SSB “public markets” showed the largest decrease -22.7%, (-4.7 ml/capita/week), followed by “small neighborhood stores” (-11.4%, -84.3 ml/capita/week) (Table 1).After the implementation of the taxes, purchases of NEDF and SSB decreased by 7.0 and 4.4%, respectively. There was also a slight decrease in purchases of untaxed foods (-1.7%), while untaxed beverages rose by 10.9%. The largest reductions for taxed foods were found in “small neighborhood stores” (-19%; -7.6 g/capita/week). For SSB “public markets” showed the largest decrease -22.7%, (-4.7 ml/capita/week), followed by “small neighborhood stores” (-11.4%, -84.3 ml/capita/week) (Table 1).

CONCLUSIONS

Heterogeneity in purchases by store types suggests the need to enforce mechanisms taken at the food retail level focused on discouraging purchases of these products, and updating the tax design to encourage reductions in their purchases further.

OAP15_08

BARRIERS AND FACILITATORS TO HEALTHY EATING AMONG UKRAINIAN REFUGEE CHILDREN IN FINLAND: COMBINED QUALITATIVE AND QUANTITATIVE ANALYSES

Dina Fedorova[1]; Emmi Tilli[1]; Maijaliisa Erkkola[1]
[1]Department of Food and Nutrition, University of Helsinki, Helsinki, Finland

BACKGROUND AND OBJECTIVES

The Russian invasion of Ukraine has caused Europe's largest child displacement since WWII. War-related stress and acculturation may affect children's eating behaviors (EB). Our 2023 study of 4,854 children in Ukraine showed that 63% experienced EB changes during the war (Gulich et al., 2024). This follow-up study aims to: (1) identify changes in eating patterns among Ukrainian school children relocated to Finland, and (2) examine barriers and facilitators to healthy eating during their adaption to life in Finland.

METHODS

We used a mixed-METHODS design, comprising a cross-sectional online survey (using validated tools such as FFQs, CEBQ, HFIAS, CATS Trauma Screen, and Academic Self-Efficacy and Resilience scales) and focus group interviews (N=28; 16 mothers, 12 children). We used Atlas software to analysis qualitative data. In January 2025, we surveyed 100 school children (grades 1–9) and 88 caregivers across 12 Finnish regions with the assistance of the Ukrainian Association in Finland. Participants were Ukrainian refugees who arrived post-invasion, lived in Finland > 1 month, with school-aged child (grades 1–9). Data are compared between children who remained in Ukraine and those resettled in Finland.

RESULTS

Focus groups revealed unfamiliar local foods, stress-eating, fussiness, and skipping school meals as major barriers, whereas free access to school lunches and community support were identified as facilitators. Stress and anxiety were frequently reported among children after relocation. After relocating to Finland, 90% of children experienced at least one parent-reported EB change, significantly higher than in Ukraine ($p < 0.001$). School meals attendance covered 82.8% of Ukrainian children who regularly eat school lunch. Although, 12.5% skipped school lunch on 1-2 days, and 4.7% skipped school lunch on 3-5 days due to unfamiliar foods and taste preferences.

CONCLUSIONS

Preliminary findings point to war exposure and acculturation challenges as major determinants of Ukrainian children's eating patterns. High school meals attendance might be a partial protective factor potentially mitigating war-related disruptions to eating patterns while supporting wellbeing and integration. Further research should examine how the war trauma and distress relates to dietary changes, informing targeted public health strategies and community interventions to promote healthy eating and well-being among displaced children.

CONFLICTS OF INTERESTS

The authors have no conflict of interest.

FOOD PROCESSING AND ORAL AND PHARYNX- AND GASTROINTESTINAL- CANCER RELATED MORTALITY IN A LARGE-SCALE EUROPEAN COHORT

Esther M. Gonzalez-Gil[1, 2]; Jeroen Berden[1]; Inge Huybrechts[1]; Epic Consortium[1]
[1]Nutrition and metabolism branch, International Agency for Research on Cancer, Lyon, France; [2]Unidad Predepartamental de Enfermería, Universidad de la Rioja, Logroño, Spain

BACKGROUND AND OBJECTIVES

Ultra-processed food (UPF) consumption has been associated with various cancer types and overall mortality, however research on cancer mortality considering subtypes is scarce. This multi-centre study investigated associations between food intake by degree of processing using the Nova classification and risk of oral and pharynx and gastrointestinal cancer mortality in Europe.

METHODS

This study involved participants from the European Prospective Investigation into Cancer and Nutrition from Denmark, France, Germany, Italy, the Netherlands, Spain, and the United Kingdom. We investigated the following mortality outcomes: oral and pharynx cancer and, for gastrointestinal cancer, digestive cancer, liver and pancreas cancer, and colorectal cancer. Hazard ratios (HRs) and 95% CIs were estimated using multivariable Cox proportional hazards regression models. We also performed substitution analyses.

RESULTS

A total of 348,890 (71·2% female) participants were included in the analysis. UPF consumption (in grams per day [g/d]) was positively associated with oral- and pharynx- cancer mortality (HRs per 1-SD: 1·24; 95% CI: 1·03,1·48), as well as mortality from gastrointestinal cancer (1·06; 95% CI: 1·01,1·11), and, more in particular, colorectal cancer (1·11; 95% CI: 1·03,1·2). RESULTS were still significant for oral and pharynx cancer- and colorectal cancer- mortality when removing alcohol from the Nova classification (1·23; 95% CI: 1·02,1·49 and 1·1; 95% CI: 1·02,1·2, respectively). Replacing processed and UPFs with unprocessed/minimally processed was inversely associated with mortality from oral and pharynx cancer- and colorectal cancer- mortality.

CONCLUSIONS

In this pan-European analysis, higher UPF consumption was associated with a greater risk for oral and pharynx cancer- and colorectal cancer- mortality. Promoting the consumption of unprocessed/minimally processed foods while discouraging highly processed foods in dietary recommendations may be beneficial for public health.

THE COMMUNITY-UP FOOD BOOST CHALLENGE APPROACH: IN WHICH ADOLESCENTS AND FOOD SYSTEM PARTNERS SEARCH FOR LEVERAGE POINTS TO CHANGE THE FOOD SYSTEM

Machteld van Lieshout[1, 2]; Wendy Scholtes-Bos[1]; Sanne I De Vries[1, 3]
[1]Research Group Healthy Lifestyle in a Supporting Environment, The Hague University of Applied Sciences, The Hague, Netherlands; [2]Nutrition and Dietetics, The Hague University of Applied Sciences, Den Haag, Netherlands; [3]Department of Public Health and Primary Care, LUMC - Health Campus The Hague, The Hague, Netherlands

BACKGROUND AND OBJECTIVES

To nurture a healthy next generation, it is essential that food policies are effective. However, there is a significant gap between these policies and the real-world food experiences, behaviors, and environments of adolescents. To address this gap, the Food Boost Challenge (FBC) approach has been developed. Here, we assessed its potential to identify feasible, accessible, affordable and endurable solutions.

METHODS

The FBC utilizes a community-based participatory action research approach, structured across five phases: (1) situational problem analysis through peer research, (2) idea generation, (3) co-creation and prototyping, (4) prototype testing and dissemination, and (5) implementation at pilot scale. Adolescents and food system partners, throughout the quadruple helix, work collaboratively through these phases to identify barriers and develop innovative ideas, concepts and prototypes and pilot test them in practice.

RESULTS

To date, 10 FBCs have been conducted in The Netherlands, addressing wicked food problems of adolescents such as: increasing the consumption of vegetables and fruit; making the healthy food choice the easy choice at hotspots where large numbers of adolescents gather (such as festivals and sports events); promoting a healthy, sustainable diet. These FBCs ranged from one-day events (n=5) for vocational scholars (n=800) and hospitality university students (n=400); to 6-week events (n=2) for vocational scholars (n=60); to 9-month events (n=3) in which 250 university students participated in phase 1 and 28 teams of adolescents (n=150) together with >50 food system partners - including educators, researchers, governemental, non-governmental and industry stakeholders. So far, this resulted in insights into drivers and barriers of >2000 adolescents; generation of 45 ideas; 28 prototypes being tested in >1500 adolescents; 15 winning pitches according to expert and popular voting (by >4500 voters); and >5 implementation projects. The RESULTS further indicate positive effects, such as changes in adolescents' attitudes toward healthy eating, skill development among students, and increased collaboration among stakeholders.

CONCLUSIONS

In conclusion, the FBC fostered creative solutions for healthy food choices, community building and created a collaborative framework that extends its impact beyond adolescent health to broader social impact and community transformation. This highlights that the search for leverage points to change the food system creates space for lasting improvements in adolescent nutrition and public health taking into account both policy and everyday reality.

OAP19_04

ASSOCIATION BETWEEN SEAFOOD, EPA, DHA CONSUMPTION AT EACH MEALTIME AND CHRONOTYPE/SOCIAL JETLAG IN SLEEP

Yun-Peng Lo[1]; Shigenobu Shibata[2, 3, 1]; Eriko Yoshida[4]; Kenji Uchida[4]; Yu Tahara[1]
[1]Graduate School of Biomedical and Health Sciences, Hiroshima University, Hiroshima, Japan; [2]Home economics, Aikoku Gakuen Junior College, Edogawa City, Japan; [3]Advanced sciences, Waseda University, Shinjuku City, Japan; [4]Food Function R & D Center, Nissui Corporation, Minato City, Japan

BACKGROUND AND OBJECTIVES

Seafood, rich in omega-3 fatty acids like EPA / DHA, has been reported to be related to sleep, and animal studies have also revealed that EPA /DHA influence the circadian clock. Social jet lag refers to the differences of the sleep phases between weekdays and weekends, often seen in the evening rather than the morning chronotype. The impact of the timing of seafood consumption on the sleep phase in humans remains unclear. Therefore, this cross-sectional study aimed to examine the relationship between seafood, EPA, and DHA intake in each mealtime and sleep patterns among Japanese individuals.

METHODS

Dietary and sleep data from 5,975 adults (aged 18–75 years) were analyzed. Multiple regression analysis assessed associations between seafood, EPA, and DHA intake at different mealtimes (breakfast, lunch, dinner, snacks) measured by the mobile food-log App. A chronotype was determined by midpoint of bedtime and wake-up time on weekend, and social jet lag by differences of midpoints on weekday and weekend. Adjustments were made for age, sex, BMI, annual income, total energy intake, and physical activity.

RESULTS

Individuals with a morning chronotype consumed significantly more seafood, EPA, and DHA at breakfast, lunch, and dinner, but less from snacks, compared to evening chronotypes. Higher daily intake of seafood, EPA, and DHA was associated with a morning chronotype and reduced social jet lag. Additionally, seafood, EPA, and DHA intake at breakfast and lunch were linked to earlier sleep patterns, with breakfast intake showing the strongest association.

CONCLUSIONS

Higher daily intake of seafood, EPA, and DHA was found to be associated with morning chronotype and less social jet lag, particularly consumption at breakfast and lunch.

ADOLESCENT NUTRITION IN BANGLADESH: EXAMINING REGIONAL DIFFERENCES IN DIETARY DIVERSITY AND NUTRITIONAL STATUS

Gulshan Ara[1]; Rafid Hassan[1]; Samira Dilruba Ali[1]; Abdullah-Al Mamun[2]; Nanna Roos[3]; Tahmeed Ahmed[1]
[1]Nutrition Research division, International Centre for Diarrhoeal Disease Research, Bangladesh (ICDDR,B), Dhaka, Bangladesh; [2]Dept. of Fisheries and Marine Science, Noakhali Science and Technology University, Noakhali, Bangladesh; [3]Dept. of Nutrition, Sports and Exercise (NEXS), University of Copenhagen, Copenhagen, Denmark

BACKGROUND AND OBJECTIVES

Adolescent girls are highly susceptible to undernutrition due to poor dietary diversity and low intake of micronutrient-rich foods. Those living in coastal and non-coastal areas of Bangladesh face unique risks of undernutrition, exacerbated by geographical and environmental factors like flooding, salinity, and drought, worsened by climate change. This study aims to explore the differences in dietary diversity and undernutrition among adolescent girls in these regions.

METHODS

Two cross-sectional surveys were conducted in the southern coastal and northern non-coastal regions of Bangladesh, selecting 400 girls from coastal and 420 girls from non-coastal areas, aged 10–19 years, using multistage cluster sampling technique. Data on socio-demographics and dietary intake were collected, and anaemia was measured using haemoglobin concentration in blood capillaries with a Hemocue-301 machine. Multiple logistic regression was used to identify factors associated with anaemia and underweight.

RESULTS

In the coastal area, girls were older, with 60% aged 15-19 years, while non-coastal girls were younger, with 65% aged 10-14 years. Educational attainment was higher among coastal girls (93.7% had secondary or higher education) compared to non-coastal girls (51.4%). Dietary diversity was low in both regions, with over 75% of girls consuming fewer than five food groups. Animal protein intake was higher among non-coastal girls (76.9%) compared to coastal girls (60.8%). The prevalence of underweight was almost similar between regions (30.6% in coastal and 34.3% in non-coastal areas), and anaemia affected about 38% of girls in both areas. In non-coastal regions, non-Muslim individuals had higher odds of anaemia compared to Muslims (AOR: 2.15, 95% CI: 1.35-3.41), and media exposure was associated with significantly lower odds of anaemia (AOR: 0.56, 95% CI: 0.37-0.83). Additionally, consuming five or more food groups was associated with nearly double the odds of being underweight (AOR: 1.99, 95% CI: 1.11-3.56). In coastal regions, girls aged 15 to 19 had higher odds of being underweight compared to those aged 10 to 14 (AOR: 2.06, 95% CI: 1.48-2.89). Improved toilet facilities were associated with a reduction in the odds of being underweight (AOR: 0.62, 95% CI: 0.41-0.94).

CONCLUSIONS

Adolescent girls in coastal and non-coastal Bangladesh face critical challenges with dietary diversity and undernutrition. Targeted interventions, including media campaigns and improved access to nutrition and sanitation, are crucial to mitigate these issues.

ORAL ADMINISTRATION OF HEAT-KILLED LACTICASEIBACILLUS PARACASEI INHIBITS THE IN VIVO GROWTH OF ORAL SQUAMOUS CELL CARCINOMA THROUGH TARGETING CANCER STEM CELLS

Wen-Wei Chang[1]; Wan-Hua Tsai,[2]; Peng-Ju Chien,[1]
[1]Department of Biomedical Sciences, Chung Shan Medical University, Taichung, Taiwan; [2]Research and Development Department, GenMont Biotech Incorporation, Tainan, Taiwan

BACKGROUND AND OBJECTIVES

Cancer stem cells (CSCs) are the source of cancer initiation, relapse, drug resistance, and metastasis. While targeting CSCs is a potential therapeutic strategy, probiotics have recently shown anti-cancer properties. This study investigates the anti-oral cancer potential of heat-killed (HK) *Lacticaseibacillus paracasei* strain GMNL-346.

METHODS

The effects of HK-GMNL-346 were evaluated on SAS and HSC3 oral cancer cell lines and a normal gingival epithelial cell line. Cell proliferation, cell cycle analysis, and tumorsphere formation were assessed. In vivo studies used SAS tumor-bearing nude mice to evaluate survival time and tumor markers. Metagenomic sequencing of intestinal tissues and short-chain fatty acid analysis of cecum contents were performed to investigate underlying mechanisms.

RESULTS

HK-GMNL-346 selectively inhibited oral cancer cell proliferation while sparing normal cells. It interrupted cell cycle progression with increased pRB and p16INK4a expression and suppressed tumorsphere formation with decreased cancer stemness gene expression, including BMI1, SOX2, and OCT4. In vivo, HK-GMNL-346 extended survival time in tumor-bearing mice and reduced tumor weights. It also modulated Ki-67 and RB expression in tumor tissues. Metagenomic analysis of gut microbiota revealed negative and positive correlations between tumor weight and *Lactobacillus spp*. and *Bacteroides spp*., respectively. HK-GMNL-346 treatment restored tumor-induced decreases in propanoic and isobutyric acid levels.

CONCLUSIONS

Heat-killed *L. paracasei* GMNL-346 demonstrates anti-CSC activity in oral cancer, suggesting its potential development as an adjuvant therapeutic agent.

AN ASSESSMENT OF THE NUTRITIONAL COMPOSITION AND ON-PACKAGED MARKETING OF COMMERCIALLY PRODUCED COMPLEMENTARY FOODS IN SUB-SAHARAN AFRICA

Janine Le Roux[1]; Tamryn Frank[1]; Alice Khan[1]; Rina Swart,[2]
[1]School of Public Health, University of the Western Cape, Cape Town, South Africa; [2]Department of Dietetics & Nutrition, University of the Western Cape, Cape Town, South Africa

BACKGROUND AND OBJECTIVES

Optimal nutrition during the first 1000 days is essential for growth and development, as well as for the prevention of childhood overweight and obesity. However, appropriate, whole complementary foods are becoming displaced by the increasing popularity of commercially produced complementary foods (CPCF). These CPCF are frequently high in nutrients of concern, such as sugar, saturated fats and sodium, while providing excess calories, but are marketed to caregivers through misleading labelling. This study aimed to investigate the nutritional composition and on-package marketing of CPCF in Sub-Saharan Africa.

METHODS

A quantitative study design was used to conduct a secondary analysis of 452 CPCF available in four Sub-Saharan African countries (Kenya, South Africa, Tanzania and Zimbabwe). Compliance with on-package marketing and health claims articles of The International Code of Marketing of Breastmilk Substitutes (The Code) was assessed using a standardised questionnaire. The nutritional composition of CPCF was evaluated against the WHO's Nutrient and Promotion Profile Model (NPPM). Although not legally required, the NPPM provides a means of assessing the nutritional adequacy and appropriate labelling of CPCF.

RESULTS

Nutrition and health claims were frequently used ($\bar{x}$ = 4.7 claims per product) on product packages in the study sample. Adherence to The Code was low with adherence with the prohibition of the promotion of bottle feeding at 48%. Adherence to required statements on the importance of breastfeeding for up to two years and beyond, and the importance of avoiding early introduction of complementary foods was even lower at 16% and 13%, respectively. In terms of nutrient content and front-of-pack labelling compliance with the NPPM, overall compliance was low, at 29%. Lowest compliance was seen for energy and sugar (36.8% and 54.4% non-compliance, respectively). Of the sample, none (0%) were compliant with all the marketing and labelling requirements of the NPPM.

CONCLUSIONS

The nutritional quality and marketing of CPCF is inappropriate in Sub-Saharan Africa. The findings of this study underscore the urgent need for stronger and effectively enforced regulations regarding the marketing and nutritional quality of CPCF in Sub-Saharan Africa. Such regulations could include banning all claims on CPCF; limiting nutrients of concern; developing a region or country-specific NPPM for CPCF; and enhancing compliance to The Code. By implementing improved policy recommendations, governments can better protect and support children during the critical 1000-day window, ensuring a better start in life.

ADHERENCE TO THE DIETARY APPROACHES TO STOP HYPERTENSION (DASH) IS ASSOCIATED WITH LOWER PRESENCE COGNITIVE IMPAIRMENT IN ELDERLY: THE MEDIATING EFFECT OF SUSTAINABLE CONSUMPTION BEHAVIORS

Murat Açık[1]
[1]Nutrition and Dietetics , Fırat University, Elâzığ, Türkiye

BACKGROUND AND OBJECTIVES

Sustainable and healthy nutrition models are known to have an important role in the prevention or improvement of cognitive impairment in elderly individuals. However, there is limited research examining the relationship of sustainable consumption behavior on cognitive impairment as well as physically intake of food in an increasing elderly population. This study investigated the mediating role of sustainable consumption behavior-nutrition (SCBN) in the relationship between DASH quailty and cognitive impairment.

METHODS

The cross-sectional study included 890 individuals over the age of 60 years admitted to the geriatrics clinic of two private hospitals in Turkey. Participants completed a questionnaire including a Mini-Mental State Examination (MMSE) test, DASH diet score (DASH-DS), SCBN scale and a demographic information form. Hierarchical regression analyses were conducted to determine the effects of independent variables on cognitive impairment. SEM analysis was performed to reveal the mediating role of SCBN. In addition, the moderating role of potential variables like age, gender, education, BMI and chronic disease were examined in SEM analysis.

RESULTS

Whilst 66.3% of the participants were at risk of mild cognitive impairment, individuals with lower income and education level, sedentary, higher age and BMI were associated with high risk of cognitive impairment. Based on hierarchical regression analysis, DASH-DS, purchasing choice (PC) and nutritional choice (NC), which are the sub-dimensions of SCBN, were found to favourably affect cognitive impairment status [β (95% CI)= 0.34 (0.31-0.37); 0.77(0.46-1.08); 0.49(0.21-0.75) and respectively] and the explanation rate of this effect was found to be 13.9%. It was found that purchase choice mediated the relationship between DASH-DS and MMSE scores [Indirect effect β (95% CI)= -0.047 (-0.21-(-0.69)), $p<0.01$]. Furthermore, performing subgroup analyses, the mediating effect of PC was sustained for both gender groups, individuals older than 75 years and sedentary individuals. NC were not found to mediate the relationship between DASH-DS and MMSE scores.

CONCLUSIONS

DASH, a sustainable and healthy diet model, was shown to provide favourable effects on cognitive impairment by motivating the formation of sustainable consumption behaviour. In the elderly, adopting sustainable food consumption behaviour patterns that include not only physical consumption of healthy food but also preventing food waste, preferring fresh, seasonal, local, organic foods and fair-trade products may improve cognitive impairment.

IDENTIFYING GAPS AND OPPORTUNITIES FOR IMPROVEMENT IN NUTRITIONAL AND DIETARY GUIDELINE COMPLIANCE IN CANADIAN LONG-TERM CARE MENUS

Caroline Middleton[1]; Daniel Zaltz[1]; Mary L'abbe[1]
[1]Department of Nutritional Sciences, University of Toronto, Toronto, Canada

BACKGROUND AND OBJECTIVES

Nutritional adequacy and food quality are critical in long-term care (LTC) settings to support the health, well-being, and quality of life of older adults. However, many LTC menus fail to meet dietary guidelines, not only in nutrient composition but also in the quality and variety of foods offered. This study aims to evaluate non-compliant LTC menus compared to compliant counterparts, identifying differences in nutrient intake, food quality, and diversity across food groups, with a focus on understanding how these menus meet or fall short of Dietary Reference Intake (DRI) and 2019 Canada's food guide (CFG) standards.

METHODS

Using a 4-week menu cycle with 1,365 items, 10,000 daily LTC menus were generated and evaluated against DRI and 2019 CFG compliance criteria. Non-compliant menus (e.g., those not meeting nutrient and food guide benchmarks) were analyzed to identify prevalent nutrient shortfalls, over-reliance on specific food categories, and barriers to incorporating nutrient-dense foods. Food categories were determined using the Healthy Eating Food Index-2019 (HEFI-2019). Mean values and standard deviations (SD) were calculated for key macronutrients and essential vitamins and minerals. The average percent difference between dietary targets and compliant menus was reported. A Welch Two Sample t-test was conducted to compare the mean values of non-compliant and compliant menus.

RESULTS

Non-compliant menus (n=9,999) exceeded energy and sodium targets by 29.7% and 18.7%, respectively, while protein and fiber fell short by 8.1% and 19.8% (all $p<0.001$). Key micronutrients, including calcium, vitamins C, A, and D, were significantly below target levels (all $p<0.001$). Food component analysis showed deficiencies in fruits and vegetables (-23.5%) and whole grains (-65.9%), alongside excessive inclusion of non-whole grains (66.7%) and animal-based proteins (80.0%) (all $p<0.001$). Discretionary "other foods" exceeded targets by 181.3% ($p<0.001$), indicating a reliance on calorie-dense, nutrient-poor items.

CONCLUSIONS

Non-compliant LTC menus showed significant gaps, including excess energy, sodium, and discretionary foods, alongside shortfalls in fibre, essential vitamins, minerals, fruits, vegetables, and whole grains. Addressing these gaps could improve menu quality and better align with dietary guidelines, supporting the health of LTC residents.

OAP22_03

Pasifika Youth Diet Study: A mixed METHODS study on the dietary intake and experience of food environment for Pasifika Adolescents in Australia

Timothy Low-wah[1]; Jason Wu[2]; David Simmons[3]; Freya Macmillan[4]; Kate Mcbride[1]
[1]Translational Health Research Institute, Western Sydney University Campbelltown Campus, Campbelltown, Australia; [2]Food Policy, The George Institute for Global Health, Barangaroo, Australia; [3]School of Medicine, Western Sydney University Campbelltown Campus, Campbelltown, Australia; [4]School of Health Sciences, Western Sydney University, Kingswood, Kingswood, Australia

BACKGROUND AND OBJECTIVES

Pasifika communities in Australia experience disproportionately high rates of obesity and type 2 diabetes (1), with dietary behaviour identified as a significant risk factor. Pasifika adolescents are 4–5 times more likely to be obese compared to the general Australian adolescent, with outdated data from 2006 indicating a prevalence of 49.1% for those aged 12–18 years (2). Adolescence is a critical period for establishing dietary behaviours that persist into adulthood and influence long-term health outcomes (3-4). Given limited research in this area, this study aims to investigate the dietary behaviours and food environment experiences of Pasifika adolescents to inform culturally tailored health strategies.

METHODS

This mixed-METHODS study recruited Pasifika adolescent (12-17 years) participants using respondent-driven sampling and network-based recruitment. Dietary intake was assessed through two non-consecutive dietitian-administered 24-hour recalls, with intake data was averaged to estimate usual intake (5). A subgroup participated in 'talanoa'-style focus groups (6) or semi-structured interviews, incorporating a photovoice element, to explore their experiences with the local food environment.

RESULTS

A total of 108 Pasifika adolescents participated, with 100 completing both recalls (mean age: 14.9±1.7 years; 37% female; 29% Melanesian, 71% Polynesian). Median energy intake was 13,083 kJ/day (IQR: 10,676–17,949), with 13.6% from saturated fat and 14.4% from added sugars. Participants consumed 2.4 sugar-sweetened beverages daily. According to Australian Dietary Guidelines, 77% met recommendations for serves of grains (median: 9.5 serves/day, IQR: 6.9-12.6, 92% refined), 23% met both fruit and vegetable (fruit: 1.6 serves/day, 1.1-3.1; vegetables: 4.5 serves/day, 3.0-7.5, 93% starchy), 63% met protein foods (3.3 serves/day, 2.1-4.8, 29% processed meats), and 7% met dairy foods (1.5 serves/day, 0.9-2.4). Qualitative data (n=17) highlighted barriers of low accessibility and availability of healthy foods, high cost and low convenience of healthy eating behaviours, saturated fast-food advertising, and low desirability of healthy foods. Households, often extending beyond the nuclear family, and church communities strongly influenced adolescents' food choices.

CONCLUSIONS

This study reveals suboptimal dietary behaviours among Pasifika adolescents in Australia, driven by an obesogenic food environment. Culturally tailored interventions within household and church settings may address these challenges and improve dietary behaviours, reducing the risk of chronic conditions in this community.

ASSESSMENT OF FACTORS AFFECTING PERCEIVED AND ACTUAL CARBOHYDRATE PORTION SIZES AMONG AN ADULT POPULATION IN ACCRA

Joseph Bamfoh Danquah[1]; Boateng Gladys Peprah[2]; Laurene Boateng[3]
[1]Department of Nutrition and Dietetics, South Tongu District Hospital, Sogakope, Ghana; [2]Dietetics, University of Ghana, Accra, Ghana; [3]Department of Dietetics, University of Ghana, Accra, Ghana

BACKGROUND AND OBJECTIVES

Portion size perception plays a critical role in dietary assessments and nutrition interventions, particularly in mitigating risks associated with overconsumption and obesity. Misjudging portion sizes of carbohydrate-rich foods, influenced by factors like age, gender and BMI, can undermine dietary counseling and intervention strategies. This study aimed to assess the relationship between these demographic factors and the perception and actual serving sizes of selected carbohydrate foods among adults in Accra.

METHODS

This cross-sectional study included adults (≥18 years) selected from four income zones in Greater Accra. Participants identified and served their perceived portion sizes of 12 common carbohydrate foods using standardised handy measures. Sociodemographic data and anthropometric measurements (height, weight, BMI) were recorded. Relationships between perceived and actual portion sizes and their associations with age, gender and BMI were analysed using paired t-tests and Pearson's correlation.

RESULTS

Preliminary findings indicate significant discrepancies between perceived and actual serving sizes with trends varying by age, gender and BMI. Notably, Overweight and obese individuals showed a tendency to underestimate portion sizes, while middle-aged women demonstrated better portion estimation accuracy and males were better able to perceive portion sizes correctly than females.

CONCLUSIONS

This study underscores the importance of personalised dietary interventions that address demographic-specific biases in portion size perception. These findings have implications for improving nutrition counseling practices and formulating public health strategies to combat obesity and other non-communicable diseases.

VITAMIN D SUPPLEMENTATION AND DOSE RESPONSE IN WOMEN OF REPRODUCTIVE AGE AND PREGNANT WOMEN IN TWO DOUBLE-BLIND, RANDOMIZED, CONTROLLED MICRONUTRIENT DOSE RESPONSE (MINDR) TRIALS IN RURAL BANGLADESH

Sulagna Bandyopadhyay[1]; Towfida Siddiqua[2]; S. M. Tafsir Hasan[3]; Khalid Bin Ahsan[2]; Eleonor Zavala[1]; Anjan Kumar Roy[3]; Ximing Ge[1]; Lee Shu Fune Wu[1]; Brooke Langevin[4]; Mathangi Gopalakrishnan[4]; Kerry J Schulze[1]; Parul Christian[1]

BACKGROUND AND OBJECTIVES

Antenatal multiple micronutrient supplements (MMS) with recommended levels of 15 nutrients improve pregnancy outcomes but may not eliminate micronutrient deficiencies. Vitamin D status is compromised in settings with poor diet and limited sunlight exposure. We report on two ongoing bioefficacy trials of micronutrient supplementation with increasing amounts of vitamin D along with other micronutrients, in women of reproductive age (WRA) and pregnant women (PW) aged 18-35 years in rural northern Bangladesh, to determine the amounts of each nutrient that minimizes deficiency. This abstract focuses on Vitamin D.

METHODS

The trials are double-blind, placebo-controlled, and randomized, with 240 PW and WRA (60 per arm) in each (NCT06081114). Daily doses of micronutrients are provided in a reconstituted powdered drink, including a placebo, with a balanced energy-protein product containing ~1 recommended dietary allowance (RDA) of 18 micronutrients/serving. Vitamin D doses are 600, 1400, 2200, and 3000 IU/day per arm, ~1-5 times the RDA, and up to 75% of the tolerable upper intake level. Trial duration is 3 months for WRA and ~6 months in PW (12-16 weeks gestation to birth), with biospecimens collected at baseline, midpoint, at/near the end of supplementation, and at 1 month postpartum for PW. Serum 25-hydroxy vitamin D [25(OH)D] is measured by autoanalyzer (Roche Diagnostics). Serum calcium will be measured by mass spectrometry (7850 ICP-MS; Agilent) to ensure the absence of hypercalcemia, associated with vitamin D excess. Pharmacokinetic (PK) and pharmacodynamic (PD) analytical approaches will be applied to ascertain the threshold of intake at which vitamin D sufficiency is attained without any evidence of excess.

RESULTS

In total, 289 WRA and 354 PW were enrolled, with follow-ups ending in December 2024 and April 2025, respectively. The study arms were comparable in terms of baseline characteristics. Preliminary blinded data on baseline vitamin D status shows that among WRA (n=281) and PW (n=337), 49.8% and 58.2% were vitamin D insufficient (30 to <50 nmol/L) and 4.3% and 6.2% deficient (<30 nmol/L), respectively. PK and PD RESULTS for the complete dataset will be presented by baseline status at the conference.

CONCLUSIONS

Vitamin D insufficiency is high among WRA and PW in Bangladesh. Findings from the dose-response trials will inform vitamin D dosing in MMS products for settings with a high risk of vitamin D deficiency.

SCREEN USE DURING PREGNANCY: ITS EFFECTS ON CHRONOTYPE, NIGHT EATING HABITS, AND SLEEP QUALITY AT THIRD TRIMESTER

Ee Yin Kok[1]; Satvinder Kaur Nachatar Singh[1]; Nurul Husna Mohd Shukri[2]; Abdul Razak Nurliyana[1]; Masaki Takahashi[3]
[1]Department of Food Science and Nutrition, UCSI University, Kuala Lumpur, Malaysia; [2]Department of Nutrition, Faculty of Medicine and Health Sciences, Universiti Putra Malaysia, Selangor, Malaysia; [3]Institute for Liberal Arts, Institute of Science Tokyo, Tokyo, Japan

BACKGROUND AND OBJECTIVES

Increased screen usage has highlighted potential risks of disturbed sleep and erratic eating behaviours. Pregnant women are vulnerable to environmental exposures, as changes in maternal lifestyle behaviours significantly influence pregnancy outcomes. Hence, this study aims to determine the associations of screen time with chronotype, chrononutrition habits, and sleep quality among pregnant women.

METHODS

This prospective cohort study recruited 143 pregnant women at the third trimester from nine randomly selected government maternal and child health clinics in Kuala Lumpur, Malaysia. Screen time, chronotype, chrononutrition habits, and sleep quality were assessed using the Screen Time Questionnaire (STQ), Morningness-Eveningness Questionnaire (MEQ), Chrononutrition Profile Questionnaire-Pregnancy (CPQ-P), and Pittsburgh Sleep Quality Index (PSQI) respectively.

RESULTS

The average smartphone screen use on weekdays was 10.09±5.02 hours, while weekend was 10.04±4.89 hours. Background screen use was 2.24±3.32 hours on weekdays, and 2.60±3.46 hours on weekends. On weeknights, smartphone screen use was 3.33±1.73 hours, while background screen use was 1.19±1.73 hours. Pregnant womens' chronotype were mainly with intermediate (60%), followed by morningness (34%), and 6% eveningness. There were 12.5% who had breakfast skipping habits and 81.5% had night snacking habits. The mean global PSQI score was 6.17±3.40, with 60% of pregnant women experiencing poor sleep quality.

Generalized estimating equations showed an association of smartphone screen use during weekdays on increased night eating habits (B=0.049, p=0.017). On weeknights, increased background screen use had a significant effect on poor sleep quality (B=0.143, p=0.005). Pregnant women with increased smartphone screen use during weekends were found to have later chronotype (B=-0.439, p=0.001).

CONCLUSIONS

Pregnant women with increased screen use tend to have later chronotypes, increased night eating habits, and experience poor sleep quality. Future studies are warranted to determine the implications of prolonged maternal screen time with birth outcomes.

BALANCED ENERGY PROTEIN SUPPLEMENTATION IN PREGNANCY AND MATERNAL MORBIDITY AND BLOOD PRESSURE IN A CLUSTER RANDOMIZED CONTROLLED TRIAL IN RURAL BANGLADESH

Hasmot Ali[1]; Kaniz Ayesha[1]; Eleonor Zavala,[2]; Andrew Thorne-Lyman,[2]; Rezwanul Haque[1]; Lee Shu Fune Wu[2]; Hasan Mahmud[1]; Shahnaz Parvin[1]; Towfida J Siddiqua[1]; Diwakar Mohan[2]; Daniel Erchick,[2]; Parul Christian[2]
[1]JiVitA, Maternal and Child Health & Nutrition Research Project, Rangpur, Bangladesh; [2]Center for Human Nutrition and Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore MD USA, United States of America

BACKGROUND AND OBJECTIVES

In South Asia, pregnancy related morbidities including weakness, nausea, vomiting, breathlessness, fever, lower abdominal pain and vaginal discharge are common and associated with adverse pregnancy outcomes. Hypertension during pregnancy is associated with risk of pre-eclampsia/eclampsia and maternal death. Multiple micronutrient supplements (MMS) reduces adverse birth outcomes and calcium reduces the risk of hypertension. However, evidence is lacking on the effects of fortified balanced energy protein (BEP) supplementation on pregnancy-related morbidities and hypertension. Our aim is to evaluate the effect of targeted and untargeted fortified BEP supplementation (containing 15 micronutrients at an RDA for pregnancy and 500 mg of calcium) versus multiple micronutrient supplements (MMS using the UNIMMAP formulation) as control in pregnancy, on morbidity and hypertension.

METHODS

The ongoing TARGET-BEP study is a four-arm cluster randomized trial that enrolled 3,390 pregnant women who were assigned to receive: MMS (Arm 1 control); BEP (Arm 2); BEP if low pre-pregnancy BMI (<18.5 kg/m²), or MMS otherwise (Arm 3); or BEP if low pre-pregnancy BMI, MMS for others and BEP if found to have inadequate gestational weight gain (Arm 4). 30-day morbidity recalls were collected at enrollment (9.9 weeks) and in the third trimester (~32 weeks gestation). Blood pressure was measured 7 times between 20 weeks gestation and birth outcome. Prevalence rates of morbidities and high blood pressure (systolic:>140 diastolic:>90 mmHg) will be compared using log-binomial regression models with generalized estimating equations to adjust for the cluster design.

RESULTS

Baseline characteristics including maternal age, parity, and nutritional status did not differ between groups. The prevalence of nausea, vomiting, low grade fever and lower abdominal pain at enrollment was 67.1%, 40.3%, 31.8% and 16.6%, respectively. The mean systolic and diastolic blood pressure was 101.3 (9.2) mmHg and 62.7 (7.1) mmHg, respectively, with less than 1% hypertensive at baseline (Table 1). Effects of targeted and untargeted BEP versus MMS in pregnancy on these outcomes will be presented.

CONCLUSIONS

RESULTS of this study will inform whether targeted and untargeted fortified BEP supplementation in pregnancy reduces the risk of pregnancy-related morbidities and hypertension among pregnant women in rural Bangladesh.

LONGITUDINAL TRENDS IN ULTRA-PROCESSED FOOD CONSUMPTION ACROSS EATING OCCASIONS IN CHILEAN CHILDREN AND ADOLESCENTS

Camila Zancheta[1]; Natalia Rebolledo,[2]; Ana Pereira[1]; Camila Corvalán[1]
[1]CIAPEC, Institute of Nutrition and Food Technology, University of Chile, Santiago, Chile; [2]CIAPEC, Institute of Nutrition and Food Technology, University of Chile, Santiago, Chile

BACKGROUND AND OBJECTIVES

Ultra-processed foods (UPFs), traditionally represented by products such as confectionery, soft drinks, and salty snacks, have expanded in variety and availability, potentially displacing traditional foods during meals (1). This study aimed to analyze trends in UPF consumption during meal and snack occasions among Chilean children and adolescents over a seven-year period.

METHODS

We analyzed longitudinal data from 872 children and 841 adolescents (mean age at baseline: 4.9±0.5 and 13.8±0.4 years, respectively), with at least two dietary assessments collected annually between 2016 and 2023 (average number of measures: 4.5 for children and 3.2 for adolescents). Food consumption was recorded using 24-hour dietary recalls (2), and foods and beverages were classified according to the NOVA food system (3). Eating occasions were categorized as meals (breakfast, lunch, dinner) and snacks (snack, teatime, beverage break) based on participant reports (mothers reported for children). We assessed changes in the contribution of UPF and the proportion and amounts of UPF consumed during meals over time using mixed linear regression models adjusted for sex, age in months, parental education, nutritional status, and total caloric intake. Given the longitudinal nature of the study and the growth of participants, we used margins to perform descriptive analyses, presenting adjusted means for UPF consumption considering the covariates.

RESULTS

The adjusted mean caloric proportion of UPF decreased in children, from 49.2% in 2016 to 40.2% in 2023 (p-trend<0.001), but remained stable in adolescents (42.7% in 2016 to 41.7% in 2022, p-trend=0.531). Among children, this decrease was attributed to reduced UPF intake during snacks (from 384 to 314 g, p<0.001; from 503 to 402 kcal, p<0.001) with stable UPF consumption in meals (p>0.05). Conversely, in adolescents, we observed a reduction in calories, though not in grams, of UPF during snacks (566 to 509kcal; p=0.005; 406 to 432g, p=0.249) and an increase in UPF consumption during main meals (282 to 339kcal; p<0.001; 300 to 413g, p<0.001).

CONCLUSIONS

While the decrease in ultra-processed food consumption as snacks is promising, the observed increase in UPF consumption during mealtimes among adolescents raises concerns and warrants further investigation.

BACKGROUND AND OBJECTIVES

Consumption of organic foods may limit exposure to neurotoxic pesticides. The objective of this work was to analyse the relationship between the consumption of organic foods during pregnancy and infancy and child cognitive development up to 6 years of age.

METHODS

Analyses included 12,098 children from a French nationwide birth cohort. The consumption of organic foods was assessed through a single item reporting the frequency of from “never” to “always or almost always”, retrospectively at delivery for the pregnancy period, and monthly during the infant complementary feeding period. Child cognitive development was assessed using the Child Development Inventory (CDI) at 1, 3.5, and 5.5 years; the MacArthur-Bates Communicative Development Inventory at 2 years; and the Picture Similarities test from the British Ability Scale at 3.5 years. School performance, considering math and reading dimensions, was evaluated at 4 and 6 years. Associations between organic food consumption and neurodevelopmental scores were evaluated using linear or logistic regressions, adjusting for main confounders, including maternal socioeconomic status, migration, depression, parity, diet quality, and learning difficulties during childhood.

RESULTS

The consumption of organic foods during pregnancy was positively associated with CDI scores at 1 and 3.5 years, negatively with the risk of developmental delay at 5.5 years, positively with language at 2 years and reading performance at 4 and 6 years. RESULTS remained similar after adjusting for breastfeeding. Findings were less consistent when organic foods during complementary feeding was considered, mainly for the positive association for the reading performances at 4 and 6 years which was not statistically significant anymore.

CONCLUSIONS

These RESULTS suggest that frequent consumption of organic food during pregnancy, rather than during complementary feeding, may be beneficial for cognitive development, independent of maternal diet quality. Further studies are needed to confirm these findings and should use more detailed exposure level of organic food consumption.

OAP23_03

BALANCED ENERGY PROTEIN SUPPLEMENTATION IN PREGNANCY AND HEMOGLOBIN AND ANEMIA IN THE THIRD TRIMESTER IN A CLUSTER RANDOMIZED CONTROLLED TRIAL IN RURAL BANGLADESH

Kaniz Ayesha Fahmida[1]; Hasmot Ali,[1]; Eleonor Zavala,[2]; Andrew Thorne-Lyman[2]; Rezwanul Haque[1]; Lee Shu Fune Wu[2]; Hasan Mahmud Sujan[1]; Shahnaz Parvin[1]; Towfida Siddiqua[1]; Diwakar Mohan[2]; Daniel Erchick,[2]; Parul Christian[2]
[1]JiVitA, Maternal and Child Health & Nutrition Research Project, Rangpur, Bangladesh; [2]Center for Human Nutrition and Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States of America

BACKGROUND AND OBJECTIVES

Anemia in pregnancy remains a public health challenge in low-resource countries like Bangladesh, contributing to adverse maternal and neonatal outcomes. Fortified balanced energy protein (BEP) supplementation, which combines daily multiple micronutrients (MMS) with additional energy (~400 kcal) and protein (~15g), has been identified as a potential strategy for improving maternal nutrition and birth outcomes. Our aim is to evaluate the effect of fortified BEP, with and without targeting, compared to MMS as control using the UNIMMAP formulation (both containing 30 mg of iron), on hemoglobin (Hb) level and anemia prevalence among pregnant women in rural Bangladesh, in a cluster-randomized controlled trial assessing the effects of BEP targeting strategies on birth outcomes.

METHODS

The TARGET-BEP study is a cluster randomized controlled trial is ongoing in rural northwestern Bangladesh. Married women of reproductive age 15-35 years underwent monthly pregnancy surveillance and were enrolled in the study at 12-14 weeks gestation. Based on their cluster allocation, they were assigned to the following supplementation groups: MMS (control, arm-1); BEP (arm-2); BEP for women with pre-pregnancy body mass index (BMI) <18.5 kg/m2 and MMS for others (arm-3); BEP for women with pre-pregnancy BMI<18.5 kg/m2 and inadequate gestational weight gain switched to BEP from MMS and MMS for others (arm-4). Hb level was measured at enrollment and in late pregnancy by trained workers using capillary blood draw and HemoCue Hb-301 machine. Anemia was defined as Hb<110 g/L. Continuous Hb level will be analyzed using linear regression and prevalence of anemia will be analyzed using log-binomial regression, both with generalized estimating equations to adjust for the trial design in comparing the intervention groups to the control group.

RESULTS

A total of 3390 pregnancies were enrolled in the trial from October, 2022 to August, 2024. Baseline characteristics including maternal age, parity, and nutritional status did not differ by groups. The mean (SD) gestational age at enrollment was 9.9 (3.6) weeks. At enrollment the mean (SD) Hb concentration was 116 (11.7) g/L and 27.4% were anemic with no differences by arm. Effects of targeted and untargeted BEP compared to MMS in pregnancy on anemia in late pregnancy will be presented.

CONCLUSIONS

RESULTS will inform if targeted and untargeted fortified BEP supplementation compared to MMS reduces the risk of third trimester anemia among pregnant women in rural Bangladesh.

BACKGROUND AND OBJECTIVES

Despite the critical importance of human milk (HM) for infant health and development, little is known about how maternal nutritional interventions affect its composition. The International Milk Composition (IMiC) Consortium analyzed HM samples from three randomized controlled trials testing different nutritional interventions: balanced energy-protein supplementation (BEP) during pregnancy and/or lactation in Burkina Faso (MISAME-III) and Pakistan (VITAL-LW), and nicotinamide supplementation during lactation in Tanzania (ELICIT). VITAL-LW and ELICIT included antibiotic interventions. The CHILD cohort (Canada), which did not involve any intervention, served as a reference for comparison.

Objective: To present findings on the impact of maternal nutritional interventions on HM composition across diverse settings and stages of lactation, and across a range of milk -omic measures.

METHODS

Data were analyzed to assess the effects of nutritional interventions on individual and combined measures of HM composition from the three IMiC inbterventional trials trials. These include macronutrients (fat, protein, carbohydraites), micronutrients (vitamins, minerals) bioactives (immunoglobuins, oligosaccharides, cytokines, immune cells) and microbiota using metabolomics, metagenomics, proteomics. A total of 1,940 HM samples, representing diverse settings and stages of lactation, were included in the analysis.

RESULTS

BEP and nicotinamide interventions significantly impacted B-vitamin concentrations in HM. Postnatal BEP supplementation affected HM composition more substantially than prenatal BEP, particularly influencing triglycerides, with a complex effect on composition over time. The effects were most pronounced in settings with higher maternal undernutrition (Pakistan vs. Burkina Faso). BEP interventions affected total protein, fat, and energy in Vital-LW, but not MISAME-III, possibly because the population was more undernourished. Nicotinamide supplementation in ELICIT primarily affected B-vitamins and the metabolome, serving as a positive control.

https://doi.org/10.1017/jns.2026.10126 Published online by Cambridge University Press

CONCLUSIONS

These findings provide novel insights into how maternal nutritional interventions modify HM composition, highlighting the importance of optimizing the design and timing of such interventions to better support lactating mothers and their infants, especially in resource-limited settings.

CONFLICTS OF INTERESTS

The authors have no conflict of interest.

NAUNEHAL; Integrated Maternal, Neonatal and Child Nutrition, Health and Immunization Interventions in Conflict-Affected Areas of Pakistan: A Mixed-METHODS Quasi-experimental Study

Amira Khan[1]; Anushka Ataullahjan,[2]; Imran Ahmed[3]; Muhammad Jawad,[3]; Rehman Tahir,[4]; Zulfiqar Bhutta[5]
[1]Centre for Global Child Health , The Hospital for Sick Children, Toronto, Canada; [2]School of Health Studies, University of Western Ontario, London, Canada; [3]Institute of Global Health and Development, Aga Khan University, Karachi, Pakistan; [4]Research Office, Trust for Vaccines and Immunization, Karachi, Pakistan; [5]Centre for Global Child Health, The Hospital for Sick Children, Toronto, Canada

BACKGROUND AND OBJECTIVES

Pakistan's ongoing struggle to improve health indicators has been challenged by political and economic instability compounded by conflict. Rising insecurity has impeded delivery of nutrition and health interventions, especially in the provinces of Balochistan (BN) and Khyber Pakhtunkhwa (KP) (1). The 'Naunehal' research project tested integrated strategies to improve coverage of maternal & child nutrition & health services in insecure areas.

METHODS

Intervention strategies adopted were; community mobilization, information sessons on maternal nutrition and infant & young child feeding (IYCF), outreach teams offering nutrition, health and immunization services, and private health care provider engagement for IYCF counselling and immunization. This mixed-METHODS quasi-experimental study was implemented in three union councils (UCs), Kharotabad (BN), Bhana Mari (KP) and Bakhmal Ahmedzai (KP) with baseline and endline surveys, between March 2021-May 2022. For each intervention UC, a control UC of comparable size, population and coverage indicators was identified, where routine care was available. Each survey covered ~450, randomly selected households per UC, with at least one child under-five. Quantitative data collected from caregivers covered demographics, nutrition & WASH practices, care-seeking, and immunization, while qualitative data from FGDs and interviews captured community, health worker and stakeholder perspectives. Coverage was calculated overall and by UC, with mean & percentage point differences estimated using mixed effects linear regression, adjusted for survey design and sampling weights.

RESULTS

At endline, fully immunized children significantly increased (19.0% difference, (10.4%-27.7%),$p<0.0001$) in intervention UCs, while early initiation of breastfeeding (7.3%, $p=0.3426$), exclusive breastfeeding (5.3%,$p=0.5621$), and minimum dietary diversity (9.8%,$p=0.0727$) showed non-significant increases. Handwashing with soap before food preparation & feeding improved significantly ($p<0.0001$). Qualitative data indicated that while nutrition especially IYCF knowledge improved, translation into practice was impeded by systemic social, cultural, and structural barriers in these complex settings.

CONCLUSIONS

This low-cost integrated strategy of community mobilization and outreach services successfully reduced gaps in immunization coverage but had limited impact on nutrition and IYCF behaviors. A potential scale-up of this integrated intervention with added multisectoral components could be a promising nutrition and health strategy in complex contexts.

ULTRA-PROCESSED FOODS AND CARDIOMETABOLIC RISK AMONG MALAYSIAN ADOLESCENTS: INSIGHTS FROM MALAYSIAN HEALTH AND ADOLESCENTS LONGITUDINAL RESEARCH TEAM STUDY (THE MYHEART STUDY)

Darwish Mohd Isa[1]; Farizah Mohd Hairi[1]; Suzana Shahar[2]; Ai Kah Ng[1]; Nithiah Thangiah[1]; Hazreen Abdul Majid[3]

[1]Social and Preventive Medicine, University of Malaya, Kuala Lumpur, Malaysia; [2]Dietetic Programme, Centre for Healthy Ageing and Wellness (H-Care), Faculty of Health Sciences, Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia; [3]School of Health and Rehabilitation Sciences, Health Sciences University, Bournemouth, United Kingdom

BACKGROUND AND OBJECTIVES

The rising consumption of ultra-processed foods (UPFs) globally has been linked to poor dietary quality and increased non-communicable disease risks. Adolescents, who may take these foods due to its convenience face heightened vulnerability, yet limited data exist on UPF intake among Malaysian adolescents. This study aimed to evaluate the relationship between UPF consumption and cardiometabolic risk among 17-year-old schoolchildren in Malaysia, using data from the 2016 Malaysian Health and Adolescents Longitudinal Research Team Study (MyHeART).

METHODS

A cross-sectional analysis was conducted on 975, 17 years old adolescents. Dietary intake was assessed through a 7-day recall and classified using the NOVA system. UPF intake was expressed as a percentage of total energy intake and categorized into quartiles. Cardiometabolic risk scores, derived from blood pressure, lipid profile, fasting glucose, body-mass-index, waist circumference, and physical fitness score were dichotomized into low and high-risk categories.. Ethics approval was obtained from Ethics Committee of University of Malaya Medical Centre (ethical approval number-14-376-20486).

RESULTS

A quarter (25.3%) of participants consumed ≥35% of their total energy from UPFs which showed positive correlation with fat ($r = 0.47$, $p < 0.001$), sugar ($r = 0.22$, $p < 0.001$), and sodium intake ($r = 0.28$, $p < 0.001$). Female adolescents were 2.38 times more likely than males to report high UPF intake (aOR: 2.38, 95% CI: 1.69–3.36, $p < 0.001$). However, no significant association was found between UPF intake quartiles and cardiometabolic risk scores ($p > 0.05$).

CONCLUSIONS

While no direct link was observed between UPF intake and cardiometabolic risk, the substantial UPF consumption highlights a critical area for public health intervention. Promoting healthier dietary choices among Malaysian adolescents could mitigate future non-communicable disease risks.

FACTORS ASSOCIATED WITH MATERNAL BODY COMPOSITION AND THE ASSOCIATION OF MATERNAL BODY COMPOSITION WITH CHILD ANTHROPOMETRIC OUTCOMES: FINDINGS FROM BANGLADESH

Md. Mokbul Hossain,[1]; Fahmida Akter[2]; Abu Ahmed Shamim[1]; Nazma Shaheen[3]; Farhana Sharmin[4]; Piyali Mustaphi[4]; Golam Mohiuddin Khan[4]; Mayang Sari[4]; Iqbal Kabir[4]; Akhter Imam[5]; Malay Kanti Mridha[1]
[1]James P Grant School of Public Health, BRAC University, Dhaka, Bangladesh; [2]BRAC James P Grant School of Public Health, BRAC University, Dhaka, Bangladesh; [3]Institute of Nutrition and Food Science, University of Dhaka, Dhaka, Bangladesh; [4]UNICEF Bangladesh, Dhaka Bangladesh, Dhaka, Bangladesh; [5]Bangladesh National Nutrition Council (BNNC), Dhaka Bangladesh, Dhaka, Bangladesh

BACKGROUND AND OBJECTIVES

Maternal body composition (MBC) is a critical determinant of child health, influencing growth and developmental outcomes. In this study, we aimed to (i) identify factors associated with MBC; and (2) explore the relationship between MBC and child anthropometric outcomes, including weight-for-age (WAZ), height-for-age (HAZ), and body-mass-index (BMI)-for-age.

METHODS

A cross-sectional study was conducted among n=3621 women of reproductive age (14-49 years) and their children (0-59 months) in rural, non-slum urban, and slum areas of Bangladesh. MBC was assessed using bioelectrical impedance analysis, measuring fat mass (FM), fat-free mass (FFM), and body fat percentage. Anthropometric measurements of children, including weight, height, and body mass index (BMI), were converted into z-scores based on WHO growth standards. Data on socio-demographic variables, and dietary diversity were collected via structured questionnaires. Multivariable regression models were used to identify factors associated with MBC and linear regression models were used to explore the association of MBC with child growth indicators.

RESULTS

Key factors associated with MBC included age, wealth quintile, educational status, and food security. Women aged 30–39 years (AOR = 5.61) and 40–49 years (AOR = 8.22) were significantly more likely to have high fat mass compared to those under 20 years ($p < 0.001$). Women in the richest quintile had higher odds of high fat mass (AOR of 1.63, $p < 0.001$) compared to the women in the poorest quintile. Food insecurity, particularly mild food insecurity, was inversely associated with high fat mass (AOR = 0.81, $p = 0.086$). Maternal height was strongly associated with child HAZ scores across age groups (e.g., regression coefficient = 0.064, $p < 0.05$, overall), while maternal fat-free mass was positively correlated with child WAZ scores, particularly for children aged 24–35 months (coefficient = 0.064, $p < 0.05$). Maternal weight was significantly associated with child WHZ scores (e.g., coefficient = 0.020, $p < 0.05$, overall), with stronger effects observed in specific age groups such as 18–23 months and 24–35 months.

CONCLUSIONS

MBC is influenced by modifiable factors and is a significant predictor of child growth outcomes in Bangladesh. Context-specific interventions focusing on improving both maternal and child nutrition are essential to improve maternal and child nutrition in resource-constrained settings.

MATERNAL PRENATAL DIET MEDIATES EPIGENETIC PATHWAYS TO SHAPE INFANT COGNITION: THE BARWON INFANT STUDY PRE-BIRTH COHORT

Lada Holland[1]; Drummond Katherine[1]; Thomson Sarah[1]; Tanner Samuel[1]; Marx Wolfgang[2]; Novakovic Boris[3]; Ponsonby Anne-Louise[1]
[1]Neuroepidemiology, The Florey Institute of Neuroscience and Mental Health, Parkville, Australia; [2]School of Medicine, The Institute for Mental and Physical Health and Clinical Translation, Geelong, Australia; [3]Royal Children's Hospital, Murdoch children research Institute, Royal Children's Hospital, Melboiurne, Australia

BACKGROUND AND OBJECTIVES

Dietary patterns during pregnancy influence the developing foetal brain, potentially through DNA methylation (DNAm), a suggested molecular mechanism with long-lasting effects. Here we tested the relationship between maternal diet, DNAm profile in cord blood and neurodevelopmental outcomes at age 2 in the Barwon Infant Study (N = 1,074, mediation analysis N=562) in Victoria, Australia.

METHODS

We explored mediation of dietary-neurodevelopment outcomes by DNAm at birth. Maternal diet was assessed using a food frequency questionnaire at 28 weeks of gestation. DNAm was measured with the Infinium MethylationEPIC array. Neurodevelopmental outcomes, assessed using the Bayley-III scales, revealed that wholefoods diet was associated with improved child cognition and language (Gogos et al., 2024). Subtle changes across many pathways that may influence child cognition and language development were explored using an advanced epigenetic network approach, specifically Weighted Gene Co-expression Network Analysis.

RESULTS

We identified a DNAm module that associated with prenatal wholefoods diet and child's cognition and language. This module mediated the relationship between a wholefoods dietary pattern and increased child cognition (indirect effect p = 0.016, proportion mediated = 13%) and receptive language development (indirect effect p = 0.03, proportion mediated = 8%). Pathway enrichment analysis revealed that this module is linked to the RHO GTPase pathway, with the hub gene, MED13L, a candidate gene for cognitive and intellectual disorders involving language deficits. Validation of the key findings is currently being undertaken in another cohort.

CONCLUSIONS

This research supports the importance of maternal diet in promoting optimal child neurodevelopment, mediated through epigenetic pathways. It highlights the potential for tailoring nutritional interventions to target the epigenetic control of genes in specific pathways to enhance neurodevelopmental outcomes.

BACKGROUND AND OBJECTIVES

The Mediterranean-DASH Intervention for Neurodegenerative Delay (MIND) diet, a sustainable diet developed to promote brain health, has been linked to reduced cognitive decline. However, the biological pathways underlying this association remain unclear. Developing a panel of objective biomarkers for adherence to this diet could give novel insights on such mechanisms and might help to identify target populations for clinical trials or prevention programs aimed at lowering cognitive aging through nutritional strategies. To address this challenge, metabolomics, including biomarkers of both external exposures and endogenous metabolism, is a valuable tool. The objective of this study was to characterize a blood metabolomic signature of adherence to the MIND diet and evaluate its prospective association with cognitive trajectories in older adults from the general population.

METHODS

We leveraged data from the French Three-City cohort, that included individuals aged ≥65 years in 1999. Two independent nested case-control samples were defined contrasting participants with higher versus lower 12-year cognitive decline trajectories: a discovery (n=418) and a validation sample (n=420). A targeted metabolomic analysis allowed to quantify 154 diet-related metabolites in plasma at study baseline. We first analyzed the 344 participants from the first sample who answered a comprehensive dietary survey to identify, with a penalized regression approach (LASSO), a signature of metabolites linked to greater MIND diet adherence. We then leveraged the full discovery and validation samples to evaluate associations between the metabolomic signature and cognitive decline.

RESULTS

Eight metabolites were selected in the metabolomic signature of the MIND diet; three metabolites were associated with greater adherence (3-HHA, 5-HIAA and betaine, mainly phenolic acids and amino acid derivatives, derived from fruits and vegetables intake), and five metabolites with lower adherence (1-methylhistidine, cyclo(L-leucyl-L-prolyl), tartaric acid, Myristoyl-carnitine and DHEA-S, derived from red meat, coffee, wine or endogenously produced). The MIND metabolomic signature was significantly associated with lower odds of cognitive decline in the discovery sample. RESULTS were in the same direction, although not statistically significant, in the validation sample.

CONCLUSIONS

This study highlights a potential metabolomic signature of the MIND diet to support brain health at the molecular level and may provide an objective measure of adherence to a brain-healthy diet for cognitive decline prevention.

OAP24_03

AI-POWERED THE CLASSIFICATION OF NOVA FOOD PROCESSING: EXPLORING TAIWANESE FOODS WITH NATIONALLY REPRESENTATIVE DATA

Hsiao-Wen Chuang[1]; Ying Hsiao[1]; Yu-Zhi Su[1]; Yi-Chen Huang[1]
[1]Department of Nutrition, China Medical University, Taichung, Taiwan

BACKGROUND AND OBJECTIVES

Tools for classifying food processing levels can assist the public in choosing healthier foods. Although studies have developed machine learning models for NOVA classification, challenges persist in categorizing complex foods, particularity in Asian regions. Large Language Models (LLMs) demonstrate powerful cross-domain capabilities and have been applied to various healthcare tasks. This study evaluates the accuracy of Claude 3.5 and GPT-4o in determining NOVA classifications for commonly consumed Taiwanese foods.

METHODS

The 2013-2016 Nutrition and Health Survey in Taiwan (NAHSIT) provided nationally representative dietary data collected through 24-hour dietary recalls. Food items were classified in to four NOVA categories: **Unprocessed or minimally processed foods, Processed culinary ingredients, Processed foods, Ultra-processed foods (UPFs).** The top 200 most frequently consumed items from each group (800 items in total) were selected as the test sample. The evaluation involved two rounds: the first assessed the accuracy of both LLMs without any prior references, while the second evaluated them after providing NOVA-related literature as calibration guidance.

RESULTS

Claude 3.5 outperformed GPT-4o overall, achieving an accuracy rate of 77.88%, compared to GPT-4o's 63.38%. For **processed foods** and **UPFs**, Claude 3.5 performed notably better, achieving accuracy rates of 73.25% and 97.75% respectively, compared to GPT-4o's 33.50% and 69.50%. However, for **unprocessed or minimally processed foods**, GPT-4o achieved slightly better accuracy (85.25%) than Claude 3.5 (79.75%). Chi-square tests revealed statistically significant differences ($p < 0.001$) between the accuracy rates of two LLMs. Indicating distinct performance variance in NOVA classification.

CONCLUSIONS

LLMs demonstrate potential in classifying food processing levels, particularly for complex foods items. Claude 3.5 outperformed GPT-4o overall, with exceptional performance in identifying UPFs. These findings highlight the potential of LLMs in food classification systems, offering AI-based initial assessments for professional validation. Such tools could support nutrition education and assist the public in choosing healthier foods. Future research should expand datasets and refine prompts with updated literature to improve accuracy, particularly for minimally processed foods.

MODELLING THE HEALTH, EQUITY, AND COST-EFFECTIVENESS IMPACTS OF FOOD TAXES AND SUBSIDIES IN AUSTRALIA

Tazman Davies[1]; Linda Cobiac[2]; Lennert Veerman[2]; Eden Barrett[1]; Daisy Coyle[1]; Jason Wu[1]; Matti Marklund[3]
[1]The George Insititute for Global Health, University of New South Wales, Sydney, Australia; [2]School of Medicine, Griffiths University, Brisbane, Australia; [3]Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, United States of America

BACKGROUND AND OBJECTIVES

The World Health Organization recommends food taxes and subsidies as part of a suite of strategies to address non-communicable diseases (NCDs). This study aimed to estimate the dietary, health, equity, and economic impacts of two fiscal food policies in Australia: (i) a 20% tax on less healthy foods (i.e., sugar-sweetened beverages, confectionery, snackfoods, biscuits, pastries, ice cream, and processed meat) and (ii) a 20% subsidy for fruits and vegetables.

METHODS

For each policy, we assumed a 100% pass-through rate and used nationally representative dietary intake and consumer purchasing data to estimate the population-level dietary impacts. We used a proportional multi-state lifetable-based model to translate the effects on fruit and vegetable intake and body mass (via energy intake) into changes in the incidence of seven diet-related noncommunicable diseases and the associated health-adjusted life years (HALYs) for the 2020 Australian population. Cost-effectiveness was assessed from an extended healthcare perspective, which included costs for policy implementation (assumed to equal 2% of tax revenue or subsidy costs, respectively), and total health care costs (i.e., costs for modelled diseases and other healthcare expenditures). Analyses were stratified by socio-economic quintile, and health-effects were attributed to individual food categories.

RESULTS

Over a 25-year period, a tax on less healthy foods could lower average daily per capita energy intake by ~400 kJ (i.e., 96 kcal), avert ~79,000 NCD deaths, produce ~750,000 HALYs, promote health equity (i.e., 26% of HALYs accruing among lowest socio-economic quintile), and be cost-saving (about -$11 billion in net costs). Approximately one-tenth of these potential gains would be attributable to taxing sugar-sweetened beverages. The subsidy for fruits and vegetables could increase daily per capita fruit and vegetable intake (i.e., ~28g, and ~29g per capita per day, respectively), prevent ~8,000 NCD deaths, generate ~33,000 HALYs, promote health equity (i.e., 24% of HALYs accruing in the poorest quintile), and be cost-effective (~$31,000 incremental cost per HALY gained).

CONCLUSIONS

Our study supports the use of taxes and subsidies as equitable and cost-effective - or even cost-saving - strategies to improve diets, prevent diet-related NCDs, save lives, and reduce health disparities in Australia.

EXPLORING FACTORS ASSOCIATED WITH DIET QUALITY AMONG SCHOOLCHILDREN IN RURAL CAMBODIA

Vannary Hun; Kroeun Hou[1]; P. Joseph Fogarty[1]; Mai-Anh Hoang[2]; Ngik Rem[3]; Lisa Litrell[2]; Aman Sen Gupta[4]; Akriti Singh[2]; Sopheab Heng[5]; Chhorvann Chhea[5]
[1]Nutrition, Helen Keller Intl Cambodia, Phnom Penh, Cambodia; [2]Nutrition, Helen Keller Intl, New York, United States of America; [3]Monitoring and Evaluation, Helen Keller Intl Cambodia, Phnom Penh, Cambodia; [4]Monitoring and Evaluation, Helen Keller Intl Nepal, Lalitpur, Nepal; [5]Public Health, National Institute of Public Health, Phnom Penh, Cambodia

BACKGROUND AND OBJECTIVES

Cambodia faces a double burden of communicable diseases and non-communicable diseases (NCDs), with NCDs accounting for 64% of all deaths in Cambodia. There is a growing trend of children consuming more ultra-processed foods and foods high in fat, salt, and sugar, but few studies have documented dietary patterns among school children. This study aims to evaluate children's diet quality in four provinces in Cambodia and identify socio-demographic factors associated with dietary choices to identify future interventions to prevent overweight and obesity.

METHODS

This analysis uses data from a cross-sectional survey conducted in 2024, encompassing 691 schoolchildren aged 6-11 years across four rural provinces: Takeo, Kampot, Kampong Speu, and Kampong Thom. Diet quality was measured using the Diet Quality Questionnaire (DQQ). The outcomes of interest were the Global Dietary Recommendation (GDR-Score), NCD-Protect Score, NCD-Risk Score, minimum dietary diversity, All-5 recommended foods, and individual healthy and ultra-processed foods. Socio-demographic factors, including child sex and age and caregiver's education, marital status, and wealth quintile, were included in bivariate and multivariate logistic regression analyses.

RESULTS

The average GDR score was 9.51, the average NCD-Risk Score was 2.21, and the average NCD-Protect Score was 2.73. Among the sampled children, approximately 63.24% had minimum food diversity, and 16% achieved All-5 recommended food groups. However, only 9% had any Vitamin A-rich fruits and 54% consumed dark green leafy vegetables. Among ultra-processed foods, 41% consumed sweet beverages, 33% consumed salty or fried snacks, and 16% consumed fast food and instant noodles. Sociodemographic characteristics did not vary between children with GDR >=10 (meeting half of the WHO recommendation for a healthy diet) vs. GDR<10.

CONCLUSIONS

The study's findings show that while, on average, schoolchildren in rural Cambodia are close to meeting half of the WHO recommendation for a healthy diet, there are opportunities to enhance diets further. Programs should promote the consumption of vitamin A-rich fruits and dark green leafy vegetables and employ a variety of approaches to discourage the consumption of ultra-processed food such as sweet beverages, salty or fried food, and fast food, including noodles. A limitation of this study is that the DQQ has not been validated for the 6-11 age group, which should be considered when interpreting the RESULTS.

What is a snack? Types of snacks and why parents in Southern Thailand give them to their children: a mixed METHODS study

Nutchanet Tayeh[1]; Charlotte Margaret Wright[1]; Ada L. Garcia[2]
[1]Human Nutrition, University of Glasgow, Glasgow, United Kingdom; [2]Human Nutrition, School of Medicine, Dentistry and Nursing , University of Glasgow, Glasgow, United Kingdom

BACKGROUND AND OBJECTIVES

Snacks contribute 15-30% of children's daily energy intake globally(1) raising concerns about unhealthy eating and obesity(2). However, snack definitions vary(3). We aim to explore 1) how parents in urban and rural areas of Thailand's southernmost border provinces (SBPs) define snacks, 2) what types of snacks are consumed by children and reasons for giving snacks.

METHODS

Four focus groups (n=10/each) with parents of children aged 3-5y living in urban and rural areas of SBPs were recruited for semi-structured interviews. Parents were asked: What is a snack? Why and when do you give snacks to your child?. Thematic analysis(4) was used to synthesise qualitative findings with NVivo 14. The International Complementary Feeding and Eating Tool (ICFET)(5) was used to survey 279 parents attending nurseries in SBPs for frequency of consumption and reasons for giving snacks. Scores for favourite snack categories (commercial, traditional, sweet, savoury) and reasons (scales 1-5) were compared between urban and rural settings using SPSS V28.

RESULTS

Qualitative findings identified five themes of snack definitions: 1) A supplementary food; 2) foods containing monosodium glutamate (MSG) or 'Tua Pong Bejing'; 3) Not rice; 4) Commercially produced snack foods; 5) Foods given for emotional control and comfort. Parents lack consensus regarding strategies about when to offer snacks. Commercially produced snacks were preferred by over 80% of young children in both urban and rural areas, while traditionally made snacks were the least favoured (<20%). More rural children preferred sweet snacks (80%) compared to urban children (55%). Parents of urban children more often reported giving snacks because of child boredom [Mean(SD) (2.79(1.03) vs (2.51(0.93)] rural, (P=0.051) and at school [(3.07(1.09) vs (2.56(0.98)] rural, (P=0.031). Rural children were more influenced by advertised snacks [(2.96(1.01) vs (2.73(1.11)] urban, (P=0.068) and peers [(2.49(0.95)) vs (2.23(1.04)] urban, (P=0.030).

CONCLUSIONS

Snack definitions are highly subjective and varied. Parents predominantly viewed snacks as foods other than rice, or commercially produced snacks, flavoured with MSG. Commercial, cultural and social norms are shaping children's snacking behaviour in Thailand's SBPs, in rural as well as urban areas.

ANTENATAL MULTIPLE MICRONUTRIENT VERSUS IRON-FOLIC ACID SUPPLEMENTATION: OUTCOMES OF AN IMPLEMENTATION TRIAL WITHIN UNRWA HEALTH SYSTEM SERVING PALESTINE REFUGEES IN JORDAN

Masako Horino[1, 2]; Luai Al-Khatib[3]; Rami Habash[1]; Akihiro Seita[1]; Tamara Al Rahahleh[1]; Klaus Kraemer[4]; Kristen Hurley[5]; Keith West[2]
[1]Department of Health, UNRWA Headquarters, Amman, Jordan; [2]Center for Human Nutrition, Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, United States of America; [3]Department of Health, UNRWA Jordan Field Office, Rashid Byouk St, Amman, Jordan, Amman, Jordan, Jordan; [4]Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, USA, Baltimo, United States of America; [5]International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, United States of America

BACKGROUND AND OBJECTIVES

Maternal anemia and micronutrient deficiencies (MNDs) are common in Palestine refugees.1-2 Multiple micronutrient supplementation (MMS) can reduce MNDs and adverse pregnancy outcomes.3-5 Since 2020, UNWRA, serving ~90,000 Palestine refugee pregnant women annually,6 has conducted implementation research, per WHO guidelines,7 to guide policy on replacing iron-folic acid (IFA) with MMS in ANC. The study objective was to compare implementation outcomes of MMS vs IFA delivery within UNRWA ANC system in Jordan.

METHODS

After a six-month MMS pilot in 2large clinics,8 a 10-month implementation trial was conducted whereby 13 clinics (2 pilot plus 11 randomized) were assigned for midwives to issue 180-ct bottles of UNIMMAP MMS9 at pregnancy registration; another 12 clinics were randomized to IFA standard-of-care whereby physicians prescribed folic acid (FA, 0.4 mg) in the 1st trimester and IFA (100 mg & 0.4 mg) thereafter, both in 10-ct blister packs. Coverage was assessed at registration. At up to 7 follow-up visits, histories of side effects and adherence, validated by weighing bottles, were assessed. Acceptability was assessed by anonymously interviewing mothers at 6 larger clinics in each group. Hemoglobin distributions and anemia, routinely assessed at registration and mid-pregnancy, were compared by clinic-assignment. Data were deidentified, abstracted from the Agency's eHealth system and analyzed, with relative risks (RR) adjusted for gestational age and design effect by GEE. UNRWA Research Review Board and Johns Hopkins IRB provided ethical approvals.

RESULTS

Throughout March-December 2023, 9754 and 5574 women registered in MMS and IFA clinics. Coverage per protocol at registration was 94% for MMS, 79% for FA, and 86% for IFA. Up to 7th follow-up visits, in MMS vs IFA recipients, 8-13% vs 16-28% reported constipation ($p<0.0001$), 82-84% vs 74-82% reported excellent ($\geq$90%) adherence, and 5-6% vs 10-17% reported poor (<70%) adherence. In exit interviews, 52% vs 41% reported improved appetite, 65% vs 59% mentioned feeling healthier and 51% vs 41% noted having more energy (all $p<0.04$). In 4222 and 2361 1st-2nd trimester registrants, in MMS vs IFA clinics, with Hb$\geq$10 g/dL (UNRWA treatment threshold), the RR of mid-pregnancy moderate-to-severe anemia (Hb<10 g/dL) was 0.66 (95% CI: 0.49-0.90), favoring MMS.

CONCLUSIONS

MMS is feasibly implemented as a standard of care within the UNRWA ANC system, evident by superior coverage, adherence, acceptability and effectiveness in anemia prevention.

GESTATIONAL WEIGHT GAIN PATTERNS AND DISTRIBUTION IN FIVE LOW- AND MIDDLE-INCOME COUNTRIES ACROSS AFRICA AND ASIA

Neeraj Sharma[1]; Xinyi Li[2]; Qing Pan[2]; Ranadip Chowdhury[3]; Fouzia Farooq[2]; Kwaku Asante Poku[4]; Zahra Hoodbhoy[5]; Anne George Cherian[6]; Wilbroad Mutale[7]; Harun Owuor[8]; Sarmila Mazumder[1]
[1]Implementation Science, Society for Applied Studies, New Delhi, India; [2]Global Health, The George Washington University, Washington, United States of America; [3]Nutrition Division, Society for Applied Studies, New Delhi, India; [4]Research and Development Division, Kintampo Health Research Centre, Kintampo, Ghana; [5]Paediatrics and Child Health, Aga Khan University, Karachi, Pakistan; [6]Obstetrics and Gynecology, Christian Medical College Vellore, Vellore, India; [7]Global Projects Zambia, University of North Carolina at Chapel Hill, North Carolina, United States of America; [8]Center for Global Health Research, Kenya Medical Research Institute, Nairobi, Kenya

BACKGROUND AND OBJECTIVES

Adequate gestational weight gain (GWG) is a crucial factor in ensuring a healthy pregnancy. However, there is limited population-based data from low- and middle-income countries (LMICs) to inform evidence-based guidelines. We aimed to assess the prevalence and trends in GWG stratified by early-pregnancy body mass index (BMI) using data from a multi-site cohort study in five LMICs across Asia and Africa

METHODS

We analyzed GWG data from the ongoing Pregnancy Risk, Infant Surveillance, and Measurement Alliance (PRISMA) open cohort study. Participant pre-pregnancy data were classified into BMI groups using weight taken at or before 9 weeks gestation or imputed using a mixed-effects restricted cubic spline mode if weight was assessed between 10 - 20 weeks gestation. We calculated total GWG and GWG adequacy based on participants' early pregnancy BMI using the Institute of Medicine (IOM) guidelines. Demographic, clinical and lifestyle characteristics were stratified by early-pregnancy BMI groups and IOM adequacy levels. Additionally, latent class trajectory modeling for GWG was used to identify patterns of GWG and group pregnant women into IOM categories based on these patterns.

RESULTS

Out of 5,134 pregnant women, 17% were underweight (BMI <18.5 kg/m2), 19% were overweight (25-29.9 kg/m2), and 10% were obese (≥30 kg/m2) prepregnancy. Mean gestational age at enrollment was 13±3.6 weeks. About one-third (37%) had inadequate gestational weight gain (I-GWG), while one-third (33%) had excessive gestational weight gain (E-GWG). Mean (SD) GWG among underweight, normal, overweight and obese women were 8.9±3.5, 8.3±3.5, 7.1±4.1, and 5.9±4.5 kg, respectively. The proportion of I-GWG was highest (54.8%) among women who were underweight at the start of pregnancy; the proportion of E-GWG was highest (54.6%) among women who were obese at the start of pregnancy. Among all births, 17% were classified as low birthweight, with 48% occurring in the I-GWG group and 22% in the E-GWG group, fetal loss before 20 weeks occurred in 1.4% of pregnancies overall, with 2.1% among E-GWG and 1.8% among I-GWG. No fetal losses were observed among those with adequate gestational weight gain.

CONCLUSIONS

Inadequate gestational weight gain is common for women underweight and normal weight at the start of pregnancy. Both I-GWG and E-GWG lead to adverse pregnancy outcomes. Given that the elimination of all forms of malnutrition remains a global priority, focused and timely interventions during pregnancy should be prioritized.

Impact of a French social marketing campaign to increase parental support and physical activity in adolescents aged 11-14 years: RESULTS from a longitudinal study

Philippine Fassier[1]; Hélène Escalon[1]; Florence Rostan[1]; Damien Tessier[2]; Anne-Juliette Serry[3]
[1]Diet and physical activity unit, Santé publique France, Saint-Maurice, France; [2]Université Grenoble Alpes, Université Grenoble Alpes, gren, France; [3]Health prevention and promotion department - Nutrition & physical activity unit, Santé publique France, Saint-Maurice, France

BACKGROUND AND OBJECTIVES

Due to the lower prevalence of teenagers who reach physical activity guidelines, Santé Publique France launched in September 2022 a social marketing campaign targeting teenagers' parents with the aim to increase several forms of parental support (1- encouraging their teenagers to be physical activity, 2- being physical activity with them, and 3- helping them to find the sport they like).

Aims of this study were to evaluate the variations of 1) parental support' determinants, 2) parental support, and 3) teenagers' physical activity between before and after campaign.

METHODS

A prospective study was conducted on the Internet. A representative sample of 4,005 French parents was recruited and questioned before the campaign was broadcast (t0), in the month that followed (t1) and 10 months later (t2). Analyses were conducted on parents who responded at t1 and t2 (N=2,808 and N=2,173 respectively). The association between changes in the indicators and recognition of the campaign was assessed using Generalized Estimation Equation (GEE) adjusted models.

RESULTS

Overall, a significant difference in the variation of self-efficacy for helping their teenager to find the sport he/she loves was observed at T1 between parents who did and did not recall the campaign ($p<0.05$), more specifically among girls (p-value=0.03) and parents with low socio-professional status ($\beta=0.06$, $p=0.02$). Among those who recalled the campaign, a significant difference for the variation of encouragements was observed at T1 ($\beta=0.04$, p-value=0.04).

Among parents with an initial low level of positive attitude, those who recalled the campaign showed more frequently positive attitude for encouraging their teenager to be physically active (p-value=0.04 at T1 and p-value=0.0008 at T2), and for engaging in physical activity with their teenager (p-value=0.0009). They increased more their practice of physical activity with their teenager at T1 (p-value=0.0003). Among parents with a teenager with an initial low physical activity level, recognition of the campaign was associated with an increasing of physical activity during the week-end, frequency of active travel for going to school, of sport practiced in a club and of informal physical activities ($p<0.05$).

CONCLUSIONS

This evaluation shown positive and encouraging RESULTS for a first broadcast, sometimes maintained over the long term. In view of these promising RESULTS, the campaign was rebroadcasted in September 2023 and will be investigated using the same cohort of parents.

COULD A BASIC INCOME IMPROVE DIET QUALITY AND REDUCE DIETARY INEQUITIES? AN AGENT-BASED COMPLEX SYSTEMS SIMULATION MODEL

Dana Olstad[1]; Brent Langellier[2]; Eldon Spackman[1]; Andres Useche[2]; Rebecca Hasdell[3]; Nicolas De Guzman Chorny[4]; Heidi Olstad[5]; Seyed Hosseini Pozveh[1]
[1]Department of Community Health Sciences, University of Calgary, Calgary, Canada; [2]Dornsife School of Public Health, Drexel University, Philadelphia, United States of America; [3]Determinants of Health and Health Equity, BC Centre for Disease Control, Vancouver, Canada; [4]Strategic Policy Branch, Public Health Agency of Canada, Ottawa, Canada; [5]Evaluation and Population and Public Health, Alberta Health Services, Edmonton, Canada

BACKGROUND AND OBJECTIVES

The inadequacies of current social protection policies in improving diet quality and reducing dietary inequities have renewed interest in a Basic Income (BI) to ensure all Canadians can afford a healthful diet. However, due to the challenges of conducting large, long-term, population-based randomized controlled trials, there are no data pertaining to the impact of different forms of a BI on diet quality and dietary inequities. We developed the first agent-based complex systems simulation model to investigate the effectiveness of 20 different forms of a BI on diet quality and dietary inequities among adults in Canada.

METHODS

Agents in our model are adults who are assigned an age, sex, ethnicity, household income, food budget, diet quality (Healthy Eating Food Index-2019 scores from 0-80; HEFI-2019), energy intake and food spending based on nationally representative data. At each bi-weekly time step, agents receive their regular income plus a BI (if eligible), calculate their new food budget, and incrementally adjust their food spending based on empirically-derived decision rules until it is within 10% of their new food budget. Agents' diet quality evolves in conjunction with incremental increases in food spending, leading to emergence of a new distribution of diet quality by income at the population level for each of the 20 forms of a BI. These 20 forms of a BI combine different BI models (universal, negative income tax, income top-up), benefit levels (low-income cut-off, low-income measure, market basket measure, living wage), and reduction rates (0-100%).

RESULTS

Different combinations of BI models, reduction rates and benefit levels did not meaningfully improve HEFI-2019 scores at a population level, with maximum improvements of 1.5 points. All BI models, reduction rates and benefit levels improved HEFI-2019 scores in the lowest income quintile by up to 4 points, which may be clinically meaningful. However, a universal BI, higher benefit levels and a 0% reduction rate also improved HEFI-2019 scores by up to 1.3 points in the middle and highest income quintiles.

CONCLUSIONS

A BI may not meaningfully improve diet quality at a population level in Canada, regardless of its design features. All forms of a BI may improve diet quality in the lowest income groups and may thereby reduce dietary inequities. However, a universal BI may be less effective in reducing dietary inequities because it also improves diet quality in higher income groups.

NUT INTAKE, FUNCTIONAL LIMITATIONS, AND QUALITY OF LIFE IN OLDER ADULTS: FINDINGS FROM NHANES 2003-12

Ilili Feyesa Regassa[1]; Elena S. George[1]; David Scott[1]; Gavin Abbott[1]; Jeew Hettiarachchi[1]; Robin M. Daly[1]; Jack Dalla Via[2, 3]; Ekavi Georgousopoulou[4, 5]; Sze-Yen Tan[1]
[1]Institute for Physical Activity and Nutrition (IPAN), Deakin University, Geelong, Australia; [2]School of Exercise and Nutrition Sciences, Deakin University, Geelong, VIC 3220, Australia; [3]Nutrition and Health Innovation Research Institute, School of Medical and Health Sciences, Edith Cowan University, Joondalup, WA 6027, Australia; [4]Discipline of Nutrition and Dietetics, University of Canberra, Canberra, Australia; [5]School of Medicine Sydney, University of Notre Dame Australia, Sydney, Australia

BACKGROUND AND OBJECTIVES

Ageing is associated with functional limitations that can compromise quality of life (1, 2). Limited research suggests nut consumption may prevent or delay these limitations in older adults (3). This study aimed to determine associations between habitual nut intake, functional limitations, and quality of life in older adults.

METHODS

This cross-sectional study included data from 5,807 adults aged 60 years and older who participated in the U.S. National Health and Nutrition Examination Survey (NHANES) between 2003 and 2012. Nut intake was assessed using two 24-hour dietary recalls. Functional limitations were measured using the NHANES Physical Functioning Questionnaire (19 common daily life activities). Quality of life was evaluated using the standard four-question health-related quality of life (HRQOL-4) questionnaire. The HRQOL-4 comprises four questions focusing on the participant's general health status, number of physically unhealthy days, number of mentally unhealthy days, and number of days with activity limitations in the 30 days preceding the survey. Negative binomial regression and logistic regression were used to examine associations between nut intake and both functional limitations and quality of life.

RESULTS

Older adults who did not consume nuts (0 g/day; n=2579 [44.4%]) experienced a higher number and greater severity of functional limitations compared to those who consumed nuts (>0 g/day; n=3228 [55.6%]). After adjusting for age, sex, body mass index (BMI), ethnicity, household size, education, smoking status, history of cardiovascular disease (CVD) and type 2 diabetes mellitus (T2DM), non-protein energy, total protein intake, history of arthritis, and physical activity, nut consumers were estimated to have 14% fewer functional limitations (IRR = 0.86, 95% CI 0.76, 0.98, p=0.019) compared with non-consumers and lower severity of these limitations (β = -0.77, 95% CI -1.22, -0.32, p=0.001). Furthermore, nut consumers compared to non-consumers had a reduced odds of poor physical health (OR = 0.79, 95% CI 0.65, 0.96, p=0.020) and activity limitations (OR = 0.72, 95% CI 0.54, 0.95, p=0.023).

CONCLUSIONS

Older individuals who consume nuts are more likely to experience fewer functional limitations and fewer physically and mentally unhealthy days. Thus, the role of nuts consumption should be further investigated for its potential.

OAP26_07

IS THE BRASCORE, AN INDEX THAT MEASURES ADHERENCE TO THE DIETARY GUIDELINES FOR THE BRAZILIAN POPULATION, ASSOCIATED WITH A REDUCED RISK OF OVERWEIGHT AND OBESITY? FINDINGS FROM THE NUTRINET-BRASIL COHORT STUDY

Thays Souza[1, 2]; Camille Lassale[3]; Maria Laura Da Costa Louzada,[2]
[1]School of Public Health, Universidade de São Paulo, São Paulo, Brazil; [2]NUPENS, Nutrition, Faculdade de Saúde Pública USP, São Paulo, Brazil; [3]Environment and health throughout the lifecourse, ISGlobal, Barcelona, Spain

BACKGROUND AND OBJECTIVES

The Dietary Guidelines for the Brazilian Population (hereinafter referred to as the Dietary Guidelines) provide recommendations for a healthy and sustainable diet. They bring important conceptual innovations by pioneering using the Nova classification system as the basis for their recommendations. The BraScore was developed to assess the adherence to Dietary Guidelines. This study aims to assess the association between the BraScore and the incidence of overweight or obesity in the NutriNet-Brasil cohort study.

METHODS

Data from 21,930 participants who completed the two firsts dietary 24-hour recalls, were free of overweight or obesity at baseline, and had no missing on covariates were used. The tool employed for dietary data collection, Nova24h, specifically collects information on food processing. The BraScore was applied on food consumption data and includes 10 components, divided into three dimensions, with scores ranging from 0 to 100 points: *1. To be consumed:* legumes (0 – 15), fruits (0 – 10), vegetables (0 – 10), diversity (0 – 5); *2. To be limited:* eggs, fish, milk, and poultry (0 – 5), red meat (0 – 5), processed foods (0 – 5), table sugar (0 – 2.5), table salt (0 – 2.5); *3. To be avoided:* ultra-processed foods (0 – 40). Higher scores indicate greater adherence. New cases of overweight or obesity (≥25 kg/m²) were assessed over the follow-up period. Crude and adjusted (age, gender, education, asset score, race/skin colour, region of the country, physical activity) Cox proportional hazard ratio models were used.

RESULTS

There were 11,516 incident cases of overweight or obesity over 58,043.3 person-years during a median follow-up of 28.8 months. Adjusted models showed that a 10% increase in the BraScore was associated with 17% reduction in the risk of overweight or obesity (HR: 0.83, CI95% 0.82-0.84). According to the BraScore quintiles, the risk of overweight or obesity in the highest quintile was 48% lower compared to the lowest quintile (HR: 0.52, CI95% 0.49-0.55).

CONCLUSIONS

The analyses demonstrated that the BraScore is associated with overweight and obesity outcomes in the NutriNet-Brasil cohort study. This finding highlights the predictive validity of the index, which holds significant potential for use in epidemiological studies on Brazilian dietary patterns, adherence to dietary guidelines, and health outcomes.

GLOBAL RESEARCH TRENDS IN SCHOOL FOOD ENVIRONMENT: A BIBLIOMETRIC ANALYSIS USING WEB OF SCIENCE AND VOSVIEWER

Bruna Menegassi[1]
[1]Department of Sociology and Communication , University of Salamanca, Salamanca, Spain

BACKGROUND AND OBJECTIVES

The school food environment is vital in shaping healthier generations and fostering lifelong nutritious habits. This study used bibliometric analysis to explore and summarise publications on the school food environment, trace the field's evolution, and predict future research trends.

METHODS

Publications from the past three decades (1995–2024) were retrieved from the Web of Science (WoS) core collection using the search terms “food environment*” (Topic) and "school*" OR "universit*" (Topic). Only articles were analysed using VOSviewer. A thesaurus file was created to deduplicate terms and ensure consistency. VOSviewer generated bibliometric maps based on keyword co-occurrence, and the association strength method was applied to normalise link strength between items.

RESULTS

1,284 articles were retrieved, with 926 (72%) published in the last decade. The USA led in publications (616), nearly five times more than England, the second-leading country (137). In the keyword co-occurrence analysis, 199 of 3,494 keywords met the threshold of at least ten occurrences, forming six clusters. Central nodes included “food environment,” “obesity,” “children,” and “association” (occurrence weight = 616, 579, 236, and 193, respectively), highlighting established research areas. Conversely, keywords like “university students,” “mixed METHODS,” “neighbourhood deprivation,” and “acculturation” (occurrence weight = 12, 11, 11, and 10, respectively) showed fewer connections, representing emerging research areas that have not yet been extensively explored. Overlay visualisation revealed emerging themes in the last five years, including “food desert”, “food insecurity,” “disease,” and “ultra-processed food.”

CONCLUSIONS

Advancing this research field requires a more holistic and multidisciplinary approach, with qualitative research offering a promising avenue for further exploration.

IDEAL CARDIOVASCULAR HEALTH AND COGNITIVE PERFORMANCE: PRELIMINARY FINDINGS FROM THE NORTHERN IRELAND COHORT OF LONGITUDINAL AGEING (NICOLA)

Danielle Logan[1]; Alison Nic Craith[1]; Nicola A Ward[1]; Bernadette Mcguinness,[1]; Jayne Woodside[1]; Claire Mcevoy,[1]
[1]Centre for Public Health, School of Medicine, Dentistry and Biomedical Sciences, Queen's University Belfast, Belfast, United Kingdom

BACKGROUND AND OBJECTIVES

Dementia is now the seventh leading cause of death worldwide [1]. Research suggests that over 40% of dementia cases can be prevented or delayed by addressing modifiable risk factors and improving cardiovascular health (CVH) [2]. Adherence to the American Heart Association Life's Essential 8 (LE8) metric for ideal CVH could be protective against cognitive impairment [3,4,5]. However, evidence is limited by the small number of studies conducted and variation in both CVH definition and cognitive measures. The objective was to investigate the cross-sectional association between CVH, as measured by the LE8 metric, and cognitive performance in older Northern Irish adults.

METHODS

The sample comprised of older adults without any pre-existing dementia or cardiovascular disease enrolled in the Northern Ireland Cohort for the Longitudinal Study of Ageing (NICOLA). The LE8 metric for CVH computed from four health behaviours (diet, physical activity, smoking status, sleep) and four clinical measures (body mass index, blood sugar, blood lipids, blood pressure) was applied to classify participants as high CVH (LE8 ≥ 80), moderate CVH (LE8 50 to 79), and low CVH (LE8 0 to 49). Global cognitive performance was assessed using the Mini-Mental State Examination (MMSE) and Montreal Cognitive Assessment (MoCA). Logistic models adjusted for age, sex, socio-economic status, educational attainment, were used to examine associations between the tertiles of CVH and cognitive performance.

RESULTS

A total of 2,352 participants (53% female) aged 64±8.9 years were studied, of whom 14.5%, 77% and 8.5% had low, moderate and high CVH respectively. Those with high CVH were more likely to be female, younger with healthy BMI and have better cognition. In adjusted models, a 5-point increase in the LE8 score was associated with a 0.07 (95% CI: 0.05-0.10) increase in MMSE, and a 0.12 (95% CI: 0.08-0.17) increase in MoCA score [both $p < 0.001$]. Participants with greatest adherence to LE8 were significantly less likely to have poor global cognitive function (≥1.5 SD below mean MoCA). Compared to low CVH, the adjusted odds ratio (95% confidence interval) for poor global cognition was 0.62 (0.41-0.93) for moderate CVH and 0.38 (0.16-0.95) for high CVH.

CONCLUSIONS

Better CVH, as measured by a higher LE8 score, was significantly associated with better cognitive performance amongst older Northern Irish adults. This suggests that LE8 recommendations may benefit both cardiovascular and cognitive health.

ASSOCIATIONS OF MATERNAL CARDIOVASCULAR HEALTH IN PREGNANCY WITH OFFSPRING NEURODEVELOPMENT WITHIN THE FIRST 5 YEARS: A PROSPECTIVE BIRTH COHORT STUDY

Han Qiu[1]; Xirui Wang[1]; Xiaodan Yu[1]
[1]Department of Developmental and Behavioral Pediatrics, Shanghai Children's Medical Center, Shanghai Jiao Tong University School of Medicine, Shanghai, China

BACKGROUND AND OBJECTIVES

The first 5 years of life are sensitive periods for neurodevelopment. So far, the effects of the combination metrics of cardiovascular health (CVH) during pregnancy on offspring's neurodevelopment in these crucial periods remain unknown.

METHODS

1007 mother-child pairs recruited from 2013 to 2016 in the Shanghai Birth Cohort were included in the study. The maternal CVH, including five metrics of BMI, blood pressure, blood glucose, sleep and smoking, was measured or collected during the second trimester. Each metric was divided into ideal, intermediate, and poor, and assigned 2, 1 and 0 points, respectively, yielding a total CVH score range of 0 to 10. The offspring neurodevelopment at 2-3 years and 4-5 years were evaluated by Bayley-III and WPPSI-IV, respectively. Scores in the lowest quartile for the Bayley-III scale and WPPSI-IV were defined as suboptimal development. Univariate linear, multivariate linear, and logistic regression were used to estimate associations between maternal gestational CVH and offspring neurodevelopment.

RESULTS

There was a correlation between the cognitive and language of Bayley-III scores at 2-3 years and the visual space index (VSI) and working memory index (WMI) of WPPSI-IV scores at 4-5 years (R = 0.23 and R = 0.22 for VSI, $p<0.001$; R= 0.14 and R =0.15 for WMI, $p<0.001$). After adjusting confounders, with a 1-point higher maternal CVH score, the scores of cognitive and language at 2-3 years were significantly increased by 1.63 [95% confidence interval (CI), 0.42-2.83, P = 0.008] and 0.84 (95%CI, 0.005-1.67, P=0.049), respectively. Similarly, the scores of VSI and WMI at 4-5 years were significantly increased by 0.92 (95%CI, 0.16-1.68, P = 0.018) and 0.71 (95%CI, 0.01–1.40, P = 0.047), respectively. The RESULTS of the logistic regression model with adjusted confounders showed that the risk of suboptimal cognitive development at 2-3 years was reduced by 0.84 (95%CI, 0.73-0.96, P = 0.013) with a 1-point higher maternal CVH score, and the risk of cognitive development in female and male offspring was decreased by 0.79 (95%CI, 0.66-0.96, P =0.017) and 0.83 (95%CI, 0.71-0.98, P =0.025), respectively.

CONCLUSIONS

Our study first proved that maternal CVH exposure in pregnancy has an enduring effect on offspring neurodevelopment in the first 5 years of life, and female offspring brain development was more sensitive to maternal CVH exposure during pregnancy. Maternal CVH metrics as an indicator may be applied to clinical practice to identify children at risk of neurodevelopment delay and then implement an early intervention.

BACKGROUND AND OBJECTIVES

Maternal nutrition is crucial for both mother and fetus (1,2), yet over 40% of pregnant women in low- and middle-income countries, including Nigeria, face micronutrient deficiencies like iron deficiency anemia, increasing risks of adverse birth outcomes (2,3). This study assessed the effects of multiple micronutrient (MMS) versus Iron-Folic Acid (IFA) supplementation on maternal hemoglobin and fetal growth.

METHODS

This double-blind, two-arm randomized controlled trial in Ogbomoso, Nigeria, recruited pregnant women at <= 24 weeks gestation. Participants were randomized to receive either IFA or MMS. Maternal hemoglobin, fetal weight (FW), femur length (FL), fetal abdominal circumference (FAC), and fetal head circumference (FHC), were assessed at baseline, four weeks, and delivery.

RESULTS

Table 1.0 Effect of MMS vs IFA on fetal growth

Study group	**Baseline FW (Kg)**	**4 weeks FW (Kg)**	**P value**
MMS group	1.64 ± 0.47	2.22 ± 0.57	0.0000
IFA group	1.38 ± 0.72	1.94 ± 0.98	0.001
	Baseline FHC (cm)	**4 weeks FHC (cm)**	**P value**
MMS group	28.32 ± 2.21	30.53 ± 2.21	0.0002
IFA group	28.39 ± 3.22	30.30 ± 2.26	0.06

Mothers were 29 years on average, fathers 36, with a parity of 2 and BMI of 28.14 ± 5.94. Most parents (51.72%) had secondary education, while 30% of mothers held higher degrees. Hemoglobin levels showed minimal changes, rising slightly in the IFA group (10.63 to 11.20 g/dL, p = 0.49) and remaining stable in the MMS group (10.79 to 10.89 g/dL, p = 0.82). The MMS group demonstrated significantly greater improvements in femur length (5.93 to 6.84 cm, p = 0.0000) and fetal head circumference (28.32 to 30.53 cm, p = 0.0002) compared to smaller changes in the IFA group.

https://doi.org/10.1017/jns.2026.10126 Published online by Cambridge University Press

CONCLUSIONS

Hemoglobin levels showed minimal changes in both groups. MMS significantly improved fetal weight, abdominal circumference, femur length, and head circumference over four weeks compared to IFA. Future research should explore long-term impacts of MMS versus IFA on maternal and infant health, including cognitive and physical development.

OAP27_03

SOCIOECONOMIC INEQUALITIES IN THE ASSOCIATION BETWEEN DIET QUALITY AND INCIDENT CARDIOVASCULAR DISEASES

Ming-Jie Duan[1]; Maartje Poelman[2]; Sander Biesbroek[3]
[1]Human Nutrition & Health, Wageningen University & Researh, Wageningen, Netherlands; [2]Chair Group Consumption and Healthy Lifestyles, Wageningen Univ, Wageningen, Netherlands; [3]Division of Human Nutrition and Health, Wageningen University & Research, P.O. Box 17, Wageningen, 6700 AA, Netherlands

BACKGROUND AND OBJECTIVES

Individuals with a lower socioeconomic position (SEP) consistently face higher risks of cardiovascular diseases (CVDs). Diet quality is crucial to the development of CVDs. Poor diet quality is more prevalent in low SEP populations, significantly increasing their CVD risk, which may partially explain the existing health inequalities. However, it remains unclear whether a socioeconomic difference exists in the association between diet quality and CVDs, and whether such difference may further contribute to health inequalities. Therefore, we aimed to evaluate how SEP modifies the associations between diet quality and incident CVDs.

METHODS

We analyzed data from 82,360 participants from the Dutch Lifelines Cohort (30-80 years, no CVDs at baseline). Incident CVD cases were identified by self-report questionnaires and electrocardiogram during follow-ups. Lifelines Diet Score – a diet quality indicator based on Dutch dietary guidelines – was calculated with a 110-item food frequency questionnaire. SEP was defined by education and income. Cox proportional hazards models were used to assess the associations of diet quality, SEP, and incident CVDs, adjusted for age, sex, employment, energy intake, BMI, alcohol intake, smoking, physical activity, sleep, social club participation, chronic stress, blood lipid profiles, hypertension, diabetes, and family history of CVDs. An interaction term between diet quality and SEP was further added test their interaction.

RESULTS

With a median follow-up of 7.4 years, 2827 (3.4%) non-fatal CVD cases were identified. Diet quality was associated with CVD risk: Quartile 1 (poorest diet quality) vs Q4 (best/ref) HR 1.18 (95%CI 1.05-1.32). Education (but not income) modifies the associations between diet quality and incident CVDs (P-interaction=0.019), indicating stronger associations in lower education groups. Stratified by education group, HRs (95%CIs) for incident CVDs comparing diet quality Q1(poorest) to Q4(best) were 1.26(1.06-1.51) in low, 1.22(1.01-1.46) in middle, and 0.93(0.72-1.20) in high education group. Analysis of a composite outcome of non-fatal CVD cases and all-cause mortality (considering fatal CVD cases) yielded similar RESULTS.

CONCLUSIONS

SEP modifies the associations between diet quality and incident CVDs, with (stronger) associations in low/middle education groups. This result shows that diet quality is associated with disproportionate harm in lower SEP populations. This difference in the association between diet quality and incident CVDs across SEP groups contributed to health inequalities. Improving diet quality may have substantial potential and should be prioritized as a fundamental strategy to reduce socioeconomic inequalities in CVD burden in the population.

OAP27_04

FACTORS ASSOCIATED WITH PROLONGED USE OF DONOR HUMAN MILK AT DA NANG HOSPITAL FOR WOMEN AND CHILDREN IN VIETNAM

Hoang Thi Tran,[1]; Tuan Thanh Nguyen[2]; Oanh Thi Xuan Nguyen,[1]; Le Thi Huynh,[1]; Roger Mathisen,[2]
[1]Neonatal Department, Da Nang Hospital for Women and Children, Da Nang, Vietnam; [2]Alive & Thrive, Family Health International, Hanoi, Vietnam

BACKGROUND AND OBJECTIVES

Donor human milk (DHM) from a human milk bank (HMB) is used to feed low birthweight (LBW) and preterm infants as the 'first alternative' when mothers are unable to provide their own milk. However, misuse of DHM could compete with mothers' own milk and weaken efforts to support breastfeeding. This study aimed to determine factors behind prolonged DHM usage by infants during the first six years of operation in the first HMB in Vietnam.

METHODS

Data on the characteristics and use of DHM by infants were extracted from the web-based digital monitoring system of the Da Nang HMB from 1 February 2017 to 31 January 2023. Prolonged use of DHM was defined as four days or more in neonatal units and two days or more in postnatal wards. Associated factors included birthweight, gestational age, and mode of birth.

RESULTS

In the first six years, 25,420 infants received DHM from the Da Nang HMB, with 45.3% being female and 54.7% male, 70.0% born via cesarean section, and 77.2% full-term. In the neonatal units (n = 7001), the average duration of using DHM was 3-4 days, and 38.0% used it for ≥ 4 days. Compared to those weighing 1500-<2000g, the adjusted odds ratios (aORs) were 0.14 for <1000g, 0.78 for 1000-<1500g, and 0.67 for ≥2000g ($p < 0.01$). Compared to gestational ages of 32-<34 weeks, the aORs were 0.26 for <28 weeks, 0.97 for 28-<32 weeks, 0.71 for 34-<37 weeks, and 0.35 for ≥37 weeks ($p < 0.01$). In postnatal wards (n = 18,419), the average duration of using DHM was 1-2 days, with 53.1% using it for ≥2 days. Compared to normal weight and term infants (≥2500g & ≥37 weeks), the aORs were 1.25 for LBW-preterm (<2500g & <37 weeks), 1.17 for LBW-term (<2500g & ≥37 weeks), and 1.21 for normal weight-preterm (≥2500g & <37 weeks) ($p < 0.05$ for all). Prolonged use of DHM was positively associated with cesarean births in neonatal units (aOR of 2.24, $p < 0.01$) and postnatal wards (aOR of 1.44, $p < 0.01$).

CONCLUSIONS

DHM in this hospital is used briefly to bridge nutritional gaps and transition to mothers' milk and breastfeeding. However, factors like LBW, preterm births, and cesarean births are linked to prolonged DHM use. These findings suggest the need for targeted interventions to optimize DHM use and transition to mothers' milk. Healthcare providers should not promote DHM as a substitute for breastmilk but offer support to those at risk of prolonged use. Reducing unnecessary cesarean births should also be prioritized.

OAP27_05

VALIDATION OF THE POLISH VERSION OF THE ORTO-R AMONG UNIVERSITY STUDENTS: COMPARISON WITH THE OTHER SCALES ASSESSING ORTHOREXIC THOUGHTS AND BEHAVIORS

Marta Plichta[1]; Radosław Rogoza[2]
[1]Institute of Human Nutrition Sciences, Warsaw University of Life Sciences, Warsaw, Poland; [2]Department of Human Sciences, University of Economics and Human Sciences in Warsaw, Warsaw, Poland

BACKGROUND AND OBJECTIVES

The ORTO-15 questionnaire and its shortened versions have been used most frequently in studies conducted over the past two decades on orthorexia nervosa (ON). Due to repeated criticism of their psychometric properties, a new version of ORTO-15 was developed, namely ORTO-R. The study's objectives were to confirm the factor structure of the Polish version of the ORTO-R, assess its internal consistency, provide evidence of validity, and compare it with other scales for assessing ON thoughts and behaviors.

METHODS

A cross-sectional quantitative study was conducted in 2021 among 478 university students. Eighteen universities from fourteen provinces in Poland participated in the study. The computer-assisted web interview (CAWI) technique was utilized to study with the Google Forms application. Participants were asked to complete the ORTO-R, the ORTO-15 and its shortened versions (ORTO-12, -11, -9, and -7), the Düsseldorf Orthorexia Scale (PL-DOS), the Three-Factor Eating Questionnaire (TFEQ-13), and the Mindful Eating Scale (MES).

RESULTS

The factor structure of the ORTO-R was confirmed, and the findings favor ORTO-R over the ORTO-15 regarding how the former was fitted to the data. Moreover, the ORTO-R was more internally consistent than the ORTO-15 and its shortened versions. The ORTO-15 and all its shortened versions correlated positively with awareness and act with awareness. Exclusively, the ORTO-R and the PL-DOS correlated negatively with awareness and act with awareness. The negative correlations were found between the ORTO-R, -9, PL-DOS, and acceptance. However, only for the ORTO-9, the correlation was weak (others were moderate). Only the ORTO-R correlated positively with cognitive restraint. Positive correlations were found between all used scales for assessing ON thoughts and behaviors and uncontrolled eating. However, only for ORTO-R and PL-DOS these correlations were moderate (others were weak). The ORTO-15, -11, and -7 correlated negatively with emotional eating, while the ORTO-R and the PL-DOS these correlations were positive. The findings support the argument that the ORTO-R was characterized by good convergent and criterion validity.

CONCLUSIONS

The ORTO-R is a valid and reliable scale to assess orthorexic thoughts and behaviors among Polish speakers. The ORTO-R better describes ON regarding eating behaviors than the original ORTO-15 and its shortened versions.

BACKGROUND AND OBJECTIVES

Micronutrient deficiency which is commonly found among pregnant and lactating women. (1, 4) has significant deleterious impact on both the mother and child, especially in developing countries (2, 3). The study investigated the effect of Multiple Micronutrient Supplementation (MMS) on selenium levels in human milk and serum of lactating mothers' milk after 10 weeks of MMS supplementation.

METHODS

Sixty-six mother-infant pairs in Jos, Nigeria, were randomized to receive either MMS with 65 µg selenium or a placebo for 10 weeks. Breastmilk and serum samples were collected at baseline (≤5 days), week 6, and week 10. Maternal-infant data and selenium intake were assessed via a 24-hour dietary recall, with selenium levels analyzed using atomic absorption spectrophotometry and compared using descriptive and bivariate statistics ($P < 0.05$).

RESULTS

At baseline, mothers were aged 30.7±4.9 years (IG) and 29.0±5.6 years (CG), with weights of 72.6±10.7 kg and 69.2±10.4 kg, respectively. Infants weighed 3.1±0.4 kg in both groups. Selenium intake averaged 60.8±44.7 µg/day (IG) and 68.3±46.9 µg/day (CG), with 59% and 51% below the Estimated Average Requirement (EAR).

Impact of MMS on human milk and serum selenium

Serum/Human Milk Se	Intervention (µg/l)	Control (µg/l)	Total (µg/l)	P value

Human milk baseline	223.2±16.5	214.29±14.4	220.2±16.1	0.16
10 weeks	129.8±5.0	129.1±6.3	129.5±5.6	0.70

At 6 weeks, stunting was observed in 9.38% of the control group but none in the intervention group ($p = 0.248$). Underweight and wasting were 4% and 24% in the intervention group versus 6.25% and 18.75% in the control group ($p > 0.05$). By 10 weeks, underweight rates were 3.7% (IG) and 3.45% (CG), while wasting rates were 36% (IG) and 31.03% (CG), with no significant differences ($p > 0.05$).

https://doi.org/10.1017/jns.2026.10126 Published online by Cambridge University Press

CONCLUSIONS

Serum and human milk selenium levels declined significantly in both groups, with higher serum selenium at 10 weeks in the group on MMS ($p = 0.02$). Despite dietary selenium inadequacy, no significant differences in infant stunting, underweight, or wasting were observed. Longer MMS supplementation during lactation warrants further study.

INTEGRATING PERSONALIZED NUTRITION AND SUSTAINABLE DIETARY PATTERNS: A LIFE CYCLE ASSESSMENT APPROACH TO ACHIEVING HEALTH AND ENVIRONMENTAL SUSTAINABILITY

Mengxue Yang[1]
[1]School of Public Health, Shandong University, Ji Nan Shi, China

BACKGROUND AND OBJECTIVES

With growing environmental concerns and the rise of lifestyle-related health issues, there is a pressing need to transform food systems and re-evaluate dietary patterns to protect both human health and planetary sustainability. This study proposes an integrated approach that combines personalized nutrition with sustainable dietary patterns, utilizing life cycle assessment (LCA) to assess the environmental impacts of various diets. The goal is to promote diets that align with personal well-being while contributing to the Sustainable Development Goals (SDGs).

METHODS

This multidisciplinary approach includes:

1. **Life Cycle Assessment (LCA)**: Mapping the carbon, water, and land footprints of different diets worldwide.
2. **Literature Review**: Reviewing existing research on the environmental impacts of diets and the role of personalized nutrition.
3. **Fieldwork**: Collecting primary data on dietary practices, environmental impacts, and health outcomes.
4. **Personalized Nutrition Model**: Developing a model for tailoring dietary recommendations based on genetic, phenotypic, and behavioral factors, aligned with LCA insights.
5. **Policy Implications**: Exploring policy recommendations to guide stakeholders in adopting sustainable dietary practices.

RESULTS

Preliminary RESULTS show significant differences in the environmental impacts of various dietary patterns, with plant-based diets having lower footprints compared to animal-based diets. Early findings also suggest that personalized nutrition can improve adherence to sustainable diets by aligning individual health goals with environmental benefits.

CONCLUSIONS

This study highlights the potential of combining personalized nutrition with sustainable dietary patterns to promote both health and environmental sustainability. Further research into policy implications will help guide effective transitions to sustainable food systems aligned with the SDGs.

PREGNANCY AND VITAMIN D INTERVENTION (PREDIN) – A RANDOMIZED DOUBLE-BLIND CONTROLLED TRIAL IN PREGNANT WOMEN AT HIGH RISK OF VITAMIN D DEFICIENCY

Mathilda Forsby[1]; Anna Winkvist[1]; Linnea Bärebring[1]; Hanna Augustin[1]
[1]Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden

BACKGROUND AND OBJECTIVES

One in ten pregnant women in Sweden has been found to be vitamin D deficient. Even so, a nationwide screening and vitamin D supplementation programme is not part of routine antenatal care. We aimed to evaluate the effects of vitamin D supplementation on vitamin D status in pregnant women at risk of vitamin D deficiency.

METHODS

The Pregnancy and Vitamin D Intervention (PREDIN) study is a three-arm, randomized, double-blind, controlled trial conducted in Gothenburg, Sweden, as part of routine antenatal care. Women (n=135) were recruited between April 2022 and February 2024. Screening for risk of vitamin D deficiency (25-hydroxyvitamin D, 25OHD <30 nmol/l) was done using a validated non-invasive screening tool consisting of five questions on vitamin D exposure in the first trimester. Based on the RESULTS from the screening tool, participants (n=99) at high risk of vitamin D deficiency (scores ≥15 points) were randomized to receive either usual antenatal care or daily supplementation with 20 or 40 µg/day of vitamin D3 throughout their pregnancy. The follow up visit was conducted in the third trimester. Background characteristics and blood samples for 25OHD analysis were collected at both the screening and follow up visit. The differences in maternal characteristics between the three study arms at baseline were tested by one-way ANOVA or chi-square test. The primary outcome is the difference between the three study arms in maternal 25OHD changes from the first to third trimester (will be analysed by liquid chromatography-mass spectrometry).

RESULTS

The primary outcome will be presented at the conference. Mean screening tool scores in the three arms were 28.3, 28.8, and 28.4 (p=0.973). Mean age was 30.7, 30.7, and 31.0 years (p=0.916), and mean BMI in first trimester was 26.4, 26.0, and 26.4 kg/m2 (p=0.977). Overall, 80% were born outside of Sweden, 40% had university level education, 28% were first-time mothers, and 48% reported use of vitamin D supplements at screening. There were no statistically significant differences between the three arms regarding continent of origin (p=0.458), education level (p=0.953), nulliparity (p=0.483), or use of vitamin D supplements at screening (p=0.932).

CONCLUSIONS

There were no statistically significant differences between the three study arms regarding maternal characteristics at baseline. The main RESULTS of the study will contribute to the evidence regarding the impact of vitamin D supplementation on 25OHD levels in pregnant women at risk of vitamin D deficiency.

HEALTHY DIETS ARE ASSOCIATED WITH LOWER DEPRESSION, ANXIETY, AND STRESS IN LOW- AND MIDDLE-INCOME COUNTRIES: A META-ANALYSIS FROM A SYSTEMATIC EVIDENCE AND GAP MAP

Thalia Sparling[1]; Cesar Cornejo-Roman,[2, 1]; Lisa Troy,[3]; Bryan Cheng,[4]; Suneetha Kadiyala,[1]
[1]Department of Population Health, London School of Hygiene and Tropical Medicine, London, United Kingdom; [2]Epidemiology and Population Health, London School of Hygiene & Tropical Medicine, London, United Kingdom; [3]School of Public Health and Health Sciences, University of Massachusetts Amherst, Amherst, United States of America; [4]Global Mental Health Lab, Teachers College, Columbia University, New York, United States of America

BACKGROUND AND OBJECTIVES

We aimed to examine the association between healthy diets and mental health (MH) in low- and middle-income countries (LMIC), because less is known about the interplay between diet and MH in LMIC compared to high income countries.

METHODS

We used a systematic Evidence and Gap Map (EGM) of peer-reviewed, English language studies (published 2000-2024; n»3055) to select studies for meta-analysis. We pooled effects from studies linking 'healthy' dietary patterns to depression, anxiety and stress. Comparable measures of 'Healthy' diets included adherence and adequacy, dietary patterns, diet diversity and diet quality indices. Random effects models with a Fisher r-to-z transformed correlation coefficient (Coeff.) were fitted for each MH group (depression, anxiety, and stress). We examined heterogeneity among studies, influential outliers and risk of bias.

RESULTS

84 studies from the EGM examined healthy diets against depression (n=71), anxiety (n=44), and stress (n=27). Most studies were cross-sectional (n=71), used factor analysis to ascertain dietary patterns (n=27), followed by diet indices (e.g., MedDiet; n=23), dietary quality (n=19), dietary diversity (n=15), and adherence measures (n=2). Most studies were from upper middle-income countries (n=69), and Asia (n=70). We found that healthy diets were consistently associated with less depression (Coeff. -0.14 (95% CI: -0.16 to -0.11), despite high heterogeneity (Coeff. ranging from -0.70 to 0.10). Healthy diets were also associated with lower anxiety (Coeff -0.12, 95% CI: -0.15 to -0.09), as well as lower stress (Coeff -0.12, 95% CI: -0.15 to -0.08; Coeff. range of studies: -0.43 to 0.08). Even though RESULTS were heterogeneous, they were not considered influential to the overall RESULTS. There was no observed publication bias or small study bias.

CONCLUSIONS

Healthy diets are linked to less depression, anxiety, and stress. These first-ever pooled estimates highlight evidence gaps in low-income countries outside of Asia. They can inform intervention gaps such as multiple marginalizations that heighten health risks, and furthermore encourage multisectoral policies and programs that improve both diet quality and mental health.

COSTS OF MANAGING MALNUTRITION IN INFANTS UNDER 6-MONTHS (MAMI) IN ETHIOPIA: A COST-CONSEQUENCE ANALYSIS OF RANDOMISED CONTROL TRIAL DATA

Cheshni Jeena[1]; Kiddus Yitbarek[2]; Catherine Pitt,[3]; Melkamu Behrane[4]; Mubarek Abera[5]; Marie Mcgrath[6]; Hatty Barthorp[7]; Hailu Endashaw[8]; Marko Kerac[9]
[1]Public Health , London School of Hygiene & Tropical Medicine, London, United Kingdom; [2]Faculty of Health, University of Technology Sydney, Sydney, Australia; [3]Faculty of Public Health and Policy, London School of Hygiene & Tropical Medicine, London, United Kingdom; [4]Department of Medicine and Health Officer, Jimma University, Jimma, Ethiopia; [5]Faculty of Medical Science, Jimma University, Jimma, Ethiopia; [6]Department of Population Health, Emergency Nutrition Network, Oxford, United Kingdom; [7]Global Nutrition Advisor, GOAL, Dublin, Ireland; [8]Nutrition Specialist, Public Health Expert and Researcher, GOAL Global, Addis Aba, Ethiopia; [9]Population Health, London School of Hygiene & Tropical Medicine, London, United Kingdom

BACKGROUND AND OBJECTIVES

Malnutrition is a major global health concern, particularly in infants aged under 6-months (infants u6m) (1, 2). The Management of small, nutritionally At-risk Infants u6m and their Mothers Care Pathway (MAMI-CP) is a behavioural tool which aligns with 2023 WHO malnutrition guidelines. It helps healthcare workers better identify, counsel and care for malnourished infants. To support future international rollout of the MAMI-CP, our project aims to provide evidence around economic evaluation and programme implementation costs (3).

METHODS

We conducted a cost-consequence analysis alongside a randomised control trial in Ethiopia using a disaggregated societal perspective (including health services and household perspectives) to determine the cost of MAMI-CP per child over a 6-month period. Sensitivity analysis was performed using a best- and worst-case scenario framework. Lifetime societal costs were estimated using the Cost of Not Breastfeeding Tool to assess the long-term impacts of improved breastfeeding.

RESULTS

The cost of MAMI-CP to society is approximately US$135.80 per child (best- and worst-case scenarios: US$12.49; US$718.84), with health services contributing US$99.27 (US$6.12; US$644.44) and households contributing US$36.53 (US$6.37; US$74.40). This compares to the standard-of-care, which costs US$99.37 per child (US$7.23; US$503.55), comprising US$68.77 in health services (US$3.47; US$444.61) and US$30.60 in household costs (US$3.76; US$58.94). Higher costs in MAMI-CP are largely due to increase resource utilisation (increased clinic visits for counselling and support). Key benefits of MAMI-CP include improved exclusive breastfeeding rates, with mixed effects on anthropometry (improved mid-upper-arm circumference but no statistically significant change in other anthropometric measures; potentially different effects in subgroups). Long term, the intervention could reduce societal costs to the economy up to US$833,337,100 (US$6.43 per person) from improved breastfeeding.

CONCLUSIONS

While MAMI-CP incurs greater short-term costs than the standard-of-care, its potential health benefits, particularly in breastfeeding improvement, may justify these costs. Further research is needed to explore its scalability and long-term impacts.

OAP31_02

EFFECTS OF A TAILORED PROGRAMME TO SUPPORT FOOD COMPANIES TO REFORM NUTRITION POLICIES AND PRACTICES (REFORM): A MULTICENTRE, CLUSTER-RANDOMISED CONTROLLED TRIAL

Cliona Ni Mhurchu[1]; Jacqui Grey,[2]; Stephanie Shen,[2]; Caitlin Haliburton,[2]; Yannan Jiang,; Leanne Young,[2]; Jasmine Chan,; Sally Schultz,[3]; Josephine Marshall,[3]; Miranda Blake[3]; Jaithri Ananthapavan,[3]; Gary Sacks,[3]
[1]Epidemiology and Biostatistics, University of Auckland, Grafton Campus, Auckland, New Zealand; [2]National Institute for Health Innovation, University of Auckland, Grafton Campus, Auckland, New Zealand; [3]Global Centre for Preventive Health and Nutrition (GLOBE), Deakin University, Melbourne, Australia

BACKGROUND AND OBJECTIVES

Many governments rely on voluntary industry actions to improve population nutrition, including voluntary front-of-pack nutrition labelling, food advertising standards, and food reformulation programmes. Research has shown that food companies vary considerably in their policies and practices on nutrition. We aimed to determine if a tailored nutrition support programme for food companies improved their nutrition policies and practices compared with control companies who were not offered the programme.

METHODS

132 major packaged food/drink manufacturers (n=96) and fast-food companies (n=36) were randomly assigned (2:1 ratio) to a 12-month tailored support programme or to the control arm (no intervention). The intervention programme was designed and delivered by public health academics and comprised regular meetings, tailored company reports, and resources and recommendations to encourage improved product composition through reformulation, nutrition labelling (e.g., adoption of Health Star Rating [HSR]) labels), responsible marketing, and improved nutrition policies and corporate sustainability reporting. The primary outcome was the nutrient profile (measured using HSR) of company food and drink products at 24 months. Secondary outcomes were the nutrient content (energy, sodium, total sugar, and saturated fat) of company products, display of HSR labels on packaged products, company nutrition-related policies and commitments, and engagement with the intervention.

RESULTS

88 eligible intervention companies (9,235 products at baseline) were invited to participate, of whom 21 accepted and were enrolled in the REFORM programme (delivered September 2021 to December 2022). 44 companies (3,551 products at baseline) were randomised to the control arm. At 24 months, the model-adjusted mean HSR of intervention company products was 2.58 compared to 2.68 for control companies, with no significant difference between groups (mean difference -0.10, 95% CI -0.40 to 0.21, p-value 0.53). A per protocol analysis of companies with no major protocol violation also found no significant difference (2.93 vs 2.64, mean difference 0.29, 95% CI -0.13 to 0.72, p-value 0.18). There were no significant differences between the intervention and control groups in secondary outcomes.

CONCLUSIONS

A 12-month tailored nutrition support for food companies did not improve the nutrient profile of company products.

OAP31_03

NUTRITIONAL EFFICACY OF READY-TO-USE THERAPEUTIC MEAL MADE FROM LOCAL INGREDIENTS FOR COMMUNITY MANAGEMENT OF ACUTE MALNUTRITION IN UNDER FIVE CHILDREN

Vivienne Ibeanu[1]; Linda Edafioghor[2]; Nkechinyerem Onodugo[1]
[1]Nutrition and Dietetics, University of Nigeria, UNN Nsukka, Nsukka, Nigeria, Federal Republic of; [2]Nutrition and Dietetics, Federal Medical Centre, Asaba, Nigeria, Federal Republic of

BACKGROUND AND OBJECTIVES

Ready-to-use therapeutic food (RUTF) is a specially formulated high protein and energy dense meal used to treat children over 6 months of age who are malnourished. The conventional imported RUTFs are often out of stock because of high cost. The aim of this study was to formulate RUTF with graded ratios of the locally sourced base ingredients – rice, soybean, ground nut, snail carrot, date palm, and vegetable oil.

METHODS

The WHO guideline and Pearson Square method for feed formulation were used in calculating the percentage each ingredient will contribute to the 3 experimental products. Rice, soybeans and groundnut served as the fixed ingredients supplying 15% protein; snail, carrot, date palm and vegetable oil were added to each formulation. Three products were formulated and coded RSG-RUTF-1, RSG-RUTF-2, and RSG-RUTF–3. The products were evaluated for energy and nutrient contents and sensory attributes using standard procedures. Data obtained were statistically analyzed using IBM-SPSS version 23 and presented in Tables as means and percentages.

RESULTS

The moisture content of the products ranged from 9.26 - 11.11%, protein 6.85 - 9.75%, fat 6.81 - 26.49%, crude fiber 2.39 - 2.79%, ash 0.99 - 1.07% and carbohydrate 50.22 - 71.01%. The vitamins A (1.14 -1.33mg), and E (20.20 – 20.27mg) and sodium (5.55 – 6.02mg) were within the recommended levels for RUTF, iron (0.68 – 0.85mg), potassium (16.22 – 24.24mg), copper (0.00 – 0.01mg), magnesium (4.27 – 5.22mg) and zinc (0.01 – 0.06mg) were slightly low. However, the energy content of the products ranged from 374Kcal in RSG-RUTF-2 to 478Kcal in RSG-RUTF-3 was adequate. There were significant ($p<0.05$) differences among the products for taste, texture and general acceptability. The RSG-RUTF-3 had the highest general acceptability score (7.17± 0.25).

CONCLUSIONS

The nutritive values of formulated RUTFs were within the standards recommended for complementary feeding as well as meet the culinary requirement of the local community. They compared favourably with other locally made RUTFs; therefore have high potential for being adopted for the management of SAM and CMAM in children.

IMPACT OF LOCALLY MADE READY-TO USE THERAPEUTIC FOOD ON THE WEIGHT AND MID UPPER ARM CIRCUMFERENCE OF THE ACUTE MALNOURISHED CHILDREN ADMITTED IN THE PAEDIATRIC WARD OF A FEDERAL UNIVERSITY TEACHING HOSPITAL, IN ABAKALIKI, EBONYI STATE

Vivienne Ibeanu[1]; Linda Edafioghor[2]; Nkechinyerem Onodugo[1]
[1]Nutrition and Dietetics, University of Nigeria, UNN Nsukka, Nsukka, Nigeria, Federal Republic of; [2]Nutrition and Dietetics, Federal Medical Centre, Asaba, Nigeria, Federal Republic of

BACKGROUND AND OBJECTIVES

Imported conventional ready-to-use therapeutic foods (RUTFs) have been shown to be effective in the nutritional rehabilitation of malnourished children but shipping costs, delays, and donor fatigue result in periodic unavailability of supplies in the hospitals thereby undermining their effectiveness. The use of locally made RUTFs is therefore, being advocated for the rehabilitation of malnourished children in developing countries. The aim of the study was to determine the impact of RUTF made from local ingredients on weight and mid upper arm circumference (MUAC) status of moderate acute malnourished (MAM) children (6 –59 months) admitted in a federal university teaching hospital.

METHODS

Three RUTFs were formulated using the WHO guideline and Pearson Square method for feed formulation. The products which contained different ratios of the base ingredients - rice, soybean, and groundnut were coded RSG-RUFT-1, RSG-RUTF-2, and RSG-RUFT-3. Snail, date palm and vegetable oil were added to each formulation. The processing, chemical analysis, sensory evaluation, and ethical approval were carried out according to standard METHODS. Twenty children admitted in the paediatric ward of a federal university teaching hospital with MAM based on their MUAC measurements (11.5cm – 12.5cm) were randomly grouped into two groups of 10 subjects per group for the feeding trial. The weight and MUAC of the subjects were measured before and after the feeding trial using standard METHODS. The RUFT-3 (had better nutrient and sensory profiles than the other two formulated RUFTs) and a conventional imported RUTF (Plumpy nut) were fed the children for four weeks using the WHO ration guide. The Group 1 consumed conventional imported RUTF while Group consumed the formulated RUTF-3.

RESULTS

The Group 1 had 32.90% weight gain while Group 2 had 20.26%. The same trend was observed in the MUAC measurements; 14.98% and 11.63%, respectively. These differences were significant ($p < 0.05$).

CONCLUSIONS

The formulated RSG-3 which was prepared with local ingredients, was accepted the mothers/caregivers in all sensory attributes and it has the potentials of serving as alternative to the conventional imported RUTF if the protein content is increased.

LONGITUDINAL GROWTH MODELS FOR INFANTS FROM THE MUMTA PREGNANT WOMEN TRIAL

Aneela Pasha[1]; Muhammad F Qazi,[1]; Shahiryar Khan,[1]; Javeria Qamar,[1]; Muhammad I Nisar,[1]; Fyezah Jehan[1]
[1]Paediatrics and Child Health, Aga Khan University, Karachi, Pakistan

BACKGROUND AND OBJECTIVES

Maternal undernutrition is a major global contributor to low birth weight, small-for-gestational-age, and preterm births. This study aimed to investigate the impact of antenatal interventions on infant linear growth trajectories from birth to 12 months of age.

METHODS

Pregnant women (8–18.9 weeks gestational age (GA)) from the Mumta trial were randomly assigned (1:1:1:1) to one of four groups: control (standard antenatal care), Balanced Energy Protein supplementation (BEP), BEP plus Azithromycin (AZ), or BEP plus nicotinamide and choline (Nic/Chol). Broken-stick models approximated non-linear growth curves from birth to 12 months, while k-means clustering identified subjects with similar growth trajectories. Random effect models assessed the impact of interventions and covariates (maternal age, height, parity and mode of delivery) on growth outcomes. Analyses were conducted in R using relevant packages.

RESULTS

Pairwise comparisons of mean growth trajectories revealed that, compared to the control arm, the BEP+AZ arm exhibited higher mean WAZ scores from birth to 2 months and beyond 6 months, higher mean LAZ scores from birth to 6 months and beyond 11 months, and higher mean WLZ scores from birth to 2 months and beyond 7 months. The BEP+Nic/Chol arm demonstrated higher mean WAZ, LAZ, and WLZ scores at birth but not up to 12 months. Cluster analysis indicated that infants in the BEP+AZ arm had the highest membership in the thriving cluster across WAZ (control 70.4%, BEP+AZ 75.8%), WLZ (control 86.6%, BEP+ AZ 87.3%), and LAZ (Control 71.5%, BEP+AZ 75.8%) measures. Faltering growth, based on WAZ (Control 29.6%, BEP+AZ 24.1%) and LAZ (Control 28.3%, BEP+AZ 23.9%) trajectories, was lowest in the BEP+AZ arm, followed by the BEP+Nic/Chol arm. Mixed-effects modeling showed that infants in the BEP+AZ arm had a 17% reduced risk of underweight (95% CI 0.72-0.96) and 17% reduced risk of stunting (95% CI 0.69-0.90) compared to the control arm. Infants in the BEP+Nic/Chol arm had a 15% reduced risk of underweight (95% CI (0.75-0.97) vs control arm, only in unadjusted analyses (p = 0.018).

CONCLUSIONS

The combined effect of BEP and AZ on longitudinal growth trajectories was observed at birth, during the post-natal period, and in late infancy. In contrast, the combined effect of BEP with Nic/Chol was observed at birth but diminished by the one-year follow-up. Antenatal interventions, such as BEP supplementation and prophylactic AZ, may have the potential to support and sustain infant growth outcomes in low-resource settings.

HOUSEHOLD USE OF IODINE-CONTAINING BOUILLON CUBES IMPROVES IODINE STATUS AMONG WOMEN AND CHILDREN IN NORTHERN GHANA: A SECONDARY OUTCOME ANALYSIS OF THE COMIT TRIAL

Seth Adu-Afarwuah[1]; Sika M. Kumordzie[2]; Dodzi Dagodzo[1]; K Ryan Wessells[2]; Charles D. Arnold[2]; Xiuping Tan[2]; Stephen A. Vosti[3]; J. Marjorie Haskell[2]; Emily R. Becher[2]; Jennie N. Davis[2]; Katherine P. Adams[2]; Reina Engle-Stone[2]
[1]Department of Nutrition and Food Science, University of Ghana, Accra, Ghana; [2]Department of Nutrition, Institute for Global Nutrition, University of California, Davis, Davis, CA, United States of America; [3]Institute for Global Nutrition, Department of Agricultural and Resource Economics, University of California, Davis, California United States of America

BACKGROUND AND OBJECTIVES

Inadequate iodine status has severe negative consequences in women and children, including increased risk of hypothyroidism, impaired mental function, and goitre. Despite mandatory iodization of edible salt (MIES) in Ghana, a substantial proportion of households uses salt that is not iodized or adequately iodized. We aimed to evaluate the impact of household use of bouillon cubes containing iodine on iodine status among non-pregnant, non-lactating women of reproductive age (WRA) and preschool children (PSC) 2-5 y in northern Ghana.

METHODS

In this doubly-masked trial in the Kumbungu and Tolon districts, recruited participants underwent baseline assessments, and their households were randomly assigned to rations of bouillon cubes containing either (1) vitamin A, folic acid, vitamin B-12, iron, zinc and iodine, or (2) iodine only, with advice to use the study cubes in place of commercial cubes in typical cooking. Both types of bouillon provided an expected iodine (as potassium iodate) dose of 75 µg/d (30 µg/g, 2.5 g/d intake) or 50% of recommended dietary allowance (RDA) for WRA and 30 µg/d (30 µg/g, 1.0 g/d intake) or 33% RDA for PSC. Spot urine samples collected at baseline and after a 9-month intervention were analyzed for urinary iodine concentration (UIC) using the Sandell-Kolthoff method. We compared median UICs (µg/L) and the percentage of participants with UIC < 50 at each time point with World Health Organization (WHO) population median thresholds of UIC <100, 100–199, 200–299, and ≥300 reflecting deficient, adequate, slight risk of > adequate, and risk of adverse consequences, respectively, and goal of maintaining < 20% of samples with UIC < 50.

RESULTS

The analysis involved 1,005 WRA (mean age, 33 y) and 688 PSC (mean age, 3.4 y). Among WRA, median UIC (Q1, Q3) was 99.5 (55.3, 171.1) and 23.3% had UIC < 50 at baseline; both indicated a population with iodine deficiency. At endline, median UIC of WRA was 122 (71.4, 192) and only 14.6% had UIC < 50; both indicated a population with adequate iodine status. Among PSC, median UIC at baseline [109 (60.6, 193)] was within the WHO range for adequate iodine status, but 22.1% had UIC < 50 at baseline. At endline, median UIC was 135 (81.6, 241) and only 12.9% had UIC < 50; both indicated a population with adequate iodine status.

CONCLUSIONS

The baseline iodine status of WRA and PSC in the Kumbungu and Tolon districts was low despite MIES in Ghana. The intervention with iodine-containing bouillon cubes improved iodine status, but further research is needed to explore its potential role in supplying sufficient iodine in this and similar settings

DEFINING AND OPERATIONALISING FOOD KNOWLEDGE, NUTRITION KNOWLEDGE, NUTRITION LITERACY, AND FOOD LITERACY: A SCOPING REVIEW

Carina Micheel[1]; Corinna Ostwinkel[1]; Sarah Depenbusch[2]; Niclas Schaper[2]; Enes Yigitbas[3]; Anette Buyken[1]
[1]Institute of Nutrition, Consumption and Health, Faculty of Natural Sciences, Paderborn University, Paderborn, Germany; [2]Institute for Human Sciences, Faculty of Cultural Studies, Paderborn University, Paderborn, Germany; [3]Department of Computer Science, Paderborn University, Paderborn, Germany

BACKGROUND AND OBJECTIVES

Existing definitions of Food Literacy (FL) and Nutrition Literacy (NL) differ within the current scientific literature, and there is a lack of consistent definitions for Food Knowledge (FK) and Nutrition Knowledge (NK). These discrepancies complicate efforts to assess and improve nutrition-related competencies in educational settings. This scoping review aims to establish distinct definitions for these domains and to derive respective sets of indicators applicable to formal educational contexts.

METHODS

A scoping review will be conducted to identify and synthesise existing definitions for the four domains. Based on these findings, standardised definitions will be developed, and corresponding sets of indicators to operationalise assessments within these domains will be derived. These indicators will consider cognitive demand levels (Level 1: Reproduction of Knowledge, 2: Reorganisation and Transfer, 3: Reflection and Problem Solving) and will be derived from relevant literature, such as Bloom's Taxonomy.

RESULTS

Preliminary RESULTS indicated that FK solely establishes a theoretical knowledge and understanding of food-related concepts (e.g. sources, production, and cultural factors of foods), while NK includes a theoretical knowledge of nutrients and their roles in health. Conversely, NL translates FK and NK into practical skills (e.g. interpretation of nutrition labels, meal preparation) while FL builds on FK, NK, and NL, integrating a systemic perspective by considering cultural, social, and environmental factors. Building on these definitions, indicators operationalising assessment for each domain were derived (e.g. "*name* food types" for FK, "*describe* functions of nutrients" for NK, "*interpret* nutrition labels" for NL, "*reflect* and *evaluate* how dietary-related choices influence others" for FL).

CONCLUSIONS

This structured set of standardised definitions for essential nutrition-related domains supplemented by operationalising indicators will facilitate consistent categorisation and evaluation of studies focused on nutritional competencies in educational contexts such as schools. This scheme will assist in evaluating nutritional competencies among teachers and students, thereby advancing nutrition education.

ANEMIA, IRON INTAKE, AND FERRITIN AMONG ADOLESCENTS WITH OBESITY

Dian Caturini Sulistyoningrum[1]; Indah Kartika Murni,[2]; Rina Susilowati,[3]; Madarina Julia[4]
[1]Department of Nutrition and Health/Faculty of Medicine Public Health and Nursing, Universitas Gadjah Mada, Yogyakarta, Indonesia; [2]Department of Child Health/Faculty of Medicine Public Health and Nursing, Universitas Gadjah Mada, Yogyakarta, Indonesia; [3]Department of Histology and Cell Biology/Faculty of Medicine, Public Health and Nursing, Universitas Gadjah Mada, Yogyakarta, Indonesia; [4]Department of Child Health/Faculty of Medicine, Public Health and Nursing, Universitas Gadjah Mada, Yogyakarta, Indonesia

BACKGROUND AND OBJECTIVES

Anemia is one of health consequences of obesity. With increasing rate of obesity with even younger age of onset, this raises health concerns about health burdens among those with obesity. Obesity can impact iron status through mechanisms such as chronic inflammation, altered iron absorption, and increased hepcidin levels. Obese adolescents may exhibit lower levels of iron stores, despite having higher body mass, due to disrupted iron homeostasis associated with adipose tissue inflammation. Additionally, the presence of comorbidities commonly seen in obesity, such as insulin resistance and metabolic syndrome, can further exacerbate the risk of anemia by affecting erythropoiesis and red blood cell production. The objective of this study is to investigate the rate of anemia among adolescents with obesity using hemoglobin levels, iron storage and intake of iron-rich dietary intake among these individuals.

METHODS

A cross-sectional study was conducted in 482 adolescents aged 14-18 years, out of which 231 were with obesity. Data on anthropometric measure and dietary intakes were collected. Blood samples were analysed for complete blood count. Out of 231, 84 adolescents had their plasma ferritin analysed for a marker of iron storage. Prevelance of anemia was calculated based on hemoglobin levels (cut off 13 g/dL for anemia in adolescents). Prevalence of low iron storage was calculated based on ferritin levels < 20 ng/mL. The association between iron-rich dietary intake was examined using a generalised linear model.

RESULTS

Prevalence of anemia was 13% (n=31/231) with an average hemoglobin levels of 15 g/dL. Despite this finding, iron intake among this population was low averaging at 9 mg/day. Daily recommendation for adolescents is between 11-15 mg/day. Furthermore, low ferritin levels was detected in 47/84 (56%). This shows that although anemia is clinically detected, iron storage which is the first sign of iron depletion starts to appear. Although not significant, this may be due to relatively low iron-rich food intake.

CONCLUSIONS

This study shows that although anemia was not of high prevalence among adolescents with obesity, trends of low iron-rich food intake and low iron storage measured by ferritin levels was evident. Further study is necessary to investigate other biomarkers of anemia other than hemoglobin that are reflective of iron metabolism disruption in adolescents with obesity.

ULTRA-PROCESSED FOOD CONSUMPTION AND BMI, WEIGHT GAIN AND OVERWEIGHT IN YOUNG CHILDREN IN THE NETHERLANDS: THE GECKO DRENTHE BIRTH COHORT

Jie Yang[1]; Gerjan Navis[2]; Eva Corpeleijn[1]
[1]Epidemiology, University Medical Center Groningen, Groningen, Netherlands; [2]Internal medicine, University Medical Center Groningen, Groningen, Netherlands

BACKGROUND AND OBJECTIVES

Ultra-processed foods (UPFs) are related to increased risk of overweight and obesity in adults and have received increasing attention in recent years. Since less is known about this association in children, this study aimed to assess the association between UPF consumption at age 3 years and the BMI, increase in BMI and overweight/obesity at age 10-11 years in Dutch children.

METHODS

Of 1091 children (50.2% male) from the Dutch GECKO Drenthe study, dietary intake was assessed using a validated 71-item Food Frequency Questionnaire (FFQ) at age 3 years. Food items were categorized according to the NOVA classification system and the proportion (weight ratio, %) of UPF (NOVA-4) in the total food weight per day was calculated. Height and weight were measured by trained nurses and used to calculate BMI Z-scores and change in BMI-z between 3 and 10/11 years of age, normalized for age and gender. Overweight/obesity was defined by IOTF criteria. Regression models were adjusted for potential confounders, including age, sex, total energy intake, BMI z-score at age 3 years, maternal factors (BMI, education level, smoking status) and the presence of siblings.

RESULTS

The mean ± SD UPF intake at age 3 years was 786 ± 310 g/d (52% of total weight of food intake). The intake of unprocessed and minimally processed foods, processed culinary ingredients, and processed foods accounted for 42%, 1%, and 5%, respectively, of total weight of food intake. The prevalence of children with overweight/obesity at 10/11 years was 16.2%. The top three UPF food categories consumed were sugary beverages, sugary dairy products, and carbohydrate-rich staple foods (including bread, cereal, fries, muesli and porridge). Children in the highest quartile of UPF consumption demonstrated a higher BMI z-score at age 10-11years ($\beta = 0.16$; 95% CI: 0.01 to 0.31; $P < 0.001$) and a greater increase in BMI z-scores from ages 3 to 10/11 years ($\beta = 0.16$; 95% CI: 0.01 to 0.31; $P < 0.001$) compared with those in the lowest quartile, independent of total energy intake and other confounders. No significant association was observed between UPF consumption and overweight status at age 10/11 years.

CONCLUSIONS

Higher UPF intake at age 3 years was associated with a greater increase in BMI z-scores and higher BMI z-scores at age 10/11 years. This study suggests that a high UPF intake in early childhood may contribute to long-term weight gain, emphasizing the importance of dietary habits in early life.

OAP32_03

ASSOCIATION BETWEEN IYCF PRACTICES AND INDICATORS OF GROWTH AND MICRONUTRIENT STATUS IN CHILDREN AGED 06-23 MONTHS: FINDINGS FROM COMPREHENSIVE NATIONAL NUTRITION SURVEY 2016-2018

Radhika Madhari[1]; Sangita Thenarangam[1]; Santu Ghosh[2]
[1]Dietetics, ICMR - National Institute of Nutrition, Hyderabad, India; [2]Biostatistics, St Johns Research Institute, Bengaluru, India

BACKGROUND AND OBJECTIVES

Inadequate Infant and Young Child Feeding (IYCF) practices are key factors contributing to undernutrition, particularly during the critical stages of early development. Addressing these practices is crucial for preventing adverse health outcomes. This study explores the relationship between Minimum Dietary Diversity (MDD), Minimum Acceptable Diet (MAD), and the nutritional status such as stunting, wasting and micronutrient status such as Anemia, Iron Deficiency and Zinc Deficiency of children aged 0-23 months.

METHODS

The study analyzed Comprehensive National Nutrition Survey (CNNS) 2016–2018 data, employing a multi-stage design with structured interviews, IYCF practices, anthropometric measurements, and biochemical indicators. Descriptive statistics were used to determine IYCF indicators, and the prevalence of stunting, wasting, and micronutrient deficiencies. The BRINDA approach accounted for inflammation in assessing iron and zinc deficiencies. Multivariate logistic regression, with adjusted odds ratios, explored the association between IYCF practices and the nutritional and micronutrient status of children aged 0–23 months, controlling for potential confounders.

RESULTS

The study revealed that only 24.9% of children met the MDD, and 44.4% followed the recommended minimum meal frequency. Additionally, only 12.3% of children met the criteria for MAD. Stunting was observed in 22.79% of the children, while 15.69% were affected by wasting. Anemia is the most prevalent condition, with a rate of 43.3%. Iron deficiency affected 48.33% of children, and zinc deficiency was present in 16.51%. Logistic regression analysis showed that meeting MDD was associated with a lower likelihood of stunting (AOR: 0.82, $p=0.002$) but did not show a significant link to wasting. Age was a strong predictor of stunting, especially in children aged 12-23 months (AOR: 3.18, $p<0.001$), while female children had lower odds of both stunting (AOR: 0.70, $p<0.001$) and wasting (AOR: 0.88, $p=0.045$). However, MDD and MAD was not significantly associated to any of the selected micronutrient deficiencies.

CONCLUSIONS

In conclusion, the study highlights the significance of dietary diversity and meal frequency in reducing stunting. Comprehensive interventions addressing socioeconomic inequalities, maternal education, and nutrient-based strategies are crucial. Empowering caregivers with knowledge and resources to provide diverse, nutrient-dense foods is essential for improving child nutrition.

DETERMINATION OF LIVER MARKERS OF CHICKEN EXPOSURE TO POLYCHLOROBIPHENYLS (PCBS) BY 1D AND 2D NMR-METABOLOMICS

Carla Remy[1]; Laurent Debrauwer[1]; Cécile Canlet[1]; Erwan Engel[2]; Jérémy Ratel[2]; Elisabeth Baeza[3]
[1]Plateform AXIOM, Inra-St Martin Toxalim, Toulouse, France; [2]UR QuaPA, Inrae - Center Clermont-Auvergne-Rhône-Alpes, Saint-Genès-Champanelle, France; [3]UMR BOA, INRAE Nouzilly, secteur 3, Nouzilly, France

BACKGROUND AND OBJECTIVES
In order to enhance food safety surveillance, sector players must benefit high-throughput, low-cost screening METHODS to control critical points in the food chain. One of the approaches proposed by the ANR SENTINEL project consists of combining the discovery and identification of food chain contamination markers by "omics" techniques with targeted high-throughput and cost-effective techniques in order to easily and quickly measure these markers in animal tissues or fluids. To do this, based on a case study (exposure of chickens to ultra-trace levels of PCBs), we explored the potential of NMR spectroscopy to identify hepatic markers of exposure of chickens to ultra-trace levels of contaminants (here PCBs). To overcome the limitations of 1D NMR for the identification and quantification of biomarkers, the interest and performance of 2D NMR has been evaluated using several fast 2D sequences.
METHODS

Following a Bligh and Dyer extraction, aqueous and lipidic extracts of liver samples from chickens exposed to low doses of PCBs in the feed for 45 days (Aroclor 1260 2 µg/kg/day, 20 µg/kg/day, 100 µg/kg/day) were analyzed by 1D proton NMR and 2D NMR sequences on a 600 MHz NMR spectrometer. Multivariate statistical analyses (PCA and PLS-DA analyses) were performed on NMR data to differentiate control and exposed animals

RESULTS
Our preliminary RESULTS on one-dimensional proton NMR data showed different lipidic profiles between control animals and the three groups of exposed animals despite low exposure doses. For polar metabolites, we observed differences between control and treated animals only for the lowest exposition dose. Work is now in progress for the identification of discriminant metabolites. 2D NMR spectra showed an improved peak separation compared to 1D NMR spectra. The various 2D datasets are undergoing treatment for statistical analyses, and already show powerful capacities.
CONCLUSIONS
These preliminary RESULTS obtained by 1D NMR metabolomics are encouraging, notably by revealing lipidic metabolism disturbances despite very low doses of exposure to PCBs. The statistical analyses on the 2D NMR data will continue with the aim of highlighting additional discriminant metabolites. Our preliminary RESULTS already demonstrate the added-value of 2D NMR for improving metabolite separation and identification capabilities. Our innovative methodology paves the way to the development of new solutions for efficient food monitoring

EFFECTS OF EXOGENOUS NUCLEOTIDES SUPPLEMENTATION ON SYMPTOMS, RECOVERY, AND IMMUNE RESPONSE IN ELDERLY COVID-19 PATIENTS

Shuyue Wang[1]; Lixia Song[1]; Rui Fan[1]; Qianqian Chen[1]; Yuxiao Wu[1]; Ruisheng Fu[1]; Li Yong[1]; Meihong Xu[1]
[1]Department of Nutrition and Food Hygiene, School of Public Health, Peking University, Beijing, China

BACKGROUND AND OBJECTIVES

The COVID-19 pandemic exposed the vulnerability of the elderly to infections due to immunosenescence. Nucleotides(NTs), essential for immune modulation, may enhance recovery and resilience. This study examines their effects on symptoms, recovery, and immunity in elderly COVID-19 patients, offering insights for broader applications in aging populations.

METHODS

This study is a subgroup analysis of a randomized, double-blind, placebo-controlled trial conducted in Chengdu, China (Clinical Trial Registration No.: NCT05243108). Elderly participants aged 60–70 were randomly assigned in a 1:1 ratio to receive either nucleotides (1.2 g/day) or a placebo, based on a computer-generated randomization sequence. Elderly participants who contracted COVID-19 after 1.5 months of nucleotides or placebo supplementation were included. Acute-phase symptoms were assessed at infection onset, and recovery was evaluated 4 weeks post-infection. T lymphocyte subsets in peripheral blood were analyzed using flow cytometry, and serum cytokines (TNF-α, IL-6, and others) were measured using QAH-CUST chip technology.

RESULTS

A total of 56 elderly COVID-19 patients (27 in the nucleotides group, 29 in the placebo group) were included.（1）Acute Phase: Symptom prevalence (e.g., cough, fever, sore throat) and duration (8.11±4.27 vs 7.97±3.49 days) showed no significant differences between groups.（2）Recovery Phase: Persistent symptoms (e.g., night sweats, nasal congestion, cough) were less frequent in the nucleotide group (3.70%, 11.11%, 40.74%) compared to the placebo group (27.59%, 20.69%, 65.52%; P=0.015, P=0.055, P=0.063).（3） Immune Response:CD4+ T lymphocyte levels increased in the nucleotide group (2.01 ± 3.59) but decreased in the placebo group (-0.35 ± 4.35, P=0.031). CD8+ T lymphocytes declined more in the nucleotide group (-2.95 ± 2.94) than in the placebo group (-0.41 ± 3.12, P=0.003). Serum IL-6 and TNF-α levels were significantly lower in the nucleotide group (P=0.045, P=0.005).

CONCLUSIONS

Exogenous nucleotides supplementation enhances immune function and recovery in the elderly by reducing persistent symptoms, boosting CD4+ T lymphocytes, and lowering inflammatory cytokines. It shows potential as an immunonutrition strategy to support health and resilience against future infections.

DIET QUALITY AND HEALTH AMONG FIRST NATIONS IN CANADA: INSIGHTS FROM THE HEALTHY EATING FOOD INDEX (HEFI-2019) AND CANADIAN HEALTHY EATING INDEX (C-HEI 2007)

Ines Sebai[1]; Amy Ing[1]; Milena Nardocci Fusco[1]; Karen Fediuk[2]; Chan Hing Man[2]; Malek Batal[3]
[1]Nutrition, UdeM – Faculté de médecine, Montreal, Canada; [2]Department of Biology, University of Ottawa, Ottawa, Canada; [3]Nutrition, Université de Montréal, Montreal, Canada

BACKGROUND AND OBJECTIVES

Diet quality is a key determinant of health, yet little is known about its relationship with health outcomes in First Nations communities, the largest group among Indigenous peoples in Canada, where historical and ongoing inequities have shaped dietary practices and influenced health outcomes with a sharp increase in chronic disease rates. This study evaluates diet quality using the Healthy Eating Food Index-2019 (HEFI-2019) and the Canadian Healthy Eating Index 2007 (C-HEI 2007) and explores associations with obesity, type 2 diabetes (T2D), and self-perceived health among First Nations adults.

METHODS

Data were drawn from the First Nations Food, Nutrition, and Environment Study (FNFNES), a 10-year community-based participatory research project encompassing dietary recalls, sociodemographic surveys, and health assessments of 6487 adults (19 years and older) from ninety-two First Nations communities across Canada. HEFI-2019 and C-HEI 2007 scores were calculated and analyzed for associations with health outcomes using regression models adjusted for demographic and lifestyle covariates.

RESULTS

Mean HEFI-2019 and C-HEI 2007 scores were 35/80 and 49/100, respectively, indicating suboptimal adherence to dietary guidelines compared to the Canadian population. Factors such as region, age, sex, education level, number of working people in the household, and smoking status significantly influenced diet quality. Traditional food consumption was significantly associated with improved diet quality, increasing scores by 5 points for both indices. Higher scores for both indices were significantly associated with increased odds of T2D, likely reflecting dietary improvements following diagnosis. No significant associations were found between diet quality and obesity or self-perceived health.

CONCLUSIONS

These findings underscore the complexity of diet quality's relationship with health outcomes, shaped by socioeconomic and structural factors. Traditional food consumption plays a pivotal role in enhancing diet quality among First Nations, reflecting its nutritional and cultural significance. While higher diet quality may follow a T2D diagnosis, culturally tailored interventions are essential to support traditional food systems, promote dietary practices, and advance health equity in Indigenous communities.

EFFICACY OF ZINC BIOFORTIFIED RICE IN IMPROVING ZINC STATUS AMONG YOUNG NON-PREGNANT NON-LACTATING WOMEN IN RURAL BANGLADESH: A RANDOMIZED CONTROLLED TRIAL

Prasenjit Mondal[1, 2]; Sabuktagin Rahman,[3]; Malay Kanti Mridha,[2]; Abu Ahmed Shamim[2]; Hai N. Phung,[1]; Md. Mokbul Hossain,[2]; Faruk Ahmed[1]
[1]Department of Public Health, Griffith University, Gold Coast Campus, Southport, Australia; [2]BRAC James P Grant School of Public Health, BRAC University, Dhaka, Bangladesh; [3]Faculty of Arts and Sciences, American International University - Bangladesh (AIUB), Dhaka, Bangladesh

BACKGROUND AND OBJECTIVES

Zinc biofortified rice (ZBR) can be a suitable approach for alleviating zinc status in Bangladesh, a country where zinc deficiency (ZD) is a public health problem. Habitual diet in Bangladesh is dominated by plant-source food with rice being the staple. Non-pregnant non-lactating (NPNL) women are more affected (57%) by ZD and bear more severe consequences owing to their reproductive life. A previous trial with ZBR among children failed to elicit any positive impact, mostly due to methodological and analytical limitations. Therefore, we decided to conduct a randomized controlled trial (RCT) among young NPNL women in rural Bangladesh with more robust methodologies to assess the efficacy of ZBR in increasing plasma zinc concentration (PZC) and improving morbidity.

METHODS

We are currently conducting a community-based, double-blind RCT among young NPNL women aged 20-29 years in the rural area of Birganj, Dinajpur, Bangladesh. We listed 3425 households in the study area and identified 359 eligible females; i.e. aged 20-29 years, neither pregnant nor lactating, apparently healthy, had not consumed micronutrient supplementation in the preceding three months and not a recipient of rice supply through social safety net program. From this sampling frame, 200 women were selected and assigned to either one of ZBR (BRRI-100 variety) or conventional rice (CR, BRRI-29 variety) arms by simple random sampling. The enrolled participants would receive a supply of raw rice for their whole family for a duration of two months. Data and venous blood samples are collected before and after intervention. Outcomes of interest are PZC and self-reported morbidity during the intervention period. Participants' compliance to the intervention is monitored every three days using pictorial cards and standard serving bowls. Habitual dietary intake of various nutrients will be estimated by a validated 7-day semi-quantitative food frequency questionnaire (SQ-FFQ) during baseline and endline surveys. The trial has been registered at ISRCTN with the registration number ISRCTN83005630.

RESULTS

Currently, we are conducting the end-line survey of the recruited 197 participants (A=98, B=99). The RESULTS of the final analysis will be presented during the conference presentation

CONCLUSIONS

Given our robust methodology, the RESULTS of this study will provide conclusive evidence regarding the efficacy of zinc-biofortified rice in improving zinc status among NPNL women in rural Bangladesh.

ROAD MAP FOR INTEGRATING SPECIALIZED LACTATION COUNSELING SERVICES INTO THE JORDANIAN HEALTH SYSTEM

Doris Youngs[1]; Alessandro Iellamo,[2]; lana Khoury[3]; Mariam Abdoh,[4]
[1]Chief of Party/ Country Representative, Community Health and Nutrition Project- FHI 360, Amman, Jordan; [2]Nutrition Advisor, FHI 360, Durham, United States of America; [3]Director of Research, Monitoring and Evaluation, Community Health and Nutrition, FHI 360, Amman Jordan; [4]Project Management Specialist, Population and Family Health, US Agency For International Development USAID, Amman, Jordan, Amman Jordan

BACKGROUND AND OBJECTIVES

The rate of exclusive breastfeeding (EBF) in Jordan has remained stagnant for the past 20 years. At 24%, it is one of the lowest rates globally. Persistent barriers to EBF in Jordan include traditional practices and norms and lack of institutionalized quality lactation counseling services to support pregnant and lactating women (PLW). Evidence shows that programs which provide support through lactation counselors (LCs) are effective in improving breastfeeding initiation, duration and rates of EBF. In response to this, the USAID funded Community Health and Nutrition (CHN) Activity developed and implemented a national Lactation Counselors Certification Program (LCCP) to create a cadre of LCs integrated within the health care system.

METHODS

CHN designed a national LCCP responsive to Jordan's needs and priorities. The process included revisions to the International Board-Certified Lactation Counsellors (IBCLC) program, the Academy of Lactation Policy and Practice programs, and regional initiatives. The program collaborated with the Ministry of Health, the Health Care Accreditation Council, and other national experts. Design of the certification pathway built on localized best practices for health care professionals to ensure integration of LC services across the health care system with a focus on strong linkages with the community and long-term sustainability. The LCCP comprises a capacity building program, including classroom training with clinical practices and supervised on- the -job practicum across the continuum of care and practical tools to mentor, supervise and document learnings.

RESULTS

The first national LCCP was launched in 2022. As of December 2024, 83 LCs were certified and have provided services to more than 8,000 PLW across Jordan. To ensure sustainability of this program, CHN advocated with the National Medical Councils securing the LCCP the maximum number of continuous professional development hours required for professional relicensing. Additionally, CHN partnered with a private insurance company to integrate LC services within their medical service package.

CONCLUSIONS

Investing in the design and adaptive roll out of a dynamic LCCP for the first time in Jordan ensures PLW can access affordable quality lactation counselling support via public and private health care systems with linkages to the community, aiming to improve future breastfeeding and nutrition outcomes.

SYSTEMATIC REVIEW ASSESSING THE IMPACT OF PRENATAL MULTIPLE MICRONUTRIENT SUPPLEMENTATION VS IRON AND FOLIC ACID SUPPLEMENTATION ON INFANTS' SIZE AT BIRTH AND SUBSEQUENT GROWTH THROUGH 2 YEARS OF AGE

Filomena Gomes[1]; Global Multiple Micronutrient Supplementation Technical Advisory Group[1]; Participating Investigators Of Included Trials[1]
[1]Healthy Mothers Healthy Babies Program, Micronutrient Forum, Washington, DC, United States of America

BACKGROUND AND OBJECTIVES

While antenatal multiple micronutrient supplements (MMS) have been shown to improve pregnancy outcomes compared to iron and folic acid supplements (IFA), their impact on infant growth up to 2 years of age remains unclear. We performed a systematic review of trials comparing antenatal MMS vs IFA, evaluating their impact on infants' anthropometric outcomes at birth, three, six, 12, 18, and 24 months of age.

METHODS

We included trials from a Cochrane review along with new studies found through systematic searches in three databases. We calculated pooled effect estimates (with 95% CI) using a generic inverse variance method, applying both fixed and random effects. We conducted subgroup analyses comparing trials with supplementation in pregnancy vs. pregnancy and postpartum, and trials with lower (≤ 11.9%) vs higher prevalence (>11.9%) rates of low birthweight (LBW). We performed additional sensitivity analyses limited to the 16 trials included in the 2020 WHO recommendation. PROSPERO registration number: CRD42024551864.

RESULTS

19 trials were included. Compared with IFA, MMS led to significantly greater length and weight from birth to six months, larger head circumference (HC) from birth to 12 months, and a greater mid-upper arm circumference (MUAC) at birth. Infants of mothers taking MMS vs IFA were significantly longer at birth (mean difference: 0.05 cm, 95% CI 0.02 to 0.08) and showed higher length-for-age Z-scores (LAZ) at birth (0.09, 0.06 to 0.12), three (0.09, 0.06 to 0.12) and six-months (0.04, 0.01 to 0.07), but not in subsequent follow-ups. MMS also resulted in significantly higher weight-for-age Z-scores and HC-for-age Z-scores from birth to six months, and higher weight-for-length Z-scores and MUAC-for-age-Z scores up to three months. MMS lowered the risk of stunting (RR 0.86, 95% CI 0.82 to 0.91), underweight (0.86, 0.81 to 0.90), small HC (0.84, 0.79 to 0.90), and low MUAC (0.90, 0.82 to 0.99) at 3 months, and reduced the risk of wasting (0.90, 0.85 to 0.96) at birth. For some outcomes, the effects of MMS vs IFA were greater among trials that continued supplementation post birth and those conducted in settings with higher prevalence of LBW. RESULTS were similar in the sensitivity analyses.
CONCLUSIONS

Antenatal MMS supplementation improved infant anthropometric outcomes at birth and during the first six months, but not thereafter. These findings further support the benefits of MMS beyond birth-related outcomes.

HEME IRON FROM RED MEAT IS ASSOCIATED WITH FUNCTIONAL INTESTINAL DISORDERS IN THE FRENCH NUTRINET-SANTÉ COHORT

Alice Le Brun[1]; Françoise Guéraud[1, 2]; Helene Eutamene[1]; Mathilde Touvier[3, 2]; Fabrice Pierre[1, 2]; Maïwenn Olier[4, 1]; Mélanie Deschasaux-Tanguy[3, 4, 2]
[1]Toxalim (Research Centre in Food Toxicology), INRAE, University of Toulouse, ENVT, INP-EI Purpan, UPS, Toulouse, France; [2]The French Network for Nutrition And Cancer Research, Réseau NACRe, Jouy-en-josas, France; [3]Centre of Research in Epidemiology and StatisticS, Nutritional Epidemiology Research Team (EREN), Université Sorbonne Paris Nord and Université Paris Cité, INSERM, INRAE, CNAM, Bobigny, France; [4]Co-last, Authors, Toulouse, France

BACKGROUND AND OBJECTIVES

Food-related intestinal disorders are common, especially in patients with irritable bowel syndrome (IBS), for whom exclusion diets may be proposed as part of symptom management. Although a particular attention has been paid to the relationship between the consumption of red meat and colorectal cancer, its role in functional intestinal disorders and abdominal pain is unknown. Heme iron contained in red meat was indeed shown to catalyze the peroxidation of dietary polyunsaturated lipids in the gut lumen, leading to the formation of reactive aldehydes, associated to colorectal cancer promotion in rodent1, but also activating pain signaling pathways2. Our objective was to investigate the association between red meat consumption and the risk to encounter functional intestinal disorders.

METHODS

Participants (n=77,128, mean age: 44.5 years, 77.7% women) were adults from the French prospective cohort NutriNet-Santé (2009-2022). Meat consumption (overall and by types) was assessed through repeated 24h dietary records every 6 months (at least 3 in the first 2 years of follow-up). Iron (total and heme iron) intake from meat was derived from the NutriNet-Santé food composition table. Functional intestinal disorders such as IBS or constipation in the past 12 months were self-reported every year in a general health questionnaire. Associations between sex-specific quintiles of intakes for red meat, poultry or heme iron from red meat, and functional intestinal disorders was analyzed using multi-adjusted Cox models.

RESULTS

Of 77,128 participants, 4,868 (6.31%) reported functional intestinal disorders during follow-up. After adjustments on potential confounding factors. Analyses by meat subtypes revealed differences according to heme iron content: higher red meat consumption was associated with more functional intestinal disorders (HR Q5 vs Q1 = 1.15, 95% CI 1.036-1.274), while such association was not observed for poultry (HR Q5 vs Q1 = 1.03, 95% CI 0.94-1.14). According to our mechanistic hypothesis, a higher intake of heme iron from red meat was also associated with more functional intestinal disorders (HR Q5 vs Q1 = 1.15, 95% CI 1.04-1.27).

CONCLUSIONS

This study suggested that consuming heme-rich meat may be associated with more functional intestinal disorders. These RESULTS should be further confirmed using Rome criteria, which would enable to target abdominal pain more specifically. Pre-clinical experiments are also needed to assess the mechanistic hypothesis of the heme-induced lipid peroxidation.

EFFECT OF FORTIFIED BALANCED ENERGY-PROTEIN SUPPLEMENTATION DURING PREGNANCY AND LACTATION ON INFANT NEURODEVELOPMENT: A COMMUNITY-BASED RANDOMIZED CONTROLLED TRIAL IN RURAL NEPAL

Tsering Lama[1, 2]; Daniel Erchick,[2]; Rita Shrestha,[1]; Parul Christian[2]; Joanne Katz,[2]; Subarna Khatry,[1]; Eleonor Zavala[2]; Steven Leclerq,[2]; James Tielsch,[3]
[1]NNIPS, Nepal Nutriton Intervention Project Sarlahi, Kathmandu, Nepal; [2]Center for Human Nutrition and Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore MD USA, United States of America; [3]Department of Global Health, George Washington University Milken Institute School of Public Health, Washing, United States of America

BACKGROUND AND OBJECTIVES

Few studies have examined the effect of balanced energy–protein (BEP) supplementation in pregnancy and/or lactation on infant neurodevelopment. We examined the effect of a fortified BEP supplement during pregnancy and lactation on infant neurodevelopment at 6 months of age.

METHODS

The Maternal Infant Nutrition Trial (MINT) is a 2x2 factorial, unblinded, household randomized efficacy trial conducted in Sarlahi District, Nepal (1). Between November 2021 and August 2023, pregnant women (n=1944) were enrolled in early pregnancy and randomized to receive a daily multiple-micronutrient fortified BEP supplement or no supplement (standard of care with iron folic acid) from 14 weeks' gestation to the pregnancy outcome. After delivery, households with at least one live birth were randomized to receive fortified BEP supplement or no supplementation to 6 months postpartum. In a sub-study of this trial, we selected the first 100 infants in each intervention group of the postpartum phase for a neurodevelopment assessment (pregnancy supplementation only, postpartum supplementation only, both, and neither). At 6 months, infants underwent assessment for cognitive, motor, language and socioemotional performance using the Bayley Scales of Infant and Toddler Development (4th edition). Generalized linear models were used to calculate the mean difference for each of the four neurodevelopment outcome domains.

RESULTS

Baseline characteristics of participants were similar across the four trial groups. Compared to the pregnancy no supplementation group, infants born to mothers who received pregnancy supplementation did not differ in their cognitive standard score (mean difference [MD]: 2.0, 95% CI: -0.29 to 4.29), language standard score (MD: 1.23, 95% CI: -0.16 to 2.63), motor standard score (MD: 0.98, 95% CI: -1.41 to 3.36), and socioemotional standard score (MD: -2.35, 95% CI: -5.27 to 0.57). The mean standard scores for children born to mothers who received postpartum supplementation compared to those who did not were also similar for all four domains. The final regression model comparing each supplementation group to the no supplementation group showed a higher mean standard score of 2.12 (95% CI: 0.16 to 4.08) for the language domain in infants born to mothers who received supplements in both pregnancy and postpartum period but no other significant differences.

CONCLUSIONS

BEP supplementation did not improve neurodevelopment at 6 months of age except for the language domain. Evaluation of children's neurodevelopment at a later age is warranted.

INCREASING UPTAKE OF NUTRITION PRACTICES ACROSS THE LIFE CYCLE: FOSTERING A SOCIAL MOVEMENT FOR TRANSFORMATIVE, COMMUNITY-LED CHANGE

Doris Youngs[1]; Claire Gillum,[2]; lana Khoury[3]; Nancy Ala'eddin,[4]; Mariam Abdoh,[5]
[1]Chief of Party/ Country Representative, Community Health and Nutrition Project- FHI 360, Amman, Jordan; [2]Research Utilization and Scale-Up Advisor, FHI 360, Durham, United States of America; [3]Director of Research, Monitoring and Evaluation, Community Health and Nutrition, FHI 360, Amman Jordan; [4]Director of Social and Behavior Change Communication, Community Health and Nutrition - FHI 360, Amman, Jordan; [5]Project Management Specialist, Population and Family Health, US Agency For International Development USAID, Amman, Jordan, Amman Jordan

BACKGROUND AND OBJECTIVES

Jordan faces a dual burden of overweight/ obesity and undernutrition. Maternal, infant and young child nutrition (MIYCN) practices affect both undernutrition and overweight/ obesity outcomes. Despite substantial attention, MIYCN behavioral indicators in Jordan have remained persistently below national and global targets (e.g., 24% of children <6 months are exclusively breastfed (EBF) and 27% of children 6-23 months consume a minimum acceptable diet). In response, the USAID funded Community Health and Nutrition (CHN) Activity seeks to foster a social movement to accelerate maternal, child, and family nutrition outcomes. The Activity uses a systems approach that empowers communities as champions of their own health.

METHODS

CHN's social movement aims to create an enabling environment for MIYCN practices and support women and families to demand quality services to support their nutrition needs throughout the life cycle. The social movement is guided by an SBC strategy, informed by findings from a literature review and formative research conducted. The SBC approaches and activities implemented have sought to reach and engage audiences across the life cycle, focusing on pregnant and lactating women, parents of children under the age of 2, and influencers, using multiple reinforcing channels: mass media to shift knowledge, attitudes, norms; peer support groups, community dialogue and mixed media to enhance skills, provide social support, promote positive attitudes and norms, and strengthen community-to-facility connections.

RESULTS

Between 2022 and 2024, CHN's community level SBC activities implemented in partnership with CBOs and primary health care level health committees reached more than 41,000 community members. CHN's two mass media campaigns each achieved national reach exceeding 10 million. Additionally, community champions promoted for MIYCN support in their communities resulting in establishment of breastfeeding rooms and implementing youth led initiatives.

CONCLUSIONS

SBC interventions in global nutrition programming have long focused on addressing individual-level behaviors and determinants and have minimally considered importance of social change in achieving nutrition objectives. Jordan CHN's experience provides a valuable case study, demonstrating how community-driven SBC programming can be designed and delivered to support a larger social movement for transformative change in nutrition.

EFFECT OF QUINTUPLY-FORTIFIED SALT ON MICRONUTRIENT STATUS OF NON-PREGNANT WOMEN OF REPRODUCTIVE AGE IN PUNJAB, INDIA

Yvonne E Goh[1]; Reena Das[2]; Mona Duggal[3]; Manu Jamwal[2]; Gurjinder Brar[2]; Bidhi Singh[2]; Julie M Long[4]; Jamie Westcott[4]; Charles D Arnold[5]; Nancy F Krebs[6]; Kenneth H Brown[5]; Christine M Mcdonald[1]
[1]Division of Gastroenterology, Hepatology and Nutrition, Department of Pediatrics, University of California, San Francisco, San Francisco, United States of America; [2]Department of Hematology, Postgraduate Institute of Medical Education and Research (PGIMER), Chandigarh, India; [3]Department of Optometry, Postgraduate Institute of Medical Education and Research (PGIMER), Chandigarh, India; [4]Section of Nutrition - Department of Pediatrics, University of Colorado School of Medicine, Aurora, United States of America; [5]Institute for Global Nutrition, University of California Davis, Davis, CA, United States of America; [6]Department of Pediatrics – Section of Nutrition, University of Colorado School of Medicine, Aurora, United States of America

BACKGROUND AND OBJECTIVES

The burden of multiple micronutrient deficiencies among women in South Asia remains unacceptably high. In India, salt may be an attractive fortification vehicle, as 94% of households consume iodized salt. Recent advancements in technology have enabled the production of quintuply-fortified salt (Q5S) with iron, zinc, folic acid, vitamin B12, and iodine. This study evaluated the effect of the novel Q5S on the micronutrient status of non-pregnant women of reproductive age (NPWRA) in Punjab, India.

METHODS

In this double-blind, randomized, controlled community-based trial, 998 NPWRA were randomized to receive i) Q5S with iron as encapsulated ferrous fumarate, zinc, vitamin B12, folic acid, and iodine (eFF-Q5S); ii) Q5S with iron as encapsulated ferric pyrophosphate plus ethylenediaminetetraacetic acid, and the same micronutrients (eFePP-Q5S), or iii) iodized salt (IS). Biomarkers of micronutrient status were assessed at enrollment, 6 m, and 12 m. The effect of the intervention was assessed using inverse-probability of censoring weighted regression models adjusting for baseline biomarker concentration.

RESULTS

At enrollment, the prevalence of anemia (hemoglobin <12 g/dL), iron deficiency (inflammation-adjusted ferritin <15 ug/L), hypozincemia (serum zinc <70 ug/dL), vitamin B12 insufficiency (serum B12 <221 pmol/L), and folate insufficiency (red blood cell folate <748 nmol/L) across all participants were 47.9%, 59.7%, 27.0%, 61.5%, and 69.7%, respectively. Salt utilization during the follow-up period was 6.0 ± 2.3 g/adult female equivalent/per day. At 6 m, the odds of zinc deficiency (OR: 0.49; 95% CI, 0.30, 0.80), $p < 0.05$), vitamin B12 insufficiency (OR: 0.20; 95% CI, 0.13, 0.31), $p < 0.001$), and folate insufficiency (OR: 0.14; 95% CI, 0.09, 0.21), $p < 0.001$) were 51%, 80% and 86% lower in the eFF-Q5S vs. IS group. At 12 m, the odds of vitamin B12 and folate insufficiency were 86% and 82% lower in the eFF-Q5S vs. IS group. Participants in the eFePP-Q5S group demonstrated similar reductions in the odds of vitamin B12 and folate insufficiency in comparison to the IS group. There was a non-significant reduction in the odds of iron deficiency in the eFF-Q5S and eFePP-Q5S vs. IS group at 6 m and 12 m.

CONCLUSIONS

Quintuply-fortified salt improved the zinc, vitamin B12, and folate status of NPWRA in Punjab. There is a need to evaluate the impact of salt fortification interventions in other nutritionally vulnerable populations.

CALIBRATING THE COSTS AND BENEFITS OF REPLACING IRON-FOLIC ACID WITH MULTIPLE MICRONUTRIENT SUPPLEMENTS IN 25 LOW- AND MIDDLE-INCOME COUNTRIES

John Hoddinot[1]; Robert Black[2]; Clayton Ajello[3]; Jennifer Busch-Hallen; Martin Mwangi[4]; Dylan Walters[5]; Filomena Gomes[6, 4]

[1]Department of Economics, Cornell University, Ithaca, United States of America; [2]Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States of America; [3]Kirk Humanitarian, Kirk Humanitarian, Salt Lake City, Utah, United States of America; [4]Healthy Mothers Healthy Babies Program, Micronutrient Forum, Washington, DC, United States of America; [5]Health Economics Unit, Nutrition International, Ottawa, Canada; [6]NOVA Medical School, Universidade NOVA de Lisboa, Lisbon, Portugal

BACKGROUND AND OBJECTIVES

While antenatal multiple micronutrient supplements (MMS) have been shown to improve pregnancy outcomes compared to iron and folic acid supplements (IFA), costs remain a concern for achieving scale and sustainability. We calculated the costs and benefits of transitioning from preventive IFA to MMS in the 25 low- and middle-income countries (LMIC) with the greatest burden of low birthweight (LBW), under different costing scenarios.

METHODS

We generated new data on the costs of: both supplements transition associated with moving from IFA to MMS; and the associated complementing activities that strengthen the provision of antenatal care (ANC).

We modeled two coverage scenarios: (1) Replacing IFA with MMS at existing levels of IFA coverage (180 tablets per woman); and (2) Providing MMS at a level of coverage equivalent to the percentage of women who have at least one ANC visit (ANC1+).

Benefits were calculated as the additional number of LBW, stillbirths, and female neonate deaths averted. We calculated the cost of a LBW averted as the total cost of replacing IFA with MMS divided by the number of LBW averted. We compared this against the discounted present value of averting a LBW. We did so for nine scenarios based on different assumptions of cost estimates and levels of coverage using a seven year time horizon (two transition years and five implementation years).

RESULTS

Costs ranged from $235.6 million, or $33.6 million/year to $1399.9 million, or $200 million/year. These amounts are equivalent to 0.7 and 5.7 percent of current global spending on nutrition. Over five years of implementation:

(1) when IFA is replaced with IFA, 3,514,594 LBW, 186,369 stillbirths and 218,914 female neonate deaths are averted;

(2) when coverage is set at ANC1+, 7,272,320 LBW, 473,471 stillbirths and 541,591 female neonate deaths are averted.

Replacing IFA with MMS generates a minimum of $1.335 billion in economic benefits; providing coverage at the level of ANC1+ generates $2.763 billion in economic benefits.

CONCLUSIONS

Replacing antenatal IFA with MMS has large health and economic benefits. The cost of doing so is a small fraction of current global spending on nutrition. These findings further support the case for shifting from the provision of IFA to MMS for pregnant women in LMIC.

OAP 37 - PUBLIC HEALTH AND NUTRITION THROUGHOUT LIFE CYCLE

OAP37_01

MULTIPLE NUTRIENT SHORTFALLS ACROSS THE LIFESPAN: THE SILENT HEALTH CRISIS IN DEVELOPED NATIONS

Carlene Starck[1]; Tim Cassettari[1]; Emma Beckett[1]; Flávia Fayet-Moore[1, 2]
[1]Science, FOODiQ Global, Sydney, Australia; [2]School of Environmental and Life Sciences, University of Newcastle (UON) - Ourimbah - Library, Ourimbah, Australia

BACKGROUND AND OBJECTIVES

Poor diet, including an overconsumption of nutrients of concern and an underconsumption of essential nutrients, is a leading cause of disease in developed nations. To improve diet quality and prevent diet-related disease, we identified the nutrients with inadequate intakes and those with the greatest association with preventing health outcomes in the United States, Australia and New Zealand across the lifespan.

METHODS

We developed a five-step process to identify the priority nutrients in each country: 1. Determine the demographic groups (age and sex); 2. Identify the health priorities based on nationally representative data; 3. Assess the nutrients consumed at insufficient levels via the most recent nutrition surveys and scientific literature; 4. Identify the associations between nutrients and health priorities using systematic review evidence; and 5. Identify the priority nutrients (for each demographic group) using a quantitative scoring matrix based on steps 2-4. Priority nutrient intake levels were compared against intakes required to reduce disease risk and the recommended dietary targets for each country.

RESULTS

Up to 22 essential nutrients were consumed below recommended levels, with four identified as the highest priority and showing high similarity between countries: vitamin D, calcium, magnesium, and dietary fiber. Nutrient shortfalls were most prevalent in older adults, teenagers, and pregnant and lactating women. Comparing priority nutrient intake levels with current requirements indicated that higher vitamin D and calcium intake could benefit health.

CONCLUSIONS

The extent of nutritional inadequacies in developed countries is high and contributes to the disease burden. Nutrient prioritization is an important part of the strategy to address this burden sustainably. The findings highlight the nutrients that must be prioritized in public health policies for nutritious and sustainable diets.

CONCURRENT OVERNUTRITION AND ANEMIA IN ADOLESCENT GIRLS IN INDONESIA : INDONESIA BASIC HEALTH SURVEY

Avliya Quratul Marjan[1]; Azahra Reyzita Putri[1]; Sintha Fransiske Simanungkalit[1]; Dian Luthfiana Sufyan,[2]
[1]Nutrition Study Program, Universitas Pembangunan Nasional Veteran Jakarta, Jakarta, Indonesia;
[2]Nutrition, Universitas Pembangunan Nasional Veteran Jakarta, Depok, Indonesia

BACKGROUND AND OBJECTIVES

Indonesia is currently experiencing a triple burden of malnutrition that occurs simultaneously, two of which have the potential to occur in the female adolescent population, namely overweight/obesity, and anemia. The Indonesia Basic Health Survey shows an increased prevalence of overweight, obesity, and anemia in Indonesian adolescents from 2013 to 2018. This study aims to determine the concurrent overnutrition and anemia in adolescent girlis based on basic health survey in Indonesia.

METHODS
This research uses quantitative METHODS with a cross-sectional study design that is analytical and observational as the basis for this research. Data analysis used the chi-square test and multiple logistic regression which aims to analyze concurrent overnutrition and anemia in adolescent girls aged 13-18 years in Indonesia and related factors based on the 2018 Indonesia Basic Health Survey analysis.
RESULTS
The RESULTS of the study show that the variables area of residence (p=0.028) and consumption of soft drinks/carbonated drinks (p=0.049) were significantly related to concurrent overnutrition and anemia in adolescent girls. Based on the RESULTS of the multivariate analysis data obtained shows that the area of residence with a p-value of 0.007 AOR 0.520 (95% CI; 0.323-0.838) was the most influential variable on the concurrent overnutrition and anemia.
CONCLUSIONS

This study concludes that adolescent girls living in rural areas are more at risk of concurrent overnutrition and anemia in Indonesia. Our recommendation is the need for equitable health development throughout Indonesia, especially in areas far from the center of the country.

MATERNAL AWARENESS OF CHILD DEVELOPMENT AND GROWTH OUTCOMES IN THE MALIAN CONTEXT: USE OF THE AGES AND STAGES QUESTIONNAIRE

Mengke Tian[1]; Agarwal Vanshika[1]; Evans Asamane Atiah[1]; Sidibe Cheick[2]; Weber Katinka[1]; Kai Yan[1]; Chang Shi[1]; Traore Lacina[1]; Sophie Budge[1]; Toure Ousmane[2]; Semira Manaseki-Holland[1]
[1]Department of Applied Health Sciences, University of Birmingham, Birmingham, United Kingdom; [2]Applied Health and Research, University of Science, Techniques and Technology Bamako, Bamako,, Mali

BACKGROUND AND OBJECTIVES

Early childhood development (ECD) is the age-related attainment of key physical, cognitive, social-emotional and language skills, affecting individuals and societies, through academic, behavioural, and economic outcomes. Challenges exist in low- and middle-income countries (LMICs), with 52.9mil infants at risk of delay, worst in conflict-affected settings like Mali. Little research has considered the role of maternal awareness on outcomes which enables her to track nutrition, stimulation or seek help for delay. We investigated ECD/ASQ3 predictors and maternal awareness of ECD milestones in 6-36 month infants using the Ages and Stages Questionnaire v3 (ASQ-3), adapted for Mali with added interviewer observations.

METHODS

We analysed cross-sectional data from 6027 children in 120 socioeconomically deprived communities through structured caregiver interviews collected during a large RCT. We calculated z-scores for the 5-domains (C=communication, GM=gross motor, FM=fine motor, PS=problem solving, P-S=personal-social), analysed for discrepancies between maternal response and interviewer observation. Mixed-effects logistic regression explored risk factors/predictors 27 child, maternal and household domains, including factors such acute/chronic illness, disability, nutrition, growth, stool pathogens, sanitation/hygiene, vaccination, internally-displaced, and maternal empowerment.

RESULTS

Infants' mean z-scores for the total sample across the five domains were C=-0.25, GM:-0.49, FM:-1.39, PS:0.77 and P-S:-0.67. Positive factors for total ASQ3 were maternal empowerment (RR=0.27;95%CI0.06,0.48), meeting min-dietary requirement, and using soap, while stunting and breastfeeding were risk factors. Disagreements between mother and observer (mothers underestimating milestone achievements) varied across domains: C:159, GM:135, FM:219, PS:193 and P-S:91, highest in FM and PS with the lowest overall z-scores. Disagreements increased with increasing age (particularly after 10 months, infant crawling); urban residence, older, girl-child, women's empowerment were risk factors.

CONCLUSIONS

In LMICs such as Mali, mothers may not be appropriately engaging to understand or gauge ECD, with reduced scores for children - likely more significant in those with high risk factors. Discrepancies and lower scores were particularly in domains which require engagement. Findings bear weight for initiatives like WHO's Integrated Management of Neonatal and Childhood Illness (IMNCI) aiming to increase maternal awareness and engagement with child development.

PARTICIPATORY WORKSHOPS TO IDENTIFY CHALLENGES AND SOLUTIONS IN IMPLEMENTING COMPREHENSIVE SCHOOL FOOD AND NUTRITION PROGRAMS IN KENYA

Mathilde Savy[1]; Milkah Wanjohi[2]; Alice Ritho[2]; Housna Hassani[1]; Dickson Amugsi[2]; Michelle Holdsworth[1]; Agnes Le Port
[1]UMR MoISA, Univ Montpellier, CIRAD, CIHEAM-IAMM, INRAE, Institut Agro, IRD, Montpellier, France; [2]Nutrition and Food Systems Unit, African Population & Health Research Centre, Nairobi, Kenya

BACKGROUND AND OBJECTIVES

While schools are important settings for implementing comprehensive school food and nutrition programs (SFNPs), the extent and challenges of implementing such programs are not well documented. We conducted participatory workshops with the school community to identify challenges and solutions in implementing SFNPs in Kenya.

METHODS

In 7 schools selected from 2 urban areas, 4 separate 'Challenge' workshops were conducted with teachers, students, parents and caterers/food vendors to identify the challenges they face with implementing SFNPs (n=28 workshops, 184 participants). At the end of the workshop, a voting game was used to select the 3 most important challenges for each school. Representatives of the teacher, student, parent, and caterer/food vendor groups were then invited to engage together in a 'solution' workshop (n=7 workshops, 60 participants) to address their top 3 challenges. A four-point matrix was used, in which the participants indicated the '**Idea'** (solution), '**Who'** should implement the solution (stakeholders), '**How'** it should be implemented (steps/processes) and '**What'** is needed for implementation (resources).

RESULTS

The school community raised many challenges, in particular related to i) Food provision, i.e. poor quality and diversity of meals, inadequate infrastructure for cooking/serving; ii) Water sanitation and hygiene, i.e. water shortage, insufficient handwashing stations and latrines, poor garbage systems; iii) School gardens, i.e. inadequate farming space and equipment, low diversity in production, poor attitudes and knowledge toward farming; iv) Food prices that are high and fluctuant; v) Food safety, i.e. poor knowledge and practices from food handlers and inadequate storage facilities; vi) Physical education, i.e. lack of skilled trainers, inadequate space and equipment, no motivation for physical activities. The school community proposed several solutions that could be implemented at government or school level, including: i) introduce taxes on unhealthy foods to fund infrastructure and SFNPs; ii) involve nutritionists and the school community, including parents and pupils, in developing school menus; iii) create school gardens and liaise with agricultural services for capacity building of students and school staff.

CONCLUSIONS

Strategies to address these challenges should be instituted for the benefit of both children and the school community. Further work is required to translate these ideas into feasible interventions, considering the perspectives of decision-makers, funders and implementers.

UNDERSTANDING WOMEN'S DECISION-MAKING AUTONOMY AND SELF-EFFICACY RELATED TO SEEKING AND ACCESSING VITAL HEALTH AND NUTRITION SERVICES IN CAMBODIA AND SENEGAL

Donya Madjdian[1]; Jennifer Nielsen[2]; Koffi Landry KOUADIO[3]; Vannary Hun[4]; Sreignep Say[4]; Ngik Rem; Pech Polet[4]; Lisa Littrell[4]; Maguette Fall Beye,[1]; Pape Ndour[1]; Mansour Ndiath[1]; Djeinam Toure[1]
[1]Senegal, Helen Keller Intl, Dakar, Senegal; [2]New York, Helen Keller Intl, NY, United States of America; [3]Côte d'Ivoire, Helen Keller Intl, Abidjan, Ivory Coast; [4]Cambodia, Helen Keller Intl, Phnom Penh, Cambodia

BACKGROUND AND OBJECTIVES

Health services that offer counseling for and access to prenatal supplements, optimal infant and child nutrition practices, acute malnutrition screening, and vitamin A supplementation for children under five are essential for improving maternal and child health in Asian and Sub-Sahara African settings. However, access to these services remains constrained due to contextual factors such as availability, accessibility, and affordability. While research has found women's empowerment and agency to be associated with positive health outcomes, structural inequalities and other gender-related barriers to these services are less understood. This study will investigate women's decision-making autonomy and self-efficacy, as well as the relationship between the two constructs and how they influence health-seeking behavior in Cambodia and Senegal as part of a larger research project that aims to understand the gender-related barriers to seeking access to and utilizing lifesaving health services in these contexts.

METHODS

Embedded within a larger multi-country program that aims to increase access to and improve quality of these services, baseline data will be collected via representative cross-sectional surveys with mothers of children under 5 years old across seven provinces in Cambodia (n=1,520) and five regions in Senegal (n=6,999) between November 2024 and May 2025. Indicators of women's agency and decision-making power include actual and preferred decision-making autonomy regarding accessing the five lifesaving interventions, perceived self-efficacy as a proxy of agency and key behavioral driver, and other indicators of women's autonomy. The items are inspired by the Real Accountability: Data Analysis for RESULTS (RADAR) and the Project-level Women's Empowerment in Agriculture (Pro-WEIA) questionnaires on women's empowerment, and the 8-item New Generalized Self-Efficacy Scale (GSES). Survey data will be analyzed using bivariate and regression analyses to describe decision-making autonomy, self-efficacy, and investigate the relationships between self-efficacy and women's decision-making power and health care-seeking behaviors. We will also explore variations in maternal autonomy and self-efficacy across the study settings.

RESULTS

Findings will be available by May 2025.

CONCLUSIONS

The study's findings will contribute to a better understanding of factors to consider in designing interventions to promote equitable healthcare access and improve maternal and child health and nutrition outcomes.

NUTRITIONAL STATUS, PHYSICAL ACTIVITY, AND STRESS LEVELS AFFECT THE BODY FAT PERCENTAGE OF INDONESIAN SCHOOL TEACHERS

Avliya Quratul Marjan[1]; Yessi Crosita Octaria[1]; Firlia Ayu Arini[1]; Nur Intania Sofianita[1]; Utami Wahyuningsih,[1]; Fatmawati Iin[1]
[1]Nutrition Study Program, Universitas Pembangunan Nasional Veteran Jakarta, Jakarta, Indonesia

BACKGROUND AND OBJECTIVES

The body fat percentage of Indonesian school teachers is influenced by three key factors: nutrition, physical activity, and stress levels. Consuming a balanced diet is essential for maintaining a healthy body. Engaging in regular exercise helps burn calories and build muscle, contributing to overall well-being. Elevated stress can alter bodily functions and affect eating habits, which in turn impacts body fat. By understanding these factors, we can identify ways to support teachers in leading healthier lives.

METHODS

The study was a cross-sectional study conducted on 146 elementary, middle and high school teachers in 6 schools in one district in Indonesia. Data collection was carried out using questionnaires and direct measurements for anthropometric tests. The measurement instruments used in this study were informed consent, GPAQ questionnaire for physical activity, DASH questionnaire for stress levels, Shoor board and scales for nutritional status, and BIA analysis for body fat percentage. Bivariate analysis was conducted to determine whether or not there was a relationship between variable.

RESULTS

Based on the characteristics of the respondents, most (48.6%) of elementary, junior high, and high school teachers who were respondents were aged between 30-49 years, dominated by female teachers (66.4%). Based on the body mass index value, as many as 90 respondents, or 61.6% had overweight nutritional status. 80.1% of teachers in this study had a high percentage of body fat. There is a relationship between nutritional status and physical activity ($p<0.05$) with the percentage of body fat of teachers who were the samples of this study.

CONCLUSIONS

There was a need to increase physical activity and implement a balanced nutritional diet for teachers in schools so that they had a normal body fat percentage and better teaching performance.

THE MUSHROOMS ON THE MENU (MOM) STUDY: VITAMIN D MUSHROOMS (UV-EXPOSED) ARE A FEASIBLE AND ACCEPTABLE WAY TO INCREASE VITAMIN D INTAKE IN A RESIDENTIAL AGED CARE FACILITY

Celeste Ferraris[1]; Michelle Blumfield,[1]; Jutta Wright[1]; Lucy Downey[1]; Emily Duve[1]; Saamia Khan[1]; Emma Beckett[1]; Flávia Fayet-Moore[1]
[1]Science, FOODiQ Global, Sydney, Australia

BACKGROUND AND OBJECTIVES

Vitamin D deficiency is highly prevalent in residential aged care due to reduced skin synthesis and less time outdoors, and it is associated with poor health outcomes. Supplementation is variable and often suboptimal. Due to limited food sources, diet is frequently overlooked, yet vitamin D mushrooms can raise vitamin D levels in deficient individuals to the same level as a supplement.

METHODS

MOM was a 10-week prospective pre-post mixed METHODS study that evaluated the feasibility of adding vitamin D mushrooms to the menu of a residential aged care facility. During the 4-week baseline phase, residential care (RC) participants ordered meals from the standard food service menu, while independent living (IL) followed their usual diet. During a 4-week MOM phase, participants were instructed to order (RC) or prepare (IL) at least one mushroom meal containing 75g of commercially available UV-exposed Agaricus bisporus mushrooms daily (18 ug of vitamin D). In RC, 28 recipes were modified to include the mushrooms. RC participants chose one vitamin D mushroom meal from the lunch or dinner menu, and IL participants were instructed to prepare one vitamin D mushroom meal daily. The participants' daily intake of energy, macronutrients, total vitamin D, vitamin D2 and sodium on the standard menu versus MOM were estimated by plate wastage (RC) and via 24-hour recalls (IL). Qualitative data were collected during and post the MOM.

RESULTS

In RC, vitamin D menu provision during MOM increased by 180% compared to the standard menu (7.0ug vs 2.5 ug, $P<0.0001$), with not significant differences in energy and other nutreints. During MOM, vitamin D intake increased by 212% for RC(6.0 vs. 18.7 ug; $p<0.001$) and 740% for IL participants (8.7ug vs. 73.1ug; $p<0.0001$) compared to baseline, representing 125% and 1387% of the Australian vitamin D targets. Over 75% of participants rated the taste of the mushroom meals as good or excellent, enjoying them as both hero and complimentary ingredients. Over 75% of staff understood the health benefits of vitamin D mushrooms, an found the meals easy to prepare while highlighting a need for low-burden processes. Participants and staff supported the continued inclusion of MOM.

CONCLUSIONS

MOM is a well-accepted food-first approach that provides substantial vitamin D among aged care residents, exceeding daily targets. A food first appraoch to addressing vitamin D deficiency in aged care is feasible and accepted.

ADOLESCENT NUTRITION ANAEMIA REDUCTION PROGRAMS AND POTENTIAL BENEFITS TO TRANSITIONING TO WHO FORMULATION

Marion Roche[1]; Shibani Sharma[1]; Sakshi Jain[2]
[1]Adolescent Nutrition, Nutrition International, Ottawa, Canada; [2]Health Economic Unit, Nutrition International, Ottawa, Canada

BACKGROUND AND OBJECTIVES

The World Health Organization (WHO) recommends Weekly Iron Folic Acid Supplementation (WIFAS) containing 60 mg elemental iron and 2.8 mg folic acid be provided to menstruating adolescents (10-19 yrs) and women (20-49 yrs) where anaemia is greater than 20%. It also aims to prevent neural tube defects (NTDs). The WHO recommended formulation was added to the WHO model list of essential medicines (EML) in 2023; however, many national adolescent nutrition programs continue to use a lower dose folic acid supplement (0.4mg folic acid) -the available formulation from maternal IFA programs, while navigating national EML procceses and a potential transition in formulation. With higher rates of unplanned pregnancies in adolescence, the increased dose of folic acid in the WHO formulation has potential for added benefits of reducing neural tube deffect (NTD) affected pregnancies. We estimated additional benefits of transitioning to the WHO WIFAS in 6 national programs.

METHODS

We used WIFAS coverage and adherence data from 2023 in government adolescent nutrition programs in Africa and Asia, supported by Nutrition International along with country specific adolescent fertility and birth rates, NTD rates, anaemia prevalences and effect sizes to model potential benefits. Using serum folate increase of 1.2 nmol/l per week (found during our previous RCT conducted with partners; Samson et. al. 2020) and the published effect sizes associated with similar changes in serum folate per week with folic acid fortification we modeled an estimate of 36% reduction in relative risk of NTD affected pregnancies and as aligned with current WHO guideline a 35% reduction in relative risk of anaemia.

RESULTS

Programs reached 4.3 million girls and we estimated averted 736,000 cases of anaemia and with a transition to the WHO formulation could have prevented 295 NTD affected pregnancies and the devastating consequences; however, some of the adolescent girls most likely to become pregnant may not access school-based WIFAS delivery.

CONCLUSIONS

Adolescent nutrition programs with the specific WHO recommended WIFAS have potential to advance anaemia reduction with their own unique formulation, while also preventing risk of NTDs in adolescent pregnancies. Programs require effective supply and procurement strategies and countries need local cost-benefit data to guide planning and decision making and to assess the potential impacts of transitioning from existing iron folic formulation to the WHO formulation with higher folic acid. Adolescent responsive health systems and social saftey nets are much needed to reach girls in vulnerable contexts.

IMPROVING ACCESS TO QUALITY NUTRITION SERVICES AND INFRASTRUCTURE IN ECCD CENTRES: BRIDGING GAPS TO ENHANCE CHILD HEALTH AND LEARNING OUTCOMES

Allen Rugambwa[1]; Joanita Aigi Muruve[2]; Kivuyo Nengilang'et[1]
[1]USAID Nutrition Project, Save the Children International Tanzania Programme, Dar es Salaam, Tanzania, United Republic of; [2]Health and Nutrition, Save the Children International Tanzania Programme, Dar es Salaam, Tanzania, United Republic of

BACKGROUND AND OBJECTIVES

Nutrition is a basic human right, one that should be fulfilled in accordance with the age and sex of the child, and this should be active during the crucial, first 1,000 days. The focus of this study (ECCD Assessment) was to identify gaps and opportunities for integrating nutrition education in early childhood care and development (ECCD) to enhance child nutrition and learning outcomes. Specifically, this study aimed at: a) evaluating the quality of infrastructure in ECCD centers to identify gaps affecting child development; b) examining service providers' certification, training, and nutrition knowledge to address human resource challenges; c) assessing the extent of multi-sectoral collaboration and its impact on nutrition practices; and d) analyzing nutritional practices, focusing on age-appropriate feeding and child growth monitoring.

METHODS

The assessment employed a quantitative survey, carried out in five regions of Tanzania (Katavi, Kigoma, Njombe, Rukwa, and Songwe), that examined 733 ECCD centers and included 3,350 participants, such as government officials, directors, and caregivers. The data collection process consisted of two phases: profiling centers through government records and conducting detailed digital surveys using Kobo Toolbox

RESULTS

The RESULTS showed low registration rates at 61%, inadequate infrastructure, with 23% of centers lacking teaching classrooms and having overcrowded sleeping areas, and challenges in human resources, as only 42% of the 1,846 service providers were certified, and fewer than 35% had basic knowledge or training in nutrition for infants and young children. Nutrition practices were found to be insufficient, with less than 35% of centers offering age-appropriate meals and only 2.3–4.3% having community health workers (CHWs) trained in child growth monitoring. Although 80% of centers worked with other sectors, only 15.4% involved nutrition officers, highlighting significant gaps in nutritional oversight.

CONCLUSIONS

It was the conclusion of the assessment that ECCD centres faces deficiencies in infrastructures, professional training of caregivers, and nutrition services. To address these deficiencies, a multifaceted approach is required, including addition of classrooms and sleeping facilities, enforcing dietary guidelines, certifying caregivers, and building the capacity of CHWs and caregivers, and engaging nutrition officers to improve child health and learning outcomes.

EVALUATING AN ADAPTED HOME FOOD INVENTORY (HFI) DEVELOPED TO MEET THE CULTURAL NEEDS OF ENGLISH- AND SPANISH-SPEAKING POPULATIONS AND THOSE WITH LOW LITERACY

Jayne Fulkerson[1]; Melissa Laska,; Leslie Lytle,[2]; Mary Hearst,[1]; Fanny Jimbo Llapa,[1]; Ziou Jiang,[3]; Aysegul Baltaci,[4]; Sarah Friend,[5]; Mariana Villegas Ramirez,[1]; Alexander Mchugh[1]; Victoria Valencia,[1]; Uriyoan Colon-Ramos,[6]

[1]School of Nursing, University of Minnesota, Minneapolis, United States of America; [2]Gillings School of Global Public Health, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA, United States of America; [3]Biostatistical Design and Analysis Center, Clinical and Translational Science Institute, University of Minnesota, Minneapolis, MN, USA, Minneapolis, MN, USA, United States of America; [4]Department of Youth Development, Extension, University of Minnesota, Minneapolis, United States of America; [5]School of Public Health, University of Minnesota, Minneapolis, United States of America; [6]Milkin Institute School of Public Health, George Washington University, Washington, United States of America

BACKGROUND AND OBJECTIVES

Development of culturally-appropriate population-level interventions are critical to improve health equity. Yet, such research is stymied by the lack of specific, appropriate, and valid measurement tools for diverse populations. Few valid home food environment assessment tools exist, and none have been validated with large non-English speaking populations. In 2008, we developed and validated a Home Food Inventory (HFI) to assess healthfulness and obesity risk of home food environments using a checklist format. The HFI showed good reliability and construct validity and has been used extensively in the field. However, the original HFI is lengthy and was developed for English-speaking populations. Our goal was to develop home food environment assessment tools (paper and electronic) for use in English- and Spanish-speaking populations; this presentation includes validation findings related to that work.

METHODS

The HFI-Core (n=133 items) was developed via secondary data analysis of four other large studies that used the 2008 HFI. English and Spanish HFI-core versions were created and contextualized with advice from local and multicultural community members. Participants (n=77 English-speaking, 75 Spanish-speaking) assessed usability, satisfaction, criterion and construct validity (comparing HFI-Core scores and dietary intake from dietary recalls), and reliability.

RESULTS

Average completion time was 22 minutes, and 93% of participants were satisfied/very satisfied with the HFI-Core. Criterion validity was acceptable with Spearman correlations between staff and participant HFI-Core food categories (r=0.62 to 0.90; all p's <.05). Significant construct validity (r=0.22-0.27; all p's <.05) was shown comparing home vegetable availability with participant intake of vegetables and related nutrients and HFI-core fruit availability with intake of fruit and related nutrients. Positive and significant (p<.05) correlations were also shown for HFI Obesogenic Score and energy intake, HFI Sodium Score and sodium intake, and HFI Ultra-Processed Score and energy and sodium intake. Reliability of responses over 2-4 weeks was significant (r=0.49-0.80; p's<0.05).

CONCLUSIONS

Evaluation findings of the HFI-Core demonstrated reduced response burden, high participant satisfaction, criterion and construct validity, and reliability. The HFI-Core is the first validated instrument in our new toolkit and it sets the stage for next steps to advance behavioral nutrition METHODS to address the persistent health inequities.

EXPLORING FACILITATORS AND BARRIERS TO SCHOOL FOOD PROGRAMS: PERCEPTIONS ON PROGRAM IMPLEMENTATION AND SUSTAINABILITY

Nina Trask[1]; Nicole Weber[1]; Emma Wedekind,[1]; Mavra Ahmed[1]; Daniel Sellen[2]
[1]Department of Nutritional Sciences, University of Toronto, Toronto, Canada; [2]Anthropology, University of Toronto, Toronto, Canada

BACKGROUND AND OBJECTIVES

As Canada progresses toward its first-ever National School Food Program (NSFP), localized evidence is essential for fostering sustainable, equitable and resilient school food programs (SFPs). Addressing the existing fragmented patchwork of SFPs requires evidence-based insights accounting for regional diversity and global priorities. This study gathered insights from key informants (i.e., school level SFP coordinators) to understand the facilitators and barriers to SFP implementation and program sustainability across Ontario.

METHODS

Researchers collaborated with community partners and regional school boards to recruit SFP coordinators (i.e., food service managers, parent volunteers, school staff) from six public English school boards, representing diverse socio-economic backgrounds, cultural contexts, and geographic regions, and enabling a comprehensive exploration of local SFP practices on implementation and sustainability. Participants completed an online survey on SFP characteristics and operations, and were invited to a follow-up interview to discuss perceived facilitators and barriers in greater depth.

RESULTS

This study included 55 participants from 51 schools across six school boards, making it the most comprehensive exploration of Ontario's SFPs to date. Data collection comprised 54 surveys, 8 focus group interviews, and 22 individual interviews. Key barriers included insufficient funding, volunteerism, limited resources, and a lack of coordinated SFP networks (e.g., procurement, funding); while facilitators included strong school-level support, positive student impacts, and community engagement.This study highlighted that these facilitators and barriers not only influenced implementation success but also had an ongoing effect on the overall program sustainability.

CONCLUSIONS

SFPs represent an opportunity to establish healthy school food environments and enhance social safety nets, however, the current fragmented and resource-limited nature of Ontario's SFPs compromises their sustainability. Findings underscore the importance of addressing systemic barriers while leveraging local strengths to build resilient, equitable and sustainable SFPs. By emphasizing localized needs and capacities, these insights provide a foundation for the successful design and implementation of Canada's NSFP, contributing to global efforts to achieve sustainable food systems for children.

ASSOCIATIONS OF TEA AND COFFEE CONSUMPTION WITH DYSMENORRHEA AMONG REPRODUCTIVE-AGE WOMEN IN BEIJING, CHINA

Jian Zhao[1]
[1]Department of Nutrition, School of Population Medicine and Public Health, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

BACKGROUND AND OBJECTIVES

With the rapid economic development and lifestyle changes in recent years, the consumption of tea and coffee has significantly increased among women in major cities in China. However, their impact on reproductive health, particularly menstrual health, remains unclear. This study aimed to examine the associations between tea and coffee consumption and dysmenorrhea among reproductive-age women.

METHODS

As part of the Multilevel Natural Population and Maternal Cohort Study, 1,247 women were recruited from 10 community health service centers in six districts of Beijing between September and November 2021. Beverage consumption, including coffee, brewed leaf tea, herbal tea, and milk tea, was assessed using a validated food frequency questionnaire (FFQ). Dysmenorrhea severity was evaluated using the Numeric Pain Rating Scale (NPRS). Multinomial logistic regression was used to assess associations between beverage consumption and dysmenorrhea.

RESULTS

Among the participants, 29.11%, 32.56%, 29.91%, and 20.69% regularly consumed coffee, brewed leaf tea, herbal tea, and milk tea, respectively (defined as more than 1 cup/bottle per day, 1 cup/bottle ≈ 300 mL). During menstruation, regular consumption rates decreased to 15.72%, 19.57%, 21.81%, and 15.08% for coffee, brewed leaf tea, herbal tea, and milk tea, respectively. During non-menstrual days, regular coffee consumption was associated with a higher prevalence of dysmenorrhea for mild dysmenorrhea (aOR = 1.97, 95% CI: 1.03–3.79) and moderate-to-severe dysmenorrhea (aOR = 3.27, 95% CI: 1.59–6.73). Regular brewed leaf tea and milk tea consumption were positively associated with moderate-to-severe dysmenorrhea (brewed leaf tea: aOR = 3.02, 95% CI: 1.31–6.96; milk tea: aOR = 2.91, 95% CI: 1.31–6.43). Occasional coffee consumption was also associated with moderate-to-severe dysmenorrhea (aOR = 2.19, 95% CI: 1.20–3.99), while occasional brewed leaf tea or milk tea consumption showed no association. No significant association was observed between herbal tea consumption and dysmenorrhea. During menstruation, only regular milk tea consumption was associated with moderate-to-severe dysmenorrhea (aOR = 2.48, 95% CI: 1.09–5.64); no associations were observed for other beverages.

CONCLUSIONS

Regular consumption of coffee and tea is associated with increased prevalence of dysmenorrhea among reproductive-age women, suggesting a potential influence of dietary habits on menstrual health.

THE SIGNIFICANT ROLE OF HEALTH CARE PROVIDERS IN PROMOTING PREGNANT WOMEN'S ADHERENCE IN TAKING MULTIPLE MICRONUTRIENT SUPPLEMENTS: INSIGHT FROM INDONESIA

Tika Rianty[1]; Akhir Riyanti[1]; Nancy Kosasih[1]; Fitri Nandiaty[1]; Trisari Anggondowati[2, 1]; Budi Utomo[3]; Monica Fox[4, 5]; Otte Santika[6]; Kristen Hurley[4, 7]; Endang Achadi[1]

BACKGROUND AND OBJECTIVES

In 2021, Implementation Research (IR) was undertaken in 25 districts to inform efforts for scaling up multiple micronutrient supplements (MMS) within the context of antenatal care (ANC) in Indonesia. The IR began with formative research, which drew attention to the importance of healthcare providers (HCPs) as pivotal figures trusted by pregnant women (PW). The objective of this analysis was to further examine the role HCPs, particularly midwives, have in encouraging MMS adherence through counseling during ANC visits.

METHODS

This study utilized mixed METHODS longitudinal system trial in which all HCPs in the 25 districts were provided an online orientation on anemia, MMS, and communication training in certain areas, along with printed and electronic educational materials. At the study midpoint, nine focus group discussions (FGDs) were employed in a sub-set (n=3) of districts. In total, 75 midwives participated in the FGDs, which included detailed probing on their role in encouraging MMS adherence through ANC counseling. Transcriptions were organized into specific themes and presented in a matrix.

RESULTS

Midwives identified several factors impacting their ability to influence and encourage PW. Midwives reported that PW tended to be more engaged in MMS counseling during individual counseling sessions than they were in group counseling sessions, and PW experiencing their first pregnancies tend to ask more questions than those with previous pregnancies. Midwives spent more time (approximately 5-15 minutes) on counseling during the first MMS administration, as opposed to less than 5 minutes in subsequent counseling sessions. Other factors that limit the midwives' counseling include (1) the time PW spent on discussing complaints or side effects, (2) uncertainties among HCPs regarding the safety of MMS, (3) the lack of immediate solutions related to dealing with side effects, and (4) resistance or rejection from certain obstetricians who have not been adequately informed about MMS. Conversely, factors that enhance the counseling process consist of (1) communication training, (2) enthusiastic acceptance from PW, (3) support from family or community members, and (4) backing from obstetricians who have been thoroughly informed and have received additional socialization.

CONCLUSIONS

It is crucial to provide sufficient training about MMS to all ANC service providers, including midwives and obstetricians. Educating HCPs about the benefits and safety of MMS as well as how to address side effects and support PW to increase adherence is vital.

MAPPING UNDISCLOSED FOOD ADDITIVES IN ULTRA-PROCESSED FOODS IN BRAZIL

Julia Nascimbem Blaser[1]; Laís Amaral Mais[2]; Daniela Canella[3]; Neha Khandpur[4]; Camila Aparecida Borges[5]
[1]Department of Food and Experimental Nutrition, University of São Paulo, São Paulo - SP, Brazil, São Paulo, Brazil; [2]Healthy and Sustainable Diets Program, Institute for Consumer Defense, São Paulo, Brazil; [3]Nutrição Aplicada, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil; [4]Division of Human Nutrition and Health, Wageningen University & Research, Wageningen, Netherlands; [5]Food Science and Technology, University of Sao Paulo, São Paulo, Brazil

BACKGROUND AND OBJECTIVES

Ultra-processed foods (UPFs) consumption is linked to noncommunicable diseases. However, UPFs' ingredients and food additives (FAs) are not fully disclosed on labels, making the assessment of their health risks challenging. This study aimed to identify FAs not declared on food labels through an in-depth analysis of UPFs' ingredient lists and verify the degree of compliance of the information on FAs with current Brazilian food labelling legislation.

METHODS

Cross-sectional study using a sample of 3,438 UPFs commercialised in Brazil. Disclosed FAs and their technological functions and ingredients which were likely to contain undisclosed FAs were identified. The most common grouping patterns (i.e patterns across at least 50% of products per type) of disclosed FAs and technological functions of ingredients with simpler formulations were identified and attributed as undisclosed to ingredients with more complex formulations in which they were part of. For example, more than 50% of the food items of the ingredient vegetable fat contain antioxidant FAs INS 319 and INS 330, which were not declared on the ingredient list of more complex ingredients in which vegetable fat is part of, such as chocolate flavoured filling and chicken flavour bouillon cubes. Therefore, vegetable fat's FAs were attributed to these ingredients as undisclosed. The same procedure was performed for ingredients with ever-increasing degrees of complexity of their formulations and finally for the UPFs of the main sample. The most common grouping patterns of both disclosed and undisclosed FAs and technological functions were estimated by UPF's subgroups such as sweet cookies, soft drinks and pizzas. The compliance of the ingredient lists with the Brazilian food labelling legislation on FAs was verified.

RESULTS

A total of 91.1% of the UPFs contain 1 to 51 undisclosed FAs in the ingredient list; one in three FAs are undisclosed; and 22.2% of the ingredient lists did not comply with the food labelling legislation on FAs.

CONCLUSIONS

This study showed that the actual number of FAs present in UPFs sold in Brazilian supermarkets frequently outgrow those described in their ingredient lists due to the existence of a large number of undisclosed FAs, in great part associated with food ingredients which were also undisclosed—which is allowed by the Brazilian legislation. The RESULTS indicate the need for strengthening the Brazilian food labelling legislation on FAs to make transparent the use of these compounds and to provide more information to consumers to help them make better food choices.

OAP41_01

HAS UNDERWEIGHT INCREASED AMONG CHILDREN AND ADOLESCENTS DURING 2012-2019 AND DOES THE PREVALENCE DEPEND ON SOCIOECONOMIC CIRCUMSTANCES? A NATIONWIDE REGISTER-BASED STUDY FROM DENMARK

Anne V. Aurup[1]; Lau C. Thygesen[2]; Marie B Klitgaard[2]; Anne Thorsted[2]; Katrine Strandberg-Larsen[3]; Camilla T. Damsgaard[1]
[1]Department of Nutrition, Exercise and Sports, University of Copenhagen, Frederiksberg Campus, Frederiksberg, Denmark; [2]National Institute of Public Health, University of Southern Denmark, Copenhagen, Denmark; [3]Department of Public Health, University of Copenhagen, Frederiksberg Campus, Copenhagen, Denmark

BACKGROUND AND OBJECTIVES

Childhood underweight, indicated by low body mass index for age and sex, is associated with morbidity, mortality and poverty in low-income settings. However, it is largely overlooked in high-income countries, due to unequivocal focus on overweight. In this study, we investigated the development and socioeconomic characteristics of underweight among children and adolescents in Denmark during 2012-2019.

METHODS

We used nationwide register data on height and weight measured objectively in 461,041 Danish 6-7-year-olds and 365,312 Danish 14-15-year-olds during 2012-2019, covering 89% and 67% of all schoolchildren in these age groups. We calculated BMI z-scores and classified underweight using the International Obesity Task Force age- and sex-specific BMI cut-offs and linked these with data on parental education and household income.

RESULTS

The prevalence of underweight remained relatively stable at ~8.5% among 6-7-year-old girls during 2012-2019. Among 14-15-year-old girls, it was initially higher but decreased slightly (<1%-point) to 8.6% in 2019. Among boys, the prevalence increased from ~7% to just above 8% in both age groups during the period. Across all years, underweight was more common among 14-15-year-olds whose parents had long higher education (girls: 10.4%-12.1%; boys: 8.7%-10.2%) compared to primary school (girls: 5.6%-7.5%; boys: 6.1%-7.8%), with the most pronounced differences among girls. Similar, although smaller, differences were seen among 6-7-year-olds. Less distinct but comparable differences were found for income.

CONCLUSIONS

Underweight is prevalent, but has remained relatively stable during the 2010s among Danish children and adolescents. Unlike the pattern reported in low-income settings, and that seen for overweight, underweight is associated with socioeconomic advantage in this high-income setting.

DO DANISH 6-9-YEAR-OLD CHILDREN ADHERE TO DIETARY GUIDELINES AND ARE THERE SOCIODEMOGRAPHIC DIFFERENCES? THE GENERATION HEALTHY KIDS STUDY

Frederik Holmegaard[1]; Anna G. Eilersen[1]; Ulla Toft[2]; Rikke Krølner[3]; Ken D. Stark[4]; Ming Rong Liu[4]; Rikard Landberg[5]; Christian Mølgaard[1]; Lotte Lauritzen[1]; Camilla T. Damsgaard[1]
[1]Department of Nutrition, Exercise and Sports, University of Copenhagen, Frederiksberg Campus, Frederiksberg, Denmark; [2]Department of Prevention, Health Promotion and Community Care, Steno Diabetes Copenhagen, Herlev, Denmark; [3]National Institute of Public Health, University of Southern Denmark, Copenhagen, Denmark; [4]Kinesiology and Health Sciences, University of Waterloo, Waterloo, ON, Canada; [5]Department of Life Sciences, Food and Nutrition Science, Chalmers University of Technology, Gothenburg, Sweden

BACKGROUND AND OBJECTIVES

The latest national Danish dietary survey, which was conducted more than 10 years ago, showed that children consumed too little fruit and vegetables and fish, and too much sugar and SFA. The survey showed considerable social disparities, but did not include children of non-Danish descendance or assess biomarkers of nutrient intake and status. We investigated dietary intake, adherence to the national food based dietary guidelines (FBDG) and Nordic Nutrition Recommendations, as well as nutritional status of 1094 Danish 6-9-year-old children and explored potential differences according to parental education, descendance, urbanization, sex and weight status. We focused on fruit & vegetables, fish, wholegrains, meat, dairy, SFA, added sugar, n-3 LCPUFA, and iron.

METHODS

The study is based on baseline data from a large school-based trial, Generation Healthy Kids. Parents completed an online background questionnaire, a fish FFQ and an online 3-day dietary record on behalf of their child. We collected fasting venous blood samples from the children for analysis of alkylresorcinols, n-3 LCPUFA, hemoglobin, and ferritin.

RESULTS

Mean age±SD was 7.8±0.6 years and 13% had overweight or obesity, equivalent to national numbers. Only 12%, 45% and 12% adhered to the FBDG for fruit & vegetables, wholegrains, and fish, of which they consumed (median (IQR)) 222 (137-326) g/d, 47 (28-70) g/d, and 14 (8-23) g/d, respectively. Only 17% adhered to the iron recommendation with an intake of 7.2±1.9 mg/d. Further, 86% and 67% of the children consumed too much meat and SFA, respectively, whereas the majority adhered to the guidelines for intake of dairy, sugar, dietary fibre, and vitamin D supplements. Long vs. short education was associated with higher intake of wholegrains and less meat, and rural vs. urban residence with lower intake of fruit & vegetables and higher intake of SFA and sugar, but also of wholegrains (all $P<0.05$). Non-Danish descendants had 28 (41;16) g/10 MJ lower intake of wholegrains, but also of sugar, than Danish descendants (both $P<0.001$). Boys consumed 58 (31;84) g/10 MJ less fruit & vegetables, but also less sugar and more wholegrains than girls ($P<0.01$). Weight status was not associated with the foods or nutrients investigated. Nutrient biomarkers will be presented at the conference.

CONCLUSIONS

Fulfilment of dietary guidelines still appears to be inadequate in many children in Denmark. The observed sociodemographic disparities are considerable and could guide future tailor-made interventions to promote healthy diets in schoolchildren.

COMPARISON OF THE COSTS OF DIFFERENT STRATEGIES FOR THE DISTRIBUTION OF VITAMIN A; INSIGHTS FROM FOUR AFRICAN COUNTRIES DURING (JULY 2023 – JUNE 2024)

Mohamed Lamine Fofana[1]; Melissa Baker[2]; Fatou Berete Ndiaye,[3]; Fridah Mutea,[2]; Christine Mkenda,[2]; Abiodou Moise Owoloye,[4]; Romance Disseka,[4]; David Doledec,[2]
[1]Vitamin A Supplementation, Helen Keller INTL, Conakry, Guinea; [2]Vitamin A Supplementation, Helen Keller International, Nairobi, Kenya; [3]Vitamin A Supplementation, Helen Keller INTL - Regional & Senegal, Dakar, Senegal; [4]Vitamin A Supplementation, Helen Keller INTL, Abidjan, Ivory Coast

BACKGROUND AND OBJECTIVES
Helen Keller has supported vitamin A supplementation (VAS) for children aged 6 to 59 months in several countries, aiming for 100% coverage with efficient implementation. Strategies include door-to-door campaigns, fixed and advanced METHODS, or a combination and routine distribution. This study compares the distribution costs of door-to-door with routine METHODS for the financial years July 2023 to June 2024.
METHODS

This analysis reviewed data from Cameroon and Mali (door-to-door) and Tanzania and Mozambique (routine) where Helen Keller supported vitamin A distribution from July 2023 to June 2024. Data was collected using internal tools:

1. Financial reports: Documentation of costs incurred by Helen Keller only

2. Programmatic reports: documenting coverage and the number of children supplemented

The data were analyzed using Excel to compare the cost per supplemented child by strategy type.

RESULTS

Despite higher costs per child in Tanzania (USD 0.35) and Mozambique (USD 0.48) due to significant training and policy development expenses, these countries achieve high coverage levels (119% and 83%). In contrast, costs in Mali and Cameroon are lower (USD 0.23 and USD 0.28) with coverage of 98% and 99%.

CONCLUSIONS

Door-to-door campaigns were the most cost-effective, while routine VAS offered higher coverage at higher costs in Tanzania and lower coverage in Mozambique. Although it is expensive at first, routine coverage can be as high as door-to-door coverage. Over time, the high costs of training and developing policy documents may come down. A better understanding of costs can help guide strategic choices for effective and sustainable distribution.

OVEREATING AND ITS ASSOCIATIONS WITH CHANGE IN BMIZ DURING ADOLESCENCE

Catharina Sarkkola[1]; Reetta Lehto[1]; Sohvi Lommi[1]; Satu Männistö[2]; Heli Viljakainen[1]
[1]Folkhälsan Research Center, Samfundet Folkhälsan, Helsinki, Finland; [2]Finnish Institute for Health and Welfare, Finnish Institute for Health and Welfare, Helsinki, Finland

BACKGROUND AND OBJECTIVES

Overeating is an eating behaviour, which refers to consuming food beyond nutritional needs or consuming large amounts of food in a short time. We studied whether preadolescents with parent-reported (PR) overeating, and self-reported (SR) overeating (with or without loss of control), exhibit different food consumption and meal patterns. Additionally, we studied how lifestyle factors predict short-term changes in BMIz during adolescence.

METHODS

This study included 5827 children with a mean age of 11.2 (SD 0.8) years from the Finnish Health in Teens (Fin-HIT) cohort. At baseline, the parent answered a question on child's tendency towards overeating. The children self-reported on overeating, hours of leisure-time physical activity per week, consumption frequency of sugary products, fast food, and fruits and vegetables. A regular meal pattern was defined as having breakfast and dinner every school day. Height and weight were measured at baseline and 2.7 years later at follow-up, and BMI z-scores were calculated (IOTF reference). We used a general linear model with change in BMIz from baseline to follow-up as outcome.

RESULTS

The proportion of children with PR overeating was 9.3%, SR overeating 4.2%, and both eating behaviours 0.8%. PR overeating was more common in boys, while SR overeating in girls. Children with SR overeating ate more frequently sugary products and fast food (11.0 and 2.8 times per week, respectively) than children with PR overeating (7.8; 1.9) or than children with no overeating (8.8; 2.1), but fruit and vegetable consumption did not differ between the three groups. An irregular meal pattern was also more common in children with SR overeating than others. Children with SR overeating experienced 0.150 units (95% CI 0.073─0.227) and children with PR overeating 0.082 units (95% CI 0.028─0.135) bigger change in BMIz compared with children without overeating, after adjusting for age, physical activity and baseline BMIz. Besides eating behaviour, physical activity predicted change in BMIz (b=0.009 [95% CI 0.003─0.014]), but not food consumption or meal pattern.

CONCLUSIONS

SR overeating was the main predictor of change in BMIz during adolescence, compared with PR overeating, with physical activity also contributing, while food consumption and meal patterns showed no role. Interventions targeting overeating and physical activity should be implemented to improve adolescent weight management.

FOLATE AND VITAMIN B12 STATUS, AND ANEMIA AMONG SENEGALESE ADOLESCENTS (10-19 YEARS): A NATIONAL CROSS-SECTIONAL SURVEY

Abdou Badiane[1]; Mariame Sy[2]; Olouwafemi Mistourath Mama[1]; Ba Lo Nafissatou[3]; Marion Roche[4]; Diop Ndoye Aminata[5]; Adama Diouf[6]; Idohou-Dossou Nicole[6]
[1]Laboratoire de Recherche en Nutrition et Alimentation Humaine, Faculté Sciences et Techniques, Universite Cheikh Anta Diop (UCAD), Dakar, Senegal; [2] Laboratoire de Recherche en Nutrition et Alimentation Humaine, Faculté Sciences et Techniques, Université Cheikh Anta Diop (UCAD), Dakar, Senegal; [3]Conseil National de Développement de la Nutrition, Conseil National de Développement de la Nutrition, Dakar, Senegal; [4]Adolescent Nutrition, Nutrition International, Ottawa, Canada; [5]Conseil National de Développement de la Nutrition, Conseil National De Developpement De La Nutrition, Dakar, Senegal; [6]Laboratoire de Recherche en Nutrition et Alimentation Humaine/Biologie animale/FST, Universite Cheikh Anta Diop (UCAD), Dakar, Senegal

BACKGROUND AND OBJECTIVES

Folate and vitamin B12 deficiencies are widespread worldwide and constitute a risk factor of anemia which is a public health concern. In Senegal, the lack of recent data about anemia and its determinants, including folate and vitamin B12 deficiencies, among adolescents prevents the government from implementing adequate interventions to improve their nutritional status. The aim of this study is to determine the prevalence of folate and vitamin B12 deficiencies among Senegalese adolescents aged from 10 to 19 years.

METHODS

A quantitative, descriptive and analytical cross-sectional study was conducted at national level, area of residence, and five major ethno-cultural zones. A total of 2,193 adolescents were targeted in 2,260 households through a stratified three-stage sampling method. Socio-economic, socio-demographic, health and dietary patterns were collected using a questionnaire. Hemoglobin, serum folate and vitamin B12 were analyzed.

RESULTS

The median folate concentration was 22.3 µg/L [16-31,8 µg/L], and 2.8% of the adolescents had low serum folate (<10 nmol/L), with significant variations according to residence and wealth quintiles. Folate deficiency affected more significantly adolescents living in the southern areas (6.7%) and those of poorest households (5.5%). Only 1.8% of adolescents had low serum Vitamin B12 (<150 pmol/L). Vitamin B12 affected more adolescents 15-19 yrs old (15-19 yrs: 2.6% vs. 10-14 yrs: 1.2%; P=0.028), living in rural area (rural: 2.4% vs. urban: 0.8%; P=0.008) and in poorest households (poor: 6.3% vs. rich: 0.1%; P<0.001). Furthermore, 29.1% of the adolescents were anemic, with significant difference according to age group (10-14 years: 23.3% vs. 15-19 years: 30%). Folate deficiency was closely associated with vegetable consumption (OR=0.35; P=0.006) and household poverty (OR=10.8; P= 0.025) and is a major determinant of anemia in adolescents (OR = 2.20; P = 0.013).

CONCLUSIONS

Folate and vitamin B12 deficiencies are not public health issues among Senegalese adolescents (10-19 years). However, folate deficiency remains a risk factor of anemia and was closely linked to living conditions and dietary patterns in adolescents. Addressing these determinants could help to prevent anemia among Senegalese adolescents.

VITAMIN D PROBIOTICS FORTIFICATION REDUCE LOW-BIRTH-WEIGHT PREGNANCY OUTCOME AMONG PREGNANT WOMEN

Vivian Ayamah[1]; Charles Apprey[2]; Reginald Adjetey Annan[3]
[1]BIOCHEMISTRY, KWAME NKRUMAH UNIVERISITY OF SCIENCE AND TECHNOLOGY, Kumasi, Ghana; [2]BIOCHEMISTRY AND BIOTECHNOLGY, Knust campus, Kumasi, Ghana; [3]Department of Biochemistry and Biotechnology, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana

BACKGROUND AND OBJECTIVES

Low birth weight remains a significant predictor of long-term health outcomes, morbidity, and early infant mortality. However, there is a paucity of data regarding the dietary consumption of vitamin D-rich foods by pregnant women and its impacts on birth weight. This study, therefore, investigated the effectiveness of vitamin D-fortified probiotic yogurt intake on low-birth-weight outcomes among pregnant women in Ghana.

METHODS

The study was a randomized single blinded controlled trial study that included 126 pregnant women aged 18 years and above without symptoms of UTI attending antenatal care at the Ejisu Government Hospital and Juaben Government Hospital in Ejisu-Juaben Municipality in the Ashanti Region, Ghana. Pregnant women were further divided into the Vitamin D probiotics fortified group (63) and the non-fortified group (63) and followed for 6 months. Blood samples were collected at baseline and end line for laboratory analyses and sociodemographic and clinical data. Statistical analyses were done in SPSS version 26.0 and R Language version 4.4.4 at $p < 0.05$ and a 95% confidence interval.

RESULTS

This study found 86.5% had inadequate dietary patterns and the prevalence of low-birth-weight was 11.5%. There was a significant association between gestational age ($p = 0.038$) and low birth weight pregnancy outcomes. Also, low-birth-weight was more predominant among women with inadequate dietary patterns (90.9% vs 9.1%; $p = 0.716$) than those with adequate dietary patterns, although not statistically significant. However, the Vitamin D probiotics fortified study group had significantly decreased low-birth-weight (3.8% vs 20.9%; $p = 0.0009$) compared to the non-fortified group. Additionally, at the end line, among pregnant women with normal weight birth outcomes, the fortified study group had significantly increased levels of Vitamin D ($p < 0.05$) and TAC ($p < 0.001$) compared to non-fortified group.

CONCLUSIONS

Ther is a high prevalence of inadequate dietary patterns (86.5%) and low birth weight (11.5%) among women in Ghana. However, interventions such as Vitamin D fortified-rich foods could serve as the best strategy to improve Vitamin D levels and better pregnancy outcomes.

ASSOCIATION OF ORAL HEALTH AND NUTRITIONAL STATUS AMONG FILIPINO OLDER ADULTS

Maria Theresa Talavera[1]; Nancy Tandang[2]; S. Africa Leila[3]; Angelina Bustos[3]; Grace Cruz[4]; C Joy Cruz[4]
[1]Institute of Human Nutrition and Food, University of the Philippines Los Baños, Laguna, Philippines; [2]Institute of Statistics, University of the Philippines Los Baños, Laguna, Philippines; [3]University of the Philippines Los Banos, Institute of Human Nutrition and Food, Los Baños, Philippines; [4]University of the Philippines Diliman, UP Population Institute, Quezon City, Philippines

BACKGROUND AND OBJECTIVES

Older adults comprised 8.5% of the Philippine population in 2020, projected to reach 19.6% by 2055, signaling a shift to an aging society. Poor oral health and malnutrition are key issues, with malnutrition linked to socio-demographic factors and food insecurity. This study aims to describe the prevalence of oral health problems and nutritional status among Filipino older adults, examine their relationship and identify influencing factors.

METHODS

Data were drawn from the Longitudinal Study on Health and Aging in the Philippines, a nationally representative cohort. Using a cross-sectional design, the study analyzed oral health factors, nutritional status using BMI, lifestyle behaviors through descriptive statistics and logistic regression.

RESULTS

Filipino older adults have low tooth retention, averaging seven original teeth. Undernutrition is associated with fewer teeth, poor appetite, inadequate protein intake, lower socioeconomic status and smoking. Denture use reduces undernutrition risk by 39.6%. Better oral health, wealth, and being female increase the odds of being overweight. Psychosocial factors and physical activity and non-smoking also affect nutritional outcomes.

CONCLUSIONS

Oral health influences nutritional status in older adults. Integrated oral and nutrition interventions are essential to promoting healthy aging, focusing on affordable dental care, nutrition support, and education.

OAP41_08

MEAL PLANNING TOOL: A POTENTIAL TOOL TO REDUCE MENTAL BURDEN AND PROMOTE HEALTHIER DIETS IN THE GENERAL POPULATION?

Pauline Ducrot[1]; Gras Fanny[1]; Chloé Resche[1]; Anne-Juliette Serry[1]
[1]Health prevention and promotion department - Nutrition & physical activity unit, Santé publique France, Saint-Maurice, France

BACKGROUND AND OBJECTIVES

Meal planning is one of the components of food literacy, which encompasses the knowledge, skills, and behaviours necessary to plan, select, prepare, and consume healthy foods. Although meal planning has been suggested as an efficient practice to overcome some barriers to healthy eating, data in the literature are still scarce on the impact on diet. Many studies has demonstrated the benefice of such strategy to help people with food restrictions related to specific diseases such as diabetes, but few have been performed in the general population. The aim of this study is to evaluate the use of a web-based meal planning tool, and the self-reported impact on meal organization, and diet quality.

METHODS

The meal planning tool is available online for free since 2013, with a new version available since July 2022. The later provides a 7 days meal plan consistent with food based dietary guidelines and including seasonal products. Users of the tool were invited via a recruitment pop-in to answer a web-based questionnaire, from the 3rd to the 13th of December 2024. Questions were about: individuals characteristics (sociodemographic, meal organization), use of the tool (history and frequency of using, functionalities…), satisfaction and self-reported impact on food habits and quality.

RESULTS

2,293 users answered the questionnaire (86% women, mean age: 49, 40% living with at least one children). 79% perceived thinking about and preparing the week's meals is a mental burden. Half of the sample were new users (first day of use), while the former users (N=1,054) was roughly divided in 2 between those using the tool for more than and less than a year. The main reasons for using the tool were: find recipes (61%), have a healthy diet (50%), manage meal organization (39%). Among the former users (N=1,054), 38% reported to follow the entire proposed meal plan, 26% to only follow certain days and 36% to only pick up some recipes. The main reported impacts were on food and cooking habits (facilitates day-to-day organization, decrease of the mental burden or stress related to food organization, increase motivation to cook) and diet quality (increase food variety and food quality). Positive impacts on specific food groups were also reported and, interestingly, users from less privileged socio-professional categories were more likely to declare an increase in fruits and vegetables consumption compared to other.

CONCLUSIONS

A web-based tool helping people to manage meal planning appears of interest to overcome barriers related to food preparation and promote healthy diet in the general population.

POSITIVE DEVIANCE HEARTH PROGRAM EVALUATION TO ASSESS IMPROVEMENTS IN UNDERWEIGHT AND MODERATE ACUTE MALNUTRITION IN CHILDREN 6-59 MONTHS OF AGE IN ZAMBIA

Malelo Ilukena[1]; Thomas Chirwa[1]; Ian Mwanza[2]; Chansa Nakazwe[1]; Crispin Chaila[1]; Doreen Silukuni[1]; Diane Baik[3]
[1]Health and Nutrition, World Vision Zambia, Lusaka, Zambia; [2]Malaria and Adolescent Health, World Vision Zambia, Lusaka, Zambia; [3]Health and Nutrition, World Vision International, Monrovia, United States of America

BACKGROUND AND OBJECTIVES

Child malnutrition remains a major public health issue in Zambia, with 12% underweight and wasting reaching 8% in some provinces (GNR, 2020). World Vision Zambia is addressing this through the "Positive Deviance Hearth" (PDH) program (WVZ, 2021). PDH identifies "positive deviant" (PD), households with well-nourished children despite limited resources, and uses a formative research method called "Positive Deviant Inquiry" to identify what the PDs are doing to address the challenges contributing to malnutrition in the community (Pascale, 2010). These local solutions are designed into key messages related to feeding, caring, hygiene, and health-seeking behaviours. PDH rehabilitates underweight and moderate acute malnutrition (MAM) children without medical complications. Caregivers contribute local foods and cook a nutrient-dense meal that is fed to malnourished children as an extra meal for rehabilitation and they hear contextualized messages for 12-days.

METHODS

Data was collected using a mixed-METHODS approach using routine data by PDH volunteers in 9 districts. Children with Weight-for-Age Z-score (WAZ) <-1.0 and WAZ≥-2.0 and/or MAM (mid upper arm circumference (MUAC) <125mm and ≥115mm) without medical complications and who pass the appetite test were entered into PDH. Weight and MUAC measurements were taken on Day 1, 12, 30, and 90, with MUAC also measured at 6 and 12 months. Recovery from underweight was declared at Day 90 for children with WAZ≥-2.0 if admitted with WAZ<-2.0 or if children were admitted with WAZ<-1.0 and ≥-2.0, weight gain of ≥900g was the definition for recovery. Additionally, focus group discussions (FGDs) with 30 caregivers explored knowledge, attitudes, and practices gained through PDH.

RESULTS

In 2022-2023, 273 children were enrolled in PDH with a recovery rate of 77.3% (n=215) by Day 90. MAM prevalence dropped from 46.7% (n=172) on Day 1 to 7.5% (n=21) by Day 90 and 3.36% (n=4) by 6 months, and 0% at 1 year. Caregivers reported improved IYCF knowledge, cooking skills, and awareness of nutrient-dense local foods. Hearth sessions were valued for their practicality, cost-effectiveness, and positive impacts on both nutrition and community behavior.

CONCLUSIONS

PDH has significantly improved underweight, MAM rates, and caregiver practices, demonstrating the success of community-driven, food-based approaches in rehabilitating malnourished children. The program provides a model for scaling interventions across Zambia to achieve lasting health benefits.

UPPER ARM LENGTH ALONG WITH MID- UPPER ARM CIRCUMFERENCE FOR WASTING DIAGNOSIS AND PREVALENCE ESTIMATION: SENSITIVITY AND SPECIFICITY IN 6–59-MONTHS-OLDCHILDREN

Mouhamed Barro[1]; Barro Mohamed[2]; Djibril Cissé[2]; Zagre Noel[3]; Thierno Ba[4]; Shanti Neff Baro[5]; Yacouba Diagana[6]
[1]Nutrition, Association Nutrition et Développement , Nouakchott, Mauritania; [2]Nutrition, UNICEF, Nouakchott, Mauritania; [3]Nutrition, UNICEF, Dakar, Senegal; [4]Nutrition, Ministry of Health, Nouakchott, Mauritania; [5]., Independent, Paris, France; [6]Nutrition, University, Nouak, Mauritania

BACKGROUND AND OBJECTIVES

Child wasting remains a significant global health challenge, necessitating timely detection for effective management. Our prior research demonstrated the potential of incorporating upper arm length (UAL) alongside mid-upper arm circumference (MUAC) to enhance the diagnosis and prevalence estimation of wasting. This study aimed to evaluate the reproducibility of this approach using data from a second cross-sectional survey in Mauritania.

METHODS

UAL and standard anthropometric measurements were collected during two separate nutritional surveys conducted in Mauritania. In the initial survey, children were grouped into three UAL categories (UALG1: ≤150 mm, UALG2: 151–180 mm, and UALG3: ≥181 mm). Receiver Operating Characteristic (ROC) curves were used to identify optimal MUAC cut-offs for each group, with weight-for-height Z-score (WHZ) as the reference standard. Wasting prevalence, sensitivity, and specificity were compared across diagnostic METHODS. Identical MUAC cut-offs were applied to the second survey to assess the repeatability of findings.

RESULTS

The first survey included 12,590 children, with wasting prevalence rates of 16.1% (WHZ <−2), 5.0% (MUAC <125 mm), and 12.5% (MUAC–UALG). The MUAC–UALG method increased sensitivity for wasting diagnosis from 17.98% (MUAC <125 mm) to 39.43%, albeit with a decrease in specificity from 97.49% to 92.71%. Comparatively, the MUAC-height Z-score method (MUAC <138 mm) yielded a sensitivity of 69.76% and specificity of 75.64%. RESULTS from the second survey, assessing the method's replicability, will be presented during the conference.

CONCLUSIONS

The integration of UAL into MUAC measurements enhances the diagnostic accuracy for child wasting and provides a more reliable estimate of prevalence. This approach shows promise for rapid nutritional assessments in emergency contexts. The replicability of these findings using data from the second survey will offer further insights into the method's robustness.

BACKGROUND AND OBJECTIVES

Food insecurity (FI) is associated with poorer mental health and academic outcomes among university students (Bruening et al., 2018). However, the specific pathways through which FI may affect academic performance remain underexplored (Raskind et al., 2019). For this reason, we examined whether psychosocial health mediates the association between FI and changes in academic and/or research progression (ARP) in a sample of university students.

METHODS

This study is part of the Food Insecurity among European University Students during the COVID-19 Pandemic (FINESCOP) project, an observational, cross-sectional investigation of students enrolled in European universities, which aimed to better understand the vulnerable and challenging situation that students were experiencing during the COVID-19 pandemic. This abstract presents part of the RESULTS registered at a Spanish university and includes socio-demographic and economic data, perceived stress (Remor, 2006), hope (Synder, 1996), ARP (Mahdy, 2020), and FI status (Ballard et al., 2013). A total of 422 students completed the survey, using the Qualtrics software (Provo, UT, USA). The recruitment and data collection were conducted between December 2021 and January 2022. Univariable analysis and binary logistic regressions adjusted by sociodemographic and economic characteristics, and field of education were applied. In addition, Sobel-Goodman tests were conducted to rigorously assess mediation.

RESULTS

Overall, 18.6% of university students were food insecure**.** FI was associated with a worsening ARP (OR 1.75, 95% CI 1.66−1.84, $p<0.001$) and with perceived stress (OR 1.05, 95% CI 1.04−1.06, $p<0.001$) and hope (OR 0.94, 95% CI 0.94−0.95, $p<0.001$). The indirect association of FI status on ARP (worsening), as mediated by psychosocial health, was significant (B 0.19, 95% CI 0.09−0.31, $p<0.05$). According to the mediation percentages, hope can explain 54.6% of the association between FI and ARP.

CONCLUSIONS

This study provides evidence that the experience of FI hinders ARP through its harmful consequences on psychosocial health (being hope a protective factor in this relationship). These findings highlight the need for support programs and institutional and governmental policies that strengthen protective factors in ensuring food security among university students.

DIETARY EVOLUTION PROFILES AND THEIR VARIATION IN NUTRIENT INTAKE ADEQUACY

Elie Perraud[1]; Hafsa Toujgani[1]; Justine Berlivet[1]; Mathilde Touvier[1]; Benjamin Allès[1]; Emma Meyer[1]; Florine Berthy[1]; Juhui Wang[2]; Hélène Fouillet[2]; Julia Baudry[1]; Emmanuelle Kesse-Guyot[1]; François Mariotti[2]
[1]Équipe de Recherche en Épidémiologie Nutritionnelle (EREN), Sorbonne Paris Nord University, Inserm, CNAM, INRAE, Bobigny, France; [2]AlimH, Université Paris-Saclay, AgroParisTech, INRAE, UMR PNCA, Palaiseau, France

BACKGROUND AND OBJECTIVES

Changes in dietary intake play a significant role in long-term health, and nutrient intake adequacy has been identified in the population. These patterns of change have shown significant transitions in plant and animal shares. The lower consumption of animal products known for their nutrient richness could endanger the nutritional status of these populations. Some transitions could thus be associated with deficiencies in certain nutrients and excessive consumption of other nutrients. Therefore, this study aimed to estimate the adequacy of nutrient intake for different dietary change profiles.

METHODS

Our study is based on data from a subsample of 17,187 individuals who completed at least two of the three food frequency surveys in 2014, 2018, and 2022. Food trajectory profiles were identified using the multi-trajectory modeling method based on factors from a Principal Component Analysis of consumption data adjusted for total energy intake. The adequacy of nutrient intakes for each profile and each frequency period was analyzed using the probabilistic method. Similarly, the PANDiet and SecDiet were calculated to obtain an overall view of nutritional adequacy and nutritional security.

RESULTS

Six dietary change profiles were identified in the population with varying initial diets and evolutions (Average, Traditional, Fast Food, Healthy, Aged/Vegetarian, Risky). The Healthy and Aged/Vegetarian profiles have the highest PANDiet, and the Risky and Fast Food profiles have the lowest PANDiet. Conversely, the Healthy profile has the lowest SecDiet. PANDiet and SecDiet scores vary similarly between profiles, with some stability across the population. The probability of inadequacy of bioavailable zinc intake increases for all profiles except for the Healthy profile, which has a bell-shaped curve. The probability of inadequacy of bioavailable iron intakes decreased significantly in 2018 but increased again across all profiles in 2022. The Health profile has the highest probability of inadequacy in vitamin B12 and the lowest probability of inadequacy in fiber, alpha-linolenic acid.

CONCLUSIONS

From the analysis of dietary change profiles, we report that the changes in nutrient adequacy are similar. However, the nutritional risk is different initially, depending on the profiles. Overall, two profiles (Health and Aged/Vegetarian) have a better quality nutrient profile. The analysis of recent changes in diet allows us to specify the nutritional risk and its evolution for different types of consumption profiles and understand its determinants.

DETERMINANTS OF SCHOOLCHILDREN'S FOOD CHOICES IN TUNISIA AND LEBANON: A COMPARATIVE ANALYSIS USING A GAMIFIED CHOICE EXPERIMENT

Ali Chalak[1]; Christelle Akl[2]; Rawan Traboulsi[2]; Jalila Elati[3]; Hala Ghattas[4]; Scale Research Group[2]
[1]Department of Agriculture, Faculty of Agricultural and Food Sciences, American University of Beirut, Beirut, Lebanon; [2]Center for Research on Population and Health, American University of Beirut, Beirut, Lebanon; [3]Nutrition Surveillance and Epidemiology in Tunisia (SURVEN) Research Laboratory, National Institute of Nutrition and Food Technology (INNTA), Tunis, Tunisia; [4]Arnold School of Public Health, University of South Carolina, Columbia, United States of America

BACKGROUND AND OBJECTIVES

In the MENA region, school-aged children face a dual burden of malnutrition within rapidly transitioning food environments. Understanding the determinants of food choices in this population is essential to inform effective interventions to promote healthier eating behaviors. This study investigates how scenario attributes (peer/parental modeling, food placement, preparation time, and food price), alongside socioeconomic, behavioral, and contextual variables, determine schoolchildren's food choices in Tunisia and Lebanon.

METHODS

Using data from the School and community drivers of child diets in two Arab cities (SCALE) study, we examine 119,772 food choice occasions in Tunisia and 64,152 in Lebanon, collected from 2,441 and 2,065 schoolchildren, respectively, through a gamified choice experiment. The experiment simulated real-life food choice scenarios across various settings (home, school, and neighborhood) and nodes (breakfast, recess, lunch, snack, and dinner) where children were presented with nine food items categorized into three levels of healthiness (healthy, medium healthy, and unhealthy). We used population-averaged logit models with applied weights to estimate choice probabilities by scenario attributes. We used post-estimation analyses to explore the predicted probabilities of choosing specific food types across different covariate levels and constructed profiles combining significant covariates to assess their cumulative effects on the outcome.

RESULTS

Scenario attributes such as food placement and preparation time significantly influence food choices in both countries. Harder-to-reach unhealthy food items are less likely to be chosen compared to easy to reach unhealthy food items Lebanon (OR=0.65; 95% CI: 0.61–0.69) and Tunisia (OR=0.85; 95% CI: 0.81–0.89). Behavioral variables (nutrition knowledge, physical activity, diet diversity) and contextual factors (eating in front of screen, purchasing food in/outside school) also significantly altered food choice probabilities, with varied effects across contexts and food healthiness. Post-estimation analyses are underway to explore cumulative effects of these factors.

CONCLUSIONS

This analysis contributes to our understanding of the determinants of food choices among schoolchildren in Tunisia and Lebanon. It also provides insights for evidence-based recommendations for context-specific interventions aimed at addressing the key drivers of healthy food choices, ultimately improving childhood nutrition.

EXAMINING THE RELATIONSHIP BETWEEN DIET COSTS AND DIETARY INTAKES AMONG CANADIAN ADULTS

Gabriella Luongo[1]; Valerie Tarasuk[2]; Leah Cahill[3]; Mohammad Hajizadeh[1]; Yanqing Yi[4]; Catherine L. Mah[1]
[1]School of Health Administration, Dalhousie University, Halifax, Canada; [2]Department of Nutritional Sciences, University of Toronto, Toronto, Canada; [3]Department of Medicine, Dalhousie University, Halifax, Canada; [4]Division of Population Health and Applied Health Sciences, Memorial University of Newfoundland, St. John's, Canada

BACKGROUND AND OBJECTIVES

Dietary risk factors including inadequate intakes of fibre, fruits, and vegetables, and excess sodium, processed meats, and caloric beverages, are leading causes of premature death and disability according to the Global Burden of Disease study (1). Diet costs have been shown to influence dietary adequacy (2-6). This is the first population-representative study to examine the relationship between diet costs and dietary adequacy among Canadian adults.

METHODS

Weighted cross-sectional data using a single 24-hour dietary recall from the 2015 Canadian Community Health Survey–Nutrition, Canada's most recent population-representative nutrition survey administered by the federal government, was analyzed. Energy density and gram weight of intakes of total fibre, sodium, fruits, vegetables, processed meats, and caloric beverages, were estimated for adults 19 and older in the ten provinces (n=12,268 weighted to represent 24.4 million Canadian adults). Food prices from the Canadian Consumer Price Index program were matched to intakes to estimate individual daily diet costs ($CAD/day). Multivariate linear regression was used to estimate significant associations ($p<0.05$) between tertiles of daily diet costs, and energy density and gram weight of intakes, while controlling for socio-demographic factors comprising independent influences on food expenditure and energy intake for the gram weight intakes. Sensitivity analyses examined the impact of energy adjustment in diet cost estimation.

RESULTS

Daily diet costs varied significantly, from an average of $4.9/day in the lowest tertile of diet cost to $16.5/day in the highest tertile. The tertile with the highest diet cost was comprised of a greater proportion of males (as compared to females) and those of higher household income (as compared to lower household income) as compared to the lowest tertile of diet cost. In the final adjusted model, those in the highest tertile of daily diet cost had significantly lower energy density (kcal/g) of the diet, but also, higher intakes (grams) of sodium and vegetables, as compared to those in the lowest tertile of diet cost. No significant differences were noted for caloric beverages, processed meats, fibre, and fruits, but some differences were noted within sociodemographic strata.

CONCLUSIONS

Higher diet costs were associated with both the consumption of foods that can reduce the burden of diet related diseases as well as those that exacerbate the burden. Continued monitoring and surveillance measures are needed to examine how consumers make food purchasing and consumption decisions within a given diet cost.

DIFFERENCES IN HIGH QUALITY PROTEIN INTAKE, FISH AND PROCESSED MEAT BETWEEN ETHNIC MINORITIES IN THE UK IS NOT FULLY EXPLAINED BY SOCIOECONOMIC DISADVANTAGE – DATA FROM THE UK BIOBANK

Mayada Demashkieh[1]; Rebecca Hardy[1]; Pooja Shah[2]; Basma Ellahi[3]; Hibbah Osei-Kwasi[1]; Lee-Ann Fenge[2]; Reena Vijayakumaran[2]; Sophia Doyo Amenyah[4]; Jane Murphy[2]
[1]School of Sports Exercise and Health Sciences, Loughborough University, Loughborough, United Kingdom; [2]Faculty of Health and Social Sciences, Bournemouth University, Bournemouth, United Kingdom; [3]Faculty of Health, Medicine and Society, University of Chester, Chester, United Kingdom; [4]Faculty of Health and Life Sciences, Northumbria University, Newcastle upon Tyne, United Kingdom

BACKGROUND AND OBJECTIVES

Ethnic minority groups in the UK (South Asian, black African, and Caribbean) face health disparities, poorer overall health, greater socioeconomic disadvantages, and higher levels of deprivation compared to the white British group1.Nutritional habits, including adequate intake of fish2 and high-quality protein3, as well as limiting processed meat intake4, play a key role in healthy ageing by helping to prevent age-related malnutrition and muscle loss. As part of a larger research study to improve nutritional health in older adults [TANGERINE: nuTritional heAlth aNd aGeing in oldER ethnIc miNoritiEs.(https://www.bournemouth.ac.uk/research/projects/tangerine)], this research aimed to identify key factors influencing high-quality protein intake for healthier ageing in ethnic minorities using data from UK Biobank5.

METHODS

We grouped high-quality protein foods (poultry, beef, pork, oily fish, non-oily fish, cheese) to estimate weekly consumption, and compared it to the recommended intake of 2-3 portions/day6. Logistic regression was used to assess the association between ethnic groups and meeting dietary recommendations, adjusting for age, sex, Townsend index, and household income. We repeated the analysis for fish intake, (≥2 portions/week7), and processed meat (≤2 portions/week8) intake.

RESULTS

The odds of meeting high-quality protein intake recommendations, was higher in African and Bangladeshi and lower in Indian and Pakistani, than the white group. Adjusted odds ratios (ORs) [95% CI] were: African 2.56 [0.88, 1.20], Bangladeshi 2.20 [1.31, 3.70], Indian 0.65 [0.55, 0.77], Pakistani 0.62 [0.46, 0.85], and Caribbean 1.03 [0.88, 1.20]. Compared to the white group, Indian (0.32 [0.30, 0.74]) and Pakistani (0.65 [0.56, 0.74]) had lower ORs of meeting weekly fish recommendations, while Caribbean, African, and Bangladeshi had higher ORs after full adjustment. For processed meat, all ethnic minority groups had lower ORs than the white group: Caribbean 0.58 [0.53, 0.63], African 0.56 [0.51, 0.62], Indian 0.35 [0.32, 0.38], Pakistani 0.50 [0.44, 0.57], and Bangladeshi 0.36 [0.24, 0.52].

CONCLUSIONS

The findings suggest differences in fish, processed meat and protein intake between different ethnic groups compared with the white majority group. There is a need for interventions addressing the ethnic-specific cultural and socioeconomic factors that influence dietary patterns to inform policies aimed at supporting healthy ageing in ethnic minorities. Project funded by a grant from the MRC/UKRI (MR/Y010752/1).

ASSOCIATIONS BETWEEN FAT-SOLUBLE VITAMIN AND MINERAL INTAKE AND DENTAL CARIES AMONG CHILDREN AND ADOLESCENTS IN THE UNITED STATES, NHANES 2011-2018

Durdana Khan[1]; Ixel Hernandez-Castro[2]; Doreen Y. Larvie[3]; Seth M. Armah[4]; Andres Cardenas[2]; Ashley J. Malin[1]

[1]Department of Epidemiology, College of Public Health and Health Professions, University of Florida, Gainesville, United States of America; [2]Department of Epidemiology and Population Health, Stanford School of Medicine, Stanford, United States of America; [3]Division of Nutritional Sciences, Cornell University, Ithaca, New York, United States of America; [4]Department of Nutrition, University of North Carolina Greensboro, North Carolina, United States of America

BACKGROUND AND OBJECTIVES

Historic research shows that a diet rich in calcium, phosphorus, fat-soluble vitamins, and vitamin C, and low in phytates may help to prevent and arrest dental caries; yet current research on this topic is scarce. We examined associations of dietary intake of these nutrients with dental caries prevalence in youth.

METHODS

The study included 2,676 young children (1–5 years), 3,214 older children (6–11 years), and 3,701 adolescents (12–19 years.) from the National Health and Nutrition Examination Survey 2011–2018. Nutrient intake was ascertained via two 24-hour recalls. We assessed the number of decayed and/or filled teeth (DFT) among young children and decayed, missing, and/or filled teeth (DMFT) among older children and adolescents. We also assessed the presence of DFT or DMFT (yes/no). Covariate-adjusted survey-weighted negative binomial regression examined associations of nutrient quartiles with DFT or DMFT scores. We examined joint associations of nutrients with the probability of caries using the probit extension of Bayesian Kernel Machine Regression.

RESULTS

Dental caries prevalence among young children, older children and adolescents was 17.43%, 50.65%, and 56.25%, respectively. Mean (SD) DFT or DMFT scores were 0.82 (2.23) for young children, 2.08 (2.81) for older children and 2.51 (3.35) for adolescents. Higher phosphorus, vitamin A, and phytate intake was associated with fewer DFT among young children (IRR= 0.60, 95% CI: 0.37 to 0.95, $p = 0.03$; IRR= 0.52, 95% CI: 0.29 to 0.94, $p = 0.03$; and IRR= 0.37, 95% CI: 0.21 to 0.65, $p = 0.001$, respectively). Higher phosphorus and vitamin E intake was associated with fewer DMFT among older children (IRR = 0.58, 95% CI: 0.40 to 0.84, $p = 0.03$ and IRR = 0.73, 95% CI: 0.54 to 0.97, $p = 0.03$, respectively). For adolescents, higher phosphorus and vitamin K intake was associated with fewer DMFT (IRR = 0.72, 95% CI: 0.53 to 0.99, $p < 0.05$; IRR= 0.82, 95% CI: 0.67 to 1.00, $p = 0.05$, respectively). The nutrient mixture was associated with lower odds of DMFT. Nutrients at their 75th relative to 50th percentiles were associated with 0.87 (95% CrI: 0.81, 0.94) and 0.92 (95% CrI: 0.85, 0.99) lower odds of DMFT in older children and adolescents, respectively. Phosphorus and vitamin K contributed most to these associations.

CONCLUSIONS

Fat-soluble vitamins and phosphorus may have systemic dental benefits that warrant further investigation.

N–6 AND N–3 FATTY ACID INTAKES AND PROPORTIONS IN SERUM AMONG FINNISH CHILDREN ON VEGAN, VEGETARIAN AND OMNIVORE DIETS

Riitta Freese[1]; Venla Tilli[1]; Elina Kettunen[1]; Topi Hovinen[2]; Hanna Ruhanen[3, 4]; Minna Holopainen[3, 4]; Reijo Käkelä[3, 4]; Anu Suomalainen[2, 5, 6]; Liisa Korkalo[1]
[1]Department of Food and Nutrition, University of Helsinki, Helsinki, Finland; [2]Research Programs Unit, Stem Cells and Metabolism, University of Helsinki, Helsinki, Finland; [3]Helsinki University Lipidomics Unit, (HiLIPID), Helsinki Institute of Life Science (HiLIFE) and Biocenter Finland, Helsinki, Finland; [4]Molecular and Integrative Biosciences Research Programme, University of Helsinki, Helsinki, Finland; [5]HUS Diagnostics, Helsinki University Hospital, Helsinki, Finland; [6]Neuroscience Center, HiLife, University of Helsinki, Helsinki, Finland

BACKGROUND AND OBJECTIVES

Vegan diets are rich in the essential fatty acids (EFA) linoleic (LA, 18:2n-6) and α-linolenic (ALA, 18:3n-3) acids, but the intake of long-chain (LC) n-3 fatty polyunsaturated fatty acids (PUFA) eicosapentaenoic (EPA, 20:5n–3) and docosahexaenoic (DHA, 22:6n–3) acids is negligble without supplementation. In the absence of preformed EPA and DHA, the individual is dependent on the conversion from ALA. Dietary LA to ALA -ratio may affect the conversion efficiency. We studied the intake and status of EFAs and their LC derivatives arachidonic acid (AA, 20:4n-6), EPA and DHA in Finnish children on vegan, vegetarian or omnivore diets.

METHODS
The cross-sectional MIRA2 study collected data in 2021–22 among daycare-aged (2–7 y) children and their caregivers. Three-day food records and fasting serum samples were obtained from 65 children (n= 25, 16 and 24 following vegan, vegetarian and omnivore diets, respectively). Serum total FAs (weight-%) were analyzed with gas-liquid chromatography. Differences between groups were tested with Wilcoxon signed-rank test with false discovery rate adjustments ($p<0.01$ for all present differences). RESULTS are given as median (25–75 percentiles).
RESULTS
Fat intakes were 32 % of energy (E%) in all groups. The intakes of LA [6.4 (5.8–7.5) vs. 3.9 (3.3–4.4) E%] and ALA [1.5 (1.3–1.9) vs. 1.0 (0.8–1.2) E%] were higher, and those of EPA [0 vs. 16.6 (7.5–92.5) mg/d] and DHA [0 vs. 58.0 (14.7–262.3) mg/d] lower in the vegan group than in the omnivore group, respectively. The LA to ALA intake ratios did not differ between the groups (medians 3.7 to 4.0). Serum FAs in the vegan group contained less saturated FAs and more PUFAs. The proportions of serum LA and ALA were higher [32.6 (31.3–33.5) and 1.2 (1.1–1.5) %] and DHA lower [1.5 (1.2–1.6) %] in the vegan group than in the omnivore group [29.5 (27.5–32.3), 0.9 (0.7–1.0) and 2.3 (1.8–2.6) %, respectively]. No differences in AA or EPA were seen. The serum ratio of n–6 to n–3 PUFA was higher in the vegan group [10.3 (9.4–11.4)] than in the omnivore group [8.0 (7.1-9.6)]. The vegetarian group RESULTS tended to fall between the vegan and omnivore groups.
CONCLUSIONS

The dietary intakes of LA and ALA were sufficient, and their dietary ratios were balanced in all groups. The higher intakes of LA and ALA from vegan diets was reflected in serum FAs. ALA may be efficiently converted to EPA in children following a vegan diet, but the serum DHA levels are low compared to children on omnivorous diets. Whether the serum DHA proportions reflect adequate status should be investigated further.

OPPOSING EFFECTS OF SELENIUM AND COPPER ON SARCOPENIA IN INSTITUTIONALIZED OLDER ADULTS

Sara Estéfani Sousa[1]; Angélica Campêlo[2]; Daniela Pacheco[2]; Márcia Sales[3]; Karine Sena-Evangelista[4]; Fernando Barbosa[5]; Vanessa Sousa[6]; Kenio Lima[7]; Lucia Pedrosa[4]
[1]Graduate Program in Health Sciences, Federal University of Rio Grande do Norte, Natal, Brazil; [2]Graduate Program in Nutrition, Federal University of Rio Grande do Norte, Natal, Brazil; [3]Undergraduate Medical Course, State University of Roraima, Boa Vista, Brazil; [4]Department of Nutrition, Federal University of Rio Grande do Norte, Natal, Brazil; [5]Faculty of Pharmaceutical Sciences, University of São Paulo, Ribeirao Preto, Brazil; [6]Faculty of Health Sciences of Trairi, Federal University of Rio Grande do Norte, Santa Cruz, Brazil; [7]Department of Dentistry, Federal University of Rio Grande do Norte, Natal, Brazil

BACKGROUND AND OBJECTIVES

Older adults are more susceptible to exposure to various toxic and essential metals, which play different roles in diseases, and nutritional status during the aging process. Deficiencies in essential elements have been associated with sarcopenia, cognitive decline, and loss of functionality. Selenium is well-regarded for enhancing muscle function, particularly due to its antioxidant properties. In addition, studies showed the impact of serum copper on muscle loss. Concomitant in this scenario, exposure to toxic elements is a risk factor for accelerated DNA methylation aging, worsening the predisposition for many diseases.

METHODS

A cross-sectional study was conducted with 149 institutionalized older adults living in Natal city, Brazil. Plasma Se, zinc (Zn), Cu, arsenic (As), cadmium (Cd), nickel (Ni), and lead (Pb) levels were analyzed by inductively coupled plasma mass spectrometry, ICP-MS. European Working Group diagnosed sarcopenia on Sarcopenia in Older People (adapted). The criteria used were based on the discrimination of reduced concentrations of muscle mass (assessment of calf perimeter), associated with a reduction in strength (handgrip test) and/or functionality (walking speed test). The Mann-Whitney test and logistic regression model were applied in statistical analysis.

RESULTS

Long-lived older adults were predominant in a sample of the study, being the majority of females and residents in non-profit nursing homes. Concerning anthropometric parameters, the participants were predominantly classified as underweight. Se plasma levels [(mean) (SD)] were 92.62 (30.2) µg/L and Cu plasma levels were 1403.00 (383.1). Higher plasma Se decreased the chance of sarcopenia (OR=0.975, 95%CI=0.956 to 0.994), while sarcopenia was more prominent through increased copper (OR=1.002, 95%CI=1.001–1.004). The other elements did not show significant associations between the variables tested.

CONCLUSIONS

Se status is positively associated with sarcopenia in older adults, and Cu showed harmful effects. The importance of nutritional supply with these elements in the older adult population is highlighted, aiming at improving muscle health.

OAP44_05

COMPARISON OF INTRAVENOUS IRON SUCROSE AND FERROUS CARBOXYMALTOSE IN MANAGEMENT OF ANEMIA IN PREGNANCY: FINDINGS FROM THE PRISMA STUDY

Nida Salman Yazdani[1]; Erin Oakley,[2]; Jaime Marquis[2]; Emily R Smith[2]; Zahra Hoodbhoy[1]
[1]Department of Pediatrics, Aga Khan University, Karachi, Pakistan; [2]Milken Institute School of Public Health, The George Washington University, Washington, United States of America

BACKGROUND AND OBJECTIVES

Iron deficiency anemia (IDA) is one of the most common causes of anemia, accounting for about half of the cases of anemia during pregnancy [1]. The National Nutrition survey from Pakistan reported that 21% of pregnant women had IDA, with a slightly higher proportion from rural as compared to urban areas [2]. Despite the higher efficacy and tolerance of intravenous (IV) iron compared to oral formulations, there is a lack of consensus about using as priority treatment of IDA in pregnant women. This study aimed to assess the effectiveness of intravenous iron sucrose (IS) as compared to ferrous carboxymaltose (FCM) in iron-deficient versus non-iron-deficient (non-IDA) pregnant women in the PRISMA cohort.

METHODS

This secondary analysis leverages data of pregnant women from PRISMA (Pregnancy Risk Infant Surveillance, and Measurement Alliance). All women who enrolled before August 2024 and received at least one dose of IS or FCM were included in the analysis. Anemia was categorized into mild, moderate, and severe using the World Health Organization classification of anemia in pregnancy by trimester [3]. Iron deficiency was defined as ferritin levels of 15 ng/ml. We used linear regression to compare the effects of FCM and IS treatment and evaluated potential effect modification by IDA status.

RESULTS

This analysis includes 439 women with IDA while 212 women had non-IDA. The mean gestational age in weeks for the first dose of iron was 27 (SD 7) and 28(SD 7) weeks respectively. Among those with IDA, 324 (74%) women received FCM while 115 (26%) received IS; in the non-IDA group, 169 (78%) women received FCM and 43 (22%) received IS. On average, participants treated with FCM had larger increases in hemoglobin after treatment (0.30g/dL) compared to those treated with IS after adjusting for pre-treatment hemoglobin; participants treated with FCM also had a 16-percentage point greater decrease in the prevalence of moderate to severe anemia over those treated with IS, adjusting for pre-treatment prevalence (Table 1). We found no significant difference in the effect of FCM vs. IS treatment by IDA status.

CONCLUSIONS

A single dose of IV iron significantly reduces moderate and severe anemia, with a more pronounced effect observed in those receiving FCM compared to those receiving IS. Given the high burden of anemia, recommendations regarding management using IV iron such as FCM need to be reconsidered for effective management of this condition.

OAP44_06

DIETARY COMPOSITION IS RESPONSIBLE FOR LOW NUTRITIONAL QUALITY AND HIGH ENVIRONMENTAL FOOTPRINT OF FOODSERVICE IN GERMAN HEALTHCARE INSTITUTIONS

Lisa M. Pörtner[1, 2]; Leon Schlenger[1]; Sabine Gabrysch[1, 2, 3]; Nathalie J. Lambrecht[1, 2, 4]
[1]Institute of Public Health, Charité Campus Mitte, Berlin, Germany; [2]Research Department Climate Resilience, Potsdam Institute for Climate Impact Research, Potsdam, Germany; [3]Heidelberg Institute of Global Health, Heidelberg University Hospital and Medical Faculty, Heidelberg, Germany; [4]Center for Innovation in Global Health, Stanford University, Stanford, United States of America

BACKGROUND AND OBJECTIVES

Foodservice in healthcare settings substantially influences the health of patients and residents, and also contributes to institutions' environmental footprint. There is hardly any data on the current status of foodservice in healthcare institutions in terms of dietary quality and sustainability, hindering its recognition as an important field of action. This study aims to provide a comprehensive assessment of the healthiness, nutritional adequacy and the environmental footprint of foodservice in German healthcare institutions.

METHODS

Two hospitals and three nursing homes from different regions in Germany were included in the study. We collected meal plans and recipes to assess 1) the overall healthiness of food composition, using the Healthy Eating Index-2020, 2) adherence to the Planetary Health Diet (PHD), using the PHD Index and 3) the nutritional adequacy of food provision, using the German nutrient database. To assess the environmental footprint, annual food procurement data were matched with a life-cycle analysis database to assess 50 food groups´contribution to greenhouse gas emissions, land use, eutrophication and acidification potential, and water use.

RESULTS

The majority of calories served were from animal-source foods, refined grains and sugar, resulting in low scores in the Healthy Eating Index-2020 and low adherence to the PHD. Wholesome plant-based foods made up less than 20% of calories in all institutions. Meals were low in fiber and high in saturated fat and salt, and nutrient provision was consistently low for vitamin C, several B vitamins, potassium and magnesium. In addition, protein supply was insufficient in nursing homes. The environmental footprint of food procurement was largely driven by a few animal-source foods, namely red meat and dairy products. Almost two-thirds of procured protein was from animal-source foods, while legumes made up <1% of procurement.

CONCLUSIONS

Our study shows drastic shortfalls in dietary quality and sustainability of healthcare foodservice, highlighting an urgent need for action. Decision-makers need to prioritize and develop foodservice changes that address both individual and planetary health.

MENTAL HEALTH AND GESTATIONAL WEIGHT GAIN: A COMPARISON BETWEEN BRAZILIAN COHORTS

Audêncio Victor[1]; Maria Paula De Carvalho Leitão[2]; Perla Pizzi Argentato[2]; Lívia Patrícia Rodrigues Batista[3]; Liania A. Luzia[4]; Rinaldo Artes[5]; Patrícia H.C. Rondó[2]
[1]DEPARTAMENT OF PUBLIC HEALTH, SÃO PAULO UNIVERSITRY, São Paulo, Brazil; [2]School of Public Health, Universidade de São Paulo, São Paulo, Brazil; [3]School of Public Health, Universidade de São Paulo, São Paulo, Brazil, Brazil; [4]School of Public Health, University of São Paulo (USP), São Paulo, Brazil, Brazil; [5]Institute of Education and Research, Institute of Education, São Paulo, Brazil

BACKGROUND AND OBJECTIVES

The mental health of pregnant women is critical as it influences both maternal and neonatal outcomes. This study investigates the association between maternal mental health and gestational weight gain (GWG) in two Brazilian cohorts conducted in different periods.

METHODS

The Jundiaí cohort (1997-2000) included 875 pregnant women, while the Araraquara cohort (2017-2024) evaluated mental health of 556 pregnant women from 2017 to 2019. Maternal mental health was assessed using the General Health Questionnaire (GHQ), the State-Trait Anxiety Inventory (STAI), and the Perceived Stress Scale (PSS) during the first, second, and third trimesters. GWG was categorized as adequate, insufficient, or excessive based on Institute of Medicine guidelines. Statistical analysis included bivariate tests (Kruskal-Wallis, chi-square, or Fisher's exact test) and multinomial ordinal logistic regression to evaluate associations.

RESULTS

: In the Jundiaí cohort, high stress levels in the first trimester were associated with lower odds of insufficient GWG (adjusted OR for second quartile: 0.36, 95% CI: 0.18-0.71). In the second trimester, high anxiety levels (TAI ≥ 40) were associated with higher odds of insufficient GWG (adjusted OR: 1.76, 95% CI: 1.12-2.76). In the third trimester, high stress levels (PSS fourth quartile) were associated with higher odds of insufficient GWG (adjusted OR: 1.72, 95% CI: 1.02-2.91). In the Araraquara cohort, no significant associations between mental health and GWG were found.

CONCLUSIONS

Our findings highlight the importance of incorporating psychosocial support in prenatal care to improve maternal and neonatal outcomes. Variations in socioeconomic and temporal contexts may influence the relationship between mental health and GWG. Future research should explore the underlying mechanisms and develop interventions tailored to different socioeconomic and temporal contexts.

OAP44_08

DEVELOPMENT AND VALIDATION OF A FOOD FREQUENCY QUESTIONNAIRE TO ASSESS DIETARY IRON, FOLATE, AND VITAMIN B12 INTAKE IN WOMEN

Aysegul Kartal,; Zeynep Goktas[1]
[1]Nutrition and Dietetics, Hacettepe University Faculty of Health Sciences, Ankara, Türkiye

BACKGROUND AND OBJECTIVES

Micronutrient deficiencies, particularly those of iron, folate, and vitamin B12, remain a significant global public health concern, especially among women of reproductive age. Accurate assessment tools are crucial for evaluating dietary intake and identifying populations at risk. This study aimed to develop a food frequency questionnaire (FFQ) tailored to assess dietary intake of iron, folate, and vitamin B12 in women and to evaluate its validity and reliability.

METHODS

The validity was assessed using 24-hour dietary recalls and biochemical parameters, while reliability was tested through repeated applications. Initially, 445 non-pregnant women aged 19–50 participated, but 25 were excluded due to medical conditions affecting diet, adherence to specific diets (e.g., gluten-free, vegetarian, weight-loss), or incomplete surveys, leaving 420 participants. The questionnaire, including sections on general information, health status, 24-hour dietary recall, and dietary intake of the target nutrients, was administered face-to-face. Biochemical data from 100 participants were collected at Hacettepe University Family Medicine Clinics.

RESULTS

Correlations between the FFQ and dietary recalls showed significant relationships for iron ($p<0.001$) and folate ($p<0.001$), but not for vitamin B12 ($p=0.058$). Biochemical validation revealed significant correlations only for vitamin B12 intake and serum levels ($p=0.001$). Bland-Altman analysis supported the validity of B12 assessments ($p<0.001$).

Reliability testing demonstrated strong correlations between repeated FFQs for iron ($p<0.001$), folate ($p<0.001$), and vitamin B12 ($p<0.001$).

CONCLUSIONS

These findings suggest the FFQ is valid for assessing iron and folate intake through dietary recalls and reliable for all three nutrients. In conclusion, the developed FFQ is a practical and reliable tool for evaluating dietary intake of iron, folate, and vitamin B12 in women, with potential applications in nutritional research and public health interventions.

OAP44_09

IMPACT OF A DIETARY GUIDELINES BOOKLET FOR PREGNANT MOTHERS ON THEIR NUTRITIONAL STATUS

Namalie Thakshila Adikari[1]; Ramiah Sivakanesan[2]
[1]Department of Nutrition and Dietetics, Wayamba University of Sri Lanka, Makandura, Sri Lanka; [2]Department of Biochemistry, University of Peradeniya, Peradeniya, Sri Lanka

BACKGROUND AND OBJECTIVES

Despite the availability of several nutrition interventions, maternal nutritional problems remain public health concerns in Sri Lanka due to unhealthy dietary choices, highlighting the need to improve dietary awareness for pregnant mothers. This study aimed to evaluate the impact of a developed dietary guidelines booklet for pregnant mothers on their nutritional status.

METHODS

A developed dietary guidelines booklet for pregnant mothers includes appropriate food consumption, incorporating locally available and nutritious foods. The impact of the booklet was assessed through pre- and post-intervention assessments. Fifty-six pregnant mothers in their second trimester attending Maternal and Child Health (MCH) clinics in Pannala were recruited as the intervention group, while 56 pregnant mothers from Kuliyapitiya clinics were the control group. The intervention group received the developed dietary guideline booklet and explanations, while the control group received only routine nutrition information from MCH clinics. Baseline data on socio-demographics, nutrition knowledge, anthropometric measurements, biochemical parameters and dietary information were collected. At the last clinic visit, all the information except sociodemographic data was collected. Nutritional status was assessed based on pre-pregnancy body mass index (BMI), dietary intake of nutrients, and biochemical parameters, including urinary iodine, total protein, albumin, haemoglobin, and zinc. The nutrient intake of participants was identified using Food-Base 2000 software. Statistical analysis was performed using SPSS version 23.0 at $p < 0.05$ significance. At the end of the interventions, the differences within groups and between two groups were calculated using dependent and independent t-tests, respectively.

RESULTS

At baseline, there were no statistically significant differences in socio-demographic and nutritional status between the intervention and control groups ($p < 0.05$). A significant increase in the intake of micronutrients by mothers in the intervention group, such as iron ($p = 0.001$), iodine ($p = 0.036$), and folic acid ($p = 0.001$) compared to the control group. The biochemical parameter assessment, serum albumin ($p = 0.000$), urinary iodine ($p = 0.003$), and haemoglobin levels ($p = 0.007$) indicated that the intervention group had significant improvements in nutritional status as well.

CONCLUSIONS

The dietary guidelines booklet for pregnant mothers demonstrated its efficacy in positively impacting the nutritional status of pregnant mothers.

HARMONISING POLICIES TO ADDRESS THE DOUBLE BURDEN OF MALNUTRITION: STAKEHOLDER INSIGHTS ON FOOD RETAIL IN SOUTHEAST ASIA

Wai Siew Teh[1]; Sameeha Mohd Jamil[1]; Sirinya Phulkerd[2]; Elaine Q. Borazon[3]; Adila Fahmida Saptari[4]; Thow Anne-Marie[5]; Bee Koon Poh[1]
[1]Centre for Community Health Studies (ReaCH), University Kebangsaan Malaysia, Kuala Lumpur, Malaysia; [2]Institute for Population and Social Research, Mahidol University, Tambon Salaya, Thailand; [3]The International Graduate Program of Education and Human Development (IGPEHD), National Sun Yat-sen University, Kaohsiung, Taiwan; [4]Reconstra Utama Integra, Reconstra Utama Integra, Jakarta, Indonesia; [5]Academic Lead, Research Education, School of Public Health, The University of Sydney, Sydney, Australia

BACKGROUND AND OBJECTIVES

Food retail policies play a pivotal role in shaping dietary behaviours and addressing the double burden of malnutrition, which contributes to rising rates of obesity and non-communicable diseases (NCDs). This study, as part of South East Asia Obesogenic Food Environment (SEAOFE) project, aims to identify facilitators and barriers in food retail policies and prioritise actions to improve access to affordable, healthy foods across Indonesia, Malaysia, the Philippines, and Thailand. This presentation will focus on findings from one of the participating Southeast Asian countries.

METHODS

A three-phase qualitative exploratory approach was adopted. Phase I involved document analysis of food-related policies from various ministries, focusing on sectors such as food, health, nutrition and retail. In Phase II, in-depth interviews were conducted with key stakeholders to assess implementation of food retail policies, using policy space analysis to identify facilitators and barriers. Phase III engaged stakeholders in deliberative workshop to prioritise policy recommendations based on concerns and feasibility of implementation. Thematic analysis was used to extract codes from policy documents, interviews, and workshops, focusing on facilitators, barriers, stakeholder concerns, decision-making processes, and implementation challenges.

RESULTS

In total, 41 food-related policy documents from 25 ministries were reviewed, highlighting areas such as food safety, health, hygiene, nutrition, and retail business operations. Key facilitators included cross-sector collaboration and regulatory development, while barriers involved gaps in food standards, enforcement coordination and limited consumer awareness. The deliberative workshop underscored the need for cross-sectoral collaboration, revealing both shared goals and diverging priorities among stakeholders. While all parties agreed on promoting affordability and consumer education, they differed in regulatory focus, market flexibility, and balancing interventions with market dynamics. Insights from Southeast Asian countries highlighted common challenges, such as regulatory ambiguities and market pressures, with strategies varying depending on local contexts.

CONCLUSIONS

These findings provide actionable guidance for future policy revisions to address the double burden of malnutrition in Southeast Asia and beyond.

BACKGROUND AND OBJECTIVES

Exposure of children and adolescents to unhealthy food through advertisements on television (TV) is associated with increased consumption of unhealthy foods and subsequently, overweight/obesity and diet related non-communicable diseases (NCDs). This study assessed the nature, frequency and exposure of children to food and beverage advertisements on TV and the perspectives of children/adolescents and parents on TV food advertisments.

METHODS

Mixed METHODS; nationally representative study, guided by the International Network for Food and Obesity / NCDs Research, Monitoring and Action Support (INFORMAS) protocol for monitoring food promotion. This entailed simultaneous recording of the three most popular national TV channels in Kenya for eight randomly selected days, 18 hours/day, over a three-month period in 2021-22. The NOVA classification was used to categorise foods advertised based on level of processing. The Kruskal Wallis test was used to compare the advertisement rates of the four NOVA food group advertisements by TV channels, peak times, recording day (weekday/weekend), and season (holiday/non-holiday).Focus group discussions (n=14) and in-depth interviews (n=29) were conducted with school children/adolescents (~9-18 years) and parents respectively in three counties, to explore their perspectives on TV food advertisements. Data were coded in NVIVO and analyzed thematically.

RESULTS

Of the 3700 advertisements recorded, about a third (36%, n=1316) comprised of food and beverages, 94.7% (n=1213) were ultra-processed foods (UPFs), with a mean rate of 2.8 ads/channel per hour, the majority (95.9%, n=557) were broadcast during peak hours (6.00am-9.00pm). The children vividly remembered some of the advertised foods, mainly brands related to UPFs. Most parents acknowledged that their children paid attention to food advertisements and sometimes requested for these foods/brands. Parents generally considered food advertising safe with no concerns about unhealthy food exposure to children.

CONCLUSIONS

Exposure of Kenyan children and adolescents to unhealthy foods through advertisements on national TV is high. These advertisements enhance recognition and recall of the food brands, while parental knowledge and concern about unhealthy food advertising is limited. Policies restricting advertising of unhealthy foods accompanied by a nutrition education campaign are urgently needed to limit unhealthy food exposure and consumption by children and adolescents, to address the increasing burden of overweight/obesity and NCDs

DEMOCRATISING NUTRITION INFORMATION AND EDUCATION: A NEW NATIONAL DIGITAL TOOLBOX TO FEED AUSTRALIAN CHILDREN UNDER THE AGE OF 5

Helen Truby[1]; Stella Boyd-Ford,[2]; Ceara Swyripa,[2]; Tash Billich,[3]; Jacqueline Palmer,[2]; Clare Dix,[4]
[1]school of Primary and Allied Healthcare, Monash University, Melbourne, Australia; [2]Faculty of Health and Behavioural Sciences, The University of Queensland, Saint Lucia, Australia; [3]Neurology, Murdoch Children's Research Institute, Parkville, Australia; [4]Nutrition and Dietetics, UniSC University of the Sunshine Coast, Sippy Downs, Australia

BACKGROUND AND OBJECTIVES

Access to and availability of evidence-based nutrition information for feeding young children is inequitable and varies in quality. Identifying evidence-based nutrition information is challenging for consumers as there are many competing sources of advice. The first 2000 days of life provides a window of opportunity for influencing health trajectory. Many groups are involved in food provision for children under the age of 5, including parents/carers, health, and education professionals. The challenge of this project was to deliver a novel digital solution.

The aim was to co-design a national open-access digital repository of evidence-based nutrition resources and education for parents/carers and health professionals and create a suite of new resources to fill evidence gaps to support food and nutrition for the under 5's.

METHODS

User-centred design underpinned all aspects of development. End-users of this digital repository were defined as parents or carers of children <5 years of age, and health and education professionals working with families of children <5 years of age. A scoping review of existing online resources was conducted to determine the resources available to host in the digital repository. All resources retrieved were subjected to quality assessment and the currency of information was reviewed by a team of paediatric dietitians prior to their addition to the digital repository. Over 170 hours of co-design panels were completed with end-users and contributed to all aspects of the project.

RESULTS

The co-design panels contributed to the design, brand identity, and content of the resulting 'Grow&Go Toolbox'. The Grow&Go Toolbox houses over 2000 open access nutrition resources, with an intuitive search engine that ensures users can locate resources that meet their needs or find a relevant health professional for support. A series of free professional development podcasts for Early Childhood Education and Care workers supports the nutrition literacy of those working in childcare settings. A unique 'Personalise a Resource' Suite provides templates and digital assets for health professionals to create tailored resources for their clients with consideration of location, food availability, culture, and specific needs.

CONCLUSIONS

Grow&Go Toolbox provides a trusted source of evidence-based nutrition information for young children across Australia. This consumer-friendly digital resource hub has the capability to evolve and expand to help health professionals access quality resources for their clients. In its first 12 weeks of operation (2024), over 3000 users were recorded.

OAP45_04

FORTIFIED BALANCED ENERGY–PROTEIN SUPPLEMENTATION DURING PREGNANCY AND MATERNAL GESTATIONAL WEIGHT GAIN: A COMMUNITY-BASED RANDOMIZED TRIAL IN SOUTHERN NEPAL

Eleonor Zavala[1]; Parul Christian[1]; Tsering P. Lama[1, 2]; Daniel Erchick[1]; Subarna K. Khatry[2]; Steven C. Leclerq[2]; Joanne Katz[1]; James M. Tielsch[3]
[1]Center for Human Nutrition and Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, United States of America; [2]NNIPS, Nepal Nutrition Intervention Project Sarlahi, Kathmandu, Nepal; [3]Department of Global Health, Milken Institute School of Public Health, George Washington University, Washington D.C., United States of America

BACKGROUND AND OBJECTIVES

To assess whether gestational weight gain (GWG) differed between supplemented and non-supplemented women in a randomized controlled trial of fortified balanced energy protein (BEP) supplementation in pregnancy in Sarlahi, Nepal.

METHODS

The Maternal Infant Nutrition Trial (MINT) is a 2X2 factorial, household randomized efficacy trial to assess the impact of fortified BEP supplementation during pregnancy and lactation on birth outcomes and infant growth. The present analysis focuses on the pregnancy period, where women were randomized to receive either daily fortified BEP (15 micronutrients at 1RDA, ~400 kcal, 14.5g protein) or no supplement, with all women receiving antenatal standard of care, from 14 weeks of gestation to pregnancy outcome. GWG (kg) and rate of GWG (kg/wk) were secondary outcomes and defined as change in weight from enrollment to third trimester (~32 weeks). GWG adequacy was calculated as the observed weight gain from enrollment to third trimester divided by the expected weight gain according to the Institute of Medicine (IOM) 2009 guidelines and expressed as a percentage. GWG adequacy was categorized as: severely inadequate <70%; inadequate <90%, adequate 90-125%; and excessive >125%. Continuous and binary outcomes were analyzed using linear regression and log-binomial or Poisson regression models with robust standard error, respectively, comparing the BEP group to the no supplement group. Mean differences and relative risk ratios with 95% confidence intervals are presented as measures of impact.

RESULTS

In total, 1944 pregnant women were enrolled with a mean±SD gestational age of 9.2±2.9 weeks, and data from 1550 participants with a singleton live birth were analyzed. Baseline characteristics were similar across groups, with mean age of 24.5±3.5 years, 20.5±3.2 kg/m2 mean BMI and 45.1% reporting no formal education. The combined mean GWG from enrollment to the third trimester was 7.1±3.0 kg with a rate of 0.33±0.14 kg/week, with no differences between groups. Overall, 31.7%, 53.4%, and 14.7% of participants experienced severely inadequate, inadequate, or excessive GWG, respectively. Mean GWG percent adequacy by early third trimester was suboptimal at 85.7%±38.0 and 90.4%±39.9 in the no supplement and supplemented groups, respectively, resulting in a 4.8% difference between groups (95CI: 0.87, 8.74).

CONCLUSIONS

Fortified BEP supplementation compared to no supplementation in pregnancy improved gestational weight gain adequacy among pregnant women in rural Nepal.

OAP45_05

EFFICACY OF FOODS AND NUTRIENTS TO IMPROVE INDICATORS OF SLEEP QUALITY: A SYSTEMATIC REVIEW

Katelyn Sinfield,[1]; Ciel Vella,[1]; Margaret Allman-Farinelli[1]
[1]Faculty of Medicine and Health, University of Sydney, Sydney, Australia

BACKGROUND AND OBJECTIVES

Diet, physical activity and sleep are three lifestyle pillars for health. While the interactions of diet and physical activity have been well investigated and promoted those of diet and sleep have been less explained. There is growing recognition that poor sleep is becoming a threat to the public's health. The objective of this systematic review was to examine the effectiveness of macronutrients, foods, and dietary patterns on components of sleep quality amongst a general adult population.

METHODS

The review was registered in PROSPERO CRD42024589004. Literature searches were conducted in five databases: Medline, Embase, PsycInfo, Web of Science and Cochrane Library on August 26, 2024. The eligible population were adults aged 18-65 years but those with diagnosed sleep disorders or chronic disease were excluded. Interventions included macronutrients, foods, or dietary patterns of any duration compared to usual diet or comparator intervention. Sleep outcomes included sleep onset latency, sleep efficiency, total sleep time, wake after sleep onset, number of awakenings and subjective sleep quality. Both randomised and non-randomised controlled trial study designs were included. Risk of bias in studies was assessed using the ROB-2 and ROBINS-I tools from the Cochrane collaboration. Data were extracted and synthesised narratively. All steps of the review were conducted in duplicate with a third researcher consulted if consensus could not be reached.

RESULTS

From 11,618 articles located only 36 studies with a total of 1086 participants met the inclusion criteria. Two of 3 studies showed positive effects of high glycaemic index diets on sleep latency as did 2 of 8 studies examining high carbohydrate meals. Consuming breakfast regularly, Jerte Valley cherry products and whey protein with galacto-oligosaccharides significantly improved all sleep quality outcomes ($p < 0.05$). Findings for 2 studies of kiwifruit produced equivocal RESULTS and 3 of 4 studies of EPA, DHA and Atlantic salmon found no effects. Proposed mechanisms of action are via the tryptophan, serotonin, melatonin pathways. Findings for tryptophan supplements are equivocal but exogenous melatonin in foods improves sleep indicators.

CONCLUSIONS

Preliminary evidence highlights the potential effectiveness of some macronutrient, food and dietary pattern interventions as an approach to improve sleep. Further research to understand the underlying mechanisms by which diet influences different components of sleep quality are indicated.

DRIVERS AND SOLUTIONS TO UNHEALTHY FOOD CONSUMPTION BY ADOLESCENTS IN URBAN SLUMS IN KENYA: A QUALITATIVE PARTICIPATORY STUDY

Milkah Wanjohi[1, 2]; Kimani-Murage Elizabeth[1]; Holdsworth Michelle[3]; Rebecca Pradeilles[4]; Wilunda Calistus[1]; Asiki Gershim[5]; Klipstein-Grobusch Kerstin,[2, 6]
[1]Nutrition and Food Systems, African Population & Health Research Centre, Nairobi, Kenya; [2]Global Public Health and Bioethics, Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands; [3]UMR MoISA, French National Research Institute for Sustainable Development (IRD) Montpellier, Montpellier, France; [4]UMR MoISA, Research and Development Institute IRD Montpellier, Montpellier, France; [5]Chronic Disease Management, African Population & Health Research Centre, Nairobi, Kenya; [6]Division of Epidemiology and Biostatistics, School of Public Health, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa

BACKGROUND AND OBJECTIVES

Ultra-processing foods (UPFs) are associated with negative health impacts including cardio-metabolic and mental health risks among adolescents. There is a dearth of evidence on UPF consumption in Sub-Saharan Africa. This study explored the perceptions, drivers, and potential solutions to UPF consumption among adolescents in urban slums, Kenya.

METHODS

Qualitative participatory research, through participatory photography (photovoice) group discussions with adolescents 10-19 years (n=102) and community dialogues with adults (n=62) in three major urban slums in Kenya. The photography and subsequent discussions focused on i) causes and solutions to undernutrition and overweight/obesity among adolescents, ii) foods commonly consumed by adolescents, in urban slums. Inductive, thematic analysis was undertaken, upon which emerging themes on perspectives, drivers and solutions to UPF consumption were identified.

RESULTS

UPF consumption emerged as a predominant theme on the causes of undernutrition and overweight/obesity and foods commonly consumed by adolescents. Adolescents described UPF as junk, oily, sugary or foods with chemicals, and associated UPF consumption with undernutrition, obesity, non-communicable diseases. They perceived UPF as modern, urban, classy, appealing to young people and minimally processed foods as boring, primitive, for older people, and those in rural areas. Individual-level drivers of UPF consumption were organoleptic attributes (taste/aroma), body size/shape, illicit drug use, convenience, adolescents' autonomy. Social environment drivers were peer-pressure and social status/aspirations. Physical environment drivers were UPF availability and accessibility in the slums. Education on healthy eating and adverse effects of consuming UPF, through existing structures was proposed as potential solution to UPF consumption

CONCLUSIONS

UPF were perceived as associated with poor nutrition and health, yet were preferred over unprocessed/minimally processed foods. Interventions to promote healthy diets beyond raising awareness are important, while address the underlying perceptions and drivers of UPF consumption at individual-level, and social and physical food environments.

OAP45_07

MONITORING THE NUTRITION INFORMATION AVAILABILITY AND QUALITY OF CANADIAN RESTAURANT MENU ITEMS BETWEEN 2010 TO 2024

Hayun Jeong[1]; Mary R. L'abbe[1]
[1]Nutritional Sciences, University of Toronto, Toronto, Canada

BACKGROUND AND OBJECTIVES

The increasing frequency of eating out at restaurants, coupled with the poor nutritional quality of restaurant foods, makes menu items an important point of intervention for improving population diet and health. However, restaurant foods have been largely overlooked in nutrition policies and research in Canada, which has often been attributed to the lack of quality data for monitoring the out-of-home food environment. The objectives were to assess changes in (a) the availability of nutrition information and (b) the nutritional quality of restaurant menu items in Canada between 2010 to 2024.

METHODS

Nutrition information for menu items from restaurants with 20 or more locations (the typical cut-off for menu labelling policies) was collected at five time points (2010, 2013, 2016, 2020, and 2024). Proportion of eligible restaurants reporting nutrition information, the number of restaurants and menu items included in the Menu-Food Label Information and Price (Menu-FLIP) database, and the percent market share represented by the database were reported. Nutritional quality was assessed by comparing mean serving sizes, calories, and nutrients-of-concern across years.

RESULTS

Proportion of restaurants reporting nutrition information increased over time, with 49% in 2010, 70% in 2020, and 76% in 2024. Correspondingly, the sample sizes of the Menu-FLIP database grew, with a two-fold increase in restaurants and approximately five-fold increase in menu items. Percent market share represented also grew from 42% in 2016 to >75% in 2024. Mean calorie levels per serving fluctuated over time, ranging from 392 in 2010, 489 in 2013, 449 in 2016, 483 in 2020, and 427 in 2024 (preliminary). Sodium, sugars, and saturated fat levels consistently exceeded Canada's 'high in' thresholds (15% Daily Value) across all years.

CONCLUSIONS

This study highlights progress in the availability of nutrition information for restaurant menu items in Canada, and the expansion of the Menu-FLIP database to include a larger, more representative sample. However, the absence of standardized reporting guidelines for menu nutrition information poses challenges for longitudinal monitoring, policy development, and evaluation. Additionally, the persistently poor nutritional quality of menu items highlights the need for robust nutrition policies targeting the restaurant sector. These findings underscore the importance of working towards a healthier out-of-home food environment to better support informed consumer choices and population health.

ASSOCIATION OF NUTRIENT INTAKE AND GESTATIONAL WEIGHT GAIN WITH GUT MICROBIOTA COMPOSITION IN PREGNANT WOMEN FROM A RURAL SETTING IN A LOWER-MIDDLE-INCOME COUNTRY

S. M. Tafsir Hasan[1]; Md. Mamun Monir[2]; Mst. Noorjahan Begum[2]; Matthew Hibberd[3]; Nathaniel Mcnulty[3]; Michael Barratt[3]; Jeffrey Gordon[3]; Tahmeed Ahmed[1]
[1]Nutrition Research Division, International Centre for Diarrheal Disease Research, Bangladesh (icddr,b), Dhaka, Bangladesh; [2]Infectious Diseases Division, International Centre for Diarrheal Disease Research, Bangladesh (icddr,b), Dhaka, Bangladesh; [3]The Newman Center for Gut Microbiome and Nutrition Research, Washington University School of Medicine, Washington, MO, USA, United States of America

BACKGROUND AND OBJECTIVES

Maternal gut microbiota composition plays a critical role in perinatal outcomes, yet its relationship with nutrient intake and gestational weight gain remains underexplored in low-resource settings. This study assessed the associations of nutrient intake and gestational weight gain patterns with gut microbiota composition in pregnant women.

METHODS

The study included a subsample of 47 pregnant women from the IMNiM study (NCT04868669), who provided fecal samples at 24, 28, 32, and 36 weeks of gestation. DNA was isolated from the fecal samples and shotgun sequencing was conducted using NovaSeq 6000 platform. Gordon Lab Metagenomic Assembly Pipeline was used to construct metagenome-assembled genomes (MAGs) and abundance tables were used for downstream association analyses. Usual dietary intake was assessed via a 7-day quantitative food frequency questionnaire in the first trimester and at 36 weeks of gestation, with nutrient values derived using the Food Composition Table for Bangladesh. The weekly rate of weight gain during pregnancy was categorized following the Institute of Medicine 2009 guidelines.

RESULTS

The women had a mean (SD) age of 23.9 (4.6) years and a BMI of 20.9 (2.1) kg/m² in the first trimester, with 13 (27.7%) being nulliparous. Using the assembly pipeline, 936 MAGs were identified. Significant associations were observed between nutrient intake and specific gut microbiota species, such as *Roseburia* and *Lachnospira*, which metabolize fermentable carbohydrates and produce metabolites like butyrate and acetate, influencing glucose metabolism. Gestational weight gain was associated with dynamic changes in MAGs over the weeks of pregnancy. The relative abundance of MAGs corresponding to *Akkermansia muciniphila*, *Bifidobacterium longum*, and *Ruminococcus D bicirculans* increased in the optimal weight gain group, while the abundance of *Escherichia coli*, *Acetatifactor sp.*, and *Agathobacter rectalis* increased in the inadequate weight gain group. In contrast, the abundance of several species, including *Akkermansia muciniphila* and *Ruminococcus D bicirculans*, significantly decreased in the excessive weight gain group.

CONCLUSIONS

This study highlights the influence of nutrient intake and gestational weight gain on maternal gut microbiota composition, underscoring the importance of targeted nutritional counseling and dietary interventions to optimize pregnancy outcomes through microbiome modulation.

CHILDHOOD GROWTH STUNTING IS ASSOCIATED WITH HIGH LEAN TISSUE HYDRATION: ANALYSIS OF MULTI-COUNTRY DATABASE

Daniel Hoffman[1]; Gwenyth Lee[2]; Susan Roberts,[3]
[1]Nutritional Sciences, Rutgers University, New Brunswick, United States of America; [2]Global Health Institute, Rutgers University, New Brunswick, United States of America; [3]Geisel School of Medicine, Dartmouth College, Hanover, United States of America

BACKGROUND AND OBJECTIVES

Poor growth early in life (i.e. linear growth restriction, LGR, or stunting) has been associated with an increased risk for several chronic illnesses. LGR is associated with metabolic conditions that may be a result of delayed or poor lean tissue development. The objective of this study was to determine the relationship between LGR and body composition compartments using a global database.

METHODS

Data used for this study were derived from the Doubly Labeled Water Global Database. LGR was assessed using a categorial variable based on the WHO cutoff of stunting (WHZ < -2.00) and height-for-age (HAZ) as a continuous variable. Children with HAZ < -4.00 or < 4.00 were excluded from the analyses. Body composition was determined using the deuterium dilution technique. Differences between groups were analyzed using independent t-tests and linear regression analysis was used to determine the relationship between LGR as a categorical or continuous variable, controlling for body composition.

RESULTS

A total of 2243 children were included in the main analyses with a mean age of 10.9 ± 4.4 years, height of 142.4 ± 24.8cm, weight of 42.0 ± 21kg, and HAZ of 0.20 ± 1.29. For body composition, the mean fat-free mass (FFM) and fat mass (FM) was 30.1 ± 14.8kg and 11.9 ± 9.0kg, respectively, and a mean total body water (TBW) of 1257 ± 607mol. Children with LGR, compared to those with normal height, had no difference in hydration, but significantly lower TBW 901 ± 331 mol v.1272 ± 611mol, FFM 21.6± 8.1kg v. 30.5 ± 15.0kg, and FM 8.6kg 9.5 v. 12.0 ± 8.9kg, respectively. Using linear regression, stunting and HAZ were both significantly associated with higher TBW compared to normal height children (b= 5.40, p=0.002) and (b= 2.52, p=0.005), controlling for FFM and FM.

CONCLUSIONS

The RESULTS of this secondary analysis of body composition in children with and without LGR indicate that growth restriction may inhibit normal lean tissue development. Given that lean tissue hydration decreases with age, it may be that growth deficits inhibit normal lean tissue development resulting in delayed tissue development. Improving the physiological understanding of how LGR influence health and disease later in life remains an important scientific and public health issue. OAP46_01

HEALTHY AND SUSTAINABLE FOOD EDUCATION IN PRIMARY SCHOOLS: GLOBAL PERSPECTIVES FROM TEACHERS IN AUSTRALIA, SWEDEN AND THE UK

Jessica Kempler[1]; Claire Margerison,[1]; Janandani Nanayakkara,[2]; Alison Booth,[1]; Christel Larsson[3]; Jayne Woodside[4]; Felicia Tyllsjö[3]; Dilara Olgacher[5]
[1]Institute for Physical Activity and Nutrition, Deakin University, Burwood, Australia; [2]Institute for Physical Activity and Nutrition, Deakin University, Geelong, Australia; [3]University of Gothenburg, University of Gothenburg, Gothenburg, Sweden; [4]Centre for Public Health, School of Medicine, Dentistry and Biomedical Sciences, Queen's University Belfast, Belfast, United Kingdom; [5]Centre for Public Health, Queen's University Belfast, Belfast, United Kingdom

BACKGROUND AND OBJECTIVES

Healthy and sustainable (HS) food behaviors are crucial for population and planetary health. Primary schools can instil HS food behaviors through education and the food environment, though little is known about actual food practices in primary schools. This study aimed to analyse current practices in HS food education and environments in Australian (AU), Swedish (SW) and UK primary schools and to compare cross-country practices.

METHODS

A cross-sectional survey (2022-2024) collected data about teacher perceptions (importance, self-efficacy) and practices (frequency, training, funding) about HS food education, and school food environments (food gardens, food waste systems, kitchens, lunchtime, policies). Cross-country analyses were conducted using chi-square and ANOVA tests ($p<0.05$).

RESULTS

Participants were 1110 primary school teachers (AU:37%, UK:37%, SW:26%). HS food education was considered equally important to all subjects except English (48%)/Swedish (46%) and Maths (48%). Teachers agreed this should be in the curriculum (89%) and reported high rates of self-efficacy to teach this. Swedish teachers were more likely trained to teach nutrition (SW:44%, UK:33%, AU:30%), to teach HS food education frequently (SW:40%, AU:30%, UK:20%) and to have funding for HS food activities (SW:37%, AU:30%, UK:23%) and training (SW:23%, AU:20%, UK:10%) (all $p<0.001$). Australian schools more likely had food gardens (AU:76%, UK:49%, SW:19%) and food waste systems (AU:56%, SW:29%, UK:25%) for teaching, whilst kitchens were more likely to be available in Swedish schools (SW:67%, AU:59%, UK:28%) (all $p<0.001$). UK schools allowed 33min (SD=14min) for students to eat lunch compared to 27min (SD=8min) and 18min (SD=13min) in Sweden and Australia respectively ($p<0.001$). Swedish schools more likely had policies in place about healthy food services (SW:59%, UK:49%, AU:29%), food sustainability (SW:54%, AU:15%, UK:9%) and food-related curricula (SW:53%, UK:49%, AU:29%) (all $p<0.001$).

CONCLUSIONS

Teachers value HS food education though the degree to which this is taught in primary schools may be impacted by factors such as inadequate training, funding or supportive environments. Differences in HS food education and environments may be explained by geographic and socio-cultural differences. Learnings from the countries analysed, including what supports or hinders HS food education and environments at school, can be used to

https://doi.org/10.1017/jns.2026.10126 Published online by Cambridge University Press

strengthen the position of HS food practices in the primary school sector. This is a critical next step for public health research, policy and practice.

[1]Nutrition, Diets, and Health, International Food Policy Research Institute, Washington, United States of America; [2]Independent consultant, Independent consultant, London, United Kingdom; [3]Independent consultant, Independent consultant, Cairo, Egypt; [4]Development Strategies and Governance, International Food Policy Research Institute, Cairo, Egypt; [5]Poverty, Gender, and Inclusion, International Food Policy Research Institute, Washington, United States of America

BACKGROUND AND OBJECTIVES

Half a billion children live in conflict-affected zones. Children are particularly vulnerable to conflict-related risks, including direct and indirect effects on mortality, morbidity, and malnutrition. Malnutrition during school-age can adversely affect health and human capital outcomes in the long-term. Little evidence exists on leveraging school feeding programs to improve children's outcomes during conflict. This study assessed the impact of adding milk to a micronutrient fortified high energy biscuits (HEB) school feeding program on children and caregivers' outcomes in Yemen.

METHODS

We conducted a longitudinal cluster-randomized controlled trial where 42 schools in Al Mukha district were randomized to: (1) control (21 schools), where children received daily 2 packets (100 grams) of HEB; or (2) milk (21 schools), where children received daily 2 packets (100 grams) of HEB plus a single use 120 ml carton of ultra-high temperature milk. We assessed impacts on children's (dietary diversity, school attendance, anthropometry, cognition, learning, and behaviour) and caregivers' (food security and mental health) outcomes using linear mixed effects models adjusting for clustering and looked at interactive effects by child age and sex. The trial was registered with ISRCTN (ISRCTN12225603).

RESULTS

The study included 1,285 children (49% girls, 51% boys) aged 9.3 years (SD 1.8) on average. The school milk intervention was delivered at high fidelity throughout the study period. Adding milk to the HEBs reduced the proportion of households experiencing severe or moderate food insecurity by 11 percentage points (pp) and the proportion of caregivers experiencing mental health problems by 3 pp. In children, the addition of milk reduced conduct problems (mean difference (MD) -0.52 (95% CI -0.97, -0.08)) and improved cognition (mean difference (MD) 1.00 (98% CI 0.40, 1.61)), literacy (MD 1.14 (95% CI 0.36, 1.92)), and numeracy (MD 1.06 (95% CI 0.46, 1.67)) scores. Effects were larger among girls than boys. There was no evidence of interaction by child age. We found no impacts on children's dietary diversity, school attendance, or anthropometry.

CONCLUSIONS

Adding a daily milk ration to a fortified HEB school feeding program improved household food security, caregiver mental health, and child behavior, cognition, and learning during conflict. Hybrid models to incrementally improve meal quality are feasible, acceptable, and lead to meaningful impacts. More research is needed on cost effectiveness and long-term benefits.

PATTERNS OF PERINATAL EXPOSURE TO POLYUNSATURATED FATTY ACIDS AND CHILD CARDIOMETABOLIC HEALTH IN A FRENCH MOTHER-CHILD COHORT STUDY

Aline Abou Assi[1]; Jonathan Y. Bernard[1]; Catherine Sarté[2]; Muriel Tafflet[1]; Olfa Khalfallah[3]; Laeticia Davidovic[3]; Wen Lun Yuan[1]; Marie-Aline Charles[1]; Martine Armand[2]; Barbara Heude[1]
[1]Université Paris Cité and Université Sorbonne Paris Nord, Inserm, INRAE, Centre for Research in Epidemiology and StatisticS (CRESS), F-75004, Paris, France; [2]Aix Marseille Univ, CNRS, CRMBM, Marseille, France; [3]Institut de Pharmacologie Moléculaire et Cellulaire, CNRS UMR7275, Inserm U1323, Université Côte d'Azur, Valbonne, France

BACKGROUND AND OBJECTIVES

Perinatal exposure to omega-3 and omega-6 polyunsaturated fatty acids (PUFAs) has been associated with child cardiometabolic health. However, findings from the literature are heterogeneous, potentially due to the variability in the type of biofluid used for PUFAs measurement, and the specific PUFAs examined. Our objectives were to overcome this gap by examining perinatal exposure to PUFAs using patterns derived from three biological biofluids (maternal blood, cord blood, and breast milk), and assess their association with child cardiometabolic health.

METHODS

This study was conducted in 1,140 mother-child pairs from a French cohort. Fatty acid levels in erythrocyte membranes were measured in maternal blood (collected at 24–28 weeks of gestation), cord blood, and colostrum using gas chromatography. Patterns of exposure were derived using principal component analysis of the 34 PUFA species identified in these biofluids. Clinical and biological examination at age 5–6 years provided data on clinical (heart rate, blood pressure), and fasting blood (glucose, insulin, leptin, cholesterol [total, HDL, LDL], triglycerides) parameters. Associations between PUFA exposure patterns and cardiometabolic factors were analysed using partial Pearson's correlations adjusted for confounders. Interactions with child sex were tested, and stratification was performed when significant (p-value<0.05).

RESULTS

Five patterns of perinatal exposure to PUFAs were identified explaining 51% of total variance in PUFA levels. Overall, these patterns were not associated with the child cardiometabolic parameters. However, Pattern 4, characterized by higher levels of linoleic acid (LA) and dihomo-gamma linolenic acid (DGLA) across all three biofluids, was associated with higher insulin resistance indices in girls only (Correlation coefficient r(Insulin) = 0.14, r(HOMA-IR) = 0.14; p-value<0.005).

CONCLUSIONS

Our integrative analysis of patterns of perinatal exposure to PUFAs suggested no overall impact on cardiometabolic health of children aged 5–6 years. The positive association found between the pattern characterised by higher levels of LA and DGLA and insulin resistance in girls only, needs replication in further epidemiological and mechanistic studies.

ASSOCIATION BETWEEN MATERNAL DIETARY GLYCEMIC INDEX DURING PREGNANCY AND CHILDREN'S NEURODEVELOPMENT: A CHINESE BIRTH COHORT STUDY

Guansen Zeng[1]; Yujie Xu[2]; Xiaoyu Wang[2]; Jingyuan Xiong[3]; Guo Cheng[2]; Jikai Zeng[4]
[1]Steinhsrdt School of Culture, Education and Human Development, New York University, New york, United States of America; [2]Maternal & Child Nutrition Center, West China Woman's and Children's Hospital, Sichuan University, Chengdu, China; [3]West China School of Public Health and West China Fourth Hospital, Sichuan University, Chengdu, China; [4]Food Safety and Quality Control, Haikou Medical Foods Center, Hainan, China

BACKGROUND AND OBJECTIVES

A growing body of evidence suggests a role for dietary glycemic index (GI) during pregnancy in fetal development. However, the long-term impact of maternal GI on infant neurodevelopment remains insufficiently explored. We aim to examine this association among children at 36 months of age in a Chinese birth cohort.

METHODS

Pregnant women (>18 years of age) at 9-11 weeks' gestation were enrolled in the Nutrition in Pregnancy and Growth study while attending routine antenatal visits at a hospital in China. Children were followed up from birth to 36-month year of age. Maternal GI was derived from dietary data obtained from food frequency questionnaires. Children's neurodevelopment at 36-month-old was evaluated using the Bayley Scales of Infant and Toddler Development, third edition (BSID-III). Linear mixed effects regressions models adjusting for potential confounding factors were performed.

RESULTS

1890 women were enrolled between January 5, 2018, and March 31, 2022. Of the 1862 livebirths, 1065 (68%) children were included in the 36-month follow-up. Children of mothers who in the highest tertile of dietary GI during pregnancy had a 21% higher risk of developmental delay than those in the lowest tertile. Specifically, these children showed lower scores on the BSID-III across multiple domains, including receptive and expressive language, cognitive, fine motor, and gross motor.

CONCLUSIONS

The findings suggest that high GI during pregnancy is associated with neurodevelopment delay in children, highlighting the importance of maternal nutrition for long-term child developmental outcomes.

OAP46_05

CONTENT ANALYSIS OF OUT-OF-HOME (OOH) FOOD AND BEVERAGE ADVERTISEMENTS ALONG AN URBAN AVENUE

Precious Jemuelle Viola[1]; Irma Danao[1]; Genrev Esguerra[1]
[1]Institute of Human Nutrition and Food, University of the Philippines Los Baños (UPLB), Los Baños, Philippines

BACKGROUND AND OBJECTIVES

Overnutrition is one of the most extensive global public health crises, driven significantly by food marketing. While many efforts have been made to examine and address the effects of food advertisements on the health and nutrition of individuals, out-of-home (OOH) advertising remains understudied, especially in the locale of this study. Thus, this study analyzed OOH food and beverage (F&B) advertising along an urban avenue, focusing on locational aspects, executional elements, extent, and content quality.

METHODS

Conducted in May-June 2024, this cross-sectional study gathered primary data through four on-site observations and photo and video documentation along the 24-kilometer urban avenue that traverses six municipalities and serves as a vital public transportation corridor. The data processing involved encoding advertisements observed along the avenue and classifying them as food or non-food. Then, food advertisements were coded based on size, placement, format, informational cues, and nutritional quality. The study followed and modified the coding from a global network that promotes healthy food environments.

RESULTS

The RESULTS of the study show that the avenue is a prime location for OOH advertising due to its highly urbanized and densely populated surroundings. Local government units along the avenue also face public health concerns because of the high prevalence of overnutrition, which is influenced by the food environment. Of an average of 1,694 advertisements identified, 567 (33%) were promoting food and beverages. Most OOH F&B ads were small (48%) to medium (44%) in size and placed along the roads (65%). The common formats were billboards (49%) and posters/banners (44%). The ads mainly appealed through sensory information (18.8%) and characteristics or images of users (16.57%). More than half of the advertised food products were non-core/unhealthy (63%), while 34% were miscellaneous, and 3% were core/healthy. The frequently promoted non-core products include sugar-sweetened drinks (33%), fast food (32%), and alcoholic beverages (15%).

CONCLUSIONS

The current OOH F&B advertising landscape along the avenue is an obesity-promoting environment. Given that commuters, employees, and pedestrians around the avenue are regular and intent audiences for F&B advertising, OOH advertising along the urban avenue may pose a significant risk to public health, underscoring policies and regulations.

WOMEN'S EMPOWERMENT AND NUTRITIONAL STATUS OF CHILDREN: NEW EVIDENCE FOR BANGLADESH

Saira Parveen Jolly[1]; Jurjen Van Der Schans[2]; Robert Lensink[3]; Kaosar Afsana[4]; Md Atiqul Islam[5]; Regien Biesma[6]
[1]BRAC James P Grant School of Public Health, BRAC University, Dhaka, Bangladesh; [2]Health Sciences, University Medical Center Groningen, Groningen, Netherlands; [3]Department of Economics, Econometrics and Finance, University of Groningen, Groningen, Netherlands; [4]James P Grant School of Public Health, Johns Hopkins Bloomberg School of Public Health, Dhaka, Bangladesh; [5]Statistics, Jagannath University, Dhaka, Bangladesh; [6]Julius Center Global Health, UMC Utrecht, Utrecht, Netherlands

BACKGROUND AND OBJECTIVES

This study examines aspects of women's empowerment related to the nutritional status of the under-five children in Bangladesh, including their age-appropriate diet intake and access to healthcare during acute respiratory tract infection (ARI).

METHODS

Three waves of data from the Bangladesh Demographic Health Survey (2011, 2014, 2017-18) were utilized to construct a survey-based women's empowerment index which consists of three latent variables: 1) social independence, 2) intrinsic agency, and 3) instrumental agency for measuring women's empowerment. Our sample contains married women aged 15-45 years, who were residing with their husbands, and had at least one under-five child. The height-for-age-z (HAZ), weight-for-age-z (WAZ) and weight-for-height-z (WHZ) scores were used to measure the nutritional status of children. A composite variable was created to measure age-appropriate food intake among these children. Descriptive, inferential statistical analyses, as well as generalized structural equation modeling were performed to develop pathways between the different concepts of women empowerment and the nutritional status of children. We analyzed data by using Stata version 17.0.

RESULTS

Women's social independence positively impacted HAZ [coefficient 0.22;95% CI (0.15,0.29)], WAZ [0.17;(0.11,0.23)], and WHZ [0.06;(0.02,0.09)] scores, age-appropriate food consumption [0.03;(0.02,0.04)], and healthcare access [0.03;(0.01,0.06)]. Intrinsic agency was associated with better WAZ score [0.02;(0.009,0.03)] and food consumption [0.74;(0.62,0.86)], while instrumental agency had a negative effect on food consumption [-0.0025;(-0.004, -0.0002)]. An age-appropriate diet significantly improved child nutrition. Seeking treatment from medical professionals at the onset of ARI improved HAZ [0.17;(0.07,0.27)], and WAZ [0.16;(0.08,0.25)] scores.

CONCLUSIONS

Maternal social independence and intrinsic agency enhance the nutritional status, food consumption, and healthcare access of under-five children in Bangladesh. This study highlights the importance of interventions targeting women's empowerment for sustainable improvements in child nutrition and health.

QUALITATIVE ANALYSIS OF DRIVERS INFLUENCING ADOLESCENTS' FRUIT AND VEGETABLE CHOICES IN SRI LANKA

Hasara Sitisekara[1]; Bavatharani Rameskumar[1]; Gayathri Dissanayaka[1]; Ishani Rangajeewa[1]; Nilmini Karunarathna[2]; Thilanka Ranathunga[1]; Thushanthi Perera[1]; Renuka Silva[1]
[1]Department of Applied Nutrition, Faculty of Livestock, Fisheries and Nutrition, Wayamba University of Sri Lanka, Makandura, Gonawila, 60170, Sri Lanka; [2]Department of Applied Nutrition, Faculty of Livestock, Fisheries and Nutrition, Wayamba University of Sri Lanka, Makandura, Sri Lanka

BACKGROUND AND OBJECTIVES

Low fruit and vegetable (F&V) consumption among adolescents poses significant health concerns. Understanding the factors influencing these dietary habits is crucial for developing interventions to enhance F&V intake in Sri Lanka. This study aimed to identify individual, social, physical, and macrosystem factors affecting F&V acquisition, preparation, and consumption behavior among Sri Lankan adolescents.

METHODS

Eighteen Focus Group Discussions (FGDs) were conducted with adolescents (both males and females) aged 14-16 years from secondary schools in selected districts reflecting sociodemographic diversity. Data were analyzed using NVivo 12 (QSR International Pty Ltd) software through deductive thematic analysis.

RESULTS

Parental beliefs influence adolescents' F&V choices, including cultural perceptions of F&V as "hot", "cold", "good," or "bad". Key influencing factors were personal preferences, family dynamics, availability, marketing, and media influence. Adolescents prioritize sensory aspects over nutrition in their choices and lacked awareness of F&V intake recommendations. Despite this, they demonstrated a good understanding of health benefits of consuming F&V. Suggestions to increase consumption of F&V included promoting culinary diversity, ensuring affordability and access to quality F&V and managing seasonal availability.

CONCLUSIONS

Adolescents' F&V choices are influenced by cultural beliefs, preferences, family, availability, and media. Addressing sensory priorities, improving access, and promoting diversity can enhance consumption, providing a basis for targeted interventions. Further quantitative and qualitative research across diverse consumer groups is needed to develop impactful strategies to promote F&V intake.

JOINT ASSOCIATION OF FOOD INSECURITY AND OVERWEIGHT/OBESITY WITH HYPERTENSION AMONG WOMEN OF REPRODUCTIVE AGE (WRA)

Paola Arevalo[1]; Amy Auchincloss[1]; Fernanda Kroker,[2]; Felice Le-Scherban[1]
[1]Dornsife School of Public Health, Drexel University, Philadelphia, United States of America; [2]Unit of Chronic Diseases and Nutrition, Institute of Nutrition of Central America and Panama, Guatemala City, Guatemala

BACKGROUND AND OBJECTIVES

Food insecurity and obesity could coexist as consequences of economic and social disadvantage, rather than causally related. Among women of reproductive age (WRA), this 'double burden' may contribute to poor mental health, unhealthy lifestyles, and increased risk of hypertension and other chronic diseases. However, the cardiovascular risk implications of this 'double burden' remain understudied. We aimed to examine the joint association of food insecurity and overweight/obesity (OWT/OB) with hypertension among WRA of a middle-income country.

METHODS

Data came from a 2018-2019 cross-sectional national survey, collecting sociodemographic, nutritional and health information on women and households. Our analytic sample included 1538 women aged 15-49 years. Blood pressure was measured and classified as normotension, pre-hypertension and hypertension, according to standard protocols. Food security was assessed via the 8-item Food Insecurity Experience Scale and dichotomized (yes/no). Using measured weight and height, OWT/OB was classified as yes/no. The exposure was a 4-category cross-classification of food insecurity and OWT/OB. Multinomial logistic regression was used, adjusting for confounders.

RESULTS

Mean age was 30 years, with nearly 40% of the sample having elevated blood pressure (28% pre-hypertension/11% hypertension). About 44% experienced the 'double burden' of OWT/OB and food insecurity. Significant positive associations with pre-hypertension and hypertension were found for 'only OWT/OB' and 'double burden'. Women experiencing 'double burden' had 66% (OR=1.66 [1.05-2.62]) and 297% (OR=3.97 [1.53-10.30]) higher odds of pre-hypertension and hypertension, respectively, compared to those experiencing neither OWT/OB nor food insecurity.

CONCLUSIONS

Food insecurity alone may not independently increase hypertension risk, but its interaction with metabolic factors like OWT/OB could exacerbate cardiovascular risk. While OWT/OB alone had a stronger association with hypertension, the increased risk observed in the 'double burden' group, along with the high prevalence of elevated blood pressure in our sample, reinforces the need for targeted preventive health strategies. OWT/OB and its 'double burden' with food insecurity are associated with increased odds of hypertension. Future research should explore longitudinal trends to better understand causal pathways and design effective interventions for middle-income countries.

USING AI TO EXTRACT AND ANALYSE INGREDIENT LISTS FROM PACKAGED FOODS AND BEVERAGES ACROSS EUROPE - A CASE STUDY USING FABLE ON THE PRESENCE OF SUGARS AND NON-SUGAR SWEETENING INGREDIENTS IN BREAKFAST CEREALS

Joana Dias[1]; Evangelia Grammatikaki[2]; Jan Wollgast[1]
[1]F.1 Disease Prevention Unit, European Commission - Joint Research Centre, Ispra, Italy; [2]European Dynamics, - , Milan, Italy

BACKGROUND AND OBJECTIVES

With the goal to support public monitoring of the nutritional quality of the food offer, the JRC developed the web-based tool FABLE (Food Beverages and Labels Explorer) [1]. FABLE aims to not only be a repository of data from labels of food and beverage products, but to also make sense of such data by providing visualisations and other insights of their analysis. The aim of this study was to explore the presence and content of sugars and non-sugar sweeteners (NSS) in breakfast cereals, across different European countries.

METHODS

A new procedure using artificial intelligence (Llama 3.70b instruct model) was developed to allow for the extraction of separate ingredients from ingredient lists of packaged food and beverages. A FABLE reference ingredient list was created for different ingredient classes. Data collected from the Joint Action Best-ReMaP across 19 countries were used to assess the use of specific ingredients in breakfast cereals. The second version of the WHO Europe Nutrient Profile Model was used to assess products' eligibility for marketing to children due to their sugar content.

RESULTS

For the overall breakfast cereals category (n=7451), the majority of the products (>70%) had listed an added or a free sugar as an ingredient; less than 2.5% of the products listed a NSS as an ingredient. Proportion of products having an added or free sugar ingredient varied among sub-categories, from about half of the products (i.e. 'other ready-to-eat cereals') to all products (i.e. all 'chocolate and caramel cereals' and 'filled cereals') having such ingredients.

The average sugar content per 100g of product was 15.9 g, ranging for the different sub-categories from 1.2 g to 28.7g / 100g of product (for 'cereals without added sugar' and 'filled cereals', respectively). Almost two-thirds of the products would not be eligible for marketing to children due to their high sugar content.

CONCLUSIONS

The extraction and analysis of the use of sugars and NSS from ingredient lists of packaged food and beverage products across Europe can give experts and the public better understanding of the food offer quality.

SOCIO-DEMOGRAPHIC DETERMINANTS OF DOUBLE BURDEN OF MALNUTRITION IN GUATEMALAN HOUSEHOLDS: EVIDENCE FROM THE EPIDEMIOLOGICAL HEALTH AND NUTRITION SURVEILLANCE SYSTEM (2013-2019)

Diana Sagastume[1, 2]; Mónica Mazariegos,[3]; Katja Polman,[1, 4]; Mireya Palmieri,[5]; Karla Mesarina,[3]; José L. Peñalvo,[2, 6]; Lenka Beňová,[1]; Manuel Ramírez-Zea[3]
[1]Department of Public Health, Institute of Tropical Medicine Antwerp, Antwerpen, Belgium; [2]Global Health Institute, University of Antwerp, Wilrijk, Belgium, Belgium; [3]Research Center for the Prevention of Chronic Diseases, Institute of Nutrition of Central America and Panama, Guatemala City, Guatemala; [4]Department of Health Sciences, Vrije Universiteit Amsterdam, Amsterdam, Netherlands; [5]-, Secretariat of Food and Nutrition Security (SESAN), Guatemala City, Guatemala; [6]National Center for Epidemiology, Carlos III Health Institute, Madrid, Spain

BACKGROUND AND OBJECTIVES

Guatemala is a case in point concerning double burden of malnutrition (DBM). To strengthen national programmes in Guatemala targeting DBM, it is important to identify the main drivers of DBM and the degree of overlap with drivers of its disaggregated forms. This study aimed to identify socio-demographic factors uniquely associated with households with DBM, and those shared with households with single forms of malnutrition in Guatemala.

METHODS

This cross-sectional study is a secondary data analysis of the Epidemiological Health and Nutrition Surveillance System 2013-2019. DBM was defined as the co-existence of a woman with overweight and a child with stunting within the same household. Households with single forms of malnutrition were those with a woman with overweight or a child with stunting. The unit of analysis was households with a mother-child pair. Descriptive statistics and multinomial logistic regression were applied.

RESULTS

Based on data from 3,622 households with a woman-child pair collected between 2013 and 2019, we found that one-fifth of households suffered from DBM without a significant change over the period examined. Over the same period, the prevalence of households with a child with stunting decreased from 26% to 23%, and the prevalence of households with a woman with overweight increased from 29% to 31%. Compared to households with neither condition, socio-demographic factors uniquely associated with DBM were middle-income (aOR: 1·81, 95%CI: 1·05-3·12) and women without health insurance (aOR:1·62, 95%CI: 1·00-2·62). Shared factors for households with DBM and households with a woman with overweight were Central region, women aged >25 years and children >18 months. For households with DBM and households with a child with stunting, shared factors were women's primary education and indigenous background. Women reporting no academic education, parity >3 and having children aged 18-36 months, were shared factors for households with DBM and households with single forms of malnutrition.

CONCLUSIONS

These findings represent context-specific opportunities to address various forms of malnutrition in Guatemala simultaneously. Decision-makers should consider these findings when formulating programmes to address malnutrition with a particular focus on health equity among the most vulnerable to DBM.

ASSOCIATION BETWEEN JAPANESE DIET SCORE AND THE DEVELOPMENT OF CHRONIC KIDNEY DISEASE: THE OHASAMA STUDY

Megumi Tsubota-Utsugi[1]; Masahiro Kikuya[1]; Kei Asayama[1]; Yukako Tatsumi[1]; Michihiro Satoh[2]; Takahisa Murakami[2]; Takuo Hirose[3]; Hirohito Metoki[2]; Atsushi Hozawa[4]; Yoshitaka Tsubono[5]; Takayoshi Ohkubo[1]

[1]Department of Hygiene and Public Health, Teikyo University School of Medicine, Itabashi City, Japan; [2]Division of Public Health, Hygiene and Epidemiology, Faculty of Medicine, Tohoku Medical and Pharmaceutical University, Sendai, Japan; [3]Division of Nephrology and Endocrinology, Faculty of Medicine, Tohoku Medical and Pharmaceutical University, Sendai, Japan; [4]Division of Epidemiology, School of Public Health, Tohoku University Graduate School of Medicine, Sendai, Japan; [5]Department of Virology, Tohoku University Graduate School of Medicine, Sendai, Japan

BACKGROUND AND OBJECTIVES

Preventive interventions focusing on lifestyle, particularly healthy dietary choices, are recommended as an effective approach to control modifiable risk factors for chronic kidney disease (CKD). Although the association between dietary score and CKD has been investigated mainly in Western countries using DASH and Mediterranean diet, few studies have focused on the Japanese diet as food score. The aim of the present study is to examine the association between Japanese diet score (JDS) and the development of CKD.

METHODS

A total of 897 individuals without CKD (68% women; mean age, 59 years old) from Ohasama Town, Japan, were examined. CKD incidence was defined as the presence of proteinuria and/or an estimated glomerular filtration rate (eGFR) of <60 ml/min/1.73 m². The JDS was derived from the components of seven from a priori dietary patterns (beans and bean products, fishes and shellfishes, vegetables, Japanese pickles, fungi, seaweeds and fruits) based on the food frequency questionnaire. The total score ranged from 0 to 7, and participants were divided into quartiles based on scores (0-2, 3, 4-5 and 6-7), with the first quartile (0-2 points) as the REF. Multivariable hazard ratios (HRs) and 95% confidence intervals (CIs) for CKD incidence across each quartile were estimated using a Cox regression model adjusted for potential confounding variables.

RESULTS

During the average follow-up of 9.0 years, 128 CKD incidents were recorded. In women, the HRs (95% CIs) in the JDS score 4-5 and 6-7 groups were 0.40 (0.20–0.80) and 0.31 (0.13–0.71) for CKD incidence and 0.43 (0.20–0.94) and 0.39 (0.16–0.95) for eGFR of <60 ml/min/1.73 m², respectively. These associations were not observed in men.

CONCLUSIONS

Our findings suggest that a higher habitual intake of the Japanese food consisting of food combinations characterized by a Japanese diet may be associated with the reduced risk of CKD incidence in women.

RELATIONSHIP BETWEEN EXCLUSIVE BREASTFEEDING AND INFANT GROWTH: EARLY FINDINGS FROM A POPULATION-BASED COHORT STUDY IN SOUTHEAST ASIA AND SUB-SAHARAN AFRICA USING THE SMALL VULNERABLE NEWBORN FRAMEWORK

Savannah O'malley[1]; Jaime Marquis[1]; Irene Apewe Adjei[2]; Stephaney Gyaase[2]; Ellen Boamah-Kaali[2]; Victor Akelo[3]; Amna Khan[4]; Mutale Sampa[5]; Anne George Cherian[6]; Emily Smith[1]; Kwaku Asante Poku[2]; Prisma Research Working Group: Participating Investigators Of Mnh Study[1]
[1]Global Health, The George Washington University, Washington, DC, United States of America; [2]Research and Development Division, Kintampo Health Research Centre, Kintampo, Ghana; [3]Center for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya; [4]Paediatrics and Child Health, Aga Khan University, Karachi, Pakistan; [5]Global Projects Zambia, University of North Carolina at Chapel Hill, Lusaka, Zambia; [6]Obstetrics and Gynecology, Christian Medical College Vellore, Vellore, India

BACKGROUND AND OBJECTIVES

No studies have yet examined the relationship between exclusive breastfeeding (EBF) and infant growth using the new “small vulnerable newborns” (SVN) conceptual framework: an umbrella term that includes preterm, small for gestational age (SGA), and low birthweight (LBW) newborns. Investigating this relationship across the various SVN phenotypes could enhance our understanding of their unique challenges, informing targeted interventions. We utilized data from a multi-country open cohort study to investigate the association between EBF and the growth trajectories of infants in the first six months of life.

METHODS

We conducted a secondary analysis of data from the ongoing Pregnancy Risk, Infant Surveillance, and Measurement Alliance (PRISMA) open cohort study in Ghana, India, Kenya, Pakistan, and Zambia. We evaluated the incidence of EBF at six weeks and six months, and conducted descriptive statistics to explore feeding patterns across SVN categories. Additionally, we computed weight-for-age z-scores (WAZ) at the same time points using INTERGROWTH standards and generated plots to compare growth trajectories between preterm and SGA subgroups. Analyses were stratified by birth SVN phenotype.

RESULTS

3,359 infants were included. Maternal-reported EBF prevalence was 95% at six weeks and dropped to 31% at six months. At six weeks, EBF was highest among term AGA infants (96%) and lowest among preterm SGA infants (88%). Of those non-EBF infants, term SGA infants were most likely to receive water (23%) while no preterm SGA infants received water or gruel/porridge. WAZ was higher among EBF infants at 6 weeks compared to non-EBF, particularly among term infants. By 200 days, WAZ trends converged for EBF and non-EBF preterm AGA infants; however, for term SGA and term AGA infants, WAZ remained higher among EBF infants as compared to non-EBF infants of the same phenotype.

CONCLUSIONS

Our findings suggest that the SVN framework is useful for understanding differences in early feeding practices and infant growth. Preterm SGA infants are less likely to be EBF, yet generally are taking only breastmilk and infant formula. While term AGA infants are more likely to be EBF, those not EBF are often exposed to inappropriate early feeding practices. WAZ trends indicate that EBF infants, particularly those who are term SGA or term AGA, tend to have higher growth scores compared to their non-EBF counterparts. These findings highlight a need for more comprehensive and inclusive support to ensure all infants receive appropriate nutrition in the first 6 months of life.

EFFECTS OF FERRIC CARBOXYMALTOSE ON PICA AMONG PREGNANT ANEMIC WOMEN IN MALAWI

Leila Larson[1]; Martin Mwangi[2]; Rebecca Harding[3]; Ernest Moya[4]; Ricardo Ataide[3]; Glory Mzembe[4]; Ashley Thurber[1]; Sera Young[5]; Sabine Braat[3]; Kamija Phiri[4]; Sant-Rayn Pasricha[6]
[1]Department of Health Promotion, Education, and Behavior, University of South Carolina, Columbia, United States of America; [2]HMHB, Micronutrient Forum, Washington, United States of America; [3]Population Health and Immunity Division, Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia; [4]Department of Public Health, Kamuzu University of Health Sciences, Blantyre, Malawi; [5]Department of Anthropology, Northwestern University, Evanston, United States of America; [6]Population Health and Immunity, WEHI - Walter and Eliza Hall Institute of Medical Research, Parkville, Australia

BACKGROUND AND OBJECTIVES

Pica is the craving and consumption of non-food items, and includes the ingestion of earth (geophagy), raw starch (amylophagy), and ice (pagophagy). The prevalence of pica varies widely, but it is common in Sub-Saharan Africa, especially during pregnancy. Despite being ubiquitous, its etiology is not well understood. We leveraged the randomized trial of intravenous iron for anemia in Malawian pregnant women (REVAMP) to determine the effects of iron therapy in the second trimester, compared to standard-of-care oral iron, on pica behaviors among anemic pregnant women.

METHODS

The REVAMP trial was an open-label, individually randomized controlled trial, conducted in Blantyre and Zomba districts of Malawi. A total of 862 pregnant anemic women in their second trimester were randomized at baseline to receive either 1) a single dose of ferric carboxymaltose (FCM) (Vifor Pharma) at 20 mg/kg up to 1000mg or 2) standard-of-care oral iron (60 mg elemental iron twice daily for 90 days). Engagement in pica was assessed at baseline (i.e., during the second trimester) and 4 weeks thereafter by asking respondents about whether they had craved and consumed any of the following items in the past two weeks: earth (geophagy), unripe mango (amylophagy), raw rice (amylophagy), ice (pagophagy), ash, charcoal, or chalk. Venous blood samples were collected concurrently for hemoglobin and ferritin. A longitudinal Poisson model with a log-link was used to examine the treatment effect of FCM on the outcomes (i.e., any pica and types of pica).

RESULTS

At baseline, the prevalence of any pica was 71.7%, and geophagy was 31.9%. Hemoglobin and ferritin concentrations improved following FCM compared to standard-of-care and were lower among participants with geophagy (but not other types of pica) at baseline and 4 weeks post-randomization. From baseline to 4 weeks post-randomization, the prevalence of geophagy decreased more among women assigned to FCM compared to the standard-of-care (FCM: 33.5% to 12.9% vs standard-of-care: 30.4% to 22.3%, prevalence ratio=0.53 [95% CI 0.39–0.72], p<0.0001). There was no evidence of a treatment effect for overall pica, amylophagy, or pagophagy.

CONCLUSIONS

This study provides causal evidence that geophagy is reduced by improvements in iron status and anemia during pregnancy. Further research on the mechanisms through which iron deficiency drives pica and how different nutritional and behavioral therapies influence pica will further improve understanding of this complex phenomenon.

OAP48_06

DIETARY INTAKE TRAJECTORIES FROM CHILDHOOD AND SUBSEQUENT HEALTH OUTCOMES: A SYSTEMATIC REVIEW

Seon Park[1]; Kristy Bolton[1]; Miaobing Jazzmin Zheng[2, 1]
[1]Institute for Physical Activity and Nutrition, Deakin University, Melbourne, Australia; [2]School of Health Sciences, University of New South Wales, Sydney, Australia

BACKGROUND AND OBJECTIVES

The vital role of early dietary intake in shaping later health has been widely acknowledged, but how changes in dietary intake from early life influence subsequent health outcomes remains unclear. This systematic review aimed to synthesize the literature that examined the associations between changes in dietary intake (i.e., trajectories) from childhood and subsequent health outcomes later in life.

METHODS

Electronic searches were conducted in PubMed, Embase, and ScienceDirect to gather literature from inception to May 2024. Longitudinal cohort studies investigating dietary intake trajectories from childhood and subsequent health outcomes were included. Reporting of the review followed PRISMA guidelines and study quality was assessed using the SIGN 50 checklist.

RESULTS

Fifteen studies were included. Of which, 13 reported significant associations between dietary intake trajectories (diet quality, dietary pattern or intake of specific nutrients) in childhood (n=9) or from childhood to adolescence(n=6) and subsequent dental, cardiometabolic, neurocognitive, liver or gut health outcomes from age 2 years up to age 31 years. A healthy dietary pattern trajectory during infancy was associated with a lower risk of dental caries, while a high or increasing sugar intake trajectory was linked to a higher risk of dental caries in early childhood. A poor diet quality or high discretionary food or red meat intake dietary pattern trajectory from childhood to adolescence was associated with increased obesity and cardiometabolic risks at adolescence and early adulthood. Moreover, a healthy dietary pattern trajectory was also linked to better neurocognitive development in childhood. Significant positive associations were also found between macronutrient intake trajectories (e.g., protein, carbohydrates, fibre) during infancy and better language and motor skills in early childhood. There was also evidence to support associations between high energy intake trajectory from early childhood to adolescence and poor liver health outcomes in adulthood, as was for carbohydrate intake from infancy to early adulthood and gut microbiota composition in early adulthood. No evidence of association was found between breakfast diet quality or fibre intake trajectory and obesity outcomes in early childhood.

CONCLUSIONS

Dietary intake trajectories from childhood have been associated with various health outcomes from early childhood to adulthood. Early dietary interventions from childhood are crucial for promoting lifelong health.

A mixed-METHODS assessment of the mother-child interaction during the STIMNUT intervention (psychosocial stimulation of severely malnourished children) in Koutiala, Mali

Giulia Scarpa[1, 2]; Aissatou Diallo[3]; Sara Mazzilli[4]; Sofia Payotte[2]; Pascale Lissouba[2]; Karine Le Roch[5]; Youssouf Sidibe[3]; Oumar Samake[3]; Thomas Roederer[2]; Claire Bossard[2]
[1]Department of public health, Institute of Tropical Medicine Antwerp, Antwerpen, Belgium; [2]Public Health, Epicentre Medecins Sans Frontieres, Paris, France; [3]Public Health, Medecins Sans Frontiers (MSF), Belgique, Mali, Bamako, Mali; [4]Public Health, Santé publique France (French National Public Health Agency), Sainte-Maurice, France; [5]Public Health, Action Contre la faim, Montreuil, France

BACKGROUND AND OBJECTIVES

In Mali, the prevalence of global acute malnutrition reached 11.5% in 2022, while severe acute malnutrition (SAM) was 2.1%, placing the country in a concerning situation overall (1). Mother-child interaction is often at risk when the mother or the child are severely malnourished. MSF implemented a brief psychosocial stimulation intervention targeting 36 children between 6–23-months of age with SAM in Koutiala, Mali, and their primary caregivers to enhance mother-child interaction, and support recovery from SAM.

METHODS

To assess mother-chid interaction, we conducted a mixed-METHODS study. We used an adapted version of the Parenting Interactions with Children: Checklist of Observations Linked to Outcomes (PICCOLO) tool pre- and post-intervention (2). Also, we administered 'Dusukasi' scale to assess a local perinatal depression-like syndrome for mothers, and we monitored the child's weight. For the quantitative part, we calculated Cohen's d effect sizes to assess changes (pre vs. post intervention) and used a bootstrap resampling approach (10,000 iterations) to estimate 95% confidence intervals, using quantitative data from the observations and caregivers' questionnaire. For the qualitative part, we analysed field notes and debrief sessions with the local study team, and in-depth interviews with caregivers.

RESULTS

PICCOLO scores indicated a large effect size (Cohen's d = 0.97, 95%CI: 0.55, 1.40), suggesting substantial improvement in mother-child interactions. Also, maternal perinatal depression decreased (Dusukasi tool Cohen's d = -0.69, 95%CI: -1.19, -0.22), and child's weight increased significantly (Cohen's d=1.61, 95%CI; 1.28, 2.12), with a mean gain of 880g post-intervention. Qualitative findings suggested stronger emotional bonds and interactions between mothers and children in all PICCOLO domains (affection, responsiveness, encouragement, teaching) at post-intervention. Participants noted an increased in self-confidence and autonomy towards the child, and decreased of sadness, and depressive emotions in themselves.

CONCLUSIONS

Integrating psychosocial stimulation into SAM treatment programs improved mother-child relationships, maternal mental health and supported the child's recovery. The PICCOLO tool was found contextually-appropriate to assess mother-child interaction in Koutiala. Although a validation of the tool is required, PICCOLO has the potential to facilitate the assessment of complex interactions among mothers and children, including when children suffer from SAM.

A GIS-BASED MAPPING OF HEALTHY AND UNHEALTHY FOOD ACCESSIBILITY IN SRI LANKAN SCHOOL FOOD ENVIRONMENT

Thushanthi Perera[1]; Yasas Wickramarathna[2]; Madusha Karunanayaka[2]; Harsha Kumara Kadupitiya,[3]; Renuka Silva[2]
[1]Department of Nutrition and Dietetics, Faculty of Livestock, Fisheries & Nutrition, Wayamba University of Sri Lanka, Makandura, Sri Lanka; [2]Department of Nutrition and Dietetics, Faculty of Livestock, Fisheries & Nutrition, Wayamba University of Sri Lanka, Makandura, Gonawila, 60170, Sri Lanka; [3]Department of Agriculture, Natural Resources Management Center, Department of Agriculture, Sri Lanka, Peradeniya Sri Lanka

BACKGROUND AND OBJECTIVES

The formative years of students are crucial for their growth and development, with schools playing an important role in meeting a significant portion of their daily nutritional needs. As a result, the school food environment greatly influences students' dietary habits, shaping their overall health and well-being. This study aimed to apply Geographic Information System (GIS) techniques to evaluate the availability, accessibility, and distribution of healthy and unhealthy food options both within school premises and surrounding areas.

METHODS

This study was carried out in the Negombo education zone in Western Province, Sri Lanka encompassing 30 purposively selected schools across three educational divisions. Food availability and accessibility within a 500-meter radius of each school were mapped and analyzed using ArcGIS software.

RESULTS

Among the 30 schools surveyed, 25 had operational canteens, and 14 maintained aesthetically pleasing and well-maintained school gardens. Within the 500-meter radius of schools, 476 food outlets were identified, including grocery stores, pastry shops, and mobile vendors. These outlets predominantly sold unhealthy food options such as highly refined starch-based foods, sugary beverages, fried snacks, and ultra-processed products, with limited availability of healthier alternatives. While the availability of unhealthy food options within schools was comparatively lower, the widespread accessibility of such options in the surrounding environment raised significant concerns.

CONCLUSIONS

This study demonstrated the value of spatial analysis in understanding the food environment's influence on students' dietary behaviors. The findings reveal a pressing need for targeted interventions to enhance the availability and accessibility of healthy food options while reducing the availability of unhealthy choices around schools. Collaborative efforts between schools, local communities, authorities and policymakers are crucial to fostering a healthier school food environment and promoting the overall well-being of students.

ASSOCIATION OF DIETARY CHOLINE AND BETAINE INTAKE WITH ALL-CAUSE MORTALITY: A LONGITUDINAL STUDY FROM THE CHINA HEALTH AND NUTRITION SURVEY

Tan Peishan[1]; Aiping Fang[2]
[1]Department of Nutrition, Sun Yat-sen University, Guangzhou, China; [2]School of Public Health and Emergency Management, Southern University of Science and Technology, Shen Zhen Shi, China

BACKGROUND AND OBJECTIVES

Epidemiologic evidence on the association between choline-related nutrients and mortality risk remains limited, particularly among non-Western populations. We examined the association of dietary choline and betaine intake with all-cause mortality in Chinese adults.

METHODS
We included 9,027 men and 8,828 women from the China Health and Nutrition Survey 1991-2015 who were free from cardiovascular disease and cancer at baseline. Choline and betaine intake were repeatedly assessed using 3-day 24-hour dietary recalls at the individual level combined with weighing METHODS at the household level. Death was ascertained through household surveys in each wave. Participants were classified into five groups according to sex-specific quintiles of cumulative average dietary intake of choline and betaine. We used time-dependent Cox proportional hazards regression models to estimate multivariable-adjusted hazard ratios and 95% confidence intervals with the first quintile as the reference. We also conducted restricted cubic spline regression analyses to assess nonlinear associations between choline or betaine intake and mortality risk.
RESULTS

During a median follow-up of 9.1 years, 891 men and 687 women deceased. Higher dietary intake of total choline was associated with a lower risk of all-cause mortality in both men [HRQ5 vs. Q1 = 0.58 (95% CI: 0.45, 0.74)] and women [HRQ5 vs. Q1 = 0.59 (95% CI: 0.44, 0.78)]. The dose-response curve followed a reverse J-shape in men and an L-shape in women (both *P*-nonlinear ≤ 0.005). Similarly, dietary intake of fat-soluble choline was inversely associated with the risk of all-cause mortality in both men [HRQ5 vs. Q1 = 0.59 (95% CI: 0.46, 0.75)] and women [HRQ5 vs. Q1 = 0.53 (95% CI: 0.40, 0.70)], showing reverse J-shaped patterns (both *P*-nonlinear < 0.001). A J-shaped association between dietary water-soluble choline intake and all-cause mortality was observed in women (*P*-nonlinear < 0.001), but a null association was found in men. Betaine intake was not associated with all-cause mortality in either sex.

CONCLUSIONS

Our findings suggest that adequate intake of choline, but not betaine, may reduce the risk of death among Chinese adults, while excessive intake of water-soluble choline might promote death in women.

ASSESSING THE HEALTHINESS OF ADOLESCENTS' FOOD ENVIRONMENTS USING WEARABLE CAMERAS AND DEEP-LEARNING MODELS

Hala Ghattas[1, 2]; Shady Elbassuoni[3]; Gaby Massaad[3]; Christelle Akl[2]; Marie-Elizabeth Ragi[2]; Rawan Traboulsi[2]; Aya Mourad[3]; Sumaya Hariri[3]; Jalila Elati[4]; Scale Research Group[5, 6]

BACKGROUND AND OBJECTIVES

Dietary habits of young adolescents are shaped by complex exposures within their home, school, and neighborhood environments. The assessment of food environment exposures is limited by self-reports and the need for nutritional expertise. Wearable cameras, combined with machine learning could provide more objective and representative data. We aimed to develop a deep learning approach to assess the healthiness of young adolescents' food exposures captured through images from wearable cameras.

METHODS

As part of a cross-sectional study of a representative sample of school-children conducted in Lebanon (January to May 2022), a culturally acceptable wearable camera and machine-learning-based data collection system was developed through a user-centered design approach. Various technological safeguards were integrated to minimize risks. A sub-sample of 190 students (mean age 12.0±0.8 years), wore a camera fastened over their clothes, for one day, outside of school. Machine learning models were customized to detect and retain a sub-set of face-blurred images solely related to food, and categorized into food consumption, food advertisements, and food outlets. For food consumption images, an end-to-end deep learning approach using a tailored object detection model identified food items within each image. To evaluate the healthiness of food exposures, a machine learning model classified food items into the 29 food groups of the Diet Quality Questionnaire (DQQ). The model is trained on a custom dataset created by the study team, with images manually labeled by expert nutritionists using the Labelbox crowdsourcing platform.

RESULTS

The food detection model had a test precision of 95%, a test recall of 89%, and a test F1-score of 92%, while the food-consumption model had a test precision of 93%, a test recall of 98% and a test F1-score of 95%. Analysis of the DQQ classifier model's performance is currently underway, with RESULTS available to be presented at the conference.

CONCLUSIONS

Healthiness of adolescent food exposures can be determined through the generation of several diet quality indicators, including the Global Dietary Recommendations (GDR) score, reflecting dietary risk- and protective-factors for NCDs. Applying the DQQ classifier model beyond images of food consumption to images from other food exposures can offer a valuable tool to assess the quality of food in adolescent's environments.

FORTIFIED PORRIDGES OR NUTRITIONALLY IMPROVED TRADITIONAL RECIPES INCREASED ENERGY INTAKE DURING A MEAL IN INFANTS AGED 6-8 MONTHS IN THE RURAL REGION OF DOGO, NIGER

Faustine Rio Puygrenier[1]; Christèle Icard-Vernière[1]; Haoua Seini Sabo[2]; Mélanie Antoine[1]; Moussa Hainikoye[3]; Nafiou Maman Iiia Aminou[2]; Sonia Fortin[1]; Claire Mouquet-Rivier[1]
[1]QUALISUD, Research and Development Institute IRD Montpellier, Montpellier, France; [2]Faculté des Sciences et Techniques, Université Abdou Moumouni, Niamey, Niger, Republic of; [3]Alimentation et économie rurale, GRET, Niamey, Niger, Republic of

BACKGROUND AND OBJECTIVES

With 17.6% of children aged 6-23 months suffering from global acute malnutrition and 43.1% from stunting in Niger in 2022, effective strategies are needed to improve children's energy and nutritional intake from complementary foods. We compared the intakes of different food solutions: fortified infant flour (FIF) or nutritionally improved traditional recipes (NITR) versus traditional food.

METHODS

Infants from 40 rural villages in the commune of Dogo, Niger, aged 6-8 months, were recruited in a cluster-randomized controlled trial with four arms. All groups received a Water, Sanitation and Hygiene (WASH) package. The three groups other than the control (C group) benefited of Responsive Feeding (RF) awareness raising activities, either alone (RF group), or with the distribution of fortified infant flour for the preparation of two porridge meals per day (FIF group), or with training in the preparation of nutritionally improved traditional recipes, including the distribution of the necessary key ingredients, available locally (NITR group). We measured food intake twice for each child by weighing the bowl/plate before and after consumption. Associations were tested using linear mixed models with intakes as the response variable, groups as predictor, age, gender, and socioeconomic terciles as covariates, and village as a random effect.

RESULTS

Meal observations and intake measurements were completed for 244 children. The FIF group had the lowest average food intake during meal observation (44.9 ± 28.9 g /meal), lower than the NITR group (58.0 ± 39.1 g /meal) which had higher food intake than the control (48.0 ± 34.4 g /meal) and RF (49.8 ± 28.9 g /meal) groups. However, after conversion to energy, average energy intake differed significantly between groups ($p < 0,001$), with FIF (41.8kcal/meal) was higher than that of NITR (36.1kcal/meal), itself much higher than those of control (18.8kcal/meal) and RF groups (18.3kcal/meal). RF alone, with low energy dense traditional foods, did not significantly increase energy intake. However, the contribution to energy requirements from complementary foods remained low for two meals in the FIF (41.8± 26.9%) and NITR (36.1 ± 25.4%) groups. Even if energy intake was almost doubled with the food solutions, a high meal frequency (at least 4 meals/day must be maintained to ensure the full satisfaction of energy requirements.

CONCLUSIONS

NITR showed a high performance in both food and energy intake, emphasizing their potential as a sustainable and context-adapted solution to improve children's nutrition.

MEAL TIMING AND RISK OF DEPRESSIVE SYMPTOMATOLOGY IN A FRENCH COHORT

Gabriela Lugon[1, 2]; Elena Obeid[1]; Xuân Le Folcalvez[1]; Anna Palomar-Cros[2]; Valentina Andreeva[1]; Alice Bellicha[1]; Sandrine Péneau[1]; Mathilde Touvier[1]; Kyriaki Papantoniou[3]; Emmanuelle Kesse-Guyot[1]; Camille Lassale[2]; Bernard Srour[1]
[1]Nutritional Epidemiology Research Team (EREN), Center for Research In Epidemiology And Statistics (CRESS - Inserm 1153/Inra 1125/Cnam/UPC/USPN), Paris, France; [2]Environment and health throughout the lifecourse, ISGlobal, Barcelona, Spain; [3]Department of Epidemiology, Center for Public Health, Medical University of Vienna, Vienna, Austria

BACKGROUND AND OBJECTIVES

Circadian misalignment is a hallmark of depression, but whether circadian disruption linked to meal timing can affect the occurrence of depression has not been studied. The objective was to investigate associations between meal timing and risk of depressive symptomatology.

METHODS

We included 51726 participants (77% women, mean age 44.9±14.7) from the French NutriNet-Santé cohort (2009-2022), with no prevalent depression or antidepressant use at inclusion or during the first two years of follow-up. Dietary intake was assessed by averaging data from repeated sets of three non-consecutive 24-hour records, administered at inclusion and every six months over two years. Meal timing indicators included: time of first and last food intake, nighttime fasting duration, eating jetlag (difference in eating midpoint between working and non-working days), and the percentage of energy intake after 5 p.m. Depressive symptoms were assessed using the CES-D scale every 2 years, and cases were defined according to French thresholds. Multivariable Cox models, adjusted for sociodemographic, lifestyle factors and dietary patterns were used.

RESULTS

During a median follow-up of 8.5y, 9839 incident cases of depressive symptomatology were identified. Compared to those with a first food intake between 7:30-8:30 a.m., participants eating earlier (HR=1.09, 95%CI 1.03–1.14) or later (HR=1.14, 95%CI 1.08–1.20) than this range had higher risk of depressive symptomatology. Having a last food intake after 9 p.m. compared to between 8–9 p.m. was associated with higher risk (HR=1.07, 95%CI 1.01–1.13). Consuming over 60% of daily energy intake after 5 p.m. was linked to a higher risk (HR=1.40, 95%CI 1.23–1.59) compared to consuming ≤35%. A shorter nighttime fasting (≤11 hours) was associated with a higher risk (HR=1.08, 95% CI 1.01-1.15) compared to those with night fasting between 11-12h, only among those with a first meal ≤ 8 a.m. Compared to an eating jetlag intensity ≤ 1h, those with 1-2h had higher risk (HR=1.06, 95%CI 1.01–1.11).

CONCLUSIONS

This study suggests that altered meal timing patterns may increase the risk of depressive symptoms. These findings, if replicated in other cohorts, unravel a potential role of meal timing as a prevention strategy for mental health.

CONSUMPTION OF FORTIFIED COMPLEMENTARY FOOD, BUT NOT PROMOTION OF RESPONSIVE FEEDING, IMPROVED HEMOGLOBIN AND MICRONUTRIENT STATUS OF YOUNG CHILDREN IN A CONTROLLED, CLUSTER RANDOMIZED TRIAL IN MADAGASCAR

Yannick Razafindratsima,[1]; Andry Razakandrainy,[1]; Sonia Fortin[2]; Charlotte Ralison Raharintsoa[3]; Rindra Randremanana[4]; Frank T. Wieringa[2]; Claire Mouquet-Rivier[2]
[1]Madagascar, GRET, Antananarivo, Madagascar; [2]UMR QualiSud, Institut de Recherche pour le développment/Université Montpellier/SupAgo, French National Research Institute for Sustainable Development (IRD), Montpellier, Montpellier, France; [3]Food and Nutrition Sciences, University of Antananarivo, Antananarivo, Madagascar; [4]Epidemiology and Clinical Research Unit, Institut Pasteur de Madagascar, Antananarivo, Madagascar

BACKGROUND AND OBJECTIVES

Globally, micronutrient deficiencies are a serious public health problem in early childhood with >50% of children affected. We aimed to evaluate effects of Responsive Feeding (**RF**) and the consumption of Fortified Complementary Foods (**FCF**), either alone or combined, on hemoglobin concentrations and micronutrient status of young children in a rural area of Madagascar.

METHODS

Infants (n=706), age 6-7 months, were recruited in a 2x2 factorial randomized controlled intervention trial. The control group only received counselling on water, sanitation and hygiene practices (**WASH**), while the 3 interventions groups received in addition to WASH, promotion of Responsive Feeding (**RF**), provision of daily fortified complementary food (**FCF**) or both (**FCF+RF**). Hemoglobin concentrations and micronutrient status (iron, zinc, vitamin A and thiamine) were evaluated at baseline and at the end of the intervention after 9 months. Impact of interventions was evaluated with generalized mixed models.

RESULTS

Prevalence of micronutrient deficiency was high with 85% of children affected by 1 or more deficiencies. Consumption of FCF increased concentrations of hemoglobin (+5.4 g/L, 95% CI: +2.5, +8.4) and retinol-binding-protein (RBP +0.09 mmol/L, CI 95%: +0.04, +0.14), and decreased prevalence of zinc and thiamine deficiency over the intervention period. Promotion of RF had only a positive effect on RBP concentrations (+0.06 µmol/L, CI 95%: +0.01, +0.11), but surprisingly a negative impact on iron, zinc and thiamine status. There were significant interactions between RF and FCF for most biomarkers of micronutrient status.

CONCLUSIONS

This study confirms the urgent public health problem of micronutrient deficiency in young children in Madagascar, and the potential of FCF to improve micronutrient status. Surprisingly, RF tended to have a negative impact, warranting more research into appropriate RF training modules.

THE EFFECT OF YELLOW MEALWORM-ENRICHED MAIZE PORRIDGE ON GROWTH AND MICRONUTRIENT STATUS OF SCHOOL-GOING CHILDREN

Tele Boit,[1]; Violet Gwokyalya[2]; Dorothy Nakimbugwe[3]; Ezekiel Mupere[4]; Alida Melse-Boonstra[5]; Benedikte Grenov[1]; Nanna Roos[1]
[1]Department of Nutrition, Exercise and Sports, University of Copenhagen, Frederiksberg Campus, Frederiksberg, Denmark; [2]School of Public Health, Makerere, Kampala, Uganda; [3]Department of Food Technology & Nutrition, Makerere, Kampala, Uganda; [4]Department of Pediatrics and Child Health, Makerere, Kampa, Uganda; [5]Division of Human Nutrition and Health, Wageningen University & Research, Wageningen, Netherlands

BACKGROUND AND OBJECTIVES

More than 1.7 million refugees in Uganda are vulnerable to food insecurity, which increases the risk of malnutrition among children. Diets within the region are dominated by cereals and high starch vegetables with minimal intake of animal-sourced foods (ASF). Increased consumption of ASF can improve growth, nutrition and health of children. Farming edible insects provides a novel option for locally produced sustainable and nutrient-dense ASF. The nutrition and health impacts of consuming edible insects is however not well established. This study investigated the effects of a yellow mealworm-enriched porridge on the nutrition and health status of 6-9-year-old school children living in and around Kyaka II refugee settlement in western Uganda.

METHODS

The study utilized a randomized two-arm parallel design. School children aged 6-9 years were individually randomized to either an intervention group receiving an insect-enriched maize porridge with 25% inclusion of yellow mealworm or a control group receiving a standard plain maize porridge. The porridge was served daily in 2 schools (within the host community and refugee settlement) for a duration of 15 weeks. Biological samples (stool, blood, saliva) were collected at baseline and endline, along with anthropometric measurements and dietary data, which were also obtained at intermediate time points.

RESULTS

We formulated a school meal product with mealworm that was accepted by the participants. The school intervention including 342 children was completed in October 2024. Data analysis of primary outcome of height gain is ongoing, scheduled to be finalized in Q2-2025. The primary outcome will apply linear mixed-effect model for the intervention effect. Multiple outcomes from the study will include additional anthropometric measures, micronutrient biomarkers, hemoglobin, gut health markers, and body composition.

CONCLUSIONS

The RESULTS of the study will contribute to the understanding of the nutritional and health effects of edible insects as a novel, sustainable alternative animal-food protein source, with the potential to improve nutrition and health in school children in food- insecure environments.

EVALUATING FRONT-OF-PACK-NUTRITION-LABEL (FOPNL) FORMATS AMONG CONSUMERS ACROSS ECONOMIC STRATA FOR INFORMING REGULATION IN INDIA – A COUNTRYWIDE CROSS-SECTIONAL QUASI EXPERIMENTAL STUDY

Subbarao M Gavaravarapu[1]; Priyadarshini S[2]; Mokalla Tirupathi Reddy[3]; Raghavendra Pandurangi[4]; Panda Hrusikesh[5]; Rajkumar Hemalatha[6]
[1]NUTRITION INFORMATION, COMMUNICATION & HEALTH EDUCATION (NICHE), ICMR - National Institute of Nutrition, Hyderabad, India; [2]4Department of Foods, Nutrition & Dietetics Research, Madras Diabetes Research Foundation, Chennai, India; [3]Biostatistics, IU School of Public Health, Bloomington, United States of America; [4]Public health Nutrition, ICMR - National Institute of Nutrition, Hyderabad, India; [5]Nutrition Information, Communication and Health Education (NICHE) Division, ICMR - National Institute of Nutrition, Hyderabad, India; [6]Director (Retd), ICMR - National Institute of Nutrition, Hyderabad, India

BACKGROUND AND OBJECTIVES

In the context of rising overweight/obesity and non-communicable diseases, front-of-pack-nutrition labels (FoPNL) can promote informed and healthy food choices. In India, FoPNL regulation still remains a challenge, with two draft regulations introduced by the Food Safety Standards Authority of India (FSSAI) in 2015 and 2022 (color-coded warnings and star-rating respectively) not meeting wider acceptability. Given the country's diversity, context-specific evidence on the effectiveness of FoPNLs is crucial for informing the ongoing regulatory process. This study aimed to assess consumer acceptability, likeability, and understanding of five FoPNL formats—Nutri-Score (NS), HealthStarRating (HSR), Warning Labels (WL), Multiple Traffic Lights (MTL), and Nutri-Star Rating (NSR)—and compare attributes like noticeability, cognitive workload, and purchase intention.

METHODS

This was a pan-India cross-sectional study with a quasi-experimental design conducted among 3,231 participants (2,616 adults and 615 adolescents) from urban, rural, and slum populations across five regions of India. Participants completed a pre-tested, three-part questionnaire in a single contact session- Part-1 collected socio-demographic data and food label reading habits; Part-2 evaluated likeability and cognitive workload across five FoPNL formats. In Part-3, participants were randomized to each of the five formats and were shown mock-up food packs to assess noticeability, understanding, health perceptions, and purchase intentions.

RESULTS

Over 75% reported reading labels, but mostly focused on ‘manufacturing’ or 'use-by' date. Only 39% read nutrition information, only 10% read regularly. Among FoPNL formats, NS was most preferred, followed by NSR. WL were least favoured. 95% stated that summary indicator formats made identifying healthy foods easier, with 92% finding NS useful. For identifying unhealthy variants, NS (60.6%) and NSR (67.4%) were preferred. NS, NSR, and HSR were easier to understand than WL and MTL. All FoPNL formats helped identify ‘healthiest’ or ‘least healthy’ variants. Summary indicators created ‘halo effect’, making even less healthy foods appear healthy. WL deterred choosing even moderately healthy variants .

CONCLUSIONS

Summary indicators (NS, HSR) effectively promote healthier food choices, while warning labels (NSR, WL) better deter unhealthy food choices. For choosing the right format for India, FSSAI should define the purpose - to encourage choice of healthier options or to deter choice of foods high in nutrients of concern.

DIGITAL MARKETING TACTICS IN THE COMMERCIAL MILK FORMULA INDUSTRY IN CENTRAL AMERICA AND THE CARIBBEAN

Mónica Mazariegos,[1]; Renán De León José[2]; Brenda Paz[1]; Lila Alvarez[1]
[1]INCAP Research Center for the Prevention of Chronic Diseases, Institute of Nutrition of Central America and Panama, Guatemala City, Guatemala; [2]Nutrition, INCAP, Guatemala City, Guatemala

BACKGROUND AND OBJECTIVES

Digital marketing has become the predominant marketing channel in many regions, with some countries reporting that over 80% of exposure to commercial milk formula advertisements occurs online. This study aimed to characterize the digital marketing landscape and identify the most prevalent tactics used by the commercial milk formula industry in Guatemala, Panama, and the Dominican Republic**.**

METHODS

We applied the CLICK monitoring framework developed by the World Health Organization to evaluate digital marketing practices in the commercial milk formula industry. Two steps of the framework were used: 1) Comprehending the digital ecosystem and 2) analyzing the landscape of campaigns. First, we identified the top milk formula products and the main digital platforms utilized in Central America and the Caribbean. Then, we manually scanned the websites and social media feeds of these brands to document the most frequently used marketing tactics and quantify violations of the International Code of Marketing of Breastmilk Substitutes and regional legislations from November 2023 to May 2024.

RESULTS

The most commercialized products included growing-up milk (94%), infant formula (4%), and follow-up formula (2%). Key marketing strategies employed by the industry included the use of messages that manipulate and exploit parents' emotions and anxieties (58%), the use of nutritional and health claims (49%), and click-to-chat marketing (e.g., invitations to virtual support groups) (38%). We identified 358 online advertisements that violated the Code and regional laws, accounting for 2,757 specific breaches across multiple legal provisions. Additionally, we observed a cross-border marketing strategy, with campaigns targeting pregnant women and mothers across the region.

CONCLUSIONS

Our findings underscore the urgent need to strengthen legislation protecting and promoting breastfeeding in Central America and the Caribbean. Enhanced enforcement and regulatory mechanisms are essential to curb exposure to the aggressive digital marketing tactics employed by the commercial milk formula industry.

OAP52_09

A FLAVONOID-RICH DIET IS ASSOCIATED WITH IMPROVED BIOLOGICAL AGEING

Jennings Amy[1]; S. Thompson Alysha[1]; P Bondonno Nicola[2, 1]; Tilman Kühn[3, 4, 1]; Cassidy Aedin[1]
[1]Co-Centre for Sustainable Food Systems, Institute for Global Food Security, Queen's University Belfast, Northern Ireland, UK, Belfast, United Kingdom; [2]Danish Cancer Institute, Danish Cancer Institute, Copenhagen, Denmark; [3]Department of Nutritional Sciences, University of Vienna, Vienna, Austria; [4]Center for Public Health, Medical University of Vienna, Vienna, Austria

BACKGROUND AND OBJECTIVES

Flavonoids have been shown to reduce systemic inflammation and oxidative stress suggesting potential to delay the aging process. We conducted a population-based study in the UK Biobank to investigate the relationship between (1) flavodiet score and (2) intakes of flavonoid subclasses and attenuation of biological ageing.

METHODS

Flavodiet score adherence and intake of flavonoid subclasses were derived from 24-hour computerised dietary assessments. Diet quality was assessed using the alternative Healthy Eating Index (aHEI). Biological aging was quantified using the Klemera-Doubal method, which includes biomarkers of cardiometabolic, inflammatory, liver and kidney function, and can be interpreted as years of biological age [1]. Multivariable regression models adjusted for a wide range of potential confounders were used to assess associations between flavonoid intakes and biological aging.

RESULTS

In 119,393 participants (52% female, median [IQR] age, 58.7 [51.0-64.0] years) when comparing the highest with lowest quintile of flavodiet score, consuming 6 additional servings per day of flavonoid-rich foods was associated with better biological aging [βQ5-Q1 (95% CI): -0.5 y (-0.6, -0.4)]. Of the flavonoid subclasses, higher intake of flavanones [-0.4 y (-0.5, -0.4)], anthocyanins [-0.5 y (-0.6, -0.4)], flavones [-0.6 y (-0.7, -0.5)] and proanthocyanidins [-0.6 y (-0.7, -0.5)] were also associated with better biological aging. There were indications of interactions with diet quality as associations between intake of the anthocyanin subclass and biological aging were greatest in those with the poorest diet quality, as assessed using the aHEI.

CONCLUSIONS

A diet rich in commonly consumed flavonoid-rich foods such as apples, tea, and berries, was

associated with better biological ageing, particularly in those with the poorest quality diets.

UNDERSTANDING DECENTRALISED SCHOOL FOOD PROCUREMENT IN GHANA: USING PHOTOVOICE TO WALK IN SCHOOL CATERERS' SHOES

Julia Liguori[1]; Mathilde Savy[1]; Amos Laar[2]; Michelle Holdsworth[1]
[1]UMR MoISA, French National Research Institute for Sustainable Development (IRD) Montpellier, Montpellier, France; [2]Department of Population, Family & Reproductive Health, School of Public Health, University of Ghana, Accra, Ghana

BACKGROUND AND OBJECTIVES

The Ghana School Feeding Programme (GSFP) uses a decentralised procurement model, placing school caterers at the core of the programme with responsibilities to: select, purchase, transport, prepare and distribute meals. However, caterers' perspectives are not always given importance during programme implementation, monitoring and evaluation. This study aimed to better understand the lived experiences of GSFP caterers to identify context-specific challenges and solutions to programme delivery.

METHODS

A Photovoice study was conducted in March-April 2024 in three socio-economically diverse districts in the Greater Accraregion: La Nkwantanang Municipal, Ashaiman Municipal, Ningo-Prampram District. School caterers (n=30) were randomly selected and invited to attend a training on photography skills, safety ethics and to co-create two research questions. In a second phase, participants took thematic photographs, which were then used to guide discussion during individual follow-up interviews (n=19). Data analysis used a priori and emergent themes, based on a 9-step school food system framework. Finally, a photo exhibition was held to advocate for change within the GSFP.

RESULTS

While challenges and solutions were discussed in each school food system step, infrastructure support (n=19), food preparation (n=19), caterer wellbeing (n=19) and wholesale and trading (n=18), were cited as key challenges. Delayed GSFP payments to caterers cut across these themes. Delays interrupted caterers' ability to purchase food and equipment (e.g. fuel, utensils), resulting in changed school menus (e.g. switched ingredients for more affordable foods or food served in smaller quantities). Caterers also described putting other food systems actors, like vendors, at risk by taking loans that could not be reimbursed, which created stress and negatively impacted their wellbeing. Caterers' proposed solutions included: on-time GSFP payments, buying food items in bulk to reduce price per unit/kilo, gaining access to electricity for safe food storage (e.g. refrigeration) and building functional kitchens on school premises to reduce delays in meal service and associated costs of transporting meals cooked offsite.

CONCLUSIONS

This study provides insights into the everyday challenges and successes of GSFP caterers. Increased programme support, timely payments and improved caterer wellbeing are needed to ensure programme continuity and widespread provision of nutritious school meals in Ghana.

MISSION VS MARGINS: A SCOPING REVIEW OF SOCIAL ENTERPRISE BUSINESS MODELS AS A SOLUTION TO SUSTAINING HEALTH-PROMOTING FOOD AND NUTRITION-BASED INTERVENTIONS

Leila Fathi[1]; Jacqueline Walker[1]; Clare Dix[2]; Josephine Previte[3]; Dilara Olgacher[4]; Robyn Littlewood[5]; Jayne Woodside[4]; Helen Truby[1]
[1]School of Human Movement and Nutrition Sciences, The University of Queensland, Brisbane, Australia; [2]School of Health, University of the Sunshine Coast, Brisbane, Australia; [3]UQ Business School, The University of Queensland, Brisbane, Australia; [4]School of Medicine, Dentistry and Biomedical Sciences, Queen's University Belfast, Belfast, United Kingdom; [5]Health and Wellbeing Queensland, Health and Wellbeing Queensland, Brisbane, Australia

BACKGROUND AND OBJECTIVES

Most food and nutrition initiatives are abandoned within two years due to a lack of secure long-term funding. This review explored the business models of food or nutrition-based social enterprises whose mission improved the health or nutrition of communities.

METHODS

For this scoping review, eight databases were searched in July 2024, with 2502 articles retrieved. After applying inclusion and exclusion criteria, 28 studies (20 case studies, 6 evaluations, 1 cross-sectional and 1 quasi-experimental study) were included in a narrative synthesis. The operational status of each social enterprise was cross-checked via Google in October 2024.

RESULTS

Eight business models operating in 13 countries were identified. The business models included social cooperative; employment; targeted customer service; beneficiary service; market intermediary; social partnership; trading business; and social business. The targeted customer service model was the most widely applied. On average, these social enterprises had been in operation for 16.5 years, highlighting that such models that continually deliver on social impact can have longevity.

CONCLUSIONS

Social enterprises that adopt sustainable operational income generating models from their outset, can become self-sustaining, whilst improving food and nutrition-based outcomes for communities. There are various operational models, however different, have proven longevity. These models allow profit and social purpose to co-exist and benefit the communities they serve.

THE INTAKE, SUPPLEMENTATION AND BLOOD CONCENTRATIONS OF CAROTENOIDS IN THE PREVENTION OF CARDIOVASCULAR DISEASES: INSIGHTS FROM AN UMBRELLA META-ANALYSIS

Yanni Zhang[1]; Gao Xinyue[1]; Sui Jing[1]
[1]Research Institute for Environment and Health, Nanjing Univeisity of Information Science and Technology, Nanjing, China

BACKGROUND AND OBJECTIVES

Cardiovascular diseases (CVD) pose a major threat to public health worldwide, while carotenoids are considered beneficial for preventing CVD. There is a need for a systematic and comprehensive study to provide a clearer understanding of the relationship between carotenoids and CVD risk. The aim of the present study was to further conduct an umbrella review to explore the latest evidence of the influence of carotenoids on CVD.

METHODS

The literature published before September 2024 in PubMed, Web of Science, Embase, Cochrane Library and other databases on the effect of carotenoids on CVD was searched. Manual screening, quality assessment, and data extraction of search RESULTS were conducted strictly according to the inclusion and exclusion criteria. Comprehensive Meta Analysis version 3.3 software was used to perform the umbrella meta-analysis.

RESULTS

The odds ratio (OR) between carotenoids and total CVD risk was 0.924 (95% corresponding intervals (CI): 0.878–0.972; $p < 0.001$), indicating a significant negative correlation. Furthermore, our analysis revealed that the protective effect of carotenoids on CVD was significant in coronary heart disease (OR: 0.875; 95% CI: 0.822–0.932; $p < 0.001$), stroke (OR: 0.815; 95% CI: 0.734–0.906; $p < 0.001$), and myocardial infarction and ischemic heart disease (OR: 0.866; 95% CI: 0.727–1.031; $p = 0.105$). However, subgroup analysis of source of carotenoids on various CVD revealed that the carotenoids supplementation significantly increased in the risk of total CVD (OR: 1.061; 95% CI: 1.037–1.086), coronary heart disease (OR: 1.018; 95% CI: 0.982–1.057), stroke (OR: 1.090; 95% CI: 1.010–1.117), and myocardial infarction/ ischemic heart disease (OR: 1.023; 95% CI: 0.949–1.103).

CONCLUSIONS

Our study has investigated the most comprehensive evaluation of the relationship between carotenoids and CVD risk and found that multiple carotenoids were significantly associated with minimizing the risk of CVD.

USING NUTRITION EDUCATION AND SCHOOL GARDEN TO IMPROVE THE DIETS OF CHILDREN AND ADOLESCENTS IN URBAN AND PERI-URBAN AREAS OF SOUTHERN BENIN

Fifali Sam Ulrich Bodjrenou[1, 2]; Ines Mlantahou[2]; Fatoumata Barry[2]; Elie Koukou[1, 2]; Waliou Amoussa Hounkpatin[2]
[1]Food Environment and Consumer Behaviour, Alliance of Bioversity International and Ciat, Cotonou, Benin; [2]Human nutrition and Food sciences, FSA/UAC, Abomey Calavi, Benin

BACKGROUND AND OBJECTIVES

School feeding helps advance children's health and nutrition. This study evaluated the effect of a food and nutrition education (NE) program including school gardens (SG) on schoolchildren knowledge, attitude and practices (KAP) in southern Benin. This investigation supports the National Integrated School Feeding programme implemented since 2017.

METHODS

A cluster randomized trial was implemented with a group of elementary schools as intervention group and another group as control group. After a diagnostic evaluation of the food environment of elementary schools with canteens, a participatory approach was used to design an inclusive intervention combining NE sessions and SG. Innovative tools such as posters and videos were developed and used during weekly NE sessions targeting all school actors: schoolchildren, cooks, food vendors, parents and teachers. NE sessions developped mainly dietary diversity corresponding to the main gap identified during the diagnostic. SG contributed to fruit and vegetable production and school canteens supply as well as learning platforms for schoolchildren. The intervention lasted 1.5 academic year. We evaluated KAP on dietary recommendation among 800 schoolchildren. As practices, we targeted consumption of fruits and vegetables, Dietary diversity and Dietary Species Richness.

RESULTS

After 1.5years of implementation, we observed a significant increased of the overall knowledge of the schoolchildren among definition and roles of food groups as well as attitude among diversified diet in the intervention group compared to the control group. As for practices, 75-86% of schoolchildren from the intervention group reported having a diversified diet after the intervention compared to only 50% in the control group. Percentages of schoolchildren who achieved the minimum dietary diversity had decreased from baseline to endline in the control group ($p=0.011$) whereas remained constant in the intervention group similarly for dietary species richness. In terms of food groups, fruits remained globally less consumed by schoolchildren. However, percentages of chlidren having consumed and the diversity of fruits consumed had significantly increased in the different intervention schools.

CONCLUSIONS

The NE-SG program facilitated gaining of knowledge and positive attitudes as well as improving of practices such as consumption of fruits and diversified/balanced diet. Increasing the duration of the intervention and intensifying the NE are essential to ensuring the sustainability of the changes initiated by this pilot.

DIETARY INDEX FOR GUT MICROBIOTA, PHYSICAL ACTIVITY IN RELATION TO MORTALITY

Junhua Zhu[1]; Yanhua Liu[1]; Bo Yacong[2]; Lyu Quanjun[1]
[1]Department of Nutrition, The first affiliated hospital of zhengzhou university, Zhengzhou, China; [2]School of Public Health, Zhengzhou university, Zhengzhou, China

BACKGROUND AND OBJECTIVES

The gut microbiota is crucial in immune function, metabolism, and neurobehavioral processes. The Dietary Index for Gut Microbiota (DI-GM) has been developed to capture a dietary pattern that reflects the diversity of gut microbiota. However, the relationship between DI-GM and mortality risk and the potential role of physical activity in modifying this relationship have not been explored.

METHODS

We analyzed data from 22,205 eligible adults in the U.S. National Health and Nutrition Examination Survey (NHANES), linked to mortality records from the National Death Index (NDI). DI-GM scores were calculated based on 14 food components associated with gut health. Physical activity levels were assessed using the Global Physical Activity Questionnaire (GPAQ), with total activity calculated in metabolic equivalent (MET) values. Cox proportional hazards regression models were employed to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) to evaluate both the independent and joint associations between DI-GM, physical activity, and mortality.

RESULTS

During a median follow-up of 6.75 years, 1,454 all-cause deaths occurred. Compared to participants in the lowest DI-GM quartile, those in the highest quartile had a lower risk of all-cause mortality (HR = 0.82, 95% CI: 0.70–0.96). Regarding physical activity, middle-intensity and high-intensity physical activity were associated with 10% and 19% reductions in mortality risk, respectively, compared to low-intensity physical activity (HR = 0.90, 95% CI: 0.82–0.98; HR = 0.81, 95% CI: 0.69–0.93). Participants with both the highest DI-GM scores and high-intensity physical activity exhibited a 26% decreased risk of mortality (HR = 0.74, 95% CI: 0.56–0.98) compared to those with the lowest DI-GM quartile and low-intensity physical activity. Additionally, higher DI-GM scores and more intense physical activity were associated with lower risks of heart disease mortality.

CONCLUSIONS

This study demonstrates the independent and joint benefits of a gut microbiota-promoting diet and physical activity in reducing mortality risk. These findings highlight the importance of incorporating both dietary and physical activity interventions in public health strategies aimed at improving longevity.

EFFECT OF SIMPLIFIED APPROACH ON RECOVERY OF CHILDREN 6–59 MONTHS WITH WASTING IN ETHIOPIA: A NON-INFERIORITY, CLUSTER RANDOMIZED CONTROLLED TRIAL

Yetayesh Maru Temesgen[1]; Desalegn Tamiru[2]; Kaleab Baye[3]; Stanley Chitekwe[4]; Hiwot Darsene[5]; Tefera Belachew[2]
[1]Nutrition and Dietetics , Jimma University, Jimma, Ethiopia; [2]Nutrition and Dietetics, Jimma University, Jimma, Ethiopia; [3]Nutrition and food systems division, Research center for Inclusive Development in Africa (RIDA), Addis Ababa, Ethiopia; [4]Nutrition, UNICEF Ethiopia, Addis Ababa, Ethiopia; [5]Nutrition, FMOH, Addis Ababa, Ethiopia

BACKGROUND AND OBJECTIVES

Worldwide, nearly 45 million children under the age of five years were affected by wasting in 2022. Ethiopia has been challenged by disasters increasing the caseload of children with wasting. This study aimed to determine the effect of a simplified approach on recovery of children with severe acute malnutrition as compared to the standard protocol.

METHODS

A cluster randomized, controlled, non-inferiority trial was carried out in three regions of Ethiopia from December 4, 2021, to July 30, 2022. A total of 58 clusters (health posts) were randomized into intervention and control groups. Children with severe acute malnutrition (SAM) in the intervention groups received two sachets of Ready to Use Therapeutic Food (RUTF), whereas children in the control groups received RUTF based on their body weight. Children with moderate acute malnutrition (MAM) received one sachet of RUTF and one sachet of Ready to Use Supplementary Food (RUSF) daily in the intervention and control groups, respectively. Per Protocol and Intention to Treat analysis were used to compare recovery at a non-inferiority margin of 15%.

RESULTS

Data were collected from 55 health posts and 1,032 children. In the PP analysis, the recovery rate of children with wasting among the simplified group (97.8%) was non-inferior to the standard protocol group (97.7%), P= 0.399. The RUTF cost per treatment of child with SAM was 56.55 USD for the standard versus 42.78 USD for the simplified approach.

CONCLUSIONS

The simplified approach is non-inferior to the standard protocol in terms of recovery and has a lower cost of RUTF. Further study is recommended to assess the effectiveness of the simplified approach in emergency contexts.

PERCEPTION AND ACCEPTANCE OF MICRONUTRIENT-FORTIFIED BOUILLON AMONG NON-INDEX HOUSEHOLD MEMBERS OF WOMEN AND CHILDREN IN A RANDOMIZED TRIAL IN NORTHERN GHANA

Felix Kwaku Kyereh[1]; N. Agartha Ohemeng[1]; Reina Engle-Stone[2]; J. Marjorie Haskell[2]; Sika M. Kumordzie[2]; Charles D. Arnold[2]; Jennie N. Davis[2]; Emily R. Becher[2]; Katherine P. Adams[2]; Stephen A. Vosti[3]; K Ryan Wessells[2]; Seth Adu-Afarwuah[1]
[1]Department of Nutrition and Food Science, University of Ghana, Legon, Accra, Ghana; [2]Department of Nutrition, Institute for Global Nutrition, University of California, Davis, California United States of America; [3]Institute for Global Nutrition, Department of Agricultural and Resource Economics, University of California, Davis, California United States of America

BACKGROUND AND OBJECTIVES

Bouillon cube fortification could serve as a scalable, culturally appropriate strategy to address micronutrient deficiencies (MNDs) in West Africa. Household members' perceptions and acceptance of bouillon cubes are critical to any such strategy.This study aimed to examine changes in perception and acceptance of study-supplied bouillon cubes over time and explore the drivers and barriers influencing these changes among non-index household members (NIHM) in an intervention trial in Northern Ghana.

METHODS

This longitudinal mixed-METHODS study was nested in a doubly-masked clinical trial in the Kumbungu and Tolon districts in northern Ghana, in which households of index participants received rations of multiple micronutrient-fortified bouillon cubes (vitamins A and B12, folic acid, iron, zinc and iodine) vs. control bouillon cubes (iodine) for 9 months. One NIHM (≥15 years) per household was randomly selected for the study. During the first two months (early intervention, n = 731) and the final two months (late intervention, n = 796) of the intervention, quantitative data were collected using a 29-item questionnaire, most of which elicited responses on a 5-point Likert-scale. A total of 18 items (8 for perception, 10 for acceptance) were validated (Factor analysis) and used to calculate composite scores (normalized sums of weighted items) for perception and acceptance at both time points, with higher scores indicating greater perception or acceptance. Bayesian linear mixed-effects models were used to assess changes in perception and acceptance. Focus group discussions (n = 24) were conducted at the intervention midpoint and analyzed using Latent Dirichlet Allocation to explore cultural, sensory, and health influences.

RESULTS

Mean age was 40 years, with 59% being females. Perception scores increased significantly over time (3.4 ± 1.1 to 4.1 ± 0.6; Mean Difference (MD) = 0.70, 95% CI: [0.63, 0.86]), indicating a positive change. In contrast, acceptance scores remained consistently high throughout the study (4.59 ± 0.38 to 4.58 ± 0.35; MD = -0.01, 95% CI: [-0.06, -0.04]), with no differences observed between intervention groups. Key drivers of bouillon acceptance included perceived health benefits, sensory appeal, and cultural compatibility with traditional meals; barriers to acceptance included misconceptions about bouillon cubes causing long-term infertility in males and occasional changes in food color.

CONCLUSIONS

The study-supplied bouillon cubes were highly accepted, indicating that bouillon fortification has the potential to combat MNDs. Targeted education is needed to address misconceptions

ASSOCIATION OF DIETARY PATTERNS WITH CENTRAL OBESITY AMONG ADULTS: THE CHINA NUTRITION AND HEALTH SURVEILLANCE 2015–2017

Dongmei Yu[1]; Nan Jing[1]; Zhao Liyun[1]
[1]Department of Nutrition Epidemiology, National Institute for Nutrition and Health, Chinese Center for Disease Control and Prevention, Beijing, China

BACKGROUND AND OBJECTIVES

With the development of the economy and the change in dietary structure, the prevalence of central obesity has changed significantly in the world. The dietary pattern can reflect the comprehensive effects of food and nutrients, and effectively study the relationship between diet and human health. It is necessary to study the association between dietary patterns and central obesity. The purpose of this study was to extract the dietary patterns among Chinese adults aged 18 and above and to explore its relationship with central obesity.

METHODS

The data was from the China Nutrition and Health Surveillance (2015-2017), a national representative survey, and the sample participants were obtained by stratified, multi-stage, and random sampling. A total of 61,222 adults aged 18 or older from mainland China were included in this study. According to The Criteria of Weight for Adults promulgated by China（WS/T 428—2013, central obesity of Chinese adults can be judged based on the waist circumference. The prevalence of central obesity was calculated using the complex sampling weighting method. Dietary patterns were extracted by exploratory factor analysis. The relationship between Dietary patterns and central obesity and its components was analyzed by multivariate logistic regression and the models were adjusted by potential confounding covariates.

RESULTS

There were four dietary patterns were extracted, namely the " classical pattern", "vegetarian pattern", "sugar-oil pattern", and "western staple food pattern". After adjusting for all confounding factors, adults in the Q4 group of the classical pattern were less likely to have central obesity than those in the Q1 group (Q4 Vs. Q1, OR = 0.865,95 % CI = 0.802-0.932, *P*-trend < 0.0001). There was no significant association between the vegetarian pattern and central obesity (Q4 Vs. Q1, OR = 1.042,95 % CI = 0.973-1.115, *P*-trend = 0.0959). The sugar-oil pattern increased the risk of central obesity (Q4 Vs.Q1, OR = 1.168,95 % CI = 1.091-1.250, *P*-trend < 0.0001). The OR values of central obesity in the Q2 and Q3 groups of western staple food patterns was 1.077 and 1.103, respectively, compared with the Q1 group.

CONCLUSIONS

The findings suggest that the adults who stick to the classical pattern have a lower risk of central obesity. The current study provides nationally representative evidence for controlling central obesity in China.

FORTIFIED MAIZE LUNCHES ON TEA ESTATES INCREASE MICRONUTRIENT INTAKE AMONG WORKERS IN MALAWI

Shantanu Das[1]; Kris Woltering[2]; Fred Wangila[3]; Phillip Makhumula,[4]; Christina Nyhus Dhillon[5]
[1]MEL, Economics, and Public Finance, IPE Global, Delhi, India; [2]Knowledge Leadership, Global Alliance For Improved Nutrition, Utrecht, Netherlands; [3]Knowledge Leadership, Global Alliance for Improved Nutrition, Nairobi, Kenya; [4]Managing Director, LifeSciences Consulting, Lilongwe, Malawi; [5]Knowledge Leadership, Global Alliance for Improved Nutrition, Geneva, Switzerland

BACKGROUND AND OBJECTIVES

Evidence on the impact of workforce nutrition programmes on dietary improvements for low wage workers in low- and middle-income countries is limited. Malawi's tea sector, employing around 50,000 workers and sourcing from 17,000 farmers, served as the setting for this study. The aim was to assess whether a workforce nutrition programme in selected Malawian tea estates was effective in improving diet quality among tea estate workers through the provision of fortified maize lunches.

METHODS

The implementation activities for estate workers focused on increasing access to fortified foods by supporting estate managers with procuring and installing dossifiers, providing linkages to premix suppliers, training of millers, and providing external quality control checks to confirm compliance with the Malawi standard for fortified maize flour. Monitoring data on the compliance of maize fortification in the estates were collected. A pre-post repeat cross-sectional survey was conducted to collect quantitative and qualitative data.

RESULTS

Nearly all estate workers indicated they received a (daily) lunch at their estate, although only 25% of the workers were aware of their lunch being fortified at endline. Monitoring data showed that two estates had installed a dossifier before the start of the project but were not fortifying, and 12 estates installed one during the project. At the end of the project, 14 estates were providing adequately fortified lunches to their workers leading to up to a maximum of 23,009 workers during high season consuming fortified maize lunches approximately five to six days a week. All estates that installed dossifiers performed satisfactorily with acceptable nutrient contents by the end of the project. Based on 100g servings, the fortified maize flour provides males >50% of the Estimated Average Requirements (EAR) for folate, iron, vitamin B1, vitamin B12, and zinc and females >50% EAR for folate, vitamin B12, vitamin B1, and zinc. Unfortified maize flour does not provide >50% EAR for any of the analysed micronutrients.

CONCLUSIONS

The diets of estate workers improved in quality through increased micronutrient adequacy. Fortification is one of the most effective nutrition interventions and as the approach is very scalable it has the potential to extend to all tea workers (and beyond) in Malawi. A more effective approach to increasing awareness of fortification could be considered. Sourcing reliable pre-mix was a barrier to fortification and was mitigated by linking the estates to suppliers through the GAIN premix facility.

HEALTHFUL AND UNHEALTHFUL PLANT-BASED DIET DURING PREGNANCY AND CHILD NEURODEVELOPMENT UP TO AGE 6

Yvan Njongfang Mbakop[1]; Rosalie Delvert[2]; Emmanuelle Kesse-Guyot[3]; Benjamin Allès[3]; Julia Baudry[3]; Barbara Heude[1]; Marie-Aline Charles[1]; Blandine De Lauzon-Guillain[1]
[1]Université Paris Cité and Université Sorbonne Paris Nord, Inserm, INRAE, Centre for Research in Epidemiology and StatisticS (CRESS), F-75004, Paris, France; [2]Université Paris-Saclay, UVSQ, Université Paris-Sud, Inserm, Equipe d'Epidémiologie Respiratoire Intégrative, CESP, Villejuif, France; [3]Université Sorbonne Paris Nord, Inserm, CNAM, INRAE, Equipe de Recherche en Epidémiologie Nutritionnelle (EREN), Bobigny, France

BACKGROUND AND OBJECTIVES

Reducing the consumption of animal foods is a major environmental, public health and economic challenge (1). This study aimed to investigate the association between maternal plant-based diet during pregnancy and child neurodevelopment up to age 6.

METHODS

The study included 11,269 children from a French national birth cohort. Maternal diet during the last trimester of pregnancy was assessed postpartum using a validated food frequency questionnaire. The plant-based diet was measured with the Plant-based Diet Index (PDI) and its sub-scores: the healthful PDI (hPDI) for nutritionally high-quality plant-based diets and the unhealthful PDI (uPDI) for low-quality plant-based diets. Child neurodevelopment was assessed through several measures: parents evaluated overall development (Child Development Inventory, CDI) at 1, 3.5, and 5.5 years and language development (MacArthur-Bates Inventory) at 2 years; investigators measured non-verbal reasoning (Picture Similarities test from the British Ability Scales) at 3 years; and teachers assessed school achievements in mathematics and reading at ages 4 and 6. Associations between maternal diet and child neurodevelopment were analyzed using regression models adjusted for confounding factors such as socioeconomic status and parental cognitive background, but also for newborn and infant feeding characteristics.

RESULTS

The PDI and the hPDI were positively associated with the global developmental score at age 3.5 (β [95%CI] = 0.22 [0.03 ; 0.41] and 0.20 [0.04 ; 0.35] for 10-point increases in PDI and hPDI, respectively). Similarly, they were positively associated with mathematics scores (β [95%CI] = 0.03 [0.01 ; 0.06] and 0.04 [0.01 ; 0.06]) and reading scores (β [95%CI] = 0.04 [0.01 ; 0.07] and 0.05 [0.02 ; 0.07]) at age 6. Conversely, the uPDI was negatively associated with all neurodevelopmental scores up to age 6.

CONCLUSIONS

The findings suggest that higher scores on the plant-based diet index are associated with a better child neurodevelopment. However, they also highlight the importance of considering the dietary quality of plant-based diets, as lower-quality plant-based diets was linked to poorer neurodevelopment scores. These findings need to be confirmed in studies with higher number of vegetarian and vegan women.

MICRONUTRIENT STATUS OF ELDERLY WITH HIGH RISK CAID SCORE FOR DEMENTIA

G Bhanuprakash Reddy[1]; Vineela Vepakomma[1]; Kiran K Angadi[1]; Francesca Mangialasche[2]; Miia Kivipelto[2]; Vidyani Suryadevara[3]
[1]Biochemistry, ICMR-National Institute of Nutrition, Hyderabad, India; [2]Neurology, Karolinska Institute, Stockholm, Sweden; [3]Radiology, Stanford Center for Innovation in Global Health, Stanford, United States of America

BACKGROUND AND OBJECTIVES
Population ageing due to increased life expectancy is associated with the burden of several age-related disorders, particularly cognitive impairment and dementia. Dementia is a multifactorial process influenced by genetic and environmental conditions, including nutrition, and RESULTS from lifelong interactions between protective and risk factors. If the lifestyle-related risk factors are controlled or modified through appropriate interventions, these can potentially reduce the risk of dementia substantially. The Cardiovascular Risk Factors, Aging, and Incidence of Dementia (CAIDE) risk score is a validated tool to predict the risk of dementia. Hence, in this study, we have evaluated the status of micronutrients among middle-aged and older adults with high-risk CAIDE scores in the Indian context.
METHODS

This community-based cross-sectional study involved 471 middle-aged and older adults residing in Telangana, a southern state in India. Information on variables required to estimate CAIDE score: age, gender, level of education, BMI, physical activity, systolic blood pressure and total cholesterol was collected and measured. In addition, blood levels of important vitamins were estimated by HPLC and immunoanalyzer.

RESULTS

Among the study participants, 40% of subjects had a predicted risk of dementia indicated by a CAIDE score of more than ≥9.0 (n=189). The proportion of participants with a risk (≥9.0) for dementia was higher in rural areas (56%) compared to urban areas (28%). The overall prevalence of deficiency of vitamin B2 was strikingly high (63%), followed by vitamins B12 (54%), D (50%), B6 (34%), and B9 (15%) in the total cohort. Further, the prevalence of deficiency of vitamins D (57%), B2 (72%), B6 (44%), B9 (16%), and B12 (65%) was greater in the high-risk group compared to low-risk group D (42%), B2 (60), B6 (27%), B9 (13%), and B12 (45%), respectively.

CONCLUSIONS

The study demonstrated a higher prevalence of multiple subclinical vitamin deficiencies in people with a risk for dementia when compared to those with no risk. Further, this study suggests the necessity for nationally representative data to direct the appropriate nutritional intervention for middle-aged and older adults with a risk of dementia to mitigate the risk of onset of dementia.

VITAMIN A INTAKE AND STATUS AND ASSOCIATIONS WITH IRON STATUS, ANEMIA, AND BIRTH OUTCOMES OF PREGNANT WOMEN IN THE FREE STATE PROVINCE, SOUTH AFRICA

Janet Carboo[1]; Jennifer Ngounda[1]; Jeannine Baumgartner[2]; Liska Robb[1]; Marizeth Jordaan[1]; Corinna Walsh[1]
[1]Nutrition and Dietetics, University of the Free State, Bloemfontein, South Africa; [2]Department of Nutritional Sciences, King's College London, London, United Kingdom

BACKGROUND AND OBJECTIVES

Vitamin A deficiency (VAD) is a public health challenge among pregnant women and has been linked to maternal anemia and adverse birth outcomes, such as preterm delivery, intrauterine growth restriction, and low birth weight (1-4). In the Free State Province of South Africa, there is limited information on the vitamin A status of pregnant women and its link with birth outcomes. Hence, this study aimed to investigate the vitamin A intake and status of pregnant women in the Free State Province of South Africa, and the associations of vitamin A status with anemia, iron status, and birth outcomes.

METHODS

Cross-sectionally, venous blood was taken from 427 pregnant women to measure biomarkers of vitamin A status (retinol binding protein 4 (RBP4)), iron status (ferritin, soluble transferrin receptor), and anemia (hemoglobin (Hb)). Sociodemographic information, HIV exposure, birth outcomes (birth weight and gestational age at birth), and dietary vitamin A intake data were obtained using a questionnaire in a structured interview

RESULTS

Median dietary intake of vitamin A was 1007 µg RAE/d, with 19% of participants having an intake below the estimated average requirement of 550 µg/d. Median RBP4 concentration was 1.66 (0.90) µmol/L. The prevalence of insufficient and deficient vitamin A levels was 8.7% and 0.9%, respectively. Hb and ferritin concentrations were higher among participants with adequate vitamin A compared to those with insufficient or deficient vitamin A levels (11.2±1.46g/dL, vs 10.7±1.69g/dL, p=0.033) and (23.2 µg/L, vs 18.5 µg/L, p=0.022), respectively. RBP4 was positively associated with Hb (β=0.360, 95%CI: 0.181-0.539, p <0.001) and ferritin (β=0.316, 95%CI: 0.096-0.536, p=0.005). No significant association between RBP4 and birth weight as well as preterm birth was observed.

CONCLUSIONS

The low prevalence of VAD in the study population is of no public health significance. Nonetheless, the positive association between vitamin A and Hb as well as ferritin concentrations highlights the importance of adequate vitamin A status in preventing maternal anemia in pregnancy.

THE IMPACT OF MASLD ON BONE HEALTH IN ADULTS AGED 50 AND OVER: A MONOCENTRIC RETROSPECTIVE STUDY

Dr. Zubeda Tumbi[1]; Mehzamah Tumbi[2]; Vaibhavi Tailor[2]; Gunjan Temkar[3]
[1]Dietetics Department- Cheif Clinical Nutritionist at Healthwatch Nutrition Clinic, Founder, Owner Healthwatch Nutrition Clinic, Mumbai, India; [2]Dietetics Department- Assistant Dietitian at Healthwatch Nutrition Clinic, Founder, Owner Healthwatch Nutrition Clinic, Mumbai, India; [3]Dietetics Department- Documentation Officer at Healthwatch Nutrition Clinic, Founder, Owner Healthwatch Nutrition Clinic, Mumbai, India

BACKGROUND AND OBJECTIVES

The global rise in the prevalence of obesity with metabolic dysfunction and fatty infiltration in the liver(MASLD) linked to poor nutrition and irregular lifestyle is of concern. The current study aims to evaluate the incidence of obesity, nutritional deficits, and their correlation to MASLD and bone health.

METHODS

A post-observational clinical study (n=306) was conducted on urban Indians aged 50-75 years (213 females. 93 males). Documented data: Anthropometric, Biochemical, Ultrasound, Bioelectrical impedance analysis(BIA), and DEXA scan(bone density) were analyzed using ANOVA and Pearson's correlation ($p<0.05$).

RESULTS

A higher incidence of central obesity (WHtR) was noted in 87.6 % of the study group with BMI indicating obesity in 93% of females vs 87.1% of males. Incidence of metabolic dysfunction was higher in females with 36.6% having diabetes compared to 28% males; pre-DM was seen in 40% and 47% respectively. Mean HbA1C values were above 6.5 in both genders. High TG levels in males 51.6% vs 46.5% in females; low HDL-C in 76.5% of females vs 51.6% in males indicated dyslipidemia. Elevated SBP and DBP were noted in 24.8% of the group. WHR showed a strong positive correlation with all MetS indicators; HDL-C exhibited a strong inverse correlation. The incidence of MASLD with ≥3 comorbidities was higher in females 68.1%vs57% in males. Nutritional deficiencies of micronutrients were noted especially with Vitamin B12 deficiency (≤197pg/mL) in 20% and nutritional Anemia seen in 32% of females vs 35% of males. WHtR suggesting central obesity showed an inverse relation with serum Calcium levels. Severe vitamin D deficiency was seen in 61% of females and 74% of males. Incidence of Osteopenia was ≥ 52% in both genders; whereas Osteoporosis was higher in females 28% vs 17% in males. Dexa scan of females with MASLD and Osteopenia showed low bone mass in the spine(37%)and femur (31%). High fracture risk was seen in females with MASLD and Osteoporosis at the spine(24%) and femur(18%).

CONCLUSIONS

The aging urban population in India is increasingly affected by obesity, metabolic disorders, poor blood sugar control, and bone degeneration due to unhealthy diets and sedentary habits. Raising awareness about the importance of healthy eating is crucial, as well as focusing on adequate protein and micronutrient intake, especially Vitamin D, and the need for physical activity. This approach can help prevent obesity, metabolic degeneration and improve bone health ensuring better health outcomes for individuals over 50.

[1]Department Nutrition, Faculty of Public Health, Airlangga University - Campus MERR (C), Surabaya, Indonesia; [2]Nutrition Department, Faculty of Public Health, Airlangga University - Campus MERR (C), Surabaya, Indonesia; [3]Faculty of Medicine, Universitas Airlangga Dharmahusada (A) Campus, Surabaya, Indonesia; [4]Department of Epidemiology, Faculty of Public Health, Airlangga University - Campus MERR (C), Surabaya, Indonesia; [5]Health Promotion and Behavior Science, Faculty of Public Health, Airlangga University - Campus MERR (C), Surabaya, Indonesia; [6]Nutrition, Faculty of Public Health, Universitas Indonesia, Jakarta, Indonesia; [7]International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, United States of America

BACKGROUND AND OBJECTIVES

The biggest problem of existing iron folic acid (IFA) program in Indonesia is the adherence. Meanwhile WHO recommend the use of Multiple Micronutrients Supplement (MMS) for pregnant women. An implementation research on the use of MMS for pregnant women is conducting in 25 districts in Indonesia to find out the best strategy on program implementation. This study is a part of the on-going research, focusing to analyse the association of maternal characteristic and behaviour with the adherence of MMS consumption.

METHODS

A prospective study was conducted in 2 districts area, in East Java Province and Central Kalimantan Province. Three Public Health Centers (PHC) randomly selected in each district as study area. Subject of study were pregnant (PW) women who received MMS starting at the first trimester (< 12 weeks). The sample size was 575, screened from 1073 pregnant women enrolled in PHC. The outcome variable was the adherence of MMS consumption, assessed by calculating number of tablets consumed during first 3 months.The cut off point of 70% of 90 tablets was used, consider the emesis in the first trimester. Maternal characteristic (age, education, working status, gestational age, parity) and maternal behaviour (willingness to consume supplement, believe the MMS safety, believe the MMS benefit, and antenatal care visit were observed. Descriptive analysed was carried out to perform the data.

RESULTS

PW with good adherence (consume at least 63 tablets) were 53,2% (n=306), and 46,8% (n=269) consumed < 63 tablets (less adherence). Majority (59%) of pregnant women were age 20-29 years. Proportion of PW with good adherence is higher in the younger age (< 20 years) and older age (>35 years), 62,7% and 63,2% respectively. Low educated PW tend to have good adherence (57,9%) compare to the higher educated PW (48,1%). There are no different adherence between working status, as well as gestational age. Proportion of women with good adherence was higher among PW with parity of 3 (65,2%) compare to less parity (53%). PW with good will tend to consumed more than 63 tablets (53,4%), meanwhile PW with low willingness only 25% consumed MMS more than 63 tablets. All PW were believe that MMS is safe and more benefit to be consumed.

CONCLUSIONS

The adherence of MMS consumption associated with maternal age, parity and education level, but not working status and gestational age. Low education level and high parity may have better willingness to consumed MMS, and tend to have good adherence

THE ROLE OF BEEF FOR THE AFFORDABLE AND ADEQUATE PROVISION OF BIOAVAILABLE NUTRIENTS IN SUSTAINABLE DIETS THROUGHOUT THE LIFESPAN

Sylvia Chungchunlam[1]; Paul Moughan[1]
[1]Riddet Institute, Massey University, Palmerston North 4442, New Zealand

BACKGROUND AND OBJECTIVES

A promulgated global shift towards reduced animal-sourced food consumption is largely in response to the perception that animal food production is environmentally unsustainable, and that animal-sourced foods can be seamlessly replaced as a nutrient source by plant-based foods (1,2). However, these assumptions seldom consider the higher quantity and greater quality (bioavailability) of essential nutrients that are naturally present and economically viable when foods are sourced from animals compared to plants (3,4). With beef being a rich natural source of higher quality protein and bioavailable micronutrients (5,6), the inclusion levels of beef in least-cost nutritionally adequate dietary patterns were assessed throughout the life stages.

METHODS

Diet optimization models were developed to formulate least-cost dietary patterns that would meet daily energy and nutrient requirements for different age-sex population groups in the United States (US). The Linear Programming approach, with the objective to minimize daily diet cost, simultaneously take into account commonly available foods (7), food serving sizes (8), energy and nutrient requirements (9), and food prices (10). Bioavailability estimates for protein, amino acids, vitamins, iron, and zinc, were applied to their contents in foods, to consider nutrient bioavailability and ascertain whether beef was included in modelled least-cost nutritionally adequate mixed diets.

RESULTS

Animal-sourced foods, such as beef liver, milk, eggs, and fish, were needed in least-cost nutrient adequate dietary formulations, when nutrient contents in foods were given on a total basis. When dietary nutrient contents were expressed in bioavailable units, more animal-derived foods, particularly beef meat for the lowest cost provision of bioavailable protein, bioavailable vitamin A, and bioavailable zinc, were included in the modelled least-cost nutrient adequate diets. When nutrient bioavailability was taken into consideration, daily diet cost increased by 24-89 %. For example, for an average US adult, least-cost nutrient adequate diet on a total dietary nutrient basis, had a daily retail cost of US $ 1.14, compared to US $ 5.94 when the least-cost diet used bioavailable nutrient contents.

CONCLUSIONS

Beef was favorably included in adequately nutritious mixed diets at the lowest retail cost for the US population, due to their high nutrient density and bioavailability, and cost effectiveness. It is crucial to account for nutrient bioavailability to achieve nutrient adequacy, food security, and diet affordability.

EATING JETLAG AND RISK OF CARDIOVASCULAR DISEASE: PROSPECTIVE STUDY OF A LARGE FRENCH COHORT

Xuân Le Folcalvez[1]; Elena Obeid[1]; Anna Palomar-Cros[2]; Alice Bellicha[1]; Sandrine Péneau[1]; Mélanie Deschasaux-Tanguy[1]; Mathilde Touvier[1]; Valentina Andreeva[1]; David Jacobi[3]; Bernard Srour[1]
[1]Nutritional Epidemiology Research Team (EREN), Center for Research In Epidemiology And Statistics (CRESS - Inserm 1153/Inra 1125/Cnam/UPC/USPN), Paris, France; [2]ISGlobal, ISGlobal, Barcelona, Spain; [3]L'Institut du Thorax, Inserm UMR-S1087, CNRS, Univ Nantes, Nantes, France

BACKGROUND AND OBJECTIVES

Social jetlag corresponds to the misalignment between biological circadian rhythms and the social rhythm imposed by society, resulting in discrepant activity/sleep schedules during work and free days. It has been associated with worsened biological parameters such as BMI or glycemic control. Eating jetlag is a related yet emerging concept defined as the difference of meal timing between free and work days. However, it has been little explored. This study aims to evaluate the association between eating jetlag and the risk of cardiovascular disease (CVD).

METHODS

Dietary, anthropometric, socio-demographic and health data of 104,837 participants (79% women, mean age=42.7 years (14.6 SD)) were collected from the NutriNet-Santé cohort cohort. Eating jetlag was calculated using time of first and last caloric intakes on weekdays and weekends, from repeated 24h-dietary records, averaged during the 2 first years of follow-up. It was assessed as a continuous variable or as 3 categories: “Advance”, “Maintenance”, “Delay”, compared to work days. CVD was self-reported and validated against medical records. The associations between eating jetlag and CVD risk were assessed through adjusted Cox models.

RESULTS

During a median follow-up time of 8.1 years, 2,368 CVD cases were diagnosed. Eating jetlag showed a U-shaped association with CVD risk (HR Advance vs. Maintenance=1.05 (95% CI: 0.87-1.26); HR Delay vs. Maintenance=1.08 (0.96-1.21)). When the absolute value of eating jetlag was considered, there was a linear association with CVD risk (HR per 1-hour increase=1.05 (1.00-1.12)). These linear trends were confirmed in categorial models (Low: ≤1h; Moderate: 1h< to ≤2h; High: >2h): HR Moderate vs. Low=1.05 (0.94-1.18), and HR High vs. Low=1.13 (0.94-1.37); however, statistical significance was not reached.

CONCLUSIONS

Our RESULTS suggest a potential role for meal timing regularity between free and work days in CVD etiology. They need to be replicated in other studies and mechanisms are yet to be fully understood.

EVALUATING THE IMPACT OF FRONT-OF-PACKAGE NUTRITION LABELS ON CONSUMER'S FOOD CHOICES AND PERCEPTION IN A TIME-PRESSURED ENVIRONMENT

Edvina Hafner[1, 2]; Hristo Hristov[1, 3]; Klaus G Grunert[4]; Igor Pravst[1, 5, 2]
[1]Public Health, Institute for Nutrition, Ljubljana, Slovenia; [2]Nutrition, Biotechnical Faculty, University of Ljubljana, Ljubljana, Slovenia; [3]Public health, National Institute of Public Health, Ljubljana, Slovenia; [4]Department of Management, University of Aarhus, Aarhus, Denmark; [5]Research, VIST-Faculty of Applied Sciences, Ljubljana, Slovenia

BACKGROUND AND OBJECTIVES

Front-of-package nutrition labelling (FOPNL) serves as a public health tool to guide consumers quickly toward healthier food choices. Recognizing its potential, the EC aimed to introduce a harmonized FOPNL but faced disagreements preventing its implementation. Among the proposed systems, the French Nutri-Score (NS) faced some opposition, prompting Italy to propose the NutrInform Battery (NI), while the Multiple Traffic Lights (MTL) emerged as a middle-ground solution. This study investigates the impact of these FOPNLs on food choices compared to the standard nutrition facts table (NFT) under time pressure. Additionally, it explores familiarity, understanding, and subjective preferences of FOPNLs in Germany, with implemented NS, and Slovenia, with no FOPNL in place.

METHODS

An online choice experiment with a between-group design evaluated consumers food choices based on three product attributes: healthiness level indicated by FOPNL (3 levels), presence of the EU organic logo, and price (3 levels). Participants from Germany (n=820) and Slovenia (n=821) were randomized into four groups per country, each exposed to a different FOPNL format: NS, NI, MTL, or NFT. Under time pressure (20s per choice), participants made 10 choices, selecting between breakfast cereals or yogurts within each decision. The study included ranking tasks to assess FOPNL understanding, along with questions on preferences and familiarity. Choice data were analyzed using Bayesian estimation.

RESULTS

FOPNLs improved participants food choices, with notable differences between countries. MTL was most effective in Slovenia, whereas NS performed best in Germany. These differences were linked to familiarity—NS was most recognized in Germany (95%) and MTL in Slovenia (53%). However, understanding played an even greater role. Not understanding FOPNLs resulted in worse food choices compared to not understanding the NFT. Participants in both countries subjectively preferred MTL, while NS had the highest understanding among FOPNLs. All FOPNLs outperformed NFT in objective understanding.

CONCLUSIONS

This study offers key insights into FOPNL research, supporting discussions on implementing a mandatory system across Europe. The findings underline the importance of familiarity and understanding in FOPNL effectiveness and their consideration in policy design. FOPNLs demonstrate the potential to improve food choices compared to NFT, provided consumers understand and recognize them, highlighting the need for education and awareness campaigns to enhance their impact.

ASSOCIATION BETWEEN WHOLE GRAIN CONSUMPTION BEHAVIORS AND ITS DIETARY BELIEFS IN TAIWAN

Sin Tian Du[1]; Yeh Chao-Yu[1]; Chen Long-Sheng[1]
[1]Surveillance, Research and Health Education, Health Promotion Administration, Ministry of Health and Welfare, Taipei, Taiwan

BACKGROUND AND OBJECTIVES

Whole-grain (WG) foods are rich in essential nutrients that promote health. Numerous studies have demonstrated that increased WG consumption is strongly linked to a significant reduction in the risk of various non-communicable diseases and supports weight loss. Given the health benefits of WG consumption and supporting evidence, Taiwan has actively promoted WGs and unrefined cereals, recommending that these foods make up at least one-third of daily staple food intake. However, as WGs are not a traditional part of Taiwanese dietary culture, this presents challenges for policy implementation. Few studies have explored the relationship between individuals' WG consumption behaviors and dietary beliefs. This study aims to examine this connection using data from the Nutrition and Health Survey in Taiwan (NAHSIT).

METHODS

This study analyzed data from the "NAHSIT" (2017–2020), involving 4,228 participants (aged 16–64) with complete responses on WG dietary beliefs. Chi-square tests and logistic regression were used to examine participant characteristics. Factor analysis was conducted to summarize the opinions and experiences of the population regarding WG foods. The factor scores were categorized into tertiles, and logistic regression was performed to identify factors associated with self-reported adherence to the recommended WG intake.

RESULTS

Only 5.43% of individuals in Taiwan self-reported meeting the recommended daily intake of WG foods. Individuals with positive beliefs were 2.05 times more likely to meet the recommended WG intake (exhibiting a dose-response effect), with key factors including "substituting refined grains with WGs for better nutritional balance" and "feeling more comfortable after consuming WGs". Conversely, those with lower agreement to negative beliefs were more likely to meet the recommendations (also showing a dose-response effect), with influential factors being "poor taste of WGs", "infrequent preparation at home", and "difficulty increasing WG intake".

CONCLUSIONS

In Taiwan, few people meet the recommended daily WG intake. Beliefs, along with modifiable factors like accessibility, availability, taste, and awareness, play a key role. Supporting WG consumption through environmental changes can improve dietary habits and boost intake.

OAP 62 - PUBLIC HEALTH AND NUTRITION THROUGHOUT LIFE CYCLE

OAP62_01

RELIABILITY OF A 29-FOOD GROUP PAST DAY DIETARY SCREENER

Stefanie Hinkle[1]; Charlene Compher[2]; Jasmine Kaidbey,[1]; Kyle Busse[1]; Yajnaseni Chakraborti[1]; Ryan Quinn,[2]; Gary Wu,[3]; Sophia Hua,[4]
[1]Department of Biostatistics, Epidemiology and Informatics, University of Pennsylvania, Philadelphia, United States of America; [2]School of Nursing, University of Pennsylvania, Philadelphia, United States of America; [3]Department of Gastroenterology, University of Pennsylvania, Philadelphia, United States of America; [4]Department of Medical Ethics and Health Policy, University of Pennsylvania, Philadelphia, United States of America

BACKGROUND AND OBJECTIVES

The [RETRACTED] Healthy Diet (PHD) survey is a user-friendly, dietary screener of past day consumption of 29 major food groups that has been shown to take less than 5 minutes to complete. The survey was previously validated using same-day dietary information from the Automated Self-Administered 24-hour recall (ASA24) with a mean kappa of 0.44 and 15/29 items exhibiting moderate to strong agreement with the ASA24. The objective of this study was to assess the within-person reproducibility of the PHD survey across 1-3 weeks.

METHODS

The Community Health, Access to Nutrition, and Grocery Experiences (CHANGE) Study enrolled 184 individuals from a low-income, low-food access neighborhood. At enrollment and at follow-up 7-21 days later, individuals reported the number of times (ranging from 0 to +5) each food group was consumed on the prior day using the PHD survey. For each of the 29 food groups, we estimated agreement between enrollment and follow-up using weighted kappa statistics. We summed food groups according to major dietary components (i.e., fruits and vegetables, dairy, animal protein, plant protein, whole grains, and refined grains) and calculated interclass correlation coefficients (ICC) with 95% confidence intervals across timepoints. We also examined stratified ICCs for reporting of fruit and vegetables by demographic characteristics.

RESULTS

Among 117 (63.6%) individuals with both baseline and follow-up surveys, the mean age was 49.9 years (SD 14.7), 87% were non-Hispanic Black, 59.0% were women, and 61.5% were enrolled in the US Supplemental Nutrition Assistance Program (SNAP). There was only slight agreement (weighted kappa ≤0.2) between baseline and follow up for 21 of the food groups; fair agreement (weighted kappa 0.21–0.40) for 9 food groups; and moderate agreement (weighted kappa >0.4) for 1 food group (alcoholic drinks). The ICCs for the summed major dietary components ranged from 0.14 for refined grains to 0.40 for fruit and vegetables. ICCs for fruit and vegetables varied slightly across some characteristics such as gender (men ICC=.29 [.01, .52]; women ICC = 0.42 [0.21, 0.59]) and employment (employed ICC 0.47 [0.20, 0.67]; unemployed ICC=.16 [-.10, 0.40]; retired ICC=0.58 [0.19, 0.81]).

CONCLUSIONS

These findings indicate fair to moderate agreement in some food groups between repeated instances of the PHD diet screener. More research is needed to understand how to optimize the reliability of the survey. These estimates of reliability may be used with regression calibration to correct single-days estimates for this brief, acceptable dietary screener.

OAP62_02

PRENATAL IRON SUPPLEMENTATION AND CHILDHOOD UNDERNUTRITION: EVIDENCE FROM SUB-SAHARAN AFRICA

Yibeltal Bekele[1, 2]; Mehak Batra[1]; Bircan Erbas[1]
[1]School of Psychology and Public Health, La Trobe University, Mel, Australia; [2]School of Public Health, Bahir Dar University, Bahir, Ethiopia

BACKGROUND AND OBJECTIVES

Childhood undernutrition remains a major public health challenge in low-income countries, despite global efforts, including nutrition programs and policy interventions (1, 2). This study assesses whether prenatal iron supplementation impacts childhood undernutrition, focusing on stunting and underweight.

METHODS

Demographic Health Survey data from 26 sub-Saharan countries (n=157,767 under-five children) were analysed. Primary outcomes were stunting and underweight, while the exposures included ever iron supplementation during pregnancy and duration (none, <90 days, or ≥90 days). A generalised linear mixed-effects model was used to assess associations, with stratification by maternal education and family income. Effect sizes were reported as odds ratios (ORs) with 95% confidence intervals (CI), and p-value ≤0.05 denoting significance.

RESULTS

In sub-Saharan Africa stunting, and underweight prevalence were 29.4%, and 15.39%, respectively. Lack of prenatal iron supplementation increased the odds of stunting by 29% (aOR = 1.29, 95% CI: 1.22, 1.37) and underweight by 26% (aOR = 1.26, 95% CI: 1.18, 1.34). A trend was observed with supplementation duration: <90 days reduced stunting by 17% (aOR = 0.83, 95% CI: 0.78, 0.88) and underweight by 16% (aOR = 0.84, 95% CI: 0.78, 0.90), while ≥90 days reduced stunting by 30% (aOR = 0.70, 95% CI: 0.66, 0.74) and underweight by 25% (aOR = 0.75, 95% CI: 0.69, 0.80). Stratified analysis showed that iron supplementation significantly reduced the odds of stunting among lower educated women (aOR=1.32; 95% CI: 1.24, 1.40), and those with low family income (aOR=1.34; 95% CI: 1.24, 1.44). A similar trend was observed for underweight.

CONCLUSIONS

Prenatal iron supplementation can reduce stunting and underweight in low-income countries, particularly among women with lower education and those from low-income families. Strengthening these programs may improve childhood health outcomes in resource-limited settings, especially for disadvantaged women.

MEAL TIMING AND RISK OF METABOLIC SYNDROME IN THE FRENCH NUTRINET-SANTÉ BIOBANK

Elena Obeid[1, 2]; Xuân Le Folcalvez[1]; Khaled Ezzedine[3]; Anna Palomar-Cros[4]; Sandrine Péneau[1]; Alice Bellicha[1]; Mélanie Deschasaux-Tanguy[1]; Mathilde Touvier[1]; Valentina Andreeva[1]; Bernard Srour[1]

BACKGROUND AND OBJECTIVES

Circadian rhythm disruption has been associated with higher risks of cardiometabolic diseases and several cancers (1). Mistimed eating patterns can desynchronize circadian rhythms, and could therefore influence metabolic health (2). However, long-term associations between meal timing and the metabolic syndrome remain unclear (3). The aim of this study was to evaluate the association between mealtime and frequency, as well as chrononutritional behavior profiles and the risk of metabolic syndrome.

METHODS

We used measured biological and clinical data from 16 353 adults (72% women, 51 years ± 13.72) in the NutriNet-Santé biobank (2011-2014), and examined the associations between meal timing, assessed with repeated 24-hour dietary records during the first two years of follow-up (starting 2009), and the risk of metabolic syndrome, using modified Poisson regression models, adjusted for main confounders. Chrononutritional behavior profiles were identified through principal component analysis (PCA). We conducted additional analyses stratified by sex to explore potential differences across these subgroups.

RESULTS

At the end of follow-up (mean 2.1 years (SD=1.2)), later timing of the first meal of the day was associated with a moderately higher risk of metabolic syndrome (1,788 cases; RR per 1-hour delay = 1.05; 95% CI: 1.00-1.10). However, after adjusting for overall diet quality, this association was attenuated (RR: 1.04; 95% CI: 0.99-1.09). Overall, we found no evidence of an association between the occurrence of metabolic syndrome and the time of the last meal (RR: 0.99; 95% CI: 0.95-1.05), the number of eating occasions (RR: 1.00; 95% CI: 0.98 - 1.03), or night-time fasting duration (RR: 1.03; 95% CI: 0.99 1.07) after adjusting for diet quality. PCA revealed three distinct chrononutritional profiles: (1) frequent eating and late snacking, (2) late first meals with energy/nutrient-dense last meals, and (3) energy/nutrient-dense first meals. In men, a higher adherence to the third profile was associated with a reduced risk of MetS (RR = 0.91, 95% CI: 0.86–0.97) even after adjusting for overall diet quality.

CONCLUSIONS

In this study, in men, consuming a larger proportion of daily energy and nutrients during the first meal was associated with a reduced risk of MetS. The link between time of first meal and MetS seems to be explained by diet quality. Further investigations with a longer follow-up are needed to elucidate how meal timing influences metabolic health.

OAP62_04

IMPACT OF PREBIOTIC CHICORY ROOT FIBRE SUPPLEMENTATION ON GUT-BRAIN AXIS AND STRESS RESPONSES IN HUMAN INTERVENTION STUDIES

Jessica Van Harsselaar[1]; Yoghatama Cindya Zanzer,[1]; Stephan Theis,[1]
[1]BENEO-Institute, BENEO GmbH, Obrigheim (Pfalz), Germany

BACKGROUND AND OBJECTIVES

The gut-brain axis has emerged as a promising target for nutritional interventions to support mental health. Prebiotics, such as inulin-type fructans, may modulate mood and stress by influencing gut microbiota. To evaluate this, we analyzed data from two randomized controlled trials: SYN-ReduSTRESS and EFFICAD, which assessed the effects of prebiotics on psychological and physiological stress markers.

METHODS

The SYN-ReduSTRESS study enrolled 173 healthy men, who consumed 10 g/day oligofructose-enriched inulin or maltodextrin (control) for four weeks, followed by the Trier Social Stress Test (TSST). The EFFICAD trial included 92 adults with mild-to-moderate anxiety randomized to receive oligofructose, 2'-fucosyllactose, their combination, or maltodextrin for five weeks. Both trials measured psychological outcomes (anxiety, depression, affect), physiological stress responses (salivary cortisol, cortisol awakening response), and gut microbiota composition.

RESULTS

Prebiotic supplementation consistently reduced stress-related markers and improved mood. In SYN-ReduSTRESS, oligofructose-enriched inulin reduced subjective anxiety ($P = 0.04$) and salivary cortisol ($P = 0.002$) during the TSST paradigm, particularly in participants with high baseline cortisol levels. EFFICAD demonstrated significant improvements in mood scores (BDI-II, STAI, PANAS) and cortisol awakening response ($P < 0.001$) in oligofructose and combination groups. Microbiota analysis showed increases in *Bifidobacterium* and *Faecalibacterium prausnitzii*, positively correlating with mood improvements.

CONCLUSIONS

These studies provide compelling evidence that prebiotic supplementation can improve mood and mitigate stress-induced responsiveness via the gut-brain axis. Integrating findings highlights the potential of inulin-type fructans as nutritional strategies for mental health support, warranting further exploration into their mechanisms and broader applications.

FOOD INSECURITY DURING PREGNANCY IN FRENCH GUIANA: THE SCALE OF THE PROBLEM AND ASSOCIATIONS WITH UNHEALTHY DIET

Célia Basurko; Elisabeth Lyonnais[1]; Maëlys Proquot; Glwadys Forsans; Najeh Hcini[1]; Nfassory Camara[2]; Muriel Suzanne Galindo[3]; Claire Gatti[3]; Antoine Adenis[3]; Mathieu Nacher[3]; Mathilde Savy[4]
[1]Maternité, Hospital Center Westerly Guyanais, Saint-Laurent-du-Maroni, French Guiana; [2]Maternité, Centre Hospitalier de Cayenne, Cayenne, French Guiana; [3]CIC INSERM 1424, Centre hospitalier de Cayenne, Cayenne, French Guiana; [4]UMR MoISA, French National Research Institute for Sustainable Development (IRD) Montpellier, Montpellier, France

BACKGROUND AND OBJECTIVES

The post-COVID international situation, wars and food price inflation are hampering access to food for the most vulnerable households who have no safety net against unforeseen events. While pregnant women are particularly vulnerable to food shortages and nutritional imbalances, data on food insecurity (FI) during pregnancy and associated risk factors are scarce

METHODS

A 2023 multi-center, cross-sectional study was conducted among a representative sample of 730 women during the third trimester of pregnancy in French Guiana. FI (USDA Food Security Survey Module), diet quality indicators derived from a qualitative 24-hour recall (Minimum Dietary Diversity for Women MDD-W, All-5 indicator, foods associated with risks of noncommunicable diseases), pre-conceptional nutritional status (body mass index – BMI - in 4 categories as defined by WHO) and gestational weight gain (GWG), and women's self-esteem were collected. Data were weighted to ensure sample representativeness, and modified Poisson regression was used to identify risk factors for FI during pregnancy.

RESULTS

Overall, 32.4% [95%CI: 28.9-36.0] of women lived in a food insecure household; risk factors for FI included unstable household income, unhealthy housing, lack of health insurance to cover prenatal care, living alone with children, low self-esteem and low social support. Only 52.3% [95%CI: 48.4-56.3] of women reached the MDD-W, with no difference according to the food insecure status. Significantly fewer women with food insecurity had consumed the 5 recommended healthy food groups compared to women from food secure households (7.2% vs 12.9%, p-value=0.032). In both groups, more than 80% of women had consumed sweetened drinks, and 29.6% were obese prior to conception (26.9% in the food secure group vs 35.4% in the food insecure group). Finally, 28.8% of women had excessive GWG while 40.1% had insufficient GWG, with no difference according to the FI status.

CONCLUSIONS

This study highlights an insidious situation in French Guiana that threatens the first 1000 days of children's life. Appropriate policies and actions are urgently needed to reduce food insecurity and improve dietary quality among pregnant women, with special attention to unhealthy dietary behaviors and associated health risks.

CO-DESIGN PROCESS FOR A MULTI-SECTORAL NUTRITION INITIATIVE IN NEPAL: HOW LOCAL NUTRITION ACTORS USE DATA FOR EVIDENCE-BASED PLANNING

Akriti Singh[1]; Ekendra Lamsal[2]; Pravin Poudel[2]; Ramesh Prasad Adhikari,[2]; Bhim Kumari Pun[2]; Rojee Suwal[2]; Bishow Raman Neupane[2]; Indra Dhoj Kshetri[2]; Keshab Shrestha[3]; Niraj Shrestha[4]; Sampurna Rai[5]; Pooja Pandey Rana[2]
[1]USAID Integrated Nutrition, Helen Keller Intl, Seattle, United States of America; [2]USAID Integrated Nutrition, Helen Keller Intl, Lalitpur, Nepal; [3]USAID Integrated Nutrition, ENPHO, Kathmandu, Nepal; [4]USAID Integrated Nutrition, FHI 360, Kathmandu, Nepal; [5]USAID Integrated Nutrition, NTAG, Kathmandu, Nepal

BACKGROUND AND OBJECTIVES

The international development community recognizes the need to co-design interventions with local actors. However, few existing tools are designed for this exact purpose. The objective of this paper is to describe the process of developing and implementing a digital tool to assist local actors in reviewing data and selecting context-appropriate interventions as part of the annual work planning process for USAID Integrated Nutrition, a multi-sectoral nutrition initiative in Nepal.

METHODS

The award's technical team developed the decision tool by reviewing existing program design documents and incorporating tacit knowledge. Using the tool, the team conducted co-design workshops from July to September 2024 in all seven provinces across Nepal, with 780 local actors from 48 districts. The decision tool was refined as it was rolled out. Adjustments included moving the tool from Excel to a digital platform with real time data entry, reducing steps, and adding user friendly features to enhance accessibility. During the workshops, participants were divided into groups by district and a facilitator guided each group through the tool. To prioritize indicators, stakeholders reviewed data from the most recent Demographic and Health Survey or Health Management Information System. To design activities, local actors proposed activities for everyone in their area and considered specific activities for underserved groups. Feedback was sought from the technical team and workshop participants.

RESULTS

The final decision tool comprised six steps: 1. assess the nutrition situation, 2. prioritize indicators, 3. conduct social and behavior change analysis, 4. design health and WASH systems activities, 5. design food systems activities, and 6. design enabling environment activities. Workshop participants appreciated the co-design process, particularly how it built their confidence and skills in using data and ownership over the plans. Suggestions to improve included translating the tool into Nepali, holding separate discussions with representatives from underserved communities due to power dynamics, and conducting workshops at the sub-district level.

CONCLUSIONS

Co-design workshops are one step in ensuring activities meet local needs, garner ownership from local actors, and advance sustainability. However, tools to guide these workshops must be designed iteratively, and information from the workshops needs to be supplemented with community consultations.

Binka School of Public Health, University of Health and Allied Sciences, Hohoe, Ghana; [4]Food Science and Nutrition Research Directorate, Ethiopian Public Health Institute, Addis Ababa, Ethiopia; [5]Global Technical Services, Nutrition International, Ottawa, Canada; [6]Department of Pediatrics/Division of Gastroenterology, Hepatology and Nutrition, UCSF Benioff Children's Hospital - San Francisco, San Francisco, United States of America

BACKGROUND AND OBJECTIVES

The accuracy and utility of dietary folate intake data have been questioned because of incomplete and possibly inaccurate food composition tables (FCT) and uncertainties regarding folate bioavailability. Hence, the objective of this study was to investigate the association between dietary folate intake and biomarkers of folate status among women of reproductive age (WRA) in Oromia region, Ethiopia.

METHODS

We measured dietary folate using single observed weighed food records (WFRs) of 100 WRA with repeat studies in 40 WRA. We also collected blood samples for serum folate and red blood cell (RBC) folate analysis, using the CDC microbiological assay. We estimated the distribution of usual dietary folate intake using the Ethiopian FCT by adjusting for intra-individual variability using the National Cancer Institute method. We used Spearman's correlation to test associations between dietary folate intake and biomarkers of folate status.

RESULTS

Mean ± SD of usual dietary folate intake was 396.4 ± 93.6 µg/d and the prevalence of dietary folate inadequacy was 54.6%. Mean ± SD serum folate and RBC folate concentrations were 15.1 ± 4.7 nmol/L and 473.0 ± 138.5 nmol/L, respectively. About half (45.5%) of the WRA had low serum folate concentration (<14 nmol/L), 86.9% were folate deficient (RBC folate < 624 nmol/L) and 96.0% had folate insufficiency (RBC folate < 748 nmol/L), indicative of an elevated risk of neural tube defects. There was a very weak, non-significant correlation between dietary folate intake and serum folate (r= -0.09, p= 0.377) and RBC folate (r= 0.04, p= 0.714).

CONCLUSIONS

Both dietary folate intake and biomarkers of folate status indicate inadequate folate nutriture in the study population. However, the use of one or two WFRs does not capture individual usual dietary folate intake and there is no association between dietary folate intake and biomarkers of folate status.

BACKGROUND AND OBJECTIVES

Many low- and middle-income countries lack data to design LSFF strategies and inform policy processes. In Madagascar, where micronutrient deficiencies are a serious public health problem, the government released a 2020 National Strategy for Food Fortification (SNFOA) to improve micronutrient intake. However, Madagascar's large-scale food fortification (LSFF) program has not progressed beyond salt. The USAID Advancing Food Fortification Opportunities to Reinforce Diets (AFFORD) project conducted a holistic review of LSFF in Madagascar to support development of a national action plan for LSFF scale-up.

METHODS

We assessed the Malagasy LSFF policy environment; industry feasibility to deliver LSFF and access to finance; dietary inadequacy; and cost of LSFF. We reviewed the national strategy. In total, we conducted four desk reviews, 82 key informant interviews, and seven industry site visits. We analyzed interview data for themes and household consumption and expenditure survey data to identify micronutrients inadequate in the diet. We modeled the potential contribution of LSFF to achieving adequate micronutrient intake. We supported the government to hold three workshops with key stakeholders to validate the RESULTS, develop a monitoring framework, and update and cost the SNFOA operational plan.

RESULTS

In the absence of LSFF, a high proportion of Malagasy diets are inadequate in key micronutrients (thiamin [68%], riboflavin [74%], folate [91%], vitamin B12 [87%], iron [78%], and zinc [60%]). Salt is still a good fortification vehicle given its high reach and consumption, good LSFF feasibility, and access to finance for large processors. Refined oil and wheat flour are potential fortification vehicles given the high industry feasibility to fortify. Although 72% of households consume sugar, industry feasibility to fortify is moderate due to low large-scale market share. Modeling showed the potential for salt fortified with iodine, sugar and oil fortified with vitamin A, and wheat flour fortified with B vitamins and zinc to improve micronutrient intake. Insufficient resource mobilization and lack of clear plans for LSFF strategy delivery are key factors that hinder the government's LSFF program.

CONCLUSIONS

LSFF has the potential to improve micronutrient intake in Madagascar. Through USAID AFFORD support, the Government of Madagascar updated and costed its SNFOA operational plan, laying a strong foundation for the scale-up of high-quality food fortification through new and existing vehicles. Applying comprehensive LSFF assessment approaches to policy processes could strengthen LSFF programming across low- and middle-income countries.

ASSOCIATIONS OF CIRCULATING BLOOD MICRONUTRIENTS IN EARLY PREGNANCY WITH BIRTH OUTCOMES AMONG GHANAIAN WOMEN

Odeafo Asamoah-Boakye[1]; Jan Frank,[1]; Reginald Adjetey Annan[2]; Charles Apprey,[3]; Wolfgang Stuetz,[1]
[1]Institute of Nutritional Sciences, University of Hohenheim, Stuttgart, Germany; [2]Department of Biochemistry and Biotechnology, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana; [3]Biochemistry and Biotechnology, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana

BACKGROUND AND OBJECTIVES

Sufficient micronutrient status, from the onset of pregnancy are essential for fetal growth and a healthy birth outcome. However**,** detailed information on blood micronutrients in early pregnancy and their association with birth outcomes are scarce. **Objectives**: We aimed to analyse (1) concentrations and parameters of blood micronutrients in early pregnancy (≤14 gestation weeks) and (2) associations with newborns anthropometry.

METHODS

In a prospective study, women in early pregnancy were enrolled to analyse hemoglobin and other biomarkers: iron status (ferritin and soluble transferrin receptor), infection markers (CRP and AGP), fat-soluble vitamins (A, E, D), carotenoids (e.g., α-and β-carotenes), B-vitamins (folate and thiamine) and minerals (e.g., iron and zinc). The women were followed for birth outcomes, and the associations of individual blood biomarkers with newborn anthropometry (n=294) were assessed by multiple linear and logistic regressions.

RESULTS

Anemia (Hb<110 g/L) prevalence was 15.3%, while the prevalence of iron deficiency, elevated AGP and CRP was 7.8%, 7.1%, and 31%, respectively. The proportions of women with low serum vitamins D (<25 nmol/L) and E (<11.6 µmol/L) were 23% and 59%, while 65% and 68% had insufficient thiamine (<65 nmol/L) and zinc (<0.56 mg/L). The mean birth weight, length and head circumference (HC) was 3075 grams, 49.4 cm and 33.8 cm. The prevalence of preterm birth and low birth weight (LBW) was 7.1% and 10.2%, while small for gestational age (SGA) for weight, length and head circumference was 19%, 9%, and 12%, respectively. Regression models showed a positive association of serum zinc with birth weight, while retinol was inversely associated with length, and vitamin D and ferritin were inversely associated with HC. Highest tertile of zinc increased birth weight by 121 g, while the highest tertile of retinol reduced length by 0.5 cm and increased the risk of SGA for length. The highest tertiles of both vitamin D and ferritin reduced HC by 0.4 cm, and ferritin and iron increased the risk of SGA for HC. Also, elevated AGP and the lowest tertile of thiamine increased the risk of LBW and SGA for HC, respectively.

CONCLUSIONS

A high proportion of the women in early pregnancy had low zinc, vitamin D and E, and thiamine status. Higher zinc and thiamine status seemed to improve birth weight, and head circumference. The negative associations of retinol, ferritin or iron with length and head circumference may reflect indirect effects, and needs further investigation for clarification.

RELATIONSHIP BETWEEN LEUCINE INTAKE, POLYPHENOL CONSUMPTION, AND SARCOPENIA INDICATORS IN CHILEAN OLDER ADULTS PARTICIPATING IN THE PROGRAM FOR COMPLEMENTARY FOOD IN OLDER PEOPLE (PACAM) FROM THE METROPOLITAN REGION, SANTIAGO DE CHILE

Edson Bustos-Arriagada[1]; Migdalia Arazo-Rusindo,[2]; Oscar Castillo-Valenzuela,; Gonzalo Rivera,[3]; Francisco Pérez-Bravo,[3]; Conrado Camilo,[1]; María Salomé Mariotti-Celis[1]
[1]Faculty of Medicine, Nutrition and Dietetics School, Universidad Finis Terrae, Providencia, Chile; [2]Nutrición y Dietética, UST, Santiago, Chile; [3]Nutrigenomics Laboratory, Nutrition Department, INTA, Santiago, Chile

BACKGROUND AND OBJECTIVES

Leucine supports muscle anabolism, while polyphenols reduce inflammation, both key to managing sarcopenia in older adults. Their combined effects may improve metabolic health, but the need for supplementation depends on intake levels and their relationship with sarcopenia indicators (1). This study investigates the relationship between leucine intake, polyphenol consumption, and sarcopenia indicators among Chilean older adults enrolled in PACAM from the Metropolitan Region, Santiago de Chile.

METHODS

A total of 181 older adults aged 60-80 from Santiago, Chile, were assessed. Sarcopenia indicators were evaluated through anthropometric measurements, muscle strength, and functional tests. Dietary intakes of leucine and polyphenols were determined using 24-hour dietary recalls.

RESULTS

The majority of participants (80% women) had insufficient intakes of both leucine and polyphenols, failing to meet the recommended daily doses of 3 grams and 500 mg, respectively. Sarcopenia was present in 17.1% of the older adults, correlating with these dietary deficiencies. This highlights the need for targeted dietary interventions to address these gaps in nutrient intake and support healthy aging.

CONCLUSIONS

These findings emphasize the importance of adequate dietary intake of leucine and polyphenols for maintaining muscle health in older adults. Future research should focus on evaluating the effectiveness of dietary supplements and interventions tailored to improve the intake of these nutrients to mitigate sarcopenia risk among the elderly.

ASSOCIATION OF HOUSEHOLD WATER, SANITATION, FOOD HYGIENE PRACTICES, AND MICROBIAL CONTAMINATION WITH CHILDHOOD STUNTING: INSIGHTS FROM THE ACTION AGAINST STUNTING HUB

Naveen Kumar Ramachandrappa[1]; Barbara Häsler[2]; Santosh Kumar Banjara[3]; Paula Dominguez-Salas[4]; Robert Dreibelbis[5]; Little Flower Augustine[3]; Teena Dasi[3]; Munikumar Manne[3]; Raghavendra Rao Chowdavarapu[3]; Archana Konapur[3]; Claire Heffernan[6]; Bharati Kulkarni[7]

BACKGROUND AND OBJECTIVES

Childhood stunting is a significant global health issue, affecting an estimated 160 million children under five years of age. Increasing evidence highlights the role of environmental determinants, particularly water, sanitation, and hygiene (WASH), including food hygiene, in influencing infection pathways. This study explores the relationship between stunting and WASH practices, with a particular focus on food hygiene, a key dimension of child health and development that has received limited attention.

METHODS

This study is part of the larger cohort study, *Action Against Stunting Hub*, which involves pregnant women. Data on WASH practices, including food hygiene, were collected from 522 children aged 0–23 months at three time points (9, 12, and 18 months). Data collection METHODS included structured interviews, spot checks, and biological sampling. Microbial hygiene indicators were assessed in weaning foods, drinking water, kitchen surface swabs, and handwashing samples. Stunting was defined in this study using the WHO growth standards as height-for-age z-scores (HAZ) less than -2 SD. Statistical analyses used the Chi-square test to identify associations between stunting and contributing factors. Data management and analysis were performed using R software, with statistical significance set at $p < 0.05$.

RESULTS

The study found that poor hand hygiene among children and mothers and contaminated kitchen surfaces and food were significant contributors to stunting. Households using piped water for cooking and handwashing had a higher prevalence of stunting (8.4%) compared to non-stunted households (2.1%). Access to running water in kitchens was notably lower in households with stunted children (60.2%) than in those with non-stunted children (72.2%; $p = 0.02$). A significant association was observed between the presence of *Salmonella* in food samples and stunting ($p = 0.029$). Additionally, fecal coliform contamination on kitchen surfaces was strongly associated with stunting ($p = 0.003$).

CONCLUSIONS

The findings underscore the importance of improving hygiene education and promoting behavioral interventions to address contamination in handwashing practices among children and mothers. The higher prevalence of *Salmonella* contamination in food samples from households with stunted children highlights the critical need for implementing effective food safety measures to reduce the risk of stunting.

CONSUMPTION PATTERN OF COMMERCIAL SNACK FOODS AND SUGAR-SWEETENED BEVERAGES DURING THE COMPLEMENTARY FEEDING PERIOD AMONG CHILDREN LESS THAN 24 MONTHS IN IBADAN, NIGERIA

Ebunoluwa Grace Ibidapo[1]; Folake Samuel[1]; Toluwalope Emmanuel Eyinla[1]; Oluwaseun Ariyo[1]
[1]Department of Human Nutrition and Dietetics, University of Ibadan, Ibadan, Nigeria, Federal Republic of

BACKGROUND AND OBJECTIVES

Commercially produced snack foods and beverages could enhance the nutritional outcomes of young children if formulated with optimal nutrient composition. However, certain products may be nutrient-poor, promoting an increased intake of salt or sugar and displacing the consumption of more nutrient-dense alternatives. This study examined the prevalence and consumption patterns of commercially produced snack foods and sweet beverages among children aged 6–24 months during the complementary feeding period in Ibadan, Nigeria.

METHODS

A facility-based cross-sectional survey was conducted among 500 mother-child pairs with children between the ages of 6-24 months across primary, secondary and tertiary health facilities within Ibadan metropolis. A pre-tested semi-structured questionnaire including a 24h dietary recall and food frequency questionnaire were employed to obtain information on demographics and the foods consumed by the child on the preceding day and week of the survey. Data was analyzed using IBM SPSS version 25.

RESULTS
RESULTS showed that about 8 out of 10 mothers had fed their children a commercially produced snack food product since introduction of solid/semi-solid/soft foods while 52.8% and 21.4% fed at least a snack food product and sweet beverage respectively in the day preceding the survey. The commonly consumed snacks were baked and fried confections like biscuits (81.2%) and puff-puffs (47.6%), sweet confections like stick sweets (38.4%) and high sodium snacks like cheese balls (31.2%). For sweet beverages, soft drinks (41.2%), fruit-flavoured drinks (40.8%) and flavoured milk drinks (34.8%) were the most commonly consumed. The top five reasons given by mothers for feeding commercial snacks and beverages were because their children liked them, as an in-between meal option, for child distraction/pacifying, influence of older children and having older adults providing them as treats. Majority of the mothers introduced snacks (87.7%) and sweet beverages (86%) to their children between ages 6-12 months with 46.9% and 12.8% feeding their children snacks and sweet beverages respectively every day of the week.
CONCLUSIONS

Snack and sweet beverage consumption during the crucial complementary feeding period require careful evaluation as some are nutrient-dense while others contain high levels of added sugars and salt, making them inappropriate for consumption. It is recommended that nutritious snack options be promoted and national dietary standards for complementary food products be developed to improve the diets and nutrition of infants and young children.

ENHANCING PRENATAL NUTRITION AND INFECTION CONTROL: IMPACT ON CHILD GROWTH AT 24 MONTHS OF AGE IN RURAL ETHIOPIA

Anne Cc Lee[1]; Firehiwot Workneh,[2]; Yumin Kim[3]; Kalkidan Yibeltal,[4]; Nebiyou Fasil,[5]; Theresa Chin[6]; Perumal Nandita[7]; Krysten North[8]; Alemayehu Worku[2]; Parul Christian[9, 10]; Yemane Berhane[2]

BACKGROUND AND OBJECTIVES

Maternal undernutrition and inflammation in pregnancy may have long term impacts on offspring physical growth. We aimed to determine the effect of prenatal interventions to optimize nutrition and infection management in pregnancy on longitudinal child growth.

METHODS

We conducted longitudinal follow-up of mother-infant dyads enrolled in a pragmatic, 2×2 factorial randomized clinical effectiveness study in Amhara, Ethiopia. In the parent study, 12 health centers were randomized to deliver an enhanced nutrition package (ENP) (iron-folic acid [IFA], iodized salt, and targeted micronutrient fortified balanced energy protein [BEP] supplements for undernourished women (MUAC<23cm) or routine nutrition care (IFA). Pregnant women <24 wks gestation were randomized to receive an enhanced infection management package (EIMP) (genitourinary tract infection screening-treatment and enhanced deworming) or routine infection care. Interventions were delivered from enrollment until birth. We consecutively re-enrolled a subset of offspring equally from each of the four study arms, with anthropometrics measured at 12, 18, and 24 mo. We used intention to treat analysis and calculated marginal intervention effects on 24 mo weight and length for age z-scores (WAZ, LAZ) using WHO standards, controlling for birth size. GEE was used to estimate intervention effects accounting for clustering and baseline imbalance.

RESULTS

The parent study enrolled 2399 pregnant women with 2170 known outcomes. 463 mother-child dyads were re-enrolled at 12 mo, with 423 followed until 24 mo (122 ENP+EIMP, 87 ENP alone, 109 EIMP alone, 105 neither). At baseline, pregnant women in ENP had lower education and higher rates of undernutrition compared to routine nutrition care. Mean birth WAZ was similar between nutrition arms (ENP: -0.88 (sd 1.03); not-ENP: -0.87 (0.96)), however, by 24 mo WAZ was lower in the ENP arm (ENP: -1.23 (1.05); not-ENP: -0.98 (1.02); adjusted mean difference (aMD) -0.19 (95% CI:-0.27 to -0.12)). Birth LAZ was similar (ENP: -0.48 (1.60); not-ENP: -0.49 (1.34)), and by 24 mo LAZ was -1.86 (1.04) in the ENP and -2.04 (1.35) in the not-ENP arm (aMD:+0.35 (95%CI: -0.60 to 1.30)). Among pregnancies with maternal undernutrition, children of women who received prenatal BEP had higher 24 mo LAZ (aMD:+0.53 (95% CI: 0.05 to 1.01)). There were no EIMP effects.

CONCLUSIONS

https://doi.org/10.1017/jns.2026.10126 Published online by Cambridge University Press

The prenatal nutrition intervention arm was more socioeconomically disadvantaged and had greater postnatal WAZ decline, likely due to environmental factors. Among undernourished women targeted for prenatal BEP, there was improved offspring linear growth at 24 mo.

ADHERENCE TO THE PROVEGETARIAN FOOD PATTERNS AND THE RISK OF CARDIOVASCULAR DISEASE IN A MEDITERRANEAN MIDDLE-AGED POPULATION

Ainara Martinez-Tabar[1]; Carmen Sayon-Orea[1]; Carmen De La Fuente-Arrillaga[1]; Vanessa Bullon-Vela[1]; Miguel A. Martínez-González[1]; Miguel Ruiz-Canela[1]; Maira Bes-Rastrollo[1]
[1]Dpt. Preventive Medicine and Public Health, University of Navarra, Pamplona, Spain

BACKGROUND AND OBJECTIVES

A provegetarian food pattern (PVG) that emphasizes plant-based foods without completely eliminating animal-based foods has been linked to health benefits. Nevertheless, it is important to note that not all plant-based foods are healthy. The objective of study was to prospectively evaluate the association between provegetarian food patterns and the risk of cardiovascular disease (CVD) in the "Seguimiento Universidad de Navarra" (SUN) cohort.

METHODS

The SUN Project is a Mediterranean cohort study formed by Spanish university graduates. A previously validated semi-quantitative food-frequency questionnaire (FFQ) was used. An overall provegetarian (PVG) food pattern was derived following a previously published methodology, giving positive scores to plant-based foods and inverse scores to animal-based foods. Furthermore, healthy (hPVG) and unhealthy (uPVG) provegetarian food patterns were computed. Individuals were divided into quartiles according to their adherence to these patterns. Cox regression models were used, adjusted for potential confounders.

RESULTS

For the final analysis, 18,560 participants were included. The baseline mean age and standard deviation were 38 ± 12 years. During a median follow-up of 16 years, we registered 227 incident cases of cardiovascular disease. After adjusting for potential confounders, participants in the highest quartile of the PVG food pattern had a significant lower risk of cardiovascular disease than those in the lowest quartile [HR Q4 vs. Q1: 0.63 (95% CI: 0.42-0.93); p for trend= 0.046]. Similarly, the multivariable model showed that subjects with high adherence to the hPVG food pattern had lower risk of cardiovascular disease compared to those with low adherence [HR Q4 vs. Q1: 0.60 (95% CI: 0.40-0.90); p for trend=0.037]. In contrast, individuals in the highest quartile of the uPVG food pattern had an 76 % higher risk of cardiovascular disease compared to those in the lowest quartile [HR Q4 vs. Q1: 1.76 (95% CI:1.17-2.64)] with a significant dose-response relationship (p for trend=0.007).

CONCLUSIONS

Greater adherence to both an overall provegetarian food pattern and a healthy provegetarian food pattern reduced the risk of cardiovascular disease in a Mediterranean middle-aged population. However, higher adherence to an unhealthy provegetarian food pattern was associated with an increased risk of cardiovascular disease.

ADIPOSITY AS A RISK FACTOR FOR IRON DEFICIENCY IN PREGNANCY

Sabrina P. Demirdjian[1]; Maria S Mulhern[1]; Maeve A. Kerr[1]; Paul D. Thompson[1]; Mark Ledwidge[2]; Mary T. Mccann[1]
[1]Nutrition Innovation Centre for Food and Health (NICHE), Ulster University, Coleraine, United Kingdom; [2]School of Medicine, University College Dublin, Dublin, Ireland

BACKGROUND AND OBJECTIVES

Obesity and iron deficiency (ID) are both highly prevalent in pregnant women and lead to serious consequences for mother and child (1). Whilst obesity can adversely impact on nutritional status, its influence on iron status remains unclear. This study aims to investigate the influence of adiposity on prevalence of iron deficiency and iron biomarkers in pregnancy.

METHODS

A secondary analysis of the MO-VITD trial (2) was conducted, which included singleton pregnancies in women aged ≥18 years and with BMI ≥18.5kg/m2. A multivitamin that included 17 mg/d of iron was taken by all participants. Measures of BMI, fat mass, visceral fat and fat mass index (FMI) were taken/calculated at 12 gestational weeks (GW). Haemoglobin (Hb) RESULTS were recorded from clinical notes. Ferritin, transferrin saturation (TSAT), and soluble transferrin receptor (sTfR) were analysed from stored serum samples taken at 12, 28 and 36 GW. Participants were categorised by BMI as normal weight (18.5-24.9 kg/m2), overweight (25.0-29.9 kg/m2) and obesity (≥30 kg/m2). Anaemia was defined: Hb <110 g/L and used two definitions for ID: ferritin <15µg/L and sTfR >1.513µg/mL. Ferritin was adjusted for inflammation using C-reactive protein (3).

RESULTS

A total of 125 pregnant women were included (43 normal weight, 44 overweight, 38 with obesity). ID prevalence (ferritin <15 µg/L) was 7.0%, 9.1%, and 7.9% at 12 GW (p=0.936) and 35.5%, 46.9%, and 70.8% at 36 GW (p=0.032) for normal weight, overweight, and obesity. TSAT was lower in women with obesity compared to normal weight at 12 GW (23.9 ± 11.2 vs 30.3 ± 9%, p=0.006) and 28 GW (11.4 ± 4.6 vs 17.5 ± 6.5%, p<0.001). Ferritin declined more steeply during pregnancy in the obesity group, with lowest levels at 36 GW (14.4 ± 9.2 µg/L vs normal weight 20.4 ± 10.3 µg/L, p=0.027). All adiposity measures were inversely associated with ferritin (especially FMI β=-0.348, p=0.002) and positively with sTfR at 36 GW (especially visceral fat β=0.345, p=0.008). Adiposity measures predicted ID defined by ferritin at 36 GW (particularly visceral fat aOR 1.446, p=0.004) and defined by sTfR at 12 and 36 GW (particularly visceral fat 12 GW aOR 1.286, p=0.038; 36 GW aOR 1.406, p=0.015).

CONCLUSIONS

Increased adiposity significantly raises the risk of ID during pregnancy, especially in the third trimester. Improvements to current screening practices are needed to ensure that women who are most at risk of ID are identified in early pregnancy. High adiposity in early pregnancy could identify those at greater risk of ID.

OAP65_02

FIRST FOODS: NAVIGATING KNOWLEDGE PATHWAYS FOR INFANT AND YOUNG CHILD FEEDING WITHIN URBAN INDIGENOUS ENVIRONMENTS

Hannah Neufeld[1]; Jaime Cidro,[2]
[1]School of Public Health Sciences, University of Waterloo, Waterloo, Canada; [2]Nursing, Midwifery and Health, Northumbria University, Newcastle, United Kingdom

BACKGROUND AND OBJECTIVES

Generations of Indigenous women have delivered their babies with the assistance of midwives and family members (1), yet little has been published on Indigenous approaches to infant feeding and postnatal care. Decision-making must consider the larger cultural contexts (2) to offer meaningful impacts on the nutritional health and wellbeing of Indigenous infants during their early development. Study objectives included: to engage with the postnatal feeding experiences of Indigenous mothers through the process of digital storytelling; to discuss the diverse postnatal needs and challenges of families and communities within urban contexts, and to propose pathways to encourage knowledge mobilization and learning.

METHODS

Community-based participatory research (3) and digital storytelling methodologies were utilized to enhance Indigenous community capacity and agency, as well as engage with regional and national project partners. Two storytelling workshops visually captured the postnatal experiences of Indigenous mothers within cities in Manitoba and Ontario, Canada. Film screenings and focus groups with care providers took place afterwards along with interviews and sharing circles with mothers. Audio files were transcribed verbatim and thematically analysed.

RESULTS

Twelve Indigenous mothers created short films and participated in interviews and Elder-led sharing circles. Their stories were screened in each location with a total of twenty care providers who later took part in focus groups. Participants shared the importance of cultural safety and social supports through their digital stories and discussed the emotional wellness associated with community cohesion and compassion supporting their infant feeding journeys. Care providers reflected on barriers unique to cities and existing harms within colonial systems, along with the importance of humility within healthcare moving beyond cultural awareness.

CONCLUSIONS

Indigenous postnatal practices must be situated within decision-making processes around Indigenous infant and young child feeding to move beyond policies of assimilation. A collaborative approach is essential for Indigenous women in the city to feel supported in their decisions around infant and young child feeding practices, as pathways towards building Indigenous food sovereignty during these critical stages of the life course.

Sex differences in factors associated with binge eating behaviors: RESULTS from a French national random population-based study

Junko Kose; Nathalie Godart; Caroline Huas; Alexandra Rouquette

BACKGROUND AND OBJECTIVES

Studies have suggested that sociodemographic and lifestyle-related factors as well as somatic and mental comorbidities are associated with binge eating (BE) behaviors. However, most of existing studies focused on women or on clinical sample, thus data on men in general population is scarce. The objective of the present study was to investigate sex differences in factors associated with BE behaviors in a national random sample from French population.

METHODS

The study included a sample of 84,995 participants (women: 52.1%) from the EpiCov cohort. Outcome was BE behavior (No BE; BE without compensatory behavior (BE-); BE with a compensatory behavior (BE+)) assessed using the Patient Health Questionnaire Eating Disorder module (PHQ-ED) in summer 2021. Exposures were various sociodemographic and lifestyle-related factors, and history of somatic and mental health conditions. After verifying interactions between exposures and sex for BE behaviors, adjusted multinomial logistic regressions were performed to investigate the associations between exposures and BE behaviors according to sex.

RESULTS

The prevalence of BE- and BE+ among women was 3.4 [3.2-3.7] % and 1.2 [1.1-1.3] %, respectively; that among men was 2.1 [1.9-2.3] % and 0.7 [0.6-0.8] %, respectively. Regarding BE-, significant sex difference was observed for having poor perceived health status (adjusted Odds Ratio (aOR): men 2.43 [1.91–3.09], women 1.53 [1.29–1.80], interaction p= 0.017). As for BE+, significant sex difference was observed for Body Mass Index (BMI) > 30 (vs BMI 18.5–25.0; aOR: men 6.10 [3.90–9.56], women 2.14 [1.53–3.00], interaction p= 0.003). No other sex differences were observed: younger age, suicidal ideation, and high screen use were positively associated with both BE- and BE+ in both men and women. High physical activity frequency was inversely associated with BE-, while it was positively associated with BE+ in both men and women.

CONCLUSIONS

In this large study based on a national random sample from French population in 2021, while the prevalence of BE was higher in women than in men, association between BE- and perceived health status and that between BE+ and obesity are greater in men than women. The RESULTS indicate the need to raise awareness and promote prevention strategies for men as for women.

OAP65_04

SODIUM REDUCTION IN THE CANADIAN PROCESSED FOOD SUPPLY BETWEEN 2010 AND 2020

Emily Ziraldo[1]; Yahan Yang[1]; Mary R. L'abbe[1]
[1]Department of Nutritional Sciences, University of Toronto, Toronto, Canada

BACKGROUND AND OBJECTIVES

Canadians consume excess sodium, increasing risk for cardiovascular disease. Processed foods are the major contributors to sodium intakes and Health Canada has implemented policies, including voluntary sodium reduction targets (SRTs), to encourage industry to reduce sodium in processed foods. The objectives were to: 1) assess changes in sodium levels of processed foods in the Canadian food supply, and 2) evaluate progress toward achieving Health Canada's 2012-2016 SRTs between 2010 and 2020.

METHODS

Foods from four collections, 2010 (n=6,929), 2013 (n=9,366), 2017 (n=10,324) and 2020 (n=15,797) of the Food Label Information and Price (FLIP) database were categorized into sodium categories established by Health Canada. The average sodium content (mg/100g) and proportion of foods meeting Health Canada's SRTs were determined by category for each year. Sodium levels and adherence to the SRTs were compared across years.

RESULTS

Sodium levels did not change for most categories over any time period; 40/47 did not change between 2010-2013, 40/47 between 2013-2017 and 42/47 between 2017-2020. Between both 2010-2013 and 2013-2017, 7 categories decreased in sodium and 0 increased. Between 2017-2020, 1 category decreased and 4 increased. In key categories contributing to Canadians' sodium intakes, Bread products, Refrigerated and frozen dishes, and Packaged deli meats, sodium levels changed by 0% (449±125 in 2010 to 450±139 in 2020), -5% (344±158 to 328±133), and 5% (1092±348 to 1149±452) between 2010 and 2020. Overall, in 2010, 2013, 2017 and 2020, 28%, 34%, 38% and 35% of products met their goal SRT and 24%, 20%, 17% and 18% exceeded the maximum level.

CONCLUSIONS

Overall, sodium reduction between 2010-2020 was infrequent, with only minor progress towards achieving the SRTs between 2010 and 2017, and no progress between 2017 and 2020. These data provide a longitudinal assessment of sodium levels in processed foods in the Canadian food supply and demonstrate that voluntary SRTs are mostly ineffective when there are no consequences of non-compliance. Stronger policies, such as mandatory SRTs, are required for manufacturers to reduce the amount of sodium in processed foods.

FOOD ENVIRONMENTS AND DIETARY INTAKE IN URBAN AND RURAL KENYA

Céline Termote[1]; Nicanor Odongo[1, 2]; Tosin Akingbemisilu[1]; Rosina Wanyama[1]; Irene Induli[1]; Irmgard Jordan,[1]
[1]Food environment and consumer behaviour, Alliance of Bioversity International and CIAT, Nairobi, Kenya;
[2]Institute of Agricultural Policy and Market Research, Justus-Liebig-Universität Giessen, Giessen, Germany

BACKGROUND AND OBJECTIVES

Food environment (FE) is the interface between consumers & food system.Despite increasing burdens of malnutrition in all forms, little is known about how FEs shape diets in Africa.The study assessed FE and dietary patterns of adolescents and mothers in urban & rural Kenya.

METHODS

A cross-sectional survey included 836 mother/adolescent pairs in Viwandani slum (Nairobi, urban, n=631), and Kilome sub-county (Makueni, rural, n=205), Kenya. Interviews assessed socio-demographics (mothers only), knowledge & perceptions towards healthy diets and agency. A repeated 24h dietary intake recall was used to calculate Global Diet Quality Scores (GDQS)+/-. All vendors in the study area were mapped. Factors influencing food consumption were explored using Poisson regression from glm package in R.

RESULTS

GDQS+ (healthy food consumption,max=32) was lower in urban compared to rural (urban: 5.92 mother, 5.81 adolescents; rural: 6.59 mother, 6.66 adolescents) due to lower consumption of dark green leafy vegetables (DGLV) and legumes. GDQS- (unhealthy food consumption,max 17) indicated lower consumption of unhealthy food in rural compared to urban (urban: mothers 10.5, adolescents 10.3; rural: mothers 12.1, adolescents 12.0). Majority of respondents were categorized medium risk for nutrient deficiencies and/or NCDs. Urban and rural consumers prefer Tabletop vendors (TT) and kiosks (Ki) for food purchases; wet markets were liked in the rural site. TT offered highest diversity of fruit and vegetables (F&V); 55% in both sites sold DGLV, while few sold unhealthy foods (11 and 9%). Ki offered low diversity of F&V in both sites, while 83% in urban, and 95% in rural sold unhealthy foods. In the rural area DGLV and legumes were also sourced from own produce. In urban, pocket money positively influenced GDQS+ for adolescents (IRR 1.08;p:0.04), and education level (IRR 1.29;p:0.03), employment (IRR 1.22;p:<0.02), being member of a social group (IRR 1.09;p:0.01) and exposure to healthy food promotion (IRR 1.05;p:0.005) positively influenced GDQS+ for women. In the rural site, casual labor negatively influenced GDQS+ (IRR 0.84;p:0.04) compared to farming, while being member of a social group positively influenced GDQS+ for women & adolescents (IRR 1.22; P:<0.001 and IRR 1.10;p:0.01).

CONCLUSIONS

GDQS are driven by low consumption of healthy foods, rather than high consumption of unhealthy foods in both sites.Group membership positively influenced dietary behavior. Wide-spread availability of cheap, unhealthy food in urban and rural FEs, will likely result in rapid increase of unhealth food consumption as socio-economic status improves with time.

VOLUNTARY SALT REDUCTION IN THE FOOD INDUSTRY: TARGETS, STRATEGIES, AND CHALLENGES – INSIGHTS FROM A SCOPING REVIEW AND QUESTIONNAIRE SURVEY

Miwa Yamaguchi[1]; Ikuko Kashino[1]; Katsuyuki Miura[2]; Nobuo Nishi[3]; Nayu Ikeda[4]
[1]Center for Private-Public-Academic Collaboration Research, National Institutes of Biomedical Innovation, Health and Nutrition, Settsu, Osaka, Japan; [2]NCD Epidemiology Research Center, Shiga University of Medical Science, Otsu, Japan; [3]Graduate School of Public Health, St Luke's International University, Chuo, Tokyo, Japan; [4]Center for Nutritional Epidemiology and Policy Research, National Institutes of Biomedical Innovation, Health and Nutrition, Settsu, Osaka, Japan

BACKGROUND AND OBJECTIVES

Voluntary reformulation of food products by the food industry is a cost-effective strategy for reducing excessive salt intake and preventing non-communicable diseases. However, practical challenges, especially for small and medium-sized enterprises in Japan, can hinder the implementation of salt reduction initiatives. This study aimed to provide insights for Japanese companies by reviewing the experiences of food industries in high-income countries.

METHODS

We conducted a scoping review of voluntary salt reduction initiatives in major food companies from high-income countries, using literature and website searches, supplemented by a questionnaire survey. The study focused on identifying salt reduction targets, including target products, sodium content criteria, and implementation timelines, as well as the incentives and challenges influencing decision-making.

RESULTS

From 19 studies and 83 companies identified, we selected 2 studies and 23 companies for analysis. One company and two trade associations participated in the survey (23% response rate). After removing duplicates, we analyzed 40 salt reduction targets from 24 companies and 2 trade associations. Of these, 21 targets focused solely on salt, while 19 also included sugar and fat. Targets were set for all products (n=25) or specific categories (n=15), such as bakery items. The majority (n=32) used company-established sodium criteria, while 8 adhered to criteria proposed by regional or national authorities. Sodium criteria were adopted by food category in 26 targets and for all products in 14 targets. The median implementation period was five years, with 65% of targets set to end in 2025. The survey revealed that corporate investment in environmental, social, and governance (ESG) goals and multi-level collaboration were key motivators for salt reduction.

CONCLUSIONS

Food companies set salt reduction targets based on practical considerations in view of global trends and government policies. A phased, collaborative approach involving industry, government, and academia could facilitate voluntary salt reduction, particularly for small and medium-sized enterprises.

HIDDEN AGENDAS: THE USE OF CORPORATE PLAYBOOK STRATEGIES IN AUSTRALIAN GOVERNMENTAL FOOD POLICIES

Kim Anastasiou[1]; Diana Bogueva[2]; Matt Fisher[1]; Amanda Hayes[1]; Helen Miller[2]; Dora Marinova[2]; Fran Baum[1]
[1]Stretton Health Equity, The University of Adelaide, Adelaide, Australia; [2]Curtin University Sustainability Policy Institute, Curtin University, Bentley, Australia

BACKGROUND AND OBJECTIVES

Food industries increasingly influence and shape food policies to enable ongoing growth and legitimise their environmentally and health-harming practices. This study examines how Australian food policies frame food-related commercial drivers of health and environmental sustainability, and how corporate playbook strategies are used in government food policies to enable, encourage and legitimise harmful food industry practices.

METHODS

We analysed over 150 federal and state food-related strategic policies in the agriculture, environment, food processing, manufacturing, and marketing sectors. A qualitative coding framework was developed to identify instances where government policies acknowledged the harmful impacts of commercial entities, or where ‘corporate playbook’ strategies were utilised to legitimise policy actions which were commercially beneficial. NVivo 13 was used to assist the coding, distinguishing between different ‘corporate playbook’ strategies such as industry engagement in policy development, public-private partnerships, self-regulation, and corporate social responsibility activities and to identify harmful practices.

RESULTS

Our findings reveal that Australian food policies rarely identify the negative impacts of food industry actions on human health or the environment. They also suggest that Australian food policies were often created in conjunction with industry. Further, government policies endorsed common 'corporate playbook' strategies such as industry self-regulation, public-private partnerships, co-investment in 'solutions', private sector funding for food systems research and privatisation of government activities. In contrast, we found limited acknowledgment of the negative impacts of food industry actions on human health and the environment, with industry usually framed as 'part of the solution' rather than a driver of health and environmental harms.

CONCLUSIONS

This research highlights a critical need for independent, robust food policies that challenge adverse industry influences. Australian food-related policies enable and legitimise industry strategies, weakening the subsequent impact of these policies on population health and environmental sustainability. Independent governance will be critical to transforming food systems to produce health and environmental benefits.

LEVERAGE AI TO DETECT UNHEALTHY CHILD-DIRECTED MARKETING IN FOOD PACKAGING

Guanlan Hu[1, 2]; Ofek Gross[3]; Emily Ziraldo[1]; David Soberman[4]; Christine Mulligan[1]; Mary Labbe[1]
[1]Department of Nutritional Sciences, University of Toronto, Toronto, Canada; [2]The Data Science Institute, Columbia University, New York, United States of America; [3]Department of Computer Science, University of Toronto, Toronto, Canada; [4]Rotman School of Management, University of Toronto, Toronto, Canada

BACKGROUND AND OBJECTIVES
Childhood obesity and diet-related noncommunicable diseases are urgent global public health challenges, driven in part by children's continued exposure to persuasive marketing of unhealthy foods and beverages. Traditional METHODS that manually evaluate child-targeted food marketing practices are resource-intensive and inefficient. This study aims to address these limitations by leveraging artificial intelligence (AI), specifically computer vision and deep learning, to identify child-targeted food products and classify marketing elements on food packaging using a comprehensive database labeled with child-directed marketing features.
METHODS

Image classification algorithms were trained and fine-tuned on 8,283 manually labeled food package images, annotated and validated using a validated child-appealing packaging (CAP) coding tool. Three machine learning algorithms, k-nearest neighbors (kNN), support vector machines (SVM), and convolutional neural networks (CNN) were used to classify food package images targeted at children. In addition, image object detection models, including fine-tuned YOLOv10 were used to identify specific child-targeted marketing features on food and beverage packaging. Model performance was evaluated using accuracy, precision, recall, F1 score, AUC, and confusion matrix.

RESULTS

A total of 22 distinct child-directed marketing techniques featured on food and beverage packages were identified and annotated. The CNN-based image classification model outperformed kNN and SVM, achieved 0.92 accuracy and 0.98 AUC in identifying food marketing targeted at children. Fine-tuned YOLOv10 object detection model demonstrated varying performance levels across child-targeted marketing features, reflecting the complexity and diversity of marketing strategies on food packaging.

CONCLUSIONS
This study introduces the first AI-driven approach to effectively identify and categorize child-directed marketing on food and beverage packaging. These METHODS can be extended to other data sources such as social media and online video content for broader applications. This study supports evidence-based policy development to protect children from unhealthy food marketing practices and provides critical insights into its potential impacts on children's health outcomes.

ASSOCIATIONS BETWEEN EARLY-LIFE HEMOGLOBIN CONCENTRATION AND COGNITION: A LONGITUDINAL STUDY OF 9-11 YEAR OLD GHANAIAN PREADOLESCENTS

Katherine Y. Kwon[1]; Charles D. Arnold[1]; Seth Adu-Afarwuah[2]; Kathryn G. Dewey[1]; Paul D. Hastings[3]; Amanda E. Guyer[4]; Anna Lartey[2]; Mavis O. Mensah[2]; Maku O. Demuyakor[5]; Brietta M. Oaks[6]; Reina Engle-Stone[1]; Christine P. Stewart[1]

[1]Institute for Global Nutrition, University of California, Davis, Davis, United States of America; [2]Department of Nutrition and Food Science, University of Ghana, Legon, Accra, Ghana; [3]Department of Psychology, University of California, Davis, Davis, United States of America; [4]Department of Human Ecology, University of California, Davis, Davis, United States of America; [5]Nutrition Department, McKing Consulting Corporation, Atlanta, United States of America; [6]Department of Nutrition, University of Rhode Island, Kingston, United States of America

BACKGROUND AND OBJECTIVES

Infants in low- and middle-income countries are at high risk for anemia, most commonly resulting from iron deficiency (ID). Additionally, male infants are at higher risk for ID or iron deficiency anemia (IDA) compared to female infants. Anemia and IDA during the first 1000 days may negatively affect motor, behavioral, and cognitive development. Few studies have examined the association between hemoglobin (Hb) and cognition in regions at highest risk of ID, such as sub-Saharan Africa. Our objective was to investigate the associations between Hb concentration at 6 and 18 mo of age and cognitive outcomes in 9-11 y old Ghanaian preadolescents.

METHODS

This is a secondary data analysis derived from the control group of the International Lipid-based Nutrient Supplements (iLiNS)-DYAD trial in Ghana and the 9-11 y follow-up study. Child Hb was measured at 6 and 18 mo using venous blood draws. At 9-11 y old, six cognitive tests were administered to measure general intellectual ability, literacy, arithmetic ability, declarative memory, procedural memory, and executive function. We examined the associations between 6 and 18 mo Hb values and cognitive outcomes with linear and quadratic terms using linear regression. We controlled for child age, sex, and interviewer at 9-11 y in minimally adjusted models and additional maternal, child, and environmental factors in fully adjusted models. We also evaluated effect modification by child sex.

RESULTS

In our study sample (n = 599), mean ± SD Hb was 113 ± 10 g/L at 6 mo and 112 ± 11 g/L at 18 mo. In minimally adjusted models, we found a significant quadratic relationship between 6 mo Hb and general intellectual ability (p=0.004) and arithmetic score (p=0.002), as well as between 18 mo Hb and general intellectual ability (p=0.022), in which lower outcome scores were apparent at both low and high Hb concentrations. We also found positive linear relationships between 18 mo Hb and literacy (p=0.002), arithmetic (p=0.029), and procedural memory scores (p=0.001). In fully adjusted models, these associations were no longer significant. There was no significant effect modification by sex in any of the models.

CONCLUSIONS

Associations between Hb at 6 and 18 mo and cognitive outcomes at 9-11 y may be non-linear and are strongly influenced by individual and household characteristics. Further investigation into the complex relationship between early-life nutrition and child development is warranted.

OAP 67 - PUBLIC HEALTH AND NUTRITION THROUGHOUT LIFE CYCLE

OAP67_01

EVALUATION OF THE SUSTAINABILITY AND EFFICIENCY OF THE COMMUNITY INTERVENTION PROGRAM ALIMAIDANTS FOR FAMILY CAREGIVERS OF THE ELDERLY IN THE NORTH OF FRANCE

Gabriela Maria DAOU[1]; Claire Duga[1]; Véronique Vincent; Nathalie Rolland[2]; Clémence Thiry Bourse[1]; Manon Danober[1]; Lucie Lebrun[1]; Hassan Younes[1]; Carine Delayre-Orthez[1]; Anne-Kathrin Illner[1]
[1]IDEALISS,URL 7519, Institut Polytechnique UniLaSalle,Université d'Artois, Beauvais, France; [2]General Directorate of Solidarity Oise, Conférence des financeurs de l'Oise, Beauvais, France

BACKGROUND AND OBJECTIVES

The role of caregivers in elderly care significantly impacts their mental and physical well-being, often leading to adverse health outcomes.In addition, there is a lack of data on understanding their lifestyle including dietary behaviors. The objective of the 4-year community program AlimAidants is to improve the health and well-being of caregivers through their diet.Health promotion topics have been identified based on a first needs assessment in 2022 and implemented in the ongoing intervention phase(2023-2025).This study aims to evaluate the overall sustainability and efficiency of the program.

METHODS

6 topics related to caregivers' and elderlys' health issues have been identified. Data-based interventions were designed as multiple formats including digital tools,nutrition education workshops and conferences.A semi-quantitative self-administered questionnaire was disseminated as paper and web version.Data were analyzed using descriptive statistics with IBM SPSS(30.0.0.0).Several indicators for efficiency evaluation were determined such as the number of participants as well as the retention rate.

RESULTS

Nutrition education workshops were conducted between 2023 and 2024:12 interventions with 43 participants were conducted in 2023 while 15 were organized in 2024 with 57 participants.The participation was fluctuating but with a 30% increase in the retention rate. 10 web-based conferences were animated with a satisfaction rate of 80%.15 partners were engaged.The number of subscribers on social media platforms has reached n=411.In total,11 public events were animated.2 conferences were organized.Assessment confirmed that mental and physical health were impacted.Caregivers (n=31) were mostly woman (77.4%) and were on average 69 years old.Briefly, 61.3% provided daily support, performing on average 4.5 tasks(±7),impacting several health parameters: 35.5% perceived moral fatigue, 48.8% stress and anxiety and 41.9% physical fatigue. 48.8% of the caregivers considered to have a fluctuating physical health state and 38.7% a fluctuating mental health state.A total of 77.4% of caregivers give importance to the quality of their diet.

CONCLUSIONS

These RESULTS show good efficiency in participants but more fluctuating sustainability necessitating the need to digitalize participative approaches to target isolated and vulnerable caregivers

ACCELERATING THE REDUCTION IN CHILDHOOD UNDERNUTRITION IN A LOWER-MIDDLE-INCOME COUNTRY SETTING: EVIDENCE FROM A 'BEST-IN-CLASS' PUBLIC-PRIVATE PARTNERSHIP, STATE OF MADHYA PRADESH, INDIA

Mahesh Srinivas[1]; Kriti Pradhan[1]; Komal Rathi[1]; Raj Sharma[1]
[1]Public Health, American India Foundation, Delhi, India

BACKGROUND AND OBJECTIVES

Undernutrition remains a critical issue in India, with 1 in 3 children under 5 stunted and underweight (National Family Health Survey-5, 2019-20). The COVID-19 pandemic worsened this crisis, particularly in vulnerable communities. Integrated approaches addressing the multifaceted factors of child health are vital for rapid and sustainable improvement. The program, implemented as a public-private partnership, aimed to reduce the prevalence of undernutrition among children under 5 years in a high-priority geographical region in Madhya Pradesh, India.

METHODS

The program was implemented over 18 months in collaboration with the Government, targeting children aged 0–6 years. Approximately 10,000 children were covered. The program combined nutritional supplementation with caregiver, provider and broad-based community interventions to holistically address child growth and development. Key differentiators included, a) introduction of, for the first time ever, age-appropriate, nutritious hot cooked meals to children aged 6 months–3 years b) home-based inter-personal communication with caregivers on IYCF practices; c) broad based community engagement for sustaining child feeding practices and community action. Frontline workers were trained to enhance nutrition counselling and growth monitoring for effective service delivery. Focused home visits were conducted to support caregivers of young and moderately malnourished children, as well as follow-ups for SAM children post-discharge from nutrition rehabilitation centers. Community engagement initiatives involved setting-up women self-help group managed community kitchens, recipe demonstrations for promoting favourable child feeding practices. The program developed a robust real-time monitoring mechanism and the rich data collected was used to develop an AI tool to predict occurrence of undernutrition. External evaluations were conducted at baseline and endline.

RESULTS

Difference-in-Difference analysis showed a 10% decline (signifying a 21.1% reduction) in prevalence of stunting and an 8.4 % decline (signifying a 27.2% reduction) in underweight prevalence, among children under 5 years ($p<0.01$). The findings also indicated enhanced caregiver knowledge and systemic-level improvements in the intervention area.

CONCLUSIONS

Innovative approaches providing supplementary nutrition at an early age, engaging caregivers to influence feeding practices, & fostering community involvement have potential to accelerate reduction in childhood undernutrition in lower-middle-income countries.

OAP67_05

AN INDEX OF PROTEIN PRICE AND QUALITY: 2009 TO 2023

Yasmin Ooi[1]; Hui May Yeo,[1]; Chia Chia Seow,[1]; Muhammad Isa Lim,[1]
[1]Faculty of Food Science and Nutrition, University Malaysia Sabah, Kota Kinabalu, Malaysia

BACKGROUND AND OBJECTIVES

Food protein price changes over time. The challenge is to balance affordability, food preferences, quality of protein, and availability. The study was conducted periodically in 2009, 2015 and 2023 in (redacted for review). The objectives were to determine protein intake, develop a Protein Source Index (PSI) which incorporated price and quality, and finally determine relative costs of various food preferences.

METHODS

This serial cross-sectional study was completed by 1,120 adult respondents who were recruited using convenient sampling. Interviewer administered semi-quantitative food frequency questionnaire (SQ-FFQ) was used. Price of food items were surveyed from supermarkets, wet markets, and for 2023, online offerings. Protein content per 100g edible portion was determined from the national food composition database. Protein quality was determined using the FAO Amino Acid Content of Foods and Biological Data on Proteins. These elements were ranked respectively and then combined to derive one PSI for each study year.

RESULTS

Protein intake increased over the years. Mean intake was 37.2 g/day for men and 34.6 g/day for women in 2009. Median intake was 64.7 g/day for men and 49.3 g/day for women in 2015, and 107.9 g/day for men and 90.3 g/day for women in 2023. Protein intake increased from below recommended intake levels to over recommended levels, which were 51 – 62 g/day depending on sex and age. The PSI featured at least five marine fish in the top ten listing in the three study years because the study location was near the sea. Sun dried anchovies and soybeans appeared in all three PSIs. However, chicken egg only appeared in the 2009 PSI because it increased from USD0.21/100g edible portion in 2009 to USD0.29 in 2023. By 2023, the protein cost per day of an omnivorous diet was USD 5.19, lacto-ovo-vegetarian diet was USD 3.76, and vegan diet was USD 2.86.

CONCLUSIONS

Marine fish will continue to feature among the cheaper proteins in the top ten listing of the PSI as they are locally sourced. Plant protein will continue to be in the minority in the top ten listing as the country imports most of them. This calls for changes in food policies to maintain fish stock sustainability, reduce carbon footprint of protein, and maintain price stability from foreign exchange fluctuations for imports.

OAP67_06

THE IMPACT OF FRONT-OF-PACKAGE NUTRITION LABELING ON CRITICAL NUTRIENT CONSUMPTION IN LATIN AMERICA AND THE CARIBBEAN: A SYSTEMATIC REVIEW

Beatriz Torquato[1, 2]; Marilia Tokiko,[3]; Catalina Serrano,[3]; Camila Borges,[4]; Neha Khandpur,[5]; Ana Paula Bortoletto Martins[6]

[1]Departamento de Nutrição , Faculdade de Saúde Pública USP, São Paulo, Brazil; [2]Núcleo de Pesquisas Epidemiológicas em Nutrição e Saúde (NUPENS), Faculdade de Saúde Pública USP, São Paulo, Brazil; [3]Departamento de Nutrição, Faculdade de Saúde Pública USP, São Paulo, Brazil; [4]LCA, Esalq, Piracicaba, Brazil; [5]Division of Human Nutrition and Health, Wageningen University & Research, Wageningen, Netherlands; [6]Nutrition Department / School of Public Health, University of Sao Paulo, São Paulo, Brazil

BACKGROUND AND OBJECTIVES

Front-of-package nutrition labeling (FOPNL) has emerged as a prominent public health strategy widely adopted in Latin America and the Caribbean (LAC) to reduce the consumption of critical nutrients associated with non-communicable diseases (NCDs), such as sugars, sodium, and saturated fats. Evidence suggests that FOPNL is associated with the reduction in the consumption of foods rich in critical nutrients, by discouraging the consumption of such products. This study aims to evaluate and synthesize the available evidence on the impact of FOPNL on the consumption of critical nutrients in LAC.

METHODS

A systematic review was conducted, with searches in five databases (PubMed, Scopus, Web of Science, Lilacs, and FSTA) for publications in English, Spanish, and Portuguese, covering the period from January 1, 2014, to October 15, 2024. Studies included in this review assessed the impact of FOPNL on critical nutrient consumption in LAC countries. The eligibility criteria were studies conducted in countries with the policy implemented with robust designs such as interrupted time series, controlled before-and-after studies, prospective cohorts, and observational studies. Extracted data were synthesized narratively, focusing on the reported impacts on critical nutrient consumption. This review followed PRISMA guidelines and is registered in PROSPERO (CRD42024605903).

RESULTS

Eight studies on the impact of FOPNL in LAC were identified: seven conducted in Chile and one in Mexico. The studies were grouped into two categories: those assessing the impact of FOPNL on product composition (n=4) and those assessing its impact on population consumption (n=4). The presence of FOPNL effectively reduced both the critical nutrient content in products and population consumption. This reduction was even more significant in school settings, involving children and adolescents.

CONCLUSIONS

The RESULTS consistently demonstrated that FOPNL positively impacts the reduction of critical nutrients. It is important to emphasize the need for more studies investigating this outcome. Methodological and contextual differences complement the evidence, providing a comprehensive overview of the effectiveness of this public policy in two countries. These findings underscore the importance of FOPNL as an effective strategy to mitigate excessive consumption of critical nutrients and reduce the prevalence of chronic diseases.

MEASURING COVERAGE OF LARGE-SCALE FOOD FORTIFICATION AT THE HOUSEHOLD LEVEL: LIMITATIONS AND OPPORTUNITIES

Samuel Scott[1]; Emily Myers,[1]; Swetha Manohar[2]; Sumanta Neupane,[3]; Archis Banerjee,[4]; Hanna Berhane,[5]; Firehiwot Workneh,[6]; Sk Masum Billah,[7]; Sharif Uddin Lotus,[7]; Sunny Kim,[1]
[1]Nutrition, Diets and Health, International Food Policy Research Institute, Washington, United States of America; [2]PHND, International Food Policy Research Institute, Washington, United States of America; [3]Nutrition, Diets and Health, International Food Policy Research Institute, Kathmandu, Nepal; [4]Nutrition, Diets and Health, International Food Policy Research Institute, Dhaka, Bangladesh; [5]Department of Epidemiology and Biostatistics, Addis Continental Institute of Public Health, Addis Ababa, Ethiopia; [6]Department of Epidemology and Biostatistics, Addis Continental Institute of Public Health, Addis Ababa, Ethiopia; [7]Maternal and Child Health Division, Icddr,b, Dhaka, Bangladesh

BACKGROUND AND OBJECTIVES

Large-scale food fortification (LSFF) is a cost-effective approach used in over 100 countries to address widespread micronutrient deficiencies. Measuring LSFF coverage through household surveys is critical for ensuring vulnerable individuals are being reached, but challenging as fortified foods are often undetectable by design. The overarching objective of this work was to improve LSFF coverage measurement in household surveys and inform a standard set of valid LSFF coverage indicators for global use.

METHODS

In two districts in Ethiopia and in Bangladesh, we conducted market assessments (n=56 markets/shops), and interviews with women (n=84). Market assessments involved fortified food vehicle (oil, wheat flour, salt, and rice) type and brand checklists and rapid vendor interviews. Questions selected from the Global Alliance for Nutrition's (GAIN) fortification assessment toolkit (FACT) were modified through consultations with GAIN for testing. Interviews with women focused on comprehension, retrieval, judgment, and response errors.

RESULTS

Market landscaping revealed large variation in types, brands, packaging and labeling of food vehicles, with nearly all oil and salt being labeled as fortified but not wheat flour or rice. Interviews revealed that women had limited knowledge about fortified foods, and most women could not distinguish between different types of markets/shops when asked where they last purchased the food vehicles. The concept of "brand" was not well understood, and women often could not remember the brand they last purchased. Modifications to the FACT tool were made to improve validity and reduce reporting error and a set of revised coverage indicators was proposed. The revised tool is being implemented in a One Nutrition Coverage Survey in Bangladesh (n=3280 households; data collection ending in March 2025) to contribute to learning on co-coverage of LSFF with other interventions across nutrition, health, and social protection sectors.

CONCLUSIONS

Measuring LSFF coverage at the household level is inherently challenging, but essential to understand if programs are reaching the right individuals. Acknowledging the limitations of this approach, correct phrasing of key concepts as understood by respondents, and identifying key points for training of enumerators will enhance data quality and validity. A common set of indicators should be used across countries when reporting and tracking LSFF coverage.

CONFLICTS OF INTERESTS

MAPPING POWER AND INFLUENCE IN MATERNAL AND CHILD HEALTH AND NUTRITION: A NET-MAP STUDY IN MEXICO

Monica Ancira Moreno[1, 2]; Navarro, Cecilia Perez[2]; Loya, Elizabeth Hoyos[2]; Guzman, Isabel Omaña[3, 2]; Méndez, Soraya Burrola[1, 2]; Sonia Hernández-Cordero[4, 2]
[1]Health Department, Universidad Iberoamericana Ciudad de México, Ciudad de México, Mexico; [2]Maternal and Child Observatory (OMI), Universidad Iberoamericana Ciudad de México, Ciudad de México, Mexico; [3]Pediatric Obesity Clinic and Wellness Unit, Hospital General de México Dr. Eduardo Liceaga, Mexico, Mexico; [4]Research Center for Equitable Development EQUIDE, Universidad Iberoamericana Ciudad de México, Ciudad de México, Mexico

BACKGROUND AND OBJECTIVES

Maternal and child health care involves comprehensive, high-quality support for the mother-child dyad, from prenatal care to early postpartum, and continuous monitoring of growth and development during the first five years of life (1,2). In Mexico, maternal and child malnutrition remains a critical public health issue, with slow progress toward the 2030 Global Nutrition Targets—particularly in reducing stunting, low birth weight, and anemia, while improving exclusive breastfeeding rates—due to limited action, inadequate funding, low prioritization by key decision-makers, and ineffective coordination among stakeholders(3,4). This study aimed to identify key stakeholders involved in decision-making processes for maternal and child malnutrition prevention in Mexico, analyze their roles and institutional affiliations, and assess their influence and power in addressing these challenges.

METHODS

The Net-Map actor mapping methodology, developed by the International Food Policy Research Institute(5) and the World Bank (6), was employed. The mapping process involved conducting individual interviews with key informants engaged in maternal and child health and nutrition in Mexico. Interviews were conducted in two phases: 19 participants in the first stage and 15 in the second. Gephi 0.10.1 software was used to generate the network map.

RESULTS

The study identified 77 stakeholders involved in Mexico's maternal and child health and nutrition. However, decision-making authority is predominantly concentrated within government bodies and supranational organizations, with minimal involvement from organized civil society groups. Implementation is the most executed action, ranking first for the government but lower for other actors. Communication follows closely, while Training and Management rank fourth. In contrast, Financing, Advocacy, and Patient Care show limited activity, with specific actors leading each area.

CONCLUSIONS

Enhancing collaboration among the key stakeholders identified in this study is crucial to unlocking the full potential of both current and future initiatives aimed at improving maternal and child health and nutrition outcomes in Mexico. By fostering stronger partnerships, aligning strategies, and addressing systemic barriers, we can significantly amplify the impact of interventions, ultimately driving lasting change and ensuring better health and nutrition for vulnerable populations across the country.

THE HIGHER DENSITY OF UNHEALTHY FOOD STORES AROUND SCHOOLS IS ASSOCIATED WITH INCREASED CONSUMPTION OF SUGAR-SWEETENED BEVERAGES AMONG BRAZILIAN CHILDREN

Mariana De Santis Filgueiras[1]; Fernanda Martins De Albuquerque[2]; Glauce Dias Da Costa[1]; Milene Cristine Pessoa[3]; Juliana Farias de Novaes[1]
[1]Nutrition and Health Department, Universidade Federal de Viçosa, Viçosa, Brazil; [2]Nutrition Institute, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil; [3]Nutrition Department, Nursing School, Federal University of Minas Gerais, Campus Health, Belo Horizonte, Brazil

BACKGROUND AND OBJECTIVES

The rising consumption of sugar-sweetened beverages among children contributes to obesity and its comorbidities. In this context, the food environment around schools influences dietary choices, particularly unhealthy foods. We aimed to evaluate the association between the density of unhealthy food stores around schools and the consumption of sugar-sweetened beverages among Brazilian children.

METHODS

Cross-sectional study with children aged 8 and 9 years enrolled in 24 urban schools in Viçosa, Minas Gerais, Brazil. Sugar-sweetened beverages (soft drinks, packaged juices, and powdered juices) were assessed using three 24-hour dietary recalls. The total caloric contribution of these beverages (%) was categorized based on the 50th percentile (3.8% of total energy intake). Unhealthy food stores were defined as those where more than 50% of the available products for sale were ultra-processed foods (CAISAN, 2018). The density of unhealthy food stores per 1,000 inhabitants was calculated within 400-meter network buffers around the schools and categorized according to the 50th percentile (43.2 stores per 1,000 inhabitants). Generalized estimating equations logistic regression analysis was performed, estimating odds ratio (OR) with 95% CI, adjusted for sex, age, and per capita income, with α=0.05. This study was approved by the Human Research Ethics Committee.

RESULTS

A total of 378 children were assessed (51.3% female; age 8.5 ± 0.5 years), of whom 70.9% (n=268) were students at public schools. The most frequent types of unhealthy food stores around schools were cafeterias (77.6%, n=207), followed by ice cream parlors (8.6%, n=23), mobile unhealthy food vendors (4.9%, n=13), and candy stores (3.7%, n=8). Children whose school surroundings had a higher density of unhealthy food stores had 67% higher odds of increased sugar-sweetened beverage consumption (adjusted OR: 1.67; 95% CI: 1.08; 2.58).

CONCLUSIONS

A higher density of unhealthy food stores around schools is associated with increased consumption of sugar-sweetened beverages among Brazilian children. Public health policies should consider regulating the food environment near schools to promote healthier food choices.

NUTRITIONAL INTERVENTIONS IN OVERWEIGHT WOMEN WITH POLYCYSTIC OVARIAN SYNDROME

Amina Seta[1]; Mubina Hodzic-Milic[2]
[1]Internal medicine, diabetology and nutrition, UniMed - Univerzitetska Poliklinika, Sarajevo, Bosnia and Herzegovina; [2]Nutrition, Nobel lijek doo, Sarajevo, Bosnia and Herzegovina

BACKGROUND AND OBJECTIVES

Polycystic ovarian syndrome (PCOS) is one of the most common metabolic and hormonal disorders in young women. Abdominal obesity and PCOS are associated with irregular menstrual cycles and reduced pregnancy rate. The aim of the study is to evaluate the impact of nutritional interventions and weight loss on the regulation of insulin resistance, menstrual cycles and achieved pregnancy rate in overweight women with PCOS.

METHODS

57 women age 18-45 with PCOS and BMI ≥25 kg/m2 were submitted to nutritional interventions including Mediterranean diet with low carbohydrate intake for 12 months. Their baseline characteristics (age, WHR, BMI, HOMA -IR, ovulatory cycle) were recorded. They had regular follow-up controls of anthropometric and laboratory parameters.

RESULTS

There was a statistically significant difference in HOMA-IR; WHR, BMI and ovulatory cycle between overweight women with PCOS that achieved weight loss of more than 10% compared to women who did not achieve weight loss (62.3 vs. 14.1%; $p<0.001$). The RESULTS of our analysis showed that overweight women with PCOS who had a weight loss of more than 10% during 12 months had a 65% greater likelihood of achieving pregnancy (adjusted OR = 1.65; CI:1.22, 2.08; $p<0.001$)

CONCLUSIONS

Nutritional interventions including Mediterranean and low-carbohydrate diet as a treatment for overweight women with PCOS can improve reproductive and metabolic function.

[1]School of Social Sciences, Nanyang Technological University (NTU), Singapore, Singapore; [2]Department of Global Health, Georgetown University, Washington D.C, United States of America; [3]Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, United States of America; [4]Cardiovascular Health, Resolve to Save Lives, New York, United States of America; [5]Department of Science and Technology, Food and Nutrition Research Institute, Manila, Philippines; [6]Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, United States of America; [7]Welch Center for Prevention, Epidemiology, and Clinical Research, Johns Hopkins University, Baltimore, United States of America; [8]Center for Human Nutrition, Johns Hopkins Bloomberg School of Public Health, Baltimore, United States of America; [9]Food Policy, The George Institute for Global Health, Barangaroo, Australia; [10]Department of Public Health and Caring Sciences, Uppsala University, Uppsala, Sweden

BACKGROUND AND OBJECTIVES

In 2018, the Philippines implemented a tax on sweetened beverages to address diet-related morbidity and mortality. Building on its success, policymakers are exploring a tax on unhealthy packaged foods. This study aimed to estimate the health and economic impacts of a tax on packaged foods high in sugar or sodium, including reductions in disease burden, healthcare cost savings, revenue generation, and equity implications.

METHODS

Using a multiple-cohort proportional multi-state life table model, we estimated the impact of a 20% tax on packaged foods high in sugar or sodium on dietary intake, health outcomes, and economic metrics over 20 years. Data on dietary intake, food prices, and price elasticities from the 2018-2019 Expanded National Nutrition Survey were combined with food sales trends from Euromonitor to estimate the impact of taxes on sodium and sugar consumption, as well as the expected tax revenue. Data from the Global Burden of Disease Study and Philippines Health Insurance Corporation were used to translate the dietary impact into effects on incident events, prevalent cases, and deaths due to cardiovascular disease and type 2 diabetes, health-adjusted life years (HALYs), and healthcare costs related to the modelled diseases. Net costs included implementation costs, tax revenue, and healthcare cost savings, and cost-effectiveness was evaluated from both extended healthcare and government perspectives.

RESULTS

Over 20 years, the tax was estimated to avert ~9,000 deaths from cardiovascular disease and type 2 diabetes, prevent ~59,000 incident cardiovascular disease events, avoid ~18,000 new diabetes cases, generate ~594,000 health-adjusted life years (HALYs), and save an estimated PHP ~4.5 billion in related healthcare costs. From a government perspective, the intervention could be highly cost-saving, with a negative net cost of PHP ~630 billion, due to large tax revenues (i.e., PHP ~650 billion). From the extended healthcare perspective (i.e., excluding tax revenue), the intervention was still estimated to be highly cost-effective with an incremental cost of PHP ~14,000 per HALY gained. The least wealthy quintile could gain ~13% more HALYs than the wealthiest quintile.

CONCLUSIONS

A broad nutrient-based tax on unhealthy packaged foods in the Philippines could be a highly cost-effective and equitable strategy to reduce the burden of diet-related non-communicable diseases. The intervention has the potential to save lives, generate significant revenue, and reduce health disparities across socioeconomic groups.

NUTRITION AND OSTEOCLAST ACTIVITY COULD BE INVOLVED IN LOWER BONE MINERAL DENSITY OBSERVED IN SOME PATIENTS WITH PHENYLKETONURIA, WHILE EX VIVO OSTEOCLASTOGENESIS IS UNALTERED IN THESE PATIENTS

Beatrice Hanusch[1]; Thomas Lücke[1]; Kathrin Sinningen[1]
[1]Research Department of Child Nutrition, University Hospital of Pediatrics and Adolescent Medicine, Ruhr-University Bochum, Bochum, Germany

BACKGROUND AND OBJECTIVES

Phenylketonuria (PKU, MIM 261600) is a recessive inherited disorder resulting in severe mental retardation if left untreated. PKU can be detected via newborn screening and by restricting the phenylalanine (Phe) intake from the diet, mental retardation has successfully been reduced in these patients. However, non-neurological symptoms have been described. One of these is impaired bone health even in children and well-treated patients with PKU. Therefore, we analyzed bone mineral density (BMD) and osteoclasts (OC) from adult patients with PKU next to their eating patterns.

METHODS

18 adult patients with PKU (11 ♀; 35 ± 12 years) and 19 age- and sex-matched controls (10 ♀; 36 ± 11 years) participated in the study. Peripheral blood mononuclear cells were isolated via Ficoll method and incubated with differentiation factors for 14 days. Trap-positive, multinucleated cells (≥ 3 nuclei) were counted to quantify the OC formed, and the expression of selected OC genes was determined using qPCR. Nutrition was assessed using a food frequency questionnaire and the World Index for Sustainability & Health (WISH; scale: 0 - 130 points). For those affected with PKU, blood Phe concentrations of the last 5 years were taken from their medical records and the BMD was measured using dual X-ray absorptiometry (DXA) at the hip (hBMD).

RESULTS

hBMD T-Score was significantly below 0 in patients with PKU (-0.7 ± 1.0, $p = 0.02$) and patients with hBMD below -1 reached a significantly lower WISH than patients with higher hBMD. Neither WISH or OC count nor the gene expression of the OC genes differed between the patients and controls. Furthermore, there was no correlation between the OC markers, OC count and BMD and the blood Phe concentrations in the patients' during the last 5 years. OC from patients with hBMD T-Score below -1 tended to have higher relative cathepsin K (CTSK) mRNA expression (0.9 [0.6 - 3.4]) than patients with normal hBMD (0.2 [0.2 - 0.8]; $p = 0.055$), and the T-Score in the hip correlated significantly negatively with CTSK expression ($r = -0.52$; $p = 0.04$).

CONCLUSIONS

The reduced BMD described in patients with PKU cannot be attributed solely to a greater number or activity of OC. However, eating patterns and the slightly higher CTSK expression in patients with low BMD suggests that altered OC activity and diet may play a role.

ASSOCIATION BETWEEN ULTRA-PROCESSED FOODS CONSUMPTION DURING PREGNANCY AND BREAST DENSITY POST-PARTUM: THE CHILEAN MATERNAL AND INFANT NUTRITION COHORT STUDY II (CHIMICS-II)

Maria Luisa Garmendia[1]; Camila Corvalán[1]; Marcela Jacard,[2, 3]; Mariana Cifuentes,[1]; Ana Pereira[1]
[1]CIAPEC, Institute of Nutrition and Food Technology, University of Chile, Santiago, Chile; [2]Digital Hospital, Ministry of Health, Santiago, Chile; [3]Radiology Department, Clínica Alemana, San, Chile

BACKGROUND AND OBJECTIVES

The consumption of ultra-processed foods (UPF) has been linked to higher risk of breast cancer (BC). Breast density (BD) is a well-established modifiable risk factor for BC. Pregnancy itself has been associated with an estimated 12% reduction in BD per birth. However, it remains unclear whether Ultra-processed foods (UPF) intake during pregnancy could modify BD, potentially affecting BC risk. This study assessed whether UPF consumption during pregnancy is associated with breast composition measures, specifically percent fibroglandular volume (%FGV) and absolute fibroglandular volume (AFGV).

METHODS

The Chilean Maternal and Infant Nutrition Cohort Study II (CHiMICs-II) is a longitudinal study of pregnant women (n= 1954) recruited from public healthcare centers of Chile. Participants were followed from their first prenatal visit to three months after lactation ended. Dietary intake during pregnancy was assessed via 24-hour dietary recalls (24HRs), with a mean of two recalls per participant. UPF was estimated based on NOVA-classification. In random sample of 344 participants, %FGV and AFGV were measured using dual-energy X-ray absorptiometry (DXA) at least three months post-lactation. Associations between UPF consumption (as % of total kcal and grams in quartiles) and BD measures were analyzed using simple and multiple linear regression models. Models were adjusted for age, pregestational body mass index, breastfeeding, parity, smoking, alcohol intake, education and total energy intake.

RESULTS

The mean age of participants was 29.9 years (SD = 6.0), with 37% having pregestational obesity. Average daily energy intake was 1,606 kcal (SD = 479.1), with 35% of calories and 22.4% of grams from UPF. DXA measurements were performed an average of 204 days post-lactation (SD = 137). The mean %FGV and AFGV were 36.0% (SD = 11.2) and 197.0 cm^3 (SD = 70.8), respectively. By UPF quartiles, mean %FGV and AFGV were 36.0% (SD = 11.1) and 217 cm^3 (SD = 107) in Q1 versus 36.0% (SD = 10.4) and 206 cm^3 (SD = 116) in Q4. No significant associations were observed between UPF quartiles and %FGV or AFGV (e.g., UPF kcal Q4 vs. Q1, adjusted β for %FGV: -2.1, 95% CI -5.0; 0.8).

CONCLUSIONS

Our findings indicate that UPF consumption during pregnancy was not associated with breast density measures (%FGV or AFGV) in Chilean mothers. Further studies are needed to evaluate the long-term implications of UPF intake during pregnancy on BC risk and other health outcomes.

EFFECTIVENESS OF A PEER-LED DIGITAL HEALTH LIFESTYLE INTERVENTION FOR LOW-INCOME COMMUNITY AT RISK FOR CARDIOVASCULAR DISEASES (MYCARDIO-PEER)

Geok Pei Lim[1]; Jamuna Rani Appalasamy[2]; Badariah Ahmad[1]; Kia Fatt Quek[1]; Amutha Ramadas[1]
[1]Jeffrey Cheah School of Medicine and Health Sciences, Monash University Malaysia, Bandar Sunway, Malaysia; [2]School of Pharmacy, Monash University Malaysia, Bandar Sunway, Malaysia

BACKGROUND AND OBJECTIVES

Cardiovascular diseases (CVD) disproportionately affect low-income communities with limited access to preventive care. Peer-based interventions have shown promise in managing chronic diseases. However, their effectiveness in reducing the risk of CVD among low-income groups using digital health remains underexplored. This study aimed to evaluate the effectiveness of MYCardio-PEER, an 8-week peer-led digital health intervention for at-risk individuals in a low- and middle-income country.

METHODS

MYCardio-PEER was developed using five-step approach: 1) review of evidence; 2) development of behavioural change matrix; 3) creation of digital content and peer-led activities; 4) content validation; 5) feasibility and process evaluation. A quasi-experimental design was used to assess its effectiveness, where the intervention group (n=30) participated in the 8-week MYCardio-PEER program, and the control group (n=31) received standard lifestyle counselling. Changes in the Framingham General CVD Risk Score (FRS), CVD biomarkers, physical activity levels, and dietary intakes were assessed at Week 0 (baseline), Week 8 (post-intervention), and Week 20 (follow-up).

RESULTS

MYCardioPEER resulted in greater reductions in FRS ($F= 3.937$, $p<0.05$, $\eta2= 0.063$), energy intakes ($F= 8.807$, $p<0.001$, $\eta2= 0.130$), and processed foods intakes ($F= 3.248$, $p<0.05$, $\eta2= 0.052$) as compared to the control group. Additionally, participants in the intervention group had a significantly greater increase in dietary fibre intakes ($F= 11.126$, $p<0.001$, $\eta2= 0.159$).

CONCLUSIONS

MYCardio-PEER successfully improved diet and lifestyle behaviours, and reduced CVD risk scores in individuals from low-resource settings. These findings suggest that MYCardio-PEER offers a scalable solution to reduce CVD risk factors and improve health outcomes in underserved populations.

COMPARISON OF CONVENTIONAL ANTHROPOMETRY AND DUAL-ENERGY X-RAY ABSORPTIOMETRY (DEXA)-DERIVED MEASURES OF BODY COMPOSITION AND THEIR ASSOCIATIONS WITH GLYCATED HAEMOGLOBIN (HBA1C) IN A LARGE, MULTI-ETHNIC COHORT

Shehab Uddin Al Abid[1]; Nor Azian Abdul Murad[2]; Bastian Bohrmann[1]; Noraidatulakma Abdullah[2]; Fiona Bragg[1]; Fredrik Karpe[3]; Sarah Lewington[1]; Chin Siok Fong[2]; Rahman Jamal[2]; Jennifer L. Carter[1]
[1]Nuffield Department of Population Health, University of Oxford, Oxford, United Kingdom; [2]UKM Medical Molecular Biology Institute, UKM Medical Molecular Biology Institute (UMBI), Cheras, Malaysia; [3]Oxford Centre for Diabetes, University of oxford, Oxford, United Kingdom

BACKGROUND AND OBJECTIVES

No large-scale studies have robustly examined body composition measures across multi-ethnic populations using Dual Energy X-ray Absorptiometry (DEXA) scans. Additionally, the relationship between body composition and glycated haemoglobin (HbA1c) in diverse populations remains understudied.

METHODS

DEXA scans were performed on 5,443 individuals from the Malaysian Cohort (36% Malay, 44% Chinese, and 20% Indian) between 2020 and 2023, mean age was 58.1 (SD 7.8) years. Sex-specific linear regression models compared conventional anthropometry and DEXA-derived measures (total fat as a % of total mass, and regional fat as a % of total fat) across ethnicities. All anthropometric and DEXA-derived measures were standardised (mean = 0, standard deviation = 1) to facilitate the comparison of effect sizes across measures. After excluding participants with diagnosed diabetes, multivariable linear regression models compared associations of body composition with HbA1c across ethnicities.

RESULTS

Chinese participants consistently had the lowest body composition measures compared to Malay and Indian participants. At every given level of BMI, Indian participants had a higher %body fat than Chinese and Malay participants (approximately 2% higher in men, and 6% higher in women). Chinese participants had similar associations of anthropometric and DEXA-derived measures with HbA1c, but in Indian participants, DEXA measures had stronger associations with HbA1c than anthropometric measures. For example, in Indian women, a 1-SD higher waist circumference was associated with a 0.19 unit (95% CI: 0.08 to 0.31) increase in HbA1c, whereas a 1-SD higher %visceral fat was associated with a 0.29 unit (95% CI: 0.18 to 0.41) increase. Notably, no anthropometric measures were inversely associated with HbA1c, whereas DEXA-derived measures such as %gynoid fat, %leg fat and %lean body mass showed inverse associations.

CONCLUSIONS

There were distinct patterns of differences in DEXA-derived body composition across ethnicities that were not captured by conventional anthropometry. Indian participants generally had higher fat mass compared to their Malay and Chinese counterparts across BMI levels, with this difference more prominent among women. Compared to anthropometry, DEXA-derived measures showed stronger associations with HbA1c among Indian participants.

OAP 13 - NON COMMUNICABLE DISEASES

OAP13_01

GLYCAEMIC LOAD, GLYCAEMIC INDEX, AND SENSORY ASSESSMENT OF TRADITIONALLY PREPARED AND INNOVATIVE BARLEY-BASED FOOD PRODUCTS

Radhika Madhari[1]; Noorjahan Pehlari[1]; Prasanthi P S[1]; Brinda S A[1]; Srinivas E[1]
[1]Department of Dietetics, ICMR - National Institute of Nutrition, Hyderabad, India

BACKGROUND AND OBJECTIVES

Non-communicable diseases (NCDs) like cardiovascular disorders, Diabetes Mellitus, and malignancy are increasingly prevalent in developing nations, driven by a shift from traditional foods to processed meals. A diet low in glycemic index (GI) and glycemic load (GL) can help prevent and manage NCDs. Barley, recognized as a functional food for its high dietary fiber content and benefits in blood glucose regulation, remains underutilized in everyday diets despite its low GI. This study aims to develop and standardize two barley-based, easy-to-prepare recipes as alternatives to Indian traditional dishes like curd rice, while assessing their GI and GL to promote healthier dietary choices.

METHODS

Barley curd (BC) and barley porridge (BP) were developed using locally available ingredients as alternatives to curd rice and rice porridge. The recipes were dried, powdered, and analyzed for proximate composition and available carbohydrate content using AOAC METHODS. Sensory evaluation was done by 50 volunteers to assess the palatability of the developed products along with their standard counterparts. The GI testing was done in 20 volunteers once they satisfied the inclusion criteria. Anthropometric data were recorded using standard protocols. Glucose levels were measured using a glucometer at fasting (-15, 0) and post-ingestion until 120 minutes (15, 30, 60, 90, 120). The GI testing involved consuming reference glucose (25g available carbohydrate) and test foods (barley curd and porridge) with a 2-day washout between sessions, ensuring accurate blood glucose profiling.

RESULTS

The proximate analysis showed that barley-based foods had higher total and insoluble dietary fiber than rice-based counterparts, with comparable other parameters. Sensory evaluations ranked the products' acceptability as: Curd Rice > Barley Curd > Barley Beverage > Rice Beverage. Barley beverage was superior to rice beverage in taste, texture, and overall acceptability. Both barley curd and barley beverage were low-GI foods (<55), with GI values of 44.5 ± 3.46 and 39.7 ± 2.88, respectively. Their glycemic loads (GL) were also low (<10), at 3.9 for barley curd and 4.4 for barley beverage, indicating their suitability for low-GI diets.

CONCLUSIONS

The developed recipes exhibited superior fiber content and were well-accepted in sensory evaluations which demonstrates the potential of barley-based foods as viable alternatives to traditional Indian dishes. These barley products may offer a practical dietary shift to help manage and prevent non-communicable diseases.

OAP13_02

EFFICACY OF ZINC FORTIFIED AND FERMENTED WHEAT FLOUR (EZAFFAW): A RANDOMIZED CONTROLLED TRIAL

Jai Das[1]; Zulfiqar Bhutta[2]
[1]Institute for Global Health and Development, Aga Khan University, Karachi, Pakistan; [2]Center for Global Child Health, The Hospital for Sick Children, Toronto, Canada

BACKGROUND AND OBJECTIVES

Zinc deficiency poses significant health risks, particularly in low-income settings. This RCT aims to evaluate the impact of agronomically zinc biofortified (fermented and non-fermented) and post-harvest wheat flour flatbread on zinc status and metabolic health in adolescents and adult women in rural Pakistan.

METHODS

A four-arm triple-blind randomized controlled trial was conducted in a rural district of Pakistan. Participants (adolescents aged 10–19 and adult women aged 20–40) were assigned to receive fermented or unfermented high zinc agronomically biofortified wheat flour flatbread, post-harvest zinc-fortified wheat flour flatbread, or low zinc conventional whole wheatflour flatbread. teh outcomes included serum zinc concentration, zinc deficiency, Body Mass Index (BMI, HbA1C, HOMA-IR and lipid profile. The meal was served once a day, six days a week for six months. This trial adhered to CONSORT guidelines for randomized trials, with primary analysis on an intention-to-treat basis The trial is registered with number NCT06092515.

RESULTS

A total of 1044 participants were randomized to four study arms. The baseline characteristics of the participants of the four study arms were comparable. At endline all the groups showed improvement from their respective baseline levels for serum zinc, anthropometry and metabolic markers. The multivariable analysis suggests statistically significant differences among the four groups in HbA1c, fasting blood glucose and triglyceride levels, while there was no significant difference for serum zinc or BMI.

CONCLUSIONS

The RESULTS highligh the role of agronomically zinc biofortified wheat flour in improving zinc status and metabolic health. Findings may inform public health strategies to combat zinc deficiency in resource-limited settings.

OAP13_03

ASSOCIATION OF LIFESTYLE PATTERNS WITH THE INCIDENCE OF MAJOR CHRONIC DISEASES: EVIDENCE FROM THE PROSPECTIVE LIFELINES STUDY

Qian Zou[1]; Rafael Ogaz-González,[1]; Gerton Lunter,[1]; Eva Corpeleijn,[1]
[1]Epidemiology, University Medical Center Groningen, Groningen, Netherlands

BACKGROUND AND OBJECTIVES

Individual lifestyle risk factors negatively impact the incidence of major non-communicable diseases (NCDs) – type 2 diabetes (T2D), cancer, respiratory diseases (RD), and cardiovascular diseases (CVDs). However, the combined effects of lifestyle factors, as they interact in real-life scenarios, on NCDs remain unclear. We previously identified five common lifestyle patterns based on six domains of lifestyle factors (nutrition, physical activity, stress, restorative sleep, social connection, and substance use) which we termed 'Healthy but physically inactive', 'Unhealthy but no substance use', 'Healthy in a balanced way', 'Unhealthy but light drinking and never smoked' and 'Unhealthy' lifestyle patterns. We aimed to explore the relationships between these lifestyle patterns and the four leading NCDs.

METHODS

We used data from the Lifelines cohort, including adults aged ≥18 years free of the relevant diseases at baseline. Outcomes were based on questionnaires and clinical records. Competing risk models were used to estimate associations between lifestyle patterns and disease incidences while treating death as a competing event, adjusted for socio-demographics, and taking the 'Unhealthy' pattern as the reference group.

RESULTS

The overall mean age was 45 (SD 13) years and 59% were females. Among 114 919 (T2D), 131 248 (cancer), 91 711 (RD), and 77 645 (CVDs) participants from four sub-cohorts, 3114, 4685, 4133, and 2850 incident cases occurred over 17.4 years, respectively. For T2D, the 'Healthy but physically inactive', 'Healthy in a balanced way', and 'Unhealthy but light drinking and never smoked' patterns were significantly protective (sub-distribution hazard ratio (SHR) equaling 0.86 (95%CI 0.75-0.99), 0.62 (95%CI 0.55-0.69), and 0.84 (95%CI 0.75-0.93), respectively), while the 'Unhealthy but no substance use' pattern increased risk (SHR 1.32, 95% CI 1.15-1.52). For cancer, the 'Healthy in a balanced way' (SHR 0.89, 95% CI 0.81–0.99) and 'Unhealthy but light drinking and never smoked' (SHR 0.86, 95%CI 0.77-0.95) patterns were protective. Incidence risk of RD was lower within the 'Healthy but physically inactive' (SHR 0.84, 95%CI 0.74-0.96) and 'Healthy in a balanced way' (SHR 0.84, 95%CI 0.75-0.93) patterns. No significant associations were observed for CVDs. When stratified by sex, significant protective effects between lifestyle patterns and cancer incidence persisted in females but were not observed in males.

CONCLUSIONS

Diverse relationships between integrated lifestyle patterns with NCDs highlight the importance of tailored, sex-specific lifestyle pattern interventions.

Public support and perspectives on the taxation of sugar-sweetened beverages: RESULTS from a nationally representative pre-implementation survey

Annabel Yeboah-Nkrumah[1]; Stefanie Vandevijvere[2]; Kobby Mensah[3]; Elizabeth Orlan[4]; Silver Nanema[1]; Sakyi Kwame[5]; Akosua Pokua Adjei[6]; Amos Laar[1]
[1]Department of Population, Family and Reproductive Health, University of Ghana School of Public Health, Accra, Ghana; [2]Department of Epidemiology and Public Health, Sciensano, Brussels, Belgium; [3]Business School, University of Ghana, Accra, Ghana; [4]Food and Nutrition Program, Global Health Advocacy Incubator, Washington D.C, United States of America; [5]School of Health Sciences, Oakland University, Michigan, United States of America; [6]Department of Sociology, Memorial University of Newfoundland and Labrador, Newfoundland and Labrador, Canada

BACKGROUND AND OBJECTIVES

The global increase in obesity and diet-related non-communicable diseases (NCDs) is linked to the increasing consumption of sugar-sweetened beverages (SSBs). Fiscal measures such as a tax on SSBs are considered an effective public health strategy to improve diets and reduce NCDs. This study investigates the awareness of the health risks associated with the consumption of SSBs and public support for a proposed SSB tax before its implementation.

METHODS

The study was cross-sectional in design and involved a total of 7,794 adults aged 18 years and above. Data was collected through survey METHODS deployed in three phases, first via a short message service survey, with panel data of about 140,000 residents' telephone numbers. Second, through a social media survey to enhance coverage and help reach different populations. And third, through field data collection with support from trained enumerators. Stratified sampling techniques were used to ensure that the sample was nationally representative. The data was analyzed descriptively using Stata.

RESULTS

About 70% of the participants were concerned about obesity and NCDs, especially among children. A majority (90.5%) of respondents reported being aware that "too much" sugar consumption is linked to several health problems. Specifically, 77.7% of the respondents were aware that SSBs are a major contributor to the obesity problem. Furthermore, 74.8% indicated it is important for the Government to take steps that discourage the consumption of SSBs. Two out of three respondents (67.7%) indicated they would support the Government's efforts to impose a tax on SSBs. Support for a tax increased to 77.4% contingent on the tax revenue being used to support public health interventions. Support for a tax was high among those with higher education and those aware that SSBs contribute to obesity. Those who consumed SSBs most frequently expressed less (38.6%) support for the implementation of a tax on SSB.

CONCLUSIONS

The findings show that participants are aware that SSBs are a major contributor to the obesity problem and support the implementation of an SSB tax as a measure to improve diets.

DIETARY SUPPLEMENT USE AND LIFE EXPECTANCY AFTER BREAST CANCER – THE DANISH DIET, CANCER AND HEALTH COHORT

Cecilie Kyrø[1]; Mia Klinten Grand,[2]; Janne Bigaard[3]; Maria Rossing[4, 5]; Ann Knoop[6]; Niels Kroman[7, 8]; Lene Mellemkjær[1]; Christina C. Dahm[9]; Pernille Bidstrup[10]; Anne Tjønneland[1, 11]; Anja Olsen,[1, 9]
[1]Diet, Cancer and Health, Danish Cancer Institute, Copenhagen, Denmark; [2]Statistics and Data Analysis, Danish Cancer Institute, Copenhagen, Denmark; [3]Cancer Prevention and Information, Danish Cancer Institute, Copenhagen, Denmark; [4]Department of Genomic Medicine, Rigshospitalet, Copenhagen, Denmark; [5]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; [6]Department of Oncology, Rigshospitalet, Copenhagen, Denmark; [7]Management Department, Danish Cancer Society, Copenhagen, Denmark; [8]Department of Breast Surgery, Rigshospitalet, Copenhagen, Denmark; [9]Department of Public Health, Aarhus University, Aarhus, Denmark; [10]Cancer Survivorship, Danish Cancer Institute, Copenhagen, Denmark; [11]Department of Public Health, University of Copenhagen, Copenhagen, Denmark

BACKGROUND AND OBJECTIVES

Dietary supplement use is widespread among women with breast cancer, but the evidence of the possible health benefits or harms remains limited.

The objective was to investigate the association between use of dietary supplements and life expectancy after breast cancer.

METHODS

Data from the Danish Diet, Cancer and Health cohort was used. Repeated measures of dietary supplements intake were available. We followed 1948 incident cases of breast cancer from diagnosis until migration, death, end-of-follow-up or 20 years. 723 died during this time; 450 due to breast cancer. Pre-diagnostic dietary supplements use and difference in 20-year life expectancy and life years lost due to breast cancer and other causes, respectively were estimated using pseudo-observations and regression models adjusted for potential confounders.

RESULTS

No association was found for any use of dietary supplements, however use of solely multivitamins was associated with longer life expectancy after breast cancer (0.98 years, 95% CI: 0.01–1.95), particularly fewer years lost due to breast cancer (-1.06 years, -1.85–-0.28).

High supplementary intakes of vitamins A, B12 and D, iron and magnesium tended to be associated with poorer life expectancy. Indications of poorer life expectancy were found for antioxidant supplements among those that received chemotherapy.

CONCLUSIONS

Multivitamins alone may be beneficial for women with breast cancer, whereas excess use may not. High intakes of certain micronutrients from dietary supplements may impair survival, especially antioxidant supplements use during chemotherapy.

Women with breast cancer should pay caution when using dietary supplements and limit use, if any, to multivitamins only.

OAP13_07

IS INTESTINAL CD36 INVOLVED IN THE DEVELOPMENT OF WESTERN DIET-INDUCED OBESITY?

Tatiana Al Anaissy; Lorène Lebrun; Annabelle Tavernier; Jean-François Merlin; Guillaume Maquart; Jocelyn Trebern; Jean Christophe Blanchard; Isabelle Niot

BACKGROUND AND OBJECTIVES

Obesity is linked to insulin resistance, hyperglycemia, hypertriglyceridemia, and endotoxemia. The intestine plays a key role in lipid absorption, permeability, and incretin-mediated insulin secretion. CD36, an ubiquitous membrane receptor for long-chain fatty acids expressed in intestinal epithelial cells, is involved in chylomicron formation, permeability regulation (1), and peptide secretion (2). CD36 polymorphisms in humans are associated with a higher risk of metabolic syndrome (3). This study aimed to assess the contribution of intestinal CD36 in obesity development under a Western Diet (WD).

METHODS

Male and female mice deficient in CD36 in the intestinal epithelial cells (*Cd36*-Ent(-/-)) and their control littermates (CTL; *Cd36*-Ent(+/+)) were fed a WD or control diet (CD) (ssniff) for 15 weeks (n=17-20/group). Body mass, body composition and food intake were monitored. Triglyceridemia and endotoxemia were measured in fasting and postprandial states (4 hours after oil gavage). Intestinal triglyceride (TG) secretion was assessed following lipoprotein lipase inhibitor injection before oil gavage. Glucose and insulin tolerance tests (OGTT, ITT) were also performed. Mice were sacrificed in fasting (n=8) or postprandial states (n=8). Statistical analyses (ANOVA, Student's *t*-test, non-parametric tests) compared WD and CD effects within genotypes using GraphPad Prism.

RESULTS

The WD significantly increased body mass and fat mass in both mouse genotypes and genders. However, deletion of intestinal CD36 did not affect body mass nor diet efficiency but resulted in a greater fat mass gain in the WD-fed *Cd36*-Ent(-/-) mice of both genders compared to CD-fed *Cd36*-Ent(-/-) mice. Intestinal TG secretion decreased on the WD in both genotypes but remained significantly higher in *Cd36*-Ent(-/-) male mice than in CTL mice (p=0.03), without affecting postprandial triglyceridemia. After gavage, endotoxemia was elevated only in WD-fed *Cd36*-Ent(-/-) males (p=0.05). Nevertheless, WD-fed *Cd36*-Ent(-/-) mice showed enhanced insulin sensitivity (p=0.0003) and no glucose intolerance compared to CTL males (p=0.006).

CONCLUSIONS

Intestinal epithelial CD36 limits WD-induced fat mass gain, postprandial TG secretion and endotoxemia. However, it promotes glucose intolerance and insulin resistance under a WD. Further investigations are required to understand these observations.

PRIORITIZING BEHAVIOURS TO ADDRESS THE TRIPLE BURDEN OF MALNUTRITION IN ADOLESCENTS: EVIDENCE FROM CAMEROON

Diane Dione EKWOGE[1]; Brice Ulrich Foudjou Saha[2]; Jean-Arnaud Ndi Manga[3]; Joelle Laure Sobngwi-Tambekou[1]; Eugene Sobngwi[4]
[1]Research Division, RSD INSTITUTE, Yaoundé, Cameroon; [2]Department of Biochemistry, Bamenda, Cameroon, University of Bamenda, Bambili, Bamenda, Cameroon; [3]Faculty of Medicine, Pharmacy and odontostomatology, University Cheikh Anta Diop of Dakar, Senegal, Daka, Senegal; [4]Department of Endocrinology and diabetology, Faculty of Medicine and Biomedical Sciences, University of Yaounde 1, Cameroon, Yaounde, Cameroon

BACKGROUND AND OBJECTIVES

Malnutrition is a major public health problem affecting adolescents. Unhealthy dietary intake and a sedentary lifestyle contribute significantly to the rising burden. Interventions that promote few and well-contextualized healthy behaviors are effective in preventing malnutrition. This study aimed to use Kneebone's Impact-Likelihood approach to identify behaviors on which to focus a social and behavior change program for adolescents in Cameroon.

METHODS

A narrative review of published literature on malnutrition was used to identify an initial list of behavioral factors associated with malnutrition in adolescents. An online survey with 12 experts helped to generate 26 context-specific behaviors. Twenty-four experts attributed impact scores to each identified behavior. A survey with 842 adolescents was conducted to generate the participation rates and likelihood of adoption scores of each identified behavior. These scores were converted into Z scores and mapped onto a 04-quadrant graph to generate an impact-likelihood matrix.

RESULTS

Five (05) dietary behaviors: avoiding unhealthy snacking, eating 5 portions of fruits and vegetables, limiting the intake of fast foods, eating calcium-rich foods, taking breakfast every morning; and Two (02) health-related behaviors: taking iron supplements when menstruating for girls, taking dewormers twice per year were identified as behaviors with the highest impact on preventing malnutrition by experts and are likely to be easily adopted according to adolescents.

CONCLUSIONS

This study identified 07 behaviors that should inform the development of context-specific and effective social and behavior change programs for adolescents in Cameroon. By synthesizing existing literature and validating identified behaviors through expert consultation, this research provides a robust foundation for designing targeted interventions in Cameroon

LONGER BREASTFEEDING DURATION REDUCES THE RISK OF SUBCLINICAL CARDIOVASCULAR DISEASE

Maja Sandberg[1]; Ingrid Mogren[2]; Hanna Augustin[1]; Anna Winkvist[1]; Stefan Söderberg[3]; Hilde. K. Brekke[4]; Sofia Klingberg[1]
[1]Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; [2]Department of Clinical Sciences, Faculty of Medicine, Obstetrics and Gynecology, Umeå University, Umeå, Sweden; [3]Department of Public Health and Clinical Medicine, Faculty of Medicine, Umeå University, Umeå, Sweden; [4]Department of Nutrition, Institute of Basic Medical Sciences, University of Oslo, Oslo, Norway

BACKGROUND AND OBJECTIVES

Cardiovascular disease (CVD) is the number one cause of death among women worldwide. While parity increases the risk, breastfeeding is a suggested protector against CVD. Coronary artery calcification score (CACS) is a sensitive predictor for future CVD. However, previous literature on the relationship between breastfeeding and CACS is limited. We therefore aimed to determine the impact of breastfeeding duration on the subclinical CVD risk marker CACS.

METHODS

Parous women aged 50-64 years, taking part in the national cohort SCAPIS (Swedish CArdioPulmonary Bioimage study) who responded to questions on exclusive and partial breastfeeding, and who underwent a coronary computed tomography angiography (CCTA) were included in the current analysis. The calcium content of each coronary artery was determined using CCTA and scored into a total CACS according to the Agatston method. For each woman, the average duration of exclusive and any breastfeeding (exclusive plus partial) per child was calculated. The odds ratio (OR) and 95% confidence interval (CI) of calcification (CACS >0), as compared to no calcification (CACS 0), were calculated using multivariable logistic regression. Confounders were based on a priory knowledge.

RESULTS

In our sample including 957 women, CACS ranged from 0 to 2208 with 29.5 % having a CACS of >0. Among women with a CACS > 0, the median CACS was 18 (IQR: 5.0–60.3). The median duration of exclusive breastfeeding per child was 4.8 months (IQR: 3.5–5.7), and for any breastfeeding it was 8.3 months (IQR: 5.5–12.7). After adjustments for age at study inclusion, education (≤12 years vs. >12 years), smoking (ever vs. never), body mass index (BMI) before first pregnancy and number of births, duration of any breastfeeding per child significantly decreased the likelihood of CACS >0 by 3% (0.97 (0.93;1.00, p=0.039)), while duration of exclusive breastfeeding did not significantly impact CACS (0.98 (0.93;1.04). Further adjustment for family disease history (diabetes, myocardial infarction, and stroke) and weight change from before the first pregnancy until inclusion yielded similar RESULTS. When further adjusting for CVD risk factors in midlife (fasting glucose, HDL cholesterol, total cholesterol, and systolic blood pressure) RESULTS for any breastfeeding were attenuated to non- significance (0.97 (0.93;1.00, p=0.052)) and RESULTS for exclusive breastfeeding remained non-significant.

CONCLUSIONS

Subclinical CVD risk in parous women may be reduced by longer breastfeeding. However, these findings were not independent of CVD risk profile in midlife.

OAP21_02

THE EFFECT OF DIFFERENT FAT SOURCES ON POSTPRANDIAL INFLAMMATION: A RANDOMIZED DOUBLE-BLIND STUDY

Naman Limani[1]; Hege Berg Henriksen[2]; Mina Marie Minge[2]; Rikard Landberg[3]; Helen M Lindqvist[1]; Stine M Ulven[2]; Linnea Bärebring[1]
[1]Department of internal medicine and clinical nutrition, Institute of Medicine, University of Gothenburg, Gothenburg, Sweden; [2]Department of Nutrition, Institute of Basic Medical Sciences, University of Olso, Oslo, Norway; [3]Department of Life Sciences, Food and Nutrition Science, Chalmers University of Technology, Goth, Sweden

BACKGROUND AND OBJECTIVES

Low-grade inflammation is a risk factor for chronic diseases such as type 2 diabetes and cardiovascular disease. Consuming a high-fat meal can induce an acute inflammatory response, however the effect of different fat sources on postprandial inflammation is less understood. Therefore, we investigated whether different sources of saturated fatty acids (SFA) and polyunsaturated fatty acids (PUFA) have differential effects on postprandial inflammation.

METHODS

In a double-blind randomized, two site, 4-way crossover design, 18 healthy participants consumed isocaloric brownies (706 kcal) with different fat sources (butter, coconut oil, flaxseed oil, or corn oil) for breakfast. Blood samples were collected in the fasting state and at 2-hour intervals up to 6 hours post-ingestion. Inflammation markers were analyzed by multiplex immunoassay (Target 96, Inflammation panel, Olink Proteomics, analyzed by SciLifeLab, Uppsala, Sweden). In addition Glycoprotein Acetyls (GlycA) was analyzed by Nuclear Magnetic Resonance (analyzed by Nightingale Health). Data analyses were conducted in two stages. First, postprandial changes of 93 inflammation biomarkers between baseline (0 h) and up to 6 h post-ingestion were analyzed by linear mixed models. Each biomarker was set as a dependent variable and time points for study visits were included as repeated and fixed effects, while individual participants (ID) and study site as random effects. Inflammation markers that were significantly affected in the postprandial state ($p<0.05$) were included in a subsequent linear mixed model analysis that included time, fat source and their interaction as fixed factors, while ID and site were random factors.

RESULTS

A total of 20 (21%) inflammation markers were affected in the postprandial state ($p < 0.05$). Only GlycA was significantly different ($P = 0.002$) for time*fat source interaction. GlycA concentrations increased over the 6-hour period after consumption of both PUFA sources, corn oil (peaking at 2 hours) and flaxseed oil (peaking at 4 hours). SFA rich meals with butter and coconut oil did not significantly affect GlycA concentrations compared to baseline.

CONCLUSIONS

The RESULTS of the PI-Fat study demonstrates that 21% of the inflammation markers were affected in the postprandial state. Whether the source of fat is SFA or PUFA, seems to have a minor impact on postprandial inflammation.

ASSOCIATION OF FREE AND NON-FREE SUGAR INTAKE WITH DEMENTIA RISK AND THE MODULATING ROLE OF GUT MICROBIOTA: A PROSPECTIVE COHORT STUDY FROM UK BIOBANK

An Yu[1]; Cao Limin[2]; Xia Yang[3]
[1]Department of Endocrinology, Beijing Chao-Yang Hospital, Beijing, China; [2]Department of Science and Technology, The Third Central Hospital of Tianjin, Tianjin, China; [3]Department of Clinical Epidemiology, Shengjing Hospital of China Medical University, Shenyang, China

BACKGROUND AND OBJECTIVES

While consumption of free sugars has been linked to an increased risk of dementia, the association between non-free sugar intake and incident dementia remains unclear. This study aimed to investigate the effects of sugar intake on dementia and to characterize the influence of gut microbiota on this association.

METHODS

In this cohort study, 158,408 participants from the UK Biobank were analyzed. Dietary intake of free and non-free sugars was assessed through repeated web-based 24-hour dietary recalls. Polygenic risk scores (PRS) for Alzheimer's disease and specific gut microbiota were calculated from individual-level genotype data. A cause-specific competing risk model was used to estimate hazard ratios (HRs) and confidence intervals (CIs) for the associations between sugar intake, PRS, and incident dementia.

RESULTS

Over a median follow-up of 9.94 years, 1,219 participants (0.7%) developed dementia. Non-free sugar intake was positively associated with the risk of dementia in a linear relationship (HR for Quartile 4 vs. Quartile 1 = 1.26, 95% CI: 1.04–1.52). A nonlinear relationship was observed between free sugar intake and dementia risk (HR for Quartile 4 vs. Quartile 1 = 1.43, 95% CI: 1.20–1.70; P for nonlinearity = 0.04). Significant interactions were found between non-free sugar intake and PRS for *Ruminococcaceae UCG-014* (P for interaction = 0.02), and between free sugar intake and PRS for *Oscillospira* (P for interaction = 0.03). Participants with lower *Ruminococcaceae UCG-014* scores or higher *Oscillospira* scores had a higher risk of dementia associated with sugar consumption.

CONCLUSIONS

Consumption of both free and non-free sugars is associated with an increased risk of dementia onset. The influence of gut microbiota imbalance on these associations is notable. These findings underscore the importance of reducing sugar intake in dementia prevention and highlight the potential role of gut microbiota in its development.

OAP21_04

DIETARY BIOTIN INTAKE AND THE RISK OF CHRONIC KIDNEY DISEASE (CKD): A LARGE-SCALE PROSPECTIVE COHORT STUDY AND MECHANISTIC EXPLORATION

Xiaojin Shi[1]; Da Zhang[2]; Junhan Zhang[1]; Yuefeng Tan[1]; Xiaona Na[1]; Jigen Na[1]; Ai Zhao[1]
[1]Vanke school of public health, Tsinghua University, Beijing, China; [2]School of Public Health, Capital medical, Beijing, China

BACKGROUND AND OBJECTIVES

Chronic kidney disease (CKD), as an irreversible condition, affects over 800 million individuals globally. Among the multifaceted factors of CKD, lifestyle and dietary factors are considered paramount. Biotin plays an important role in certain metabolic disorders such as obesity and diabetes mellitus. However, the association between biotin and CKD remains unclear. Therefore, we conducted this study to investigate the association between biotin intake and the risk of incident CKD and preliminarily explore potential mechanisms.

METHODS

The prospective data in this population-based cohort study were derived from the UK Biobank, included 207,513 participants without a history of CKD who had completed at least one 24h dietary recall. Biotin intake was divided into low, moderate, and high groups by tertiles. Multivariable Cox proportional hazards models were used to establish the hazard ratios (HRs) for the associations between biotin intake and the risk of incident CKD, adjusted by demographic, lifestyle and other dietary factors. Stratified analyses were performed based on baseline age, sex and CKD subtypes. Sensitivity analysis was conducted among participants who had completed at least 2 times 24h dietary recall. Additionally, the STRING database was used to establish the protein-protein interaction (PPI) network for potential target genes of biotin and CKD. Based on PPI RESULTS, Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment analysis was further conducted in this study.

RESULTS

Compared with low group, moderate (HR = 0.85[0.81,0.89]) and high (HR = 0.77[0.73,0.82]) group had lower risk of CKD. Similar RESULTS were found in stratified analysis by gender and age. Biotin intake served as a significant protective factor in both acute and chronic renal failure, however, no significant association was observed for unspecified renal failure. The RESULTS also remained robust in sensitivity analysis. The PPI network comprised 62 nodes and 322 edges, featuring core genes like EGFR, CASP3, HSP90AA1, VMP9, CXCL6, SIRT1, MDM2, PARP1, ACC, C-CBL, PTGS2, and APAF1, which are key in CKD development and interact with biotin. KEGG analysis revealed that the core genes primarily affect cell proliferation, differentiation and apoptosis, as well as inflammatory and metabolic processes.

CONCLUSIONS

Our population-based study first revealed that dietary biotin plays a protective role in CKD, which may be mediated through renal electrolyte metabolism, cell proliferation and repair.

MATERNAL PREBIOTIC SUPPLEMENTATION (GOS/INULIN) DURING PREGNANCY: EFFECTS ON THE IMMUNE SYSTEM AND ATOPIC DERMATITIS PREVENTION IN CHILDREN

Carole Brosseau[1]; Nicolas Degauque[2]; Virginie Lollier[1]; Eugénie Durand[2]; Sophie Brouard[2]; Véronique Cariou[3]; Benjamin Mahieu[3]; Sébastien Barbarot[4]; Marie Bodinier[1]
[1]UR1268 BIA, Inrae, Nantes, France; [2]INSERM, CR2TI-U1064 The Center for Research in Transplantation and Translational Immunology, Nantes, France; [3]StatsSC, ONIRIS, Nantes, France; [4]Dermatology, CHU Nantes, Nantes, France

BACKGROUND AND OBJECTIVES

Atopic dermatitis (AD) is associated with early imbalances in the gut microbiota as well as in the cutaneous and peripheral immune systems. Prebiotics exhibit immunomodulatory properties and influence the composition and function of the microbiota. As prenatal life is a critical period for establishing immune tolerance, we investigated whether nutritional supplementation with prebiotics during pregnancy could prevent AD in children at high risk (PREGRALL clinical trial, NCT03183440). Despite observed modulation of the gut microbiota in mothers and children, no preventive effect on AD was found. This study aimed to characterize the impact of prebiotic supplementation during pregnancy on the immune system of mothers and children, and to understand the immune mechanisms involved in the onset of AD in children.

METHODS

The frequency of immune cell populations (T and B lymphocytes, dendritic cells) and their secretory functions were assessed using spectral flow cytometry in blood samples from 120 mothers recruited in the PREGRALL trial at 32 weeks of gestation (supplementation started at 20 weeks of gestation) and in blood samples from their children at 1 year of age.

RESULTS

At 32 weeks of gestation, the blood of mothers receiving prebiotic supplementation showed no significant differences compared to control mothers. However, the blood of children with AD at 1 year was significantly different from that of AD-free children born to prebiotic-supplemented mothers ($p < 0.01$), marked by an increase in biomarkers of immune tolerance and a decrease in biomarkers of allergy.

CONCLUSIONS

Prebiotic supplementation during pregnancy did not demonstrate a preventive effect on atopic dermatitis in children at 1 year of age but had a significant impact on their immune status by promoting tolerance and reducing pro-inflammatory biomarkers of allergy. These RESULTS suggest a potential preventive effect on other allergic diseases that may develop after the age of 1 year.

MISALIGNMENT BETWEEN CIRCADIAN PREFERENCE AND ACCELEROMETER-DERIVED SLEEP-WAKE CYCLE WITH INCREASED RISK OF CARDIOMETABOLIC DISEASES

Yue Chen; Geng Tingting[1]; Xu Xinming[2]; Zhang Zhicheng[2]; Huang Lili[2]; Dong Haiyang[2]; Yu Huan[3]; Xiang Gao[4]; Sun Liang[5]

[1]Department of Epidemiology and Biostatistics, School of Public Health, Tongji Medical College, Huazhong University of Science and Technology, Wu Han Shi, China; [2]Department of Nutrition and Food Hygiene, School of Public Health, Institute of Nutrition, Fudan University, Shanghai, China; [3]Department of Neurology, Sleep and Wake Disorders Center, Huashan Hospital, Fudan University, Shanghai, China; [4]Department of Nutrition and Food Hygiene, Fudan University, Shanghai, China; [5]Department of Nutrition and Food Hygiene, School of Public Health, Institute of Nutrition, Fudan, Shanghai, China

BACKGROUND AND OBJECTIVES

The relationship of circadian misalignment, sleep-wake cycle, and cardiometabolic diseases (CMDs) remains unclear. This prospective study investigated the associations between circadian misalignment and CMDs, including type 2 diabetes (T2D), coronary heart disease (CHD), and stroke, and explored potential mechanisms.

METHODS

Data from 60,965 participants without pre-existing CMDs from the UK Biobank study and followed for an average of 7.9 years were analyzed. Circadian misalignment was determined by comparing self-reported chronotype and accelerometer-derived sleep timing. Incident CMDs were documented via multiple medical registries and self-reported information. Cox proportional hazards models were applied to estimate HRs and 95% CIs for these associations.

RESULTS

A U-shaped relationship between circadian misalignment and both T2D and CHD was observed. Compared to individuals with aligned midsleep and circadian preferences (the third quintile, Q3), those with advanced and delayed circadian misalignment had higher risks of T2D (HR: 1.22 [95% CI: 1.03-1.45] for Q1 and 1.39 [95% CI: 1.18-1.62] for Q5). Delayed circadian misalignment also associated with higher CHD risk (HR: 1.15 [95% CI: 1.01-1.31] for Q4 and 1.16 [95% CI: 1.02-1.33] for Q5). The association between delayed circadian misalignment and CMDs was greater in women (T2D, *Pinteraction* = 0.03) and younger adults (CHD, *Pinteraction* = 0.02). Early (HR: 1.19 [95% CI: 1.06-1.34]), rather than late, chronotype was associated with an increased T2D risk.

CONCLUSIONS

Both advanced and delayed circadian misalignment were associated with an increased CMD risk, highlighting the potential health benefits of aligning sleep-wake cycles with individual circadian preferences.

MEDITERRANEAN DIETARY PATTERN AND BEHAVIOURAL INTERVENTION IN A NEW ZEALAND POPULATION AT INCREASED CARDIOMETABOLIC RISK: TWO SEQUENTIAL RANDOMISED CONTROLLED TRIALS; HE ROUROU WHAI PAINGA

Fiona Lithander[1]; Amber Parry Strong[2]; Richard Gearry[3]; Andrea Braakhuis[4]; Anna Worthington,[5]; Denise Conroy,[6]; Troy Merry,[5]; Mark Weatherall,[7]; Meika Foster,[8]; Anna Rolleston,[9]; Cecilia Ross,[2]; Jeremy Krebs,[7]

[1]Liggins Institute, University of Auckland, Auckland, New Zealand; [2]Centre for Endocrine, Diabetes and Obesity Research, Te Whatu Ora Health New Zealand Capital, Coast and Hutt Valley, Wellington, New Zealand; [3]Department of Medicine, University of Otago, Christchurch Campus, Christchurch, New Zealand; [4]Nutrition, University of Auckland, Auckland, New Zealand; [5]Department of Nutrition, University of Auckland, Grafton Campus, Auckland, New Zealand; [6]Food Innovation, Plant & Food Research, Sandringham, New Zealand; [7]Department of Medicine, University of Otago, Wellington, New Zealand; [8]Director, Edible Research;Ohoka, New Zealand, Christchurch, New Zealand; [9]Director, The Centre For Health; Tauranga, Tauranga, New Zealand

BACKGROUND AND OBJECTIVES

Cardiometabolic disease is common in New Zealand (NZ). Dietary patterns including the Mediterranean diet (MedDiet) are associated with a reduced risk of cardiovascular disease (CVD). The objectives are to test a) a NZ food-based Mediterranean diet (NZMedDiet) with behavioural intervention, and b) the effect of maintenance of the behavioural intervention on CVD health and wellbeing.

METHODS

Two sequential randomised, controlled trials (RCTs) were undertaken. The first (RCT1) was a randomised, controlled, multi-centre trial comparing 12 weeks (w) of NZMedDiet to usual diet in participants with increased CVD risk. The NZMedDiet group was provided with food, recipes and behavioural change support. At 12w, the usual diet group then received the intervention for 12w. The second RCT (RCT2) was undertaken after food provision discontinued in both groups (12 and 24w, respectively), and participants were randomised to ongoing behaviour change support versus no support for a further 12w. Primary and secondary outcome measures after 12 and 24w were the metabolic syndrome severity score (MetSSS) and quality of life (QoL) using the SF36, respectively.

RESULTS

Two hundred adults from a non-Mediterranean, multi-ethnic population took part. Baseline mean (sd) age was 49.8 (11.6)y and 49.9 (10.2)y in the NZMedDiet and control groups, respectively. In RCT1 at the end of 12w, there was no significant difference in mean MetSSS between the NZMedDiet and control group with an estimate (95% CI) of difference between groups; -0.05 (-0.16 to 0.06), p=0.35. No individual component of the MetSSS was different between groups at 12w. The difference between the NZMedDiet and control favoured a more Mediterranean dietary pattern at 12w ($p<0.001$). In RCT2, there was no significant difference in MetSSS between ongoing behaviour change support versus no support at the end of 24w with an estimate (95% CI) in mean MetSSS between the two groups; -0.02 (-0.12 to 0.09) (adjusted for baseline), p=0.75. There was a significant improvement in all components of QoL in the NZMedDiet compared with control in RCT1, but ongoing support made no difference to QoL in RCT2.

CONCLUSIONS

No improvement in the MetSSS in response to NZMedDiet over 12 or 24w was observed. Moving to a more Mediterranean dietary pattern alone is not enough to reduce the risk in this population. There was a significant improvement in QoL with the NZMedDiet and with withdrawal of food provision, ongoing support made no difference to QoL.

BACKGROUND AND OBJECTIVES

Colorectal cancer (CRC) is one of the most common and deadliest cancers worldwide. Lifestyle and anthropometric factors contribute significantly to CRC development, and the gut microbiome has been hypothesised to mediate these associations. However, studies to date have focused on the microbiome's associations with individual CRC risk factors, and the complex interactions between these factors have not been considered. Therefore, we studied associations of a lifestyle-based CRC risk index with microbial diversity and composition.

METHODS

We used data from the National FINRISK/FINDIET 2002 Study, including 1228 Finnish adults (55% women) aged 25–64 years. Diet was assessed with 48-hour dietary recalls. The CRC risk index included lifestyle and anthropometric factors strongly associated with CRC (body mass index [BMI], waist circumference [WC], height, physical activity, consumption of whole grains, dairy products, red and processed meat, and intake of alcohol). The index was scored between 0 and 4 points, higher scores indicating more favourable risk factor profiles for CRC prevention. The gut microbiome was analysed using shallow shotgun sequencing on whole metagenomic data. Individual microbial (alpha) diversity was assessed with the Shannon index and compositional differences (beta diversity) with the Bray-Curtis dissimilarity score. Statistical tests included linear models and permutational multivariate ANOVAs.

RESULTS

The CRC risk index was positively associated with alpha diversity (β 0.037, *P* 0.009). Of the index components, being physically active versus inactive was associated with a higher alpha diversity (β 0.091, *P* 0.042), whereas a higher BMI and WC were associated with a lower alpha diversity (BMI: β -0.045, *P* 0.002; WC: β -0.048, *P* 0.003). The dietary components were not statistically significantly associated with alpha diversity. The CRC risk index, as well as all index components, except for height and red meat consumption, were associated with beta diversity, explaining 0.1−0.4% of the variation in microbial compositions between participants (*P* <0.05).

CONCLUSIONS

Our RESULTS suggest that having more favourable risk factors for CRC prevention was associated with a higher individual microbial diversity compared with fewer favourable factors. Additionally, the CRC risk index contributed to compositional differences between participants. These findings support previous research indicating an inverse association between CRC risk and microbial diversity. Further research is needed to elucidate the underlying mechanisms.

FOLATE DEPLETION ALTERS DNA METHYLATION IN TISSUES RELEVANT FOR CHILDHOOD LEUKAEMIA

Jessica Saville[1]; Farah Nassar,[2]; Lisa Russell,[3]; Kay Padget,[4]; Cyrille Cuenin,[2]; Vincent Cahais,[2]; Akram Ghantous,[2]; Jill Mckay,[1]
[1]Applied Science, Northumbria University, Newcastle upon Tyne, United Kingdom; [2]Epigenomics and Mechanisms Branch, International Agency for Research on Cancer, Lyon, France; [3]Biosciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom; [4]Based at Northumbria University, St. George's University, Grenada, Newcastle upon Tyne, United Kingdom

BACKGROUND AND OBJECTIVES

Epidemiological evidence suggests maternal folate status influences childhood leukaemia risk; however, the underlying mechanisms are unclear. Genetic aberrations are considered leukaemia-initiating events, however, alone they are not sufficient for disease, with additional 'hits' required. Epigenetic alteration, i.e. DNA methylation, is one mechanism by which maternal folate is likely to contribute to disease. We investigated the relationship between folate depletion and DNA methylation in murine tissues relating to childhood leukaemia.

METHODS

Female mice were allocated low or normal folate diets for 4 weeks before mating and onwards. Offspring were sampled at 17.5 days gestation and weaning. DNA was isolated from fetal livers and bone marrow of weaned mice. Tissues correspond to specific sites of haematopoiesis throughout the lifecycle relevant to leukaemic blasts. Epigenome-wide DNA methylation was profiled using Infinium® MouseMethylation BeadChips. R/Bioconductor packages identified differentially methylated points (DMP) and regions (DMRs). Pathway analysis was conducted by DAVID.

RESULTS

There were 598 DMPs (382 hypermethylated/216 hypomethylated) and 363 DMRs with significantly (FDR) altered methylation in response to folate depletion in the fetal liver. In bone marrow, 1206 DMPs (334 hypermethylated/852 hypomethylated) and 565 DMRs had significantly altered methylation in response to folate depletion. Only 3 DMPs and 13 DMRs were altered in both tissue types, suggesting highly tissue specific responses. Pathway analysis suggested 15 and 44 pathways could be altered in response to folate depletion in liver and bone marrow respectively, with 8 overlapping between tissues.

CONCLUSIONS

Whilst loci specific altered methylation appears to be different between tissues, the impact on biological pathways is similar.

IS A HIGHER METABOLIC SYNDROME SCORE ASSOCIATED WITH BREAST DENSITY AFTER PUBERTY ONSET?

Ana Pereira[1]; Marcela Jacard,[2, 3]; Mariana Cifuentes,[1]; Maria Luisa Garmendia[1]
[1]CIAPEC, Institute of Nutrition and Food Technology, University of Chile, Santiago, Chile; [2]Digital Hospital, Ministry of Health, Santiago, Chile; [3]Radiology Department, Clínica Alemana, San, Chile

BACKGROUND AND OBJECTIVES

Metabolic syndrome (MS) is associated with an increased risk of breast cancer (BC). Puberty is a critical window of susceptibility for BC and there is limited information if MS during this period will increase BC risk. Breast density (% fibroglandular volume [%FGV]) is one of the strongest risk factors for BC and serves as an intermediate marker that can be measured at a younger age. A previous study by our group did not observe an association between MS and %FGV or absolute fibroglandular volume (AFGV) in premenopausal women. However, we observed a positive association between serum triglycerides (TG) and abdominal obesity with AFGV. Thus, the aim of this study was to evaluate the association between MS, measured at ages 16 and 19 years, and breast density parameters (%FGV and AFGV).

METHODS

Longitudinal follow-up of 602 girls recruited in 2006 (3.5y) from child care centers. We selected girls who had anthropometric data (body mass index (BMI) and waist circumference (WC)), metabolic data (insulin, glycemia, HDL-C, TG), blood pressure (BP), and breast density measurements by DXA at 16 and 19 y. Given the low prevalence of MS at this age (3-11%), we used the metabolic syndrome score (MetScore), derived by standardizing each component and summing the following variables: WC, systolic and diastolic BP, fasting insulin and glucose, and the TG/HDL-C ratio. We performed mixed linear effect models to evaluate the association of MetScore and each of its standardized components with %FGV and AFGV. Models were adjusted by BMI, age at menarche onset, and maternal education.

RESULTS

We collected data on 444 girls. The prevalence of obesity was 15.4% at 16y. Girls with obesity had a higher MetScore (16y: 3.3±0.3 vs. -0.5±0.1). MetScore and WC were inversely associated with %FGV in fully adjusted models (βMetS:-0.4; 95%CI:-0.8, -0.01 and βWC:-5.4; 95%CI:-7.0, -3.7). Glycemia, insulin, TG/HDL-C, and BP were negatively associated with %FGV, but it was lost after adjusting for BMI. In contrast, MetScore and insulin were positively associated with AFGV adjusting by age at menarche and maternal education (βMetS:4.9; 95%CI:2.6, 7.3 and βInsulin:7.0; 95%CI:0.5, 13.4), while WC was positively associated with AFGV even after adjusting for BMI (βWC:29.0; 95%CI:15.7, 42.3).

CONCLUSIONS

We observed an inverse association between MetScore and %FGV even after adjusting for BMI, but a positive association between MetScore and AFGV after adjusting for age at menarche and maternal education only. The latter could suggest that a higher metabolic risk during puberty could be a risk of breast cancer during adulthood, through a higher AFGV.

ASSOCIATION BETWEEN MUSHROOM CONSUMPTION AND DIGIT SPAN PERFORMANCE AMONG MIDDLE-AGED AND OLDER COMMUNITY-DWELLING JAPANESE: THE NILS-LSA PROJECT

Shu Zhang[1]; Muscat Joshua[2]; Yukiko Nishita[1]; Chikako Tange[1]; Djibril Ba[2]; Zhu Junjia[2]; Rei Otsuka[1]
[1]Epidemiology of Aging, National Center for Geriatrics and Gerontology, Obu, Japan; [2]Public Health Sciences, Penn State College of Medicine, Hershey, United States of America

BACKGROUND AND OBJECTIVES

Previous evidence shows that habitual consumption of mushrooms may benefit cognitive function. However, the relationship between mushroom consumption and working memory is remains unclear. This study aims to investigate this relationship.

METHODS

The analysis included 3,162 participants who participated in one or more of the third to ninth waves (2002−2022) of the National Institute for Longevity Sciences-Longitudinal Study of Aging and had complete data on mushroom consumption, digit span scores, and covariates. Consumption of mushrooms (g/day) at baseline was measured by 3-day dietary records. Working memory was assessed by (forward and reverse) digit span scores (range: 0−14 for each) from the Wechsler Adult Intelligence Scale-R. The relationships between mushroom consumption and (forward and reverse) digit span scores were analyzed using mixed-effects models with splines, adjusted for baseline information on centered age, square of centered age, sex, follow-up duration, energy intake, consumption of seafood, vegetables, and fruit, body mass index, smoking status, total physical activity, education level, medical history, and depressive symptoms.

RESULTS

The mean (standard deviation, SD) age of participants was 57.9 (13.1) years, and the mean (SD) follow-up duration was 10.5 (6.1) years. After full adjustment, natural spline regression with two degrees of freedom revealed a significant non-linear association between mushroom consumption and both forward digit span score (spline terms β_1 =1.189, p-value =0.0118; β_2 =2.509, p-value =0.0258) and reverse digit span scores (spline terms β_1 =0.961, p-value =0.0373; β_2 =2.157, p-value =0.0497), with higher mushroom consumption being related to better digit span scores.

CONCLUSIONS

Among community-dwelling middle-aged and older Japanese adults, mushroom consumption was associated with changes in digit span scores, suggesting habitual consumption of mushrooms may be beneficial for cognitive function, especially for working memory, during aging.

THE EFFECTIVENESS OF MEDIUM-CHAIN TRIGLYCERIDES OIL ON BLOOD LIPID PROFILES AND FASTING BLOOD GLUCOSE IN OVERWEIGHT AND OBESE WOMEN IN NORTH VIETNAM

Nguyen Song Tu[1]; Nguyen Thi Anh Tuyet[2]; Bui Thi Mai Huong[3]; Tran Thanh Duong[4]; Nguyen Phuong Anh Hoang[5]

[1]Planning Devision, NATIONAL INSTITUTE OF NUTRITION, HA NOI, Vietnam; [2]Department of Nutrition, Pham Ngoc Thach University of Medicine, Ha Noi, Vietnam; [3]Department of Food Microbiology and Molecular Biology, National Institute of Nutrition, Ha Noi, Vietnam; [4]Director, National Institute of Nutrition, Ha Noi, Vietnam; [5]Bachelor of Public Health, Monash University Caulfield Campus, Caulfield East, Australia

BACKGROUND AND OBJECTIVES

The rising prevalence of obesity, particularly among women, has become a significant public health concern worldwide. In Vietnam, obesity rates among women have surged, especially in urban areas. Women aged 20-45, who are at higher risk due to imbalanced diets and limited physical activity, often experience obesity-related metabolic disturbances. Medium-chain triglycerides (MCTs) have been investigated for their potential to promote weight loss and improve metabolic health, but studies, particularly in Vietnamese populations, remain limited.

This study aimed to evaluate the effectiveness of MCT oil on blood lipid profiles and fasting blood glucose in overweight and obese women in North Vietnam.

METHODS

A randomized, double-blind, community-based intervention trial was conducted from July 2019 to March 2020 in Bac Giang Province. A total of 161 women aged 20-45 with a BMI ≥ 25 kg/m² and < 40 kg/m² participated. The intervention group (n=81) consumed 20 ml/day of 100% MCT oil combined with 100g of low-sugar yogurt, while the control group (n=80) received soybean oil under similar conditions. The intervention duration was four months, with evaluations at baseline, 2 months, and 4 months.

RESULTS

The intervention group showed significant improvements in blood lipid indices and fasting blood glucose compared to the control group. After 2 months, the average reduction in total cholesterol was -0.19 mmol/L (95% CI: -0.38, -0.01; $p < 0.05$), and after 4 months, it decreased by -0.25 mmol/L (95% CI: -0.48, -0.03; $p < 0.05$). Triglyceride levels in the intervention group dropped by -0.23 mmol/L (95% CI: -0.43, -0.02; $p < 0.05$). No significant changes were observed in fasting blood glucose levels.

CONCLUSIONS

The use of MCT oil as a dietary supplement for 2 to 4 months is associated with significant improvements in blood lipid profiles (total cholesterol and triglycerides) in overweight and obese women. These findings suggest that MCT oil may serve as an effective dietary strategy for managing obesity-related metabolic disturbances in this population. Further studies are needed to explore its long-term effects and potential benefits on other metabolic parameters, including fasting blood glucose.

OAP38_05

ASSOCIATION OF SUGAR SWEETENED AND ARTIFICIALLY SWEETENED BEVERAGES AND CANCER RISK: A SYSTEMATIC LITERATURE REVIEW AND META-ANALYSIS OF COHORT STUDIES

Ahmad Jayedi[1]; Georgios Markozannes[1, 2]; Sofia Cividini[1]; Sayada Zartasha Kazmi[1]; Margarita Cariolou[1]; Rita Vieira[1]; Sonia Kiss,[1]; Katia Balducci[1]; Dagfinn Aune[1]; Konstantinos K. Tsilidis[1, 2]; Doris S. M. Chan[1]
[1]Department of Epidemiology and Biostatistics, School of Public Health, Imperial College London, London, United Kingdom; [2]Department of Hygiene and Epidemiology, University of Ioannina Medical School, Ioannina, Greece

BACKGROUND AND OBJECTIVES

Available evidence suggests that frequent consumption of sugar sweetened beverages [SSB] is associated with weight gain, and that replacing SSB with artificially sweetened beverages [ASB] could result in small improvements in body weight. Nevertheless, the evidence regarding the relationship between the consumption of SSB and ASB and the risk of site-specific cancers remains inconclusive and requires further clarification. We performed a systematic review as part of the World Cancer Research Fund International Global Cancer Update Programme (CUP Global).

METHODS

We performed a systematic search in PubMed and Embase to September 2024 to find cohort studies investigating the associations between SSB and ASB consumption and risks of site-specific cancer incidence or mortality. We conducted random-effects dose-response meta-analyses to estimate the summary relative risks (RRs) and 95% confidence intervals (CIs).

RESULTS

A total of 68 publications (37 cohorts) reporting on 22 cancer outcomes were included. We found that each one serving [355 ml] per day increment in SSB intake was associated with a 5% higher risk of postmenopausal breast cancer incidence (RR: 1.05, 95%CI: 1.00, 1.10; p = 0.031, n = 6), and that one serving/day increase in carbonated SSB intake was associated with a 13% higher risk of pancreas cancer (RR: 1.13, 95%CI: 1.04, 1.26; n=14). For mortality outcomes, the RRs for one serving/day increment in SSB consumption were 1.02 (95%CI: 1.00, 1.04; p = 0.027, n = 4) for colorectal cancer mortality, 1.38 (95%CI: 1.11, 1.71; p = 0.004, n = 2) for proximal colon cancer mortality, and 1.06 (95%CI: 1.02, 1.10; p = 0.003, n = 2) for kidney cancer mortality. We also found positive associations between ASB and kidney cancer incidence (RR: 1.25, 95%CI: 1.00, 1.55; p = 0.046, n = 2), and carbonated ASB and leukemia incidence (RR: 1.29, 95%CI: 1.01, 1.64; p = 0.038, n = 2). Replacing one serving of SSB with ASB was associated with a lower risk of proximal colon cancer incidence (RR: 0.84, 95%CI: 0.77, 0.95; n = 2) and mortality (RR: 0.80, 95%CI: 0.71, 0.95; n = 2). No association was found for other cancer outcomes.

CONCLUSIONS

Higher consumption of SSB was associated with higher risks of postmenopausal breast cancer and pancreatic cancer incidence and kidney cancer and proximal colon cancer mortality, and higher intake of ASB was associated with a higher risk of kidney cancer and leukemia incidence. Evidence from this review will be concluded by the CUP Global Expert Panel and considered for any refinements to the current recommendations.

OAP38_06

ESTIMATING THE DIETARY AND HEALTH IMPACT OF IMPLEMENTING MANDATORY FRONT-OF-PACKAGE NUTRIENT DISCLOSURES IN THE US: A POLICY SCENARIO MODELING ANALYSIS

Nadia Flexner[1, 2]; Daniel Zaltz[2]; Eva Greenthal[3]; Aviva Musicus[3, 4]; Mavra Ahmed[2]; Mary R. L'abbe[2]
[1]Food and Nutrition Program, Global Health Advocacy Incubator, Washington, United States of America; [2]Department of Nutritional Sciences, University of Toronto, Toronto, Canada; [3]Science Department, Center for Science in the Public Interest (CSPI), Washington, United States of America; [4]Department of Nutrition, Harvard T.H. Chan School of Public Health, Boston, United States of America

BACKGROUND AND OBJECTIVES

Recognized as a cost-effective policy to promote healthier diets, mandatory front-of-package labeling (FOPL) identifying foods high in sodium, sugar, and saturated fat has been adopted and implemented in ten countries and is currently under consideration in several others including the US. However, its potential impact on dietary intake and health have not yet been estimated in the US context. This study aims to estimate (1) the potential dietary impact of implementing mandatory nutrient-specific FOPL among US adults; and (2) the number of diet-related non-communicable disease (NCD) deaths that could be averted or delayed due to estimated dietary changes.

METHODS

Baseline and counterfactual dietary intakes of sodium, sugars, saturated fats, and calories were estimated among US adults (n=7,572) using both available days of 24h recall data from the 2017-2020 National Health and Nutrition Examination Survey (NHANES). The National Cancer Institute method was used to estimate usual intakes and distributions, adjusting for age, sex, misreporting status, weekend/weekday, and sequence of recall. To estimate counterfactual dietary intakes, we modeled two reduction scenarios observed in experimental and observational studies that examined changes in sodium, sugars, saturated fat and calorie content of food and beverage purchases due to nutrient-specific 'high in' FOPL. This study used the Preventable Risk Integrated ModEl (PRIME) to estimate potential health impacts.

RESULTS

Estimated mean dietary reductions of 156 mg and 259 mg/day of sodium, 10.1 g and 7.2 g/day of sugars, 1.08 g and 4.49 g/day of saturated fats, and 38 kcal and 57 kcal/day of calories were observed under the two policy scenarios tested. Between 96,926 (95% UI 89,011-105,284) and 137,261 (95% UI 125,534-148,719) diet related NCD deaths, primarily from cardiovascular diseases (74%), could potentially be averted or delayed by implementing mandatory nutrient-specific FOPL in the US. Overall, more lives would be saved in males than females.

CONCLUSIONS

Findings suggest that implementing mandatory nutrient-specific FOPL in the US could significantly reduce sodium and total sugar intakes among US adults, resulting in a substantial number of NCD related deaths that could be averted or delayed. Our RESULTS can inform current food policy developments in the US regarding the adoption and implementation of FOPL regulations.

FRAMING AS CORPORATE POLITICAL ACTIVITY STRATEGIES OF PORTUGAL'S FOOD INDUSTRY: IMPLICATIONS FOR PUBLIC HEALTH POLICIES

Sofia da Costa[1, 2]; Mélissa Mialon[3, 4]; Pedro Graça[2, 1]; Maria João Gregório[2, 5, 1]
[1]EPIUnit - ITR, Institute of Public Health of the University of Porto, Porto, Portugal; [2]Faculty of Nutrition and Food Sciences, University of Porto, Porto, Portugal; [3]Inserm Chaire, Inserm, Paris, France; [4]Trinity Business School, Trinity College Dublin, Dublin, Ireland; [5]National Healthy Eating Promotion Program, Directorate-General of Health, Lisbon, Portugal

BACKGROUND AND OBJECTIVES

The food industry plays a significant role in the population's poor health, particularly through the promotion and availability of ultra-processed foods (UPFs), which are linked to non-communicable diseases (NCDs) and public health challenges [1]. This research examines the Corporate Political Activity (CPA) of Portugal's food sector as a potential source of influence on public health policies. Previous studies have analysed the industry's actions [2], and this study focuses on framing strategies.

METHODS

Following the qualitative method outlined by Mialon et al. from the International Network for Food and Obesity/NCDs Research, Monitoring and Action Support (INFORMAS) [3], key industry actors were identified through expert consultation and EuroMonitor data. Publicly available information retrieved from official websites of industry, government, and academic sources was analyzed. A thematic analysis was conducted to categorise CPA practices using the Taxonomy of Framing Strategies [4], which is divided into five categories. Data were collected from October 2023 to April 2024, covering materials published in 2022 and 2023.

RESULTS

This analysis reveals that the food sector in Portugal predominantly uses the 'good' actor framing within the broader category of corporations, with almost all entities presenting themselves as socially responsible, key economic contributors, and legitimate scientific actors committed to preventing non-communicable diseases (NCDs) and reducing health harms, although there are variations. Seven actors framed public health issues as caused by a minority of consumers and not the result of the industry's products or services (the 'trivial' or 'individual problem'). Five actors focused on solutions targeting individuals rather than the entire population (the acceptable, 'good' solution). The unacceptable, 'bad' solution was referenced by only two actors, who rejected whole-population or statutory solutions, such as public health policies or regulations. No examples of the 'bad' actor framing were found. Coca-Cola was the most frequent user of the 'good' actor framing, followed by Cerealis and Ferrero. Danone emphasised individual problems, while the Federation of Portuguese Food Industries (FIPA) referenced statutory measures more than others. Novarroz had no strategies, and Primor Charcutaria-Prima, S.A. made minimal use of framing strategies.

CONCLUSIONS

The food industry consistently positions itself as a responsible actor while downplaying systemic challenges and promoting individual-focused solutions. These framing strategies reveal how the industry may shape public health discourse to align with its interests.

ASSOCIATION BETWEEN OXIDATIVE BALANCE SCORE AND COGNITIVE FRAILTY DEVELOPMENT THROUGH DIFFERENT TRANSITION PATHWAYS AMONG COMMUNITY-DWELLING OLDER ADULT JAPANESE INDIVIDUALS: THE NILS-LSA PROJECT

Shu Zhang[1]; Kanae Furuya[1]; Yukiko Nishita[1]; Chikako Tange[1]; Rei Otsuka[1]
[1]Epidemiology of Aging, National Center for Geriatrics and Gerontology, Obu, Japan

BACKGROUND AND OBJECTIVES

Cognitive frailty (CF), characterized by concurrent cognitive impairment and physical frailty (PF), has a complex pathogenesis. Previous evidence suggests that oxidative balance score (OBS) may be associated with cognitive impairment and PF. However, the effect of OBS on the transition from robustness to CF through cognitive impairment or PF pathways remains unclear. We investigated the association between OBS and CF onset using longitudinal data from community-dwelling older Japanese adults.

METHODS

We analyzed data from waves 2 (2000–2002) through 7 (2010–2012) of the National Institute for Longevity Sciences-Longitudinal Study of Aging. The study included 1,064 older adults (baseline age: 60–83 years; 51.4% male) who participated in multiple surveys (maximum follow-up: 10.8 years), had complete data, Mini-Mental State Examination (MMSE) scores ≥24, and were dementia- and CF-free at baseline. We calculated total OBS (range: 0–34; higher score indicates better oxidative balance) using 12 dietary factors (nutrient-food-OBS, range: 0–24) and 5 lifestyle factors (lifestyle-OBS, range: 0–10). We defined mild cognitive impairment (MCI) as MMSE scores of 24–27, PF as the presence of ≥1 Cardiovascular Health Study criteria, and CF as concurrent MCI and PF. Using multistate modeling, we estimated hazard ratios (HRs) and 95% confidence intervals (CIs) of sex-specific total OBS tertiles (T1–T3) for transitions between robustness (no MCI/PF), MCI, PF, and CF states, adjusting for potential confounders including age, sex, APOE genotype, body mass index, medical history, education level, depressive symptoms, and living arrangement.

RESULTS

At baseline, the proportions of participants with robustness, MCI, and PF were 36.7%, 14.8%, and 48.6%, respectively. The mean ± SD of total OBS for T1, T2, and T3 were 12.5 ± 2.1, 16.4 ± 1.1, and 19.9 ± 1.7 points. Among individuals with MCI, higher total OBS was associated with decreased CF risk. The multivariable-adjusted HRs (95% CI) were 1.00 (reference) for T1, 0.46 (0.23, 0.92) for T2, and 0.43 (0.20, 0.93) for T3 (p-trend =0.016). This protective effect was primarily attributed to nutrient-food-OBS.

CONCLUSIONS

These findings suggest that dietary interventions targeting older adults with MCI may help prevent or delay CF onset. Future randomized controlled trials are needed to confirm these associations.

BACKGROUND AND OBJECTIVES

Given the disease burden of breast cancer and the established benefits of the Mediterranean diet (MedDiet) in its prevention, we conducted a trial to evaluate the effects of a dietary intervention promoting adherence to a Mediterranean diet supplemented with extra-virgin olive oil (MedDiet+EVOO) compared to a low-fat diet intervention for the tertiary prevention of early breast cancer recurrence.

METHODS

The LifeBreast trial is a multicenter, randomized study evaluating a nutritional intervention with a MedDiet+EVOO compared to a low-fat diet in 375 women with stage I, II, or IIIA breast cancer. Randomization was centralized and stratified by recruitment center and menopausal status in a 1:1 ratio to either (i) the MedDiet+EVOO intervention or (ii) the low-fat dietary control.The intervention is delivered remotely via telephone and a custom-designed electronic platform, with annual in-person follow-up visits. Participants in the MedDiet+EVOO group received 0.5 L of EVOO per week during the first two years.At baseline and annual follow-up visits, data collection includes adherence scores for both diets (0–13 points for the MedDiet and 0–9 points for the low-fat diet), a food frequency questionnaire, quality-of-life assessments, biological samples, anthropometric measurements, and clinical data. Linear mixed models were used to evaluate between-group changes in dietary adherence over the first two years of follow-up.

RESULTS

Between 2020 and 2023, 376 participants were recruited and randomized, with 189 allocated to the MedDiet+EVOO group and 187 to the low-fat diet group. The mean age was 54 years, and 54% of participants were premenopausal.Over two years, adherence to the low-fat diet increased by 1.9 points (95% CI: 1.4, 2.3) in the low-fat diet group, while no significant change was observed in the MedDiet+EVOO group [0.02 points (95% CI: -0.27, 0.31)] ($p<0.001$ for time*group interaction). Conversely, adherence to the MedDiet increased by 2.9 points (95% CI: 2.5, 3.3) in the MedDiet+EVOO group, whereas no significant change was observed in the low-fat diet group [0.04 points (95% CI: -0.32, 0.40)] ($p<0.001$ for time*group interaction).

CONCLUSIONS

The remote intervention in the LifeBreast trial effectively modified participants' dietary patterns, promoting a healthier diet.

OAP 43 - NON COMMUNICABLE DISEASES

OAP43_02

DEVELOPING POLICIES TO ADDRESS DIET-RELATED NON-COMMUNICABLE DISEASES MUST MEANINGFULLY ADDRESS CORPORATE POLITICAL ACTIVITY AND CONFLICTS OF INTEREST

Silver Nanema[1]; Mélissa Mialon[2]; Akosua Pokua Adjei[1]; Virginie Hamel[3]; Amos Laar[1]
[1]Department of Population, Family & Reproductive Health, School of Public Health, University of Ghana, Accra, Ghana; [2]HRB Research Fellow, Inserm, Paris, France; [3]Département de nutrition, Faculté de médecine, Université de Montréal - Campus MIL, Montréal, Canada

BACKGROUND AND OBJECTIVES

Increasingly, limiting corporate influence on public policy is recommended to accelerate evidence-based control measures for non-communicable diseases (NCDs). Few studies have reported on how mechanisms can be implemented to limit policy influence, and even fewer have evaluated their effectiveness. In this study, we deployed and evaluated a training intervention among food policymakers regarding corporate interference and strategies to limit policy influence during the implementation of four WHO-recommended best buys.

METHODS
A two-day training intervention for public health policymakers on corporate influence in policy was developed and evaluated using a baseline and endline design. A literature review informed the workshop's design and evaluation. The workshop content was based on an evidence-informed handbook developed by the authors. The following topics were discussed during the workshop: the food regulatory environment, the commercial determinants of health, strategies used by commercial actors to influence policies, and conflicts of interest. Participants were also invited to work in small groups to identify mechanisms for limiting corporate influence in their practice. Using survey METHODS, we evaluated policymakers' perceived competencies and skills in recognizing and addressing policy influence before and after the workshop. Wilcoxon rank-sum test was employed to detect significant variations between baseline and endline data collected through survey METHODS, with alpha set at 0.05 in Stata/IC 15.0.
RESULTS

Twenty-three and seventeen policymakers participated in the baseline and endline evaluation, respectively. Before the workshop, some participants reported previous interactions with commercial actors, including receiving job offers, promotional materials, and funding for travel. After the workshop, we observed a modest increase in awareness of commercial actors using such strategies to influence policymaking, though it was not statistically significant. The mean rating of the perceived appropriateness of using these techniques by corporations to influence public policies significantly ($p<0.001$) decreased after the workshop. Participants' self-reported competencies and skills in identifying and countering these strategies significantly ($p<0.05$) increased after the workshop.

CONCLUSIONS

The training on corporate influence on public health policies enhanced food policymakers' skills and competencies in limiting policy influence in the short term. However, to address these issues at a more systemic level, a broader approach is recommended.

Naturally Occurring and Added Glutamate and Risk of Cardiovascular Diseases – RESULTS From a Large Prospective Cohort

Anaïs Hasenböhler; Guillaume Javaux[1]; Marie Payen de la Garanderie[1]; Fabien Szabo De Edelenyi[1]; Cédric Agaësse[1]; Alexandre De Sa[1]; Mélanie Deschasaux-Tanguy[1]; Léopold Fezeu[1]; Chantal Julia[1]; Emmanuelle Kesse-Guyot[1]; Bernard Srour[1]; Mathilde Touvier[1]
[1]Centre of Research in Epidemiology and StatisticS, Nutritional Epidemiology Research Team (EREN), Université Sorbonne Paris Nord and Université Paris Cité, INSERM, INRAE, CNAM, Bobigny, France

BACKGROUND AND OBJECTIVES

Monosodium glutamate (MSG) is a food additive used in many industrially processed foods to enhance flavour, and glutamic acid is an amino acid naturally occurring in various animal-based and vegetable foods. The potential cardiac toxicity of glutamate is debated and has been suggested by some epidemiological and experimental studies. This study aimed to investigate the associations between food additive and natural glutamate exposures and cardiovascular disease (CVD) risk, including cerebrovascular disease (CVA) and coronary heart disease (CHD) risks in a large prospective cohort of French adults.

METHODS

Participants (n=108,932, 79.3% women, mean age=42.4 years, SD=14.5) were 15 years old and above from the French NutriNet-Santé prospective cohort (2009-2023). We assessed dietary intakes using repeated 24h-dietary records and exposure to food additive glutamate using food composition databases and laboratory assays. We characterised associations between cumulative time-dependent continuous exposures to total glutamate, natural glutamic acid, MSG and risk of CVD, CVA, and CHD using multivariable proportional hazards Cox models adjusted for known risk factors for standardised increments of glutamate intake.

RESULTS

During follow-up (median 7.92 years), 2397, 1113, and 1284 participants were diagnosed with CVD, CVA, and CHD respectively. Higher intakes of naturally occurring glutamic acid (HRper 3000 mg/d increment=1.08, 95% CI [1.01-1.16], p-value=0.03), food additive MSG (HR per 200 mg/d increment=1.05, 95% CI [1.01-1.09], p-value=0.03), and total glutamate (HRper 3000 mg/d increment=1.09, 95% CI [1.01-1.17], p-value=0.02) were associated with higher risks of CHD (p-value for non-linearity>0.6).

CONCLUSIONS

This large prospective cohort study revealed positive linear associations between exposure to natural and the widely used glutamate food additive MSG (E621) and coronary heart disease risk. These original RESULTS provide additional evidence to previous experimental data showing a role of glutamate in regulating heart functioning at physiological doses, while also suggesting heart rate dysfunction at higher exposures. Altogether, these elements encourage caution regarding the consumption of high amounts of glutamate, in the context of cardiovascular risk prevention.

DEVELOPMENT OF INDICATORS REFLECTING HEALTHY AND UNHEALTHY PLANT-BASED DIETARY PATTERNS INTEGRATING THE LEVEL OF FOOD PROCESSING AND THEIR LONGITUDINAL ASSOCIATION WITH THE RISK OF CARDIOVASCULAR DISEASES

Clémentine Prioux[1]; Emmanuelle Kesse-Guyot[1]; Bernard Srour[1]; Léopold Fezeu[1]; Julia Baudry[1]; Sandra Wagner[2]; Serge Hercberg[1]; Mathilde Touvier[1]; Benjamin Allès[1]
[1]Équipe de Recherche en Épidémiologie Nutritionnelle (EREN), Sorbonne Paris Nord University, Inserm, CNAM, INRAE, Bobigny, France; [2]University of Lorraine, Inserm CIC 1433, Nancy CHRU, Inserm U1116, FCRIN, INI-CRCT, CIC-P de Nancy INI CRCT, NANCY, France

BACKGROUND AND OBJECTIVES

Very few studies have examined the link between plant-based dietary patterns and health accounting for the level of processing, while the latter represents a major challenge with the current increasing intake of ultra-processed foods worldwide. This study aimed to develop new dietary indices combining the contribution of plant food consumption and the level of food processing, to assess their association with the risk of cardiovascular disease, and to compare these associations with those obtained when the level of food processing is not integrated, in a French cohort.

METHODS

We analyzed data from participants in the NutriNet-Santé prospective online cohort (2009-2024). First, the two original healthy Plant Based Diet (hPDI) and unhealthy Plant-Based Diet (uDPI) scores were computed using data from 24h records. Each component of the two scores was multiplied by a factor corresponding to i) the contribution of unprocessed food, ii) the contribution of ultra-processed foods, using the NOVA classification, leading to four new scores. A higher hPDI-unprocessed score reflected a diet richer in plant-based foods which were both healthy and unprocessed, whereas a higher hPDI-ultraprocessed score reflected a diet richer in ultra-processed plant-based foods, and conversely for uPDI-unprocessed and uPDI-ultraprocessed. The association between each one of the six scores and the incidence of cardiovascular diseases (cerebrovascular and coronary) was estimated using multivariable Cox proportional hazards models, adjusted for potential confounding factors.

RESULTS

A total of 63,830 participants were included (mean follow-up duration 9.0 years [SD=4.7]). Individuals with the highest intake of healthy and unprocessed plant foods (hPDI-unprocessed) had a 30% lower risk of developing a cardiovascular disease (HR10th vs, 1st decile hPDI-unprocessed: 0.70; 95% CI: 0.54, 0.89; *p-trend*= 0.01). There was no significant association between the hPDI-ultraprocessed score and cardiovascular disease risk. Individuals with the highest intake of unhealthy and ultraprocessed plant foods had a 35% greater risk of developing a cardiovascular disease (HR10th vs, 1st decile uPDI-ultraprocessed: 1.35; 95% CI: 1.06, 1.72; *p-trend*= 0.008).

CONCLUSIONS

Our findings indicate the necessity of incorporating the degree of food processing in future investigations examining the relationship between plant-based diets and health outcomes.

ULTRA-PROCESSED DIETS AND LONG-TERM CARDIOVASCULAR DISEASE MORTALITY AMONG MYOCARDIAL INFARCTION SURVIVORS: A PROSPECTIVE ANALYSIS OF THE ALPHA OMEGA COHORT

Neha Khandpur[1]; Maria Gorety Jacobo Cejudo[1]; Iris van Damme[1]; Esther Cruijsen[1]; Daisy Coyle[2]; Marianne Geleijnse[3]
[1]Division of Human Nutrition and Health, Wageningen University & Research, Wageningen, Netherlands; [2]The George Institute, The George Institute, Baran, Australia; [3]Division of Human Nutrition and Health, Wageningen University, Wageningen, Netherlands

BACKGROUND AND OBJECTIVES

Current evidence links ultra-processed diets to an increased risk of cardiovascular disease (CVD) mortality. Whether ultra-processed diets present similar associations with mortality risk in CVD patients remains unknown. We examined the diet quality of ultra-processed diets and the association of these diets with total CVD mortality, ischemic heart disease (IHD) mortality, and stroke mortality in patients with a history of myocardial infarction (MI).

METHODS

We analyzed data from 4365 post-MI patients in the Alpha Omega cohort. Dietary data were collected at baseline (2002-2006) using a 203-item Food Frequency Questionnaire (FFQ). Diet quality was assessed using the Dutch Healthy Diet Index adapted for CVD patients (DHD-CVD, range 0-150). Ultra-processed foods (UPF) were identified and categorized according to the Nova classification system, converted to %grams/day, and divided into quartiles (Q). Q1 and Q4 of %g/day of UPF represented a low and a high ultra-processed dietary pattern, respectively. Hazard Ratios (HRs) for CVD, IHD and stroke mortality were obtained from multivariable Cox regression models.

RESULTS

Most patients were men (79%) on cardiovascular medication (88%). Mean caloric intake was 1914kcal/day. Mean UPF contribution was 962kcals (Q1 vs Q4 = 664 vs 1199kcal), 18%g (Q1 vs Q4 = 9 vs 29%g), and 53%kcals (Q1 vs Q4 = 42 vs 62%kcals). Compared to Q1, Q4 had higher intakes of total energy, lower intakes of non-ultra-processed foods, particularly fruit and leafy and cruciferous vegetables. DHD-CVD scores decreased slightly across quartiles (Q1 vs Q4 = 95 vs 82). Over a median follow-up of 14 years, 1012 participants died from CVD (659 from IHD, 208 from stroke). Compared to a low ultra-processed diet, a high ultra-processed diet was not significantly associated with CVD and IHD mortality. However, it was associated with a higher risk of stroke mortality (HRQ4 vs Q1: 1.51, 95% CI: 1.01-2.28; and HRper10% increase: 1.22, 95% CI: 1.03-1.43). This association was stronger in older patients with higher BMI, lower physical activity, and lower socio-economic status.

CONCLUSIONS

A high ultra-processed diet was linked to higher risk of stroke mortality, but not CVD and IHD mortality. IHD may have been better managed through medication in this sample of drug-treated post-MI patients. While further research is needed, RESULTS lend some support to the importance of diet in the secondary prevention of stroke mortality.

Food Additive Preservatives and Antioxidants and Risk of Cancer – RESULTS From a Large Prospective Cohort

Anaïs Hasenböhler[1]; Guillaume Javaux[1]; Marie Payen de la Garanderie[1]; Fabien Szabo De Edelenyi[1]; Cédric Agaësse[1]; Alexandre De Sa[1]; Mélanie Deschasaux-Tanguy[1]; Fabrice Pierre[2]; Xavier Coumoul[3]; Inge Huybrechts[4]; Bernard Srour[1]; Mathilde Touvier[1]
[1]Centre of Research in Epidemiology and StatisticS, Nutritional Epidemiology Research Team (EREN), Université Sorbonne Paris Nord and Université Paris Cité, INSERM, INRAE, CNAM, Bobigny, France; [2]Toxalim (Research Centre in Food Toxicology), Université de Toulouse, INRAE, ENVT, INP-Purpan, UPS, Bobigny, France; [3]INSERM T3S, UMR-S 1124, Université Paris Cité, Paris, France; [4]International Agency for Research on Cancer, World Health Organization, Lyon, France

BACKGROUND AND OBJECTIVES

Food additives such as preservatives and antioxidants are frequently and ubiquitously used to increase shelflife and protect consumers against the growth of pathogenic micro-organisms and the deterioration caused by these pathogens or by oxidation. This study aimed to investigate for the first time, the associations between exposures to a wide range of preservatives and antioxidants and cancer risk in a large population-based cohort.

METHODS

Participants (n=105,260, 78.7%women, mean age=42.0y, SD=14.5) from the French NutriNet-Santé cohort (2009-2023) completed repeated 24h-dietary records including specific brands of industrial products. Preservative and antioxidant exposures were assessed using composition databases and laboratory assays. We characterised associations between time-dependent exposures to additives and risk of cancer using multivariable Cox models adjusted for known confounders. Exposures were coded into 3 categories (sex-specific tertiles or non-consumers/lower/higher consumers separated by the sex-specific median).

RESULTS

4226 incident cancer cases were identified during follow-up (including 352 colorectal, 508 prostate, 1208 breast and 2315 obesity-related cancer cases). Higher intakes of the following additives were associated with higher cancer risks: potassium sorbate (E202) with higher risk of overall (Hazard Ratio (HR)T3vsT1= 1.14[1.04-1.24]), breast (1.26[1.07-1.49]) and obesity-related (1.23[1.09-1.39]) cancers; potassium metabisulphite (E224) with overall (1.11[1.03-1.20]), breast (1.20[1.04-1.38]), and obesity-related (1.13[1.02-1.25]) cancers; sodium nitrite (E250) with prostate (1.32[1.02-1.70]), and obesity-related (1.16[1.04-1.30]) cancers; potassium nitrate (E252) with overall (1.13[1.05-1.23]), breast (1.22[1.05-1.41]) and obesity-related (1.20[1.08-1.34]) cancers; acetic acid (E260) with overall cancer (1.12[1.01-1.25]); sodium ascorbate (E301) with obesity-related cancers (1.11[1.00-1.24]); sodium erythorbate (E316) with overall (1.12[1.04-1.22]), breast (1.21[1.04-1.41]) and obesity-related (1.19[1.06-1.33]) cancers. In contrast, higher intakes of food additive phosphoric acid (E338) and extracts of rosemary (E392) were associated with lower risks of prostate (0.49[0.25-0.95]) and colorectal (0.69[0.50-0.94]) cancers, respectively.

CONCLUSIONS

This large prospective cohort revealed mainly positive associations between exposure to several food additive preservatives and antioxidants widely used in industrial foods and increased risk of several cancer locations. Several mechanistic studies support these findings and encourage the re-evaluation of these food additives.

ULTRA-PROCESSED FOOD CONSUMPTION AND RISK OF HYPERTENSION AMONG PARTICIPANTS WITH AND WITHOUT OBESITY: INSIGHTS FROM THE NUTRINET BRASIL COHORT

Evelyn Frade; Maria Laura Da Costa Louzada,[1]
[1]NUPENS, Center for Epidemiological Research in Nutrition and Health, São Paulo, Brazil

BACKGROUND AND OBJECTIVES

Obesity has been increasing globally, and no country has yet managed to stop it. Scientific evidence increasingly highlights the role of ultra-processed foods for obesity and several health outcomes. However, little is known about the effect of ultra-processed foods on health prognosis of individuals with pre-existing obesity. We aimed to analyse the prospective association between ultra-processed foods intake and the risk of hypertension among individuals with and without obesity.

METHODS

The NutriNet Brazil study collects data from Brazilian adults through self-administered online questionnaires. Participants with obesity were identified based on their baseline BMI (≥ 30.0 kg/m²). Dietary intake was assessed using the Nova 24-h dietary recall screener, which captures two opposing dietary dimensions: the unprocessed and minimally processed whole plant foods (Nova-WPF, 33 items) and ultra-processed foods (Nova-UPF, 23 items). The Nova-UPF score, representing the exposure, was calculated as the average of three Nova 24-h screeners. Hypertension incidence was determined via self-reported medical diagnosis. Cox proportional hazards models were applied to examine the association between the Nova-UPF score and hypertension risk, with the fully adjusted model accounting for age, sex, others sociodemographic, health, and lifestyle factors, as well as the Nova-WPF score.

RESULTS

A total of 19,251 participants were included in the analysis, of whom 2,915 had obesity, and all were free of hypertension at baseline. The mean Nova-UPF score was 0.37 (95% CI: 0.36–0.38), 1.32 (95% CI: 1.31–1.33), 2.15 (95% CI: 2.14–2.16), and 3.63 (95% CI: 3.60–3.66), respectively across quartiles. In the fully adjusted model, the hazard ratio (HR) for the highest quartile of Nova-UPF score was 1.52 (95% CI: 1.26–1.84) among participants without obesity and 1.52 (95% CI: 1.11–2.08) among participants with obesity. However, the incidence rate (IR) of hypertension among individuals with obesity (IR: 81.94; 95% CI: 74.49–90.13) was nearly three times higher compared to those without obesity (IR: 28.33; 95% CI: 26.53–30.26).

CONCLUSIONS

The incidence of hypertension is significantly higher among individuals with obesity; however, the association between higher consumption of ultra-processed foods and an increased risk of hypertension persists in both individuals with and without obesity. Therefore, public care policies should prioritize reducing the consumption of ultra-processed foods, especially among this group.

MODELLING THE IMPACT OF SUGAR-SWEETENED BEVERAGE TAXES ON THE PRIMARY PREVENTION OF NON-COMMUNICABLE DISEASES

Selina Mantebea Tobil[1]; Kofi Micheal Boachie[2]; Bismark Akasoe[1]; Mabel Worlasi Dzenu[3]; Amos Apreku[4]; Gideon Amevinya[5]; Amos Laar[1]
[1]School of Public Health, University of Ghana, Accra, Ghana; [2]School of Public Health, University of the Witwatersrand, Johannesburg, Johannesburg, South Africa; [3]Fred N. Binka School of Public Health, University of Health and Allied Sciences, Ho, Ghana, Ho, Ghana; [4]Department of Biostatistics, T.H Chan School of Public Health, Harvard University, Cambridge, United States of America; [5]UMR MoISA (Montpellier Interdisciplinary Centre On Sustainable Agri-Food Systems), Univ Montpellier, CIRAD, CIHEAM-IAMM, INRAE, Institut Agro, IRD, Montpellier, France

BACKGROUND AND OBJECTIVES

Non-communicable diseases (NCDs) remain one of the most significant public health challenges globally, accounting for over half of the global burden of disease. SSB taxation has been promoted as an effective globally in reducing consumption, generating revenue, and promoting healthier dietary behaviours. Despite its potential, there are barriers to implementing such a tax – including. limited local data, the absence of localized models to estimate health and economic impacts of the tax intervention, and resistance from the beverage industries. This study aims to estimate the impact of the tax on the incident and prevalent cases of diabetes and diabetes related-healthcare cost savings from the tax.

METHODS

This study used Markov modelling framework to model the potential impact of the tax on diabetes incidence, prevalence, mortality, and healthcare cost averted.

RESULTS

Higher tax passthrough rates, particularly at 120%, drive significant reductions in diabetes-related outcomes-incidence, prevalence, and mortality-while delivering substantial healthcare cost savings over two decades. Among the scenarios analyzed, the retail price base demonstrated the most pronounced impact. At a 120% passthrough rate, cost savings reached $9.1 million for retail pricing and $7.43 million for ex-factory pricing, accompanied by marked declines in disease burden and mortality. In contrast, lower passthrough rates (e.g., 68%) yielded more modest health improvements and, in some cases, increased healthcare costs. These findings underscore the critical importance of implementing tax policies that optimize both public health outcomes and economic returns

CONCLUSIONS

The RESULTS demonstrate that higher tax passthrough rates, particularly at 120%, significantly reduce diabetes incidence, prevalence, and mortality while generating substantial healthcare cost savings. By adopting evidence-based frameworks, SSB taxation can be leveraged to promote health ormobilize resources for public health initiatives.

CIRCULATING BRANCHED-CHAIN AMINO ACIDS AND INCIDENCE OF TYPE 2 DIABETES MELLITUS IN MAUCO, A CHILEAN AGRICULTURAL POPULATION-BASED COHORT

Laura Huidobro[1, 2]; Sebastian Cofre,[3, 4]; Jose L. Santos[5, 6]; Fabio Paredes[7]; Catterina Ferreccio[8, 9]; Sandra Cortes[10, 2]

[1]Faculty of Medicine, Universidad Catolica del Maule, Talca, Chile; [2]Advanced Center of Chronic Diseases (ACCDiS), Pontificia Universidad Católica de Chile - Universidad de Chile, Santiago, Chile; [3]PhD in Epidemiology program, Pontifical Catholic University of Chile, Santiago, Chile; [4]School of Nutrition and Dietetics, Faculty of Health Sciences, Universidad Catolica del Maule, Talca, Chile; [5]Department of Nutrition, Diabetes and Metabolism, Pontificia Universidad Católica de Chile, Santiago, Chile; [6]Department of Health Sciences, Public University of Navarre, Pamplona, Spain; [7]Faculty of Mathematics, Pontificia Universidad Católica de Chile, Santiago, Chile; [8]School of Public Health, Pontificia Universidad Católica de Chile, Santiago, Chile; [9]Chilean Public Health Institute (ISP), Ministry of Health, Santiago, Chile; [10]CEDEUS- Centro de Desarrollo Urbano Sustentable UC -UDEC, Pontificia Universidad Católica de Chile, Santiago, Chile

BACKGROUND AND OBJECTIVES

Metabolomics has emerged as a field enabling the identification of circulating biomarkers that allow a better understanding of the causes of Type 2 diabetes (T2DM). Plasma Circulating Branched-Chain Amino Acids (BCAAs) have been repeatedly reported to be associated with cardiometabolic outcomes and T2DM. However, there are no studies in Latin American cohorts. This study aimed to evaluate the association between BCAA plasma profile and the incidence of T2DM in an agricultural cohort of Chilean adults.

METHODS

We followed 1,738 participants of the MAUCO cohort in the agricultural area of Molina (Central Chile) (47% women; aged 38-74 years; free of T2DM). We registered fasting glycemia at baseline and after follow-up. We also determined anthropometry, lifestyle habits, sociodemographic factors, diseases status based on medical records, alcohol consumption, and a Mediterranean diet score. At baseline, we quantified a plasma amino acid profile using the Nightingale metabolomic platform based on nuclear magnetic resonance spectroscopy. Statistical analyses were carried out with RStudio using Cox regression models.

RESULTS

After a 5-year follow-up, 127 new cases of T2DM were diagnosed (7.3%). T2DM incidence was significantly associated with baseline circulating BCAA. The hazard ratio (HR) for T2DM per 1-standard deviation increase (1-SD) of total BCAA was 1.27 (95% CI 1.05-1.54, P=0.014). The HR per 1-SD increase in isoleucine, leucine, and valine were 1.32 (95%CI: 1.10-1.56, P=0,002), 1.28 (95%CI: 1.05-1,57; P=0,012) and 1.23 (95%CI: 1.01-1.49, P=0,038) respectively. Plasma levels of the aromatic amino acid tyrosine were also positively associated with T2DM incidence (HR per 1-SD increase: 1.2; 95%CI: 1.0-1.49, P=0,048). All models were adjusted by sex, body mass index, age, education level, alcohol consumption, physical activity levels, smoking, and Mediterranean diet score (MDS).

CONCLUSIONS

Our epidemiologic research shows that elevated plasma BCAA concentrations were associated with a higher risk of T2DM in Chilean adults. Future directions should explore whether there is an interaction between amino acid profiles and diet on the risk of developing T2DM.

PRESCRIBING FRESH PRODUCE TO ADDRESS HEALTH EQUITY IN ADULTS WITH TYPE 2 DIABETES AND FOOD INSECURITY

Kim Glover; Megan Gow[1]; Kathy Trieu[1]; Bruce Neal[2]; Jason Wu[1]
[1]Food Policy, The George Institute for Global Health, Barangaroo, Australia; [2]Executive Director, The George Institute for Global Health, Barangaroo, Australia

BACKGROUND AND OBJECTIVES

Background: Type 2 diabetes represents one of the biggest healthcare challenges globally. Healthy eating is integral in the management of type 2 diabetes.1 However, for individuals with food insecurity, affording and accessing the foods recommended is difficult, leading to worse long-term health outcomes.2 Our research team aims to address this health equity issue using a 'Food is medicine' approach where programs, such as Produce Prescription, enable healthcare practitioners to prescribe foods for free as part of healthcare, to prevent, manage and treat diet-related diseases for people with food insecurity.

Objectives: To determine the effect of Produce Prescription on blood glucose control and other health indicators in adults with type 2 diabetes experiencing hyperglycaemia and food insecurity and/or financial hardship in Australia.

METHODS

METHODS: Using a parallel design randomised controlled trial, n=224 participants will be randomised (1:1) to Produce Prescription or usual care. Over 26 weeks, the intervention group will receive a weekly delivery of fruits, vegetables, wholegrains and nuts, and up to 3 sessions with an accredited dietitian. Controls will receive usual care. The primary outcome is change in mean HbA1c over 26 weeks, comparing the intervention and control group. Secondary outcomes include between-group differences at 26 weeks in change in blood pressure, body weight, blood lipids, food and nutrition insecurity, person-reported outcome measures, medication use, and diet quality. Implementation outcomes assessed will include feasibility, acceptability, scalability and cost effectiveness

RESULTS

Recruitment commenced in September 2024, and we anticipate recruitment and follow-up will be completed by December 2026. Preliminary RESULTS available 2025.

CONCLUSIONS

Discussion: This Australia-first Produve Prescription trial will provide novel and rigorous data for an intervention that may be feasible to improve health and health equity as part of the Australian healthcare system. We anticipate Produce Prescription will lead to a clinically meaningful reduction in HbA1c and contribute to improved health equity and long-term health benefits for adults with type 2 diabetes and food insecurity.

ASSOCIATION BETWEEN DIETARY PATTERNS AND CVD-RELATED MORTALITY IN THE JAPANESE POPULATION: THE JAPAN MULTI-INSTITUTIONAL COLLABORATIVE COHORT (J-MICC) STUDY

Kaori Kitaoka[1]; Katsuyuki Miura[1]; Naoyuki Takashima[1, 2]; Aya Kadota[1, 3]; Akiko Harada[1]; Keiko Kondo[1, 3]; Yoshikuni Kita[4, 3]; Keitaro Matsuo[5, 6]
[1]NCD Epidemiology Research Center, Shiga University of Medical Science, Otsu, Japan; [2]Department of Epidemiology for Community Health and Medicine, Kyoto Prefectural University of Medicine, Kyoto, Japan; [3]Department of Public Health, Shiga University of Medical Science, Otsu, Japan; [4]Faculty of Nursing Science, Tsuruga Nursing University, Tsuruga, Japan; [5]Division of Cancer Epidemiology and Prevention, Aichi Cancer Center Research Institute, Nago, Japan; [6]Division of Cancer Epidemiology, Nagoya University Graduate School of Medicine, Nagoya, Japan

BACKGROUND AND OBJECTIVES

Dietary patterns affect the risk of cardiovascular disease (CVD). We investigated the associations between dietary patterns and CVD-related mortality in a large-scale general Japanese cohort.

METHODS

Participants of 35,388 men and 46,838 women aged 35-69 years (mean age: 54.6 years) were followed from 2004-2014 to 2022. Dietary patterns were identified through factor analysis of 46 food and beverage items by a semi-quantitative food frequency questionnaire and alcohol consumption. Factor scores were categorized into quintiles (Q1-Q5). Cox proportional hazards models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs), adjusting for potential confounders.

RESULTS

Over a mean follow-up period of 12.6 years, 4,860 deaths (3,097 men, 1,763 women) were recorded. We identified dietary patterns; “healthy Japanese dietary pattern”, “meat and fried food rich pattern” and “high bread and low rice pattern” in men and women; “fish and shellfish rich pattern” and “high confectioneries and low alcohol pattern” in men; “vegetable rich pattern” and “high alcohol and low rice pattern” in women. The healthy Japanese dietary pattern in men was associated with reduced risks of CVD and atherosclerotic CVD mortality (Q5 versus Q1 HRs [95% CI]: 0.55 [0.40–0.77] and 0.47 [0.27–0.80], P-trend <0.001 and 0.004). Conversely, the fish and shellfish rich pattern in men was associated with atherosclerotic CVD mortality risk (Q5 versus Q1 HR: 1.91 [1.13–3.22], P-trend =0.018).

CONCLUSIONS

Promoting healthy Japanese dietary pattern among men may be effective in reducing CVD mortality, highlighting its potential in preventive health strategies.

BACKGROUND AND OBJECTIVES

Atopic Dermatitis (AD) is the most common atopic disease. AD is associated to the dysfunctions of the immune system and epithelial barriers, with an imbalance in the gut microbiota. These disorders start very early in life and some are present from birth. A primary prevention strategy for atopic diseases should therefore begin during fetal life. Nutritional intervention during pregnancy modulates the gut microbiota and implants a specific microbiota in the newborn. Prebiotics are non-digestible oligosaccharides present in food, which are able to modulate the microbiota by promoting the growth of bacteria beneficial for host health and the immune system by inducing a tolerogenic environment. Our preclinical studies highlighted that maternal prebiotic (GOS/inulin) intake reduced the risk of food allergy in the offspring. We wanted to confirm these data in AD in a clinical trial.

METHODS

PREGRALL (NCT03183440), a randomized placebo controlled trial, evaluated the ability of a GOS/inulin supplementation in 376 allergic pregnant women recruited in 4 French centers to prevent AD in high-risk children at 1-year-of-age (Cabridain et al., 2019). A unique biocollection of blood, stools and breast milk was generated in 126 mother-infant dyads to elucidate the mechanisms involved in AD development as well as the impact of the prebiotics in the mother and their children at 1-year-of age (CIMMAP Project).

RESULTS

The prebiotic supplementation was not able to protect against AD at 1 year or to decrease the severity of the disease. Surprisingly, the prevalence of AD was low compared to our estimations in a population at high risk (20% instead of 45%). Interestingly, the prebiotic intake modulated the composition of the maternal gut microbiota, particularly increasing the Bifidobacteria. This phenotype was transmitted to the children in the first week of life.

CONCLUSIONS

Altogether, prebiotic intake by mothers during pregnancy affects their gut microbiota and the effect is transmitted to their children in early life. The modulation of microbial parameters in mother and their children by the prebiotic intervention was not able to protect against AD at one year of age but encourage us to think that the strategy could have a longer-term effect on the prevention of other atopic diseases.

BACKGROUND AND OBJECTIVES

Differences in dietary protein have been associated with stroke risk, with possible heterogeneity in associations by stroke type or food sources of protein. We examined the associations of individual dietary amino acids, as the constituents of dietary protein, with risks of ischemic, hemorrhagic and total stroke.

METHODS

We analysed data from 73,830 women in the Nurses' Health Study (1984–2012), 92,333 women in the Nurses' Health Study II (1991–2013), and 43,268 men in the Health Professionals Follow-Up Study (1986–2016). Dietary intakes of 22 (20 standard and two non-standard) amino acids were assessed using validated food frequency questionnaires, administered typically every four years. Multivariable-adjusted Cox regression models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) of ischemic, hemorrhagic and total stroke in relation to the energy-adjusted intakes of individual amino acids.

RESULTS

During an average follow-up of 23.7 years, 3058 ischemic, 872 hemorrhagic and 5997 total stroke cases were documented. After correction for multiple testing, lower risks of ischemic stroke were observed with higher intakes of glutamine (HR per 1 SD higher: 0.94, 95% CI: 0.90-0.98, *p*-value=0.004) and proline (0.94, 0.90-0.98, *p*-value=0.005). The associations remained directionally consistent across sensitivity analyses, but attenuated upon mutual adjustment. All other amino acids, including branched-chain amino acids, were not significantly associated with ischaemic stroke. For hemorrhagic stroke, no significant associations were observed for any of the amino acids. For total stroke, inverse associations were also observed for both glutamine (0.94, 0.91-0.97, *p*-value<0.001) and proline (0.96, 0.93-0.99, *p*-value=0.004). In terms of dietary sources, glutamine was most strongly correlated with plant protein and whole grains, while proline was most strongly correlated with dairy protein and dairy products.

CONCLUSIONS

Higher intakes of glutamine and proline were associated with lower risks of ischemic and total stroke.

OAP47_05

DETERMINANTS OF ADHERENCE TO GLUTEN-FREE DIET IN CHILDREN WITH CELIAC DISEASE AND THE IMPACT OF DIETICIAN COUNSELING IN IMPROVING ADHERENCE

Laxmi Kant Bharti[1]; Samanta Arghya[1]; Ujjal Poddar[1]; Neelu Neelu[1]
[1]Pediatric Gastroenterology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India

BACKGROUND AND OBJECTIVES

Adherence to a gluten-free diet (GFD) is the mainstay of management of celiac disease (CD), but data on factors determining long-term adherence to GFD in children with CD is limited. Here, we aimed to compare serology, Dietician detailed interview [DDI] and various questionnaires (Biagi, modified Leffler) to assess GFD adherence and to identify determinants of GFD adherence.

METHODS

In this prospective study, consecutive children with CD on GFD and <18 years, were enrolled between November 2022 and May 2024.GFD adherence was assessed by serology (anti-tissue transglutaminase -IgA [tTG-IgA]), DDI and two questionnaires

RESULTS

Total 103 children (64 boys [62%], median age 8 years [IQR 4-12.5]) on GFD (median duration 35 months [IQR 11-52]) were enrolled. Concordance between DDI and Biagi questionnaire was fair (cohen's kappa [k]0.38) while it was good between DDI and modified Leffler questionnaire(Cohen's kappa 0.49). The concordance between serology and other METHODS of adherence assessment (DDI [k=0.11], Biagi [k=0.19] and modified Leffler [k=0.17]) was poor. Adherence as assessed by serology, DDI, Biagi score and modified Leffler score were 73.8%, 48.5%, 66.2 %, and 60.3%, respectively (figure 1). Upon regression analysis, having a sibling with CD, higher parenteral knowledge about CD were found to positively influence adherence while age>10 years and longer duration of follow-up negatively influenced adherence (table 1). Adherence by modified Leffler score (26.4% vs 72.7%, p<0.001), DDI (28% vs 68.4%, p<0.001), Biagi score (36.4% vs 70%, p= 0.046) were significantly higher in the positive serology group compared to the negative serology. After dietary counseling, GFD adherence improved in follow-up (p<0.05 in all).

CONCLUSIONS

Sibling with CD, associated T1DM, greater parental awareness about CD positively and older age negatively influenced GFD-adherence

OAP47_06

IS HIGH INTAKE OF ULTRA-PROCESSED FOOD RELATED TO ADIPOSITY OR CARDIOMETABOLIC RISK FACTORS IN CHILDREN? A CROSS-SECTIONAL STUDY

Linnea Bärebring[1]; Anna Amberntsson[1]; Mathilda Forsby[1]; Therese Karlsson[2, 1]; Anna Winkvist[1]; Hanna Augustin[1]
[1]Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; [2]Department of Life Sciences, Division of Food and Nutrition Science, Chalmers University of Technology, Gothenburg, Sweden

BACKGROUND AND OBJECTIVES

Ultra-processed foods (UPF) is by the NOVA framework a broad category of foods with both potentially positive and negative impact on dietary quality and health. These disparate health effects may be especially pronounced in children, but little is known of UPF intake of Swedish children. The aim was to study associations between UPF intake, including subtypes of UPF, with cardiometabolic risk factors and adiposity in Swedish children.

METHODS

This cross-sectional study was conducted in 8-year-old children (N=167) born within a population-based mother- and child cohort. Women were recruited during pregnancy and the children were followed up at age 8. The children's diet was assessed through a questionnaire. UPF was defined according to NOVA, and UPF items were classified into subtypes of UPF: bread/cereals, proteins/dishes, beverages, sweets/snacks. High intake was defined as servings/day ≥ energy adjusted median. Cardiometabolic risk factors included measurements of lipoproteins in non-fasting venous blood samples, blood pressure and anthropometry (waist circumference, BMI and fat mass assessed by bioimpedance). Associations between UPF intake (total and subtypes) and the cardiometabolic risk factors were assessed using linear regression analysis, adjusted for confounders.

RESULTS

Mean±SD intake of UPF was 6.1±2.1 servings/day. The largest single contributor to energy among UPF subgroups was bread, which constituted more than half (56%) of the UPF intake. High UPF intake was associated with higher BMI (β [95% CI]) (0.575 [0.057 – 1.094] kg/m2), larger waist circumference (1.301 [0.024-2.579] cm), lower LDL cholesterol (-0.207 [-0.398 – -0.016] mmol/L) and lower ApoB:ApoA1 ratio (-0.050 [-0.088 – -0.013]). Analyses of UPF subtypes showed that associations between high UPF intake and adiposity were driven by intake of UPF beverages and UPF sweets/snacks. High intake of UPF proteins/dishes was associated with lower LDL cholesterol and lower ApoB:ApoA1 ratio.

CONCLUSIONS

The observed detrimental associations between high UPF intake and measures of adiposity in children could be ascribed to intake of UPF beverages, sweets and snacks, i.e. foods already discouraged in existing dietary recommendations. High intake of UPF was also associated with improved lipid profile. More research is needed to clarify the health effects of UPF.

Contaminants from Food processing and packaging and their association with Cardiovascular Disease Risk – RESULTS from a large French prospective cohort

Xuân Le Folcalvez[1]; Nathalie Arnault[1]; Cédric Agaësse[1]; Anaïs Hasenböhler[1]; Fabien Szabo De Edelenyi[1]; Xavier Coumoul[2]; Jean-Baptiste Fini[3]; Fabrice Pierre[4]; Mélanie Deschasaux-Tanguy[1]; Emmanuelle Kesse-Guyot[1]; Bernard Srour[1]; Mathilde Touvier[1]

[1]Nutritional Epidemiology Research Team (EREN), Center for Research In Epidemiology And Statistics (CRESS - Inserm 1153/Inra 1125/Cnam/UPC/USPN), Bobigny, France; [2]INSERM UMR-S 1124, Université Paris Cité, Paris, France; [3]PhyMa Unit, CNRS UMR 7221, Muséum National d'Histoire Naturelle, Paris, France; [4]Toxalim (Research Centre in Food Toxicology), INRAE, University of Toulouse, ENVT, INP-EI Purpan, UPS, Toulouse, France

BACKGROUND AND OBJECTIVES

The food items we consume are contaminated by several substances (Polycyclic aromatic hydrocarbons – PAHs, Perfluorinated compounds, etc.) throughout their processing, packaging and cooking. However, the long-term implications of these contaminants on cardiovascular health remain unclear. This study aims to investigate the associations between exposure to contaminants originating from food processing and food packaging and the risk of cardiovascular diseases (CVD) in the NutriNet-Santé cohort.

METHODS

Anthropometric, socio-demographic, physical activity and health data of 108,923 participants (79.3% women, mean age=42.4 years, SD=14.5) aged above 15 years old were collected from the French prospective cohort NutriNet-Santé (2009-2024). We assessed dietary intakes using repeated 24h-dietary records and exposures to food contaminants (PAHs, per- and polyfluoroalkyl substances – PFAS, Furans, Brominated Flame Retardants) using food composition databases and quantitative analysis from the total diet study (TDS/EAT 2) led by the French Agency for Food, Environmental and Occupational Health & Safety (ANSES) between 2006 and 2009. We characterised associations between exposures to these contaminants (three categories: sex-specific tertiles or non-exposed/lower/higher exposed participants separated by the sex-specific median) and risk of CVD using multivariable proportional hazards Cox models adjusted for known risk factors.

RESULTS

During a median follow-up time of 7.92 years, 2,397 cases of CVD were ascertained. Higher dietary exposures to PAHs were associated with a higher risk of CVD, particularly for benz[a]anthracene (HR T3 versus T1= 1.18, 95% CI [1.06-1.32], p-trend = 0.003), phenanthrene (HR T3 versus T1= 1.14, 95% CI [1.02-1.29], p-trend = 0.02) and fluoranthene (HR T3 versus T1= 1.15, 95% CI [1.02-1.30], p-trend = 0.02). Among the PFAS, perfluorodecanoic acid (PFDA) stands out by being associated with a higher risk of CVD (HR T3 versus T1= 1.12, 95% CI [1.01-1.23], p-trend = 0.03).

CONCLUSIONS

This large prospective cohort study suggests a potential role for food contaminants such as PAHs and PFAS, known as “forever chemicals”, in CVD etiology, which is consistent with their metabolic disrupting potential suggested by previous in vivo/in vitro studies. Our findings need to be replicated in other epidemiological studies and the underlying mechanisms need to be elucidated in experimental studies. If confirmed, these elements advocate for stronger regulations on these food contaminants.

BACKGROUND AND OBJECTIVES

This study explores how non-communicable diseases (NCDs), social capital, and government subsidies/grants influence subjective well-being (SWB) among individuals aged 40 and older in rural South Africa. Understanding gender differences in these relationships provides insights for improving public health interventions in resource-constrained settings.

METHODS

We analyzed data from 2,432 participants in the HAALSI study to identify factors influencing SWB through regression analysis. Covariates such as age, education, marital status, employment, wealth, religion, social capital, and household grants were included. Interaction effects between NCDs, social capital, and grants were assessed, with gender-specific analyses to explore disparities.

RESULTS

NCDs had a significant negative impact on SWB ($\beta = -0.855$, $p < 0.01$), with a more pronounced effect observed among women ($\beta = -0.914$, $p < 0.01$) compared to men ($\beta = -0.778$, $p < 0.01$). Factors such as age, education, marital status, and wealth also influenced SWB, with older individuals (80+ years) experiencing greater declines ($\beta = -1.215$, $p < 0.01$). Secondary education was associated with improved SWB among women ($\beta = 0.544$, $p < 0.01$), while marriage significantly benefited men's SWB. The negative impact of NCDs was exacerbated by low social capital and low social grants, with men showing greater sensitivity to social capital deficits ($\beta = -1.041$, $p < 0.001$). High social grants partially mitigated these declines, particularly for women.

CONCLUSIONS

NCDs significantly reduce SWB, with gender-specific patterns linked to social capital and social grants. Public health strategies should prioritize social support, gender-sensitive frameworks, and equitable resource allocation to improve well-being in rural populations.

OAP47_09

COMPARING THE PREVALENCE OF OBESITY AND ABDOMINAL OBESITY ACROSS TWO COHORTS IN DIFFERENT STAGES OF NUTRITIONAL AND EPIDEMIOLOGICAL TRANSITION

Isabel Pereyra[1]; Sandra López-Arana[2]
[1]Nutrition, Universidad Católica del Maule, Curicó, Curicó, Chile; [2]Nutrition, Universidad Finis Terrae, Providencia, Chile

BACKGROUND AND OBJECTIVES

Obesity is a key risk factor for cardiovascular and metabolic diseases. In recent decades, Chile has undergone a significant nutritional and epidemiological transition, marked by rising obesity rates and associated comorbidities, largely due to Westernized dietary patterns and reduced physical activity. This study aims to compare the prevalence of obesity and abdominal obesity in two cohorts living in the same location, but at different stages of nutritional and epidemiological transition.

METHODS

This is a population-based cohort study included individuals from urban and rural areas. The study sample consisted of 1,985 participants (aged 22 to 28 years) from two birth cohorts: cohort 1 (born 1974–1978) and cohort 2 (born 1988–1992). Obesity was defined as a Body Mass Index (BMI) ≥ 30, and abdominal obesity as a Waist Circumference (WC) ≥ 80 cm for women or ≥ 94 cm for men. Multivariable logistic regression was used to analyze the data.

RESULTS

The mean age of participants was 24.7 ± 1.60 years, with 56.3% identifying as women. The median BMI was 25.6 kg/m² (IQR: 22.6–28.7). Overall, 20.0% of participants had obesity, and 45.2% had abdominal obesity. The prevalence of both obesity and abdominal obesity was significantly higher in cohort 2. Specifically, 15.2% of cohort 1 had obesity compared to 27.0% in cohort 2, and 37.4% of cohort 1 had abdominal obesity compared to 53.2% in cohort 2.Sex differences were observed, with women having higher prevalence rates: 22.6% of women were obese, compared to 18.7% of men; and 59.4% of women had abdominal obesity, compared to 26.6% of men.Additionally, individuals with lower incomes had higher rates of obesity (26.7%) and abdominal obesity (52.6%) compared to those with higher incomes ($p<0.05$).At the same age, individuals from cohort 2 were more likely to be obese (adjusted odds ratio [AOR]: 2.23; 95% CI: 1.76–2.81) and have abdominal obesity (AOR: 2.10; 95% CI: 1.72–2.55), after adjusting for sex and income.

CONCLUSIONS

Our findings suggest that the transition to a more Westernized diet and lifestyle—experienced during early life in cohort 2—may contribute to the higher prevalence of obesity and abdominal obesity observed in this cohort. This highlights the potential long-term impacts of nutritional and epidemiological transitions on public health.

OAP 58 - NON COMMUNICABLE DISEASES

OAP58_01

ASSESSING THE POTENTIAL IMPACT OF SALT REFORMULATION ON NON-DISCRETIONARY DIETARY SALT INTAKES IN IRISH ADULTS

Oonagh Christina Lyons[1]; Sinead O Mahony,[1, 2]; Laura Kehoe[3]; Janette Walton[3]
[1]Food Reformulation Task Force, Food Safety Authority of Ireland, Dublin, Ireland; [2]Institute of Food and Health, School of Agriculture and Food Science, University College Dublin, Belfield, Dublin, Ireland; [3]Department of Biological Sciences, Munster Technological University, Cork, Ireland

BACKGROUND AND OBJECTIVES

Annually 1.89 million deaths globally are associated with excessive salt intake (1). To date, salt reduction policies have been more effective in preventing diet-related diseases than interventions targeting sugar and saturated fat (2). The World Health Organization (WHO) has set a salt intake threshold of 5g/d to prevent diet-related noncommunicable diseases (3). In Ireland, where dietary salt intakes exceed this threshold (4), the Food Reformulation Roadmap (5) aims to reduce salt by 10% in 25 priority food categories (6). The aim of this study was to model the potential impact of this salt reduction in the 25 priority food categories on dietary salt intakes in Irish adults.

METHODS

Foods contributing to salt intake in each priority food category were identified in the National Adult Nutrition Survey II (NANSII; 2021–2022) which involved 1000 Irish adults aged 19–92 years (4). Salt content per 100g of each food item was determined and reduced by 10%. Using these reduced salt amounts, and the weight of the food consumed, the reformulated amount of salt consumed was calculated. The mean daily intake (MDI) of dietary salt for each participant before and after the 10% salt reduction was calculated. Paired t-tests were conducted in SPSS (version 29) to identify differences in the MDI of salt owing to the 10% salt reduction.

RESULTS

Prior to the 10% salt reduction, the MDI of salt was 5.6g/d and 4.4g/d for males and females, respectively. After the 10% salt reduction in the 25 priority food categories, the MDI of salt significantly decreased to 5.2g/d for males (p<0.001) and 4.1g/d for females (p<0.001). Among males aged 19–64 years, the MDI of salt significantly decreased from 6.0g/d to 5.5g/d (p<0.001), and for those ≥65 years, from 4.8g/d to 4.4g/d (p<0.001). For females aged 19–64 years, the MDI of salt significantly decreased from 4.7g/d to 4.3g/d (p<0.001), and for those ≥65 years, from 3.7g/d to 3.5g/d (p<0.001).

CONCLUSIONS

In this best-case scenario for a 10% salt reduction in priority food categories, the MDI of salt decreased in all sex/age-groups examined. However, the MDI of salt remained above the WHO salt intake threshold in younger male adults and when coupled with discretionary salt, total salt intake would be considerably higher. These findings contribute towards the evidence base for future salt reduction policies, demonstrating additional reformulation of prepacked foods is required alongside reduction in discretionary salt use.

PROSPECTIVE ASSOCIATIONS OF ANXIETY, INSOMNIA, AND THEIR COMORBIDITY WITH INCIDENT OBESITY IN FRENCH MEN AND WOMEN FROM THE GENERAL POPULATION

Pauline Duquenne[1]; Cécilia Samieri[2]; Stéphanie Chambaron[3]; Gilles Feron[3]; Marie-Claude Brindisi[3]; Emmanuelle Kesse-Guyot[4]; Serge Hercberg[1]; Pilar Galan[1]; Mathilde Touvier[1]; Léopold Fezeu[1]; Valentina Andreeva[1]

[1]Équipe de Recherche en Épidémiologie Nutritionnelle (EREN), Paris University 13 - Bobigny Campus, Bobigny, France; [2]UMR1219, Bordeaux Population Health, Bordeaux, France; [3]CNRS, INRAE, Institut Agro, Université de Bourgogne, CSGA, Dijon, France; [4]Équipe de Recherche en Épidémiologie Nutritionnelle (EREN), Sorbonne Paris Nord University, Inserm, CNAM, INRAE, Bobigny, France

BACKGROUND AND OBJECTIVES

Sleep disorders and, to a lesser extent, anxiety disorders, have been studied independently for their association with obesity. However, these mental disorders are highly comorbid. This study assessed the prospective associations of anxiety, insomnia, and anxiety-insomnia comorbidity with obesity risk in general-population adults.

METHODS

Participants in the ongoing NutriNet-Santé cohort were eligible for this analysis if: 1) they had trait anxiety data (Spielberger's State-Trait Anxiety Inventory, STAI-T, administered in 2013-2016); 2) they had chronic insomnia data (sleep questionnaire administered in 2014); 3) they did not have obesity at baseline; 4) they had body mass index (BMI) data up to 2024. Participants were assigned to one of four baseline morbidity groups: neither anxiety nor insomnia (reference), high trait anxiety only (STAI-T ≥40), chronic insomnia only, comorbid anxiety and insomnia. The associations between each of these morbidity groups and incident obesity (BMI ≥30 kg/m²) were assessed with Cox proportional hazards models with age as the time-scale and adjustment for sociodemographic (sex, education, employment, etc.) and lifestyle (diet, physical activity, sedentary behavior, smoking, etc.) confounders.

RESULTS

N= 23 797 (mean baseline age = 55.5 ± 12.7 years; 72% women) were included in the analysis. The mean follow-up duration was 6.2 ± 2.0 years. Among men and women, 21% and 29% had anxiety alone, 6% and 8% had chronic insomnia alone, and 7% and 14% had both conditions, respectively. After controlling for many potential confounders, a statistically significant association between anxiety-insomnia comorbidity and incident obesity was found in men but not in women (men: n = 207 obesity cases; HR = 1.71; 95% CI: 1.06-2.76; women: n = 526 obesity cases; HR = 1.00; 95% CI: 0.77-1.30). No significant associations were observed between insomnia alone or anxiety alone and incident obesity.

CONCLUSIONS

This large prospective study advances knowledge about multimorbidity by demonstrating a prospective association between anxiety-insomnia comorbidity and increased risk of new-onset obesity, especially in men. Future prospective studies in different populations could replicate these findings.

BACKGROUND AND OBJECTIVES

Impaired MC4R pathway signaling in patients with hypothalamic obesity (HO), or with deficiencies of proopiomelanocortin (POMC), proprotein convertase subtilisin/kexin type 1 (PCSK1) or leptin receptor (LEPR), and also Bardet-Biedl syndrome (BBS) can cause hyperphagia and severe obesity. The MC4R agonist setmelanotide has demonstrated clinically meaningful weight and hunger reduction in these populations. The weight trajectories of individual patients across these distinct populations stratified by weight category are presented.

METHODS

Patients aged ≥6 years from 4 index clinical trials and a long-term extension trial of setmelanotide who had on-treatment measurements at both baseline and 1 year were included. Changes in body mass index (BMI) and percent of the 95th BMI percentile (%BMI95) from index trial baseline to 1 year of setmelanotide were assessed and stratified by weight categories. Changes in BMI z-score at 1 year in pediatric patients were also assessed.

RESULTS

In total, 58 patients were analyzed (HO: n=12; POMC deficiency: n=9; LEPR deficiency: n=11; BBS: n=26). Most patients had class III extreme obesity at baseline (HO: 67%; POMC deficiency: 44%; LEPR deficiency: 82%; BBS: 77%). After 1 year of setmelanotide, improvements of ≥1 obesity class were observed across all cohorts (HO: 92%; POMC deficiency: 89%; LEPR deficiency: 57%; BBS: 42%). For HO and POMC deficiency, the weight category in 5 patients for each improved from obesity to overweight, and the weight category in 3 patients for each improved from obesity to healthy weight. The baseline BMI of patients with LEPR deficiency and BBS was extremely high and showed marked improvements following treatment, with clinically meaningful BMI reduction in adults (range, −8.3% to −9.5%) and reduction in BMI z-score in pediatric patients (range, −0.28 to −0.35).

CONCLUSIONS

In distinct patient populations with obesity, setmelanotide generally reduced body weight and improved weight category, albeit with differing intensity, which may be due to the variable mechanisms and location of MC4R pathway dysfunction.

ALCOHOL CONSUMPTION, SMOKING AND THEIR SYNERGY AS RISK FACTORS FOR INCIDENT TYPE 2 DIABETES

Indira Paz Graniel[1]; Junko Kose,[2]; Nancy Babio,[3]; Jordi Salas-Salvadó[3]; Pauline Duquenne,[4]; Serge Hercberg[5]; Pilar Galan,[5]; Mathilde Touvier[5]; Léopold Fezeu[5]; Valentina Andreeva[4]
[1]Fisiopatología de la Nutrición y Obesidad, Centro de Investigación Biomédica en Red, Tarragona, Spain; [2]N/a, Inserm, Villejuif, France; [3]Biochemistry and Biotechnology, Rovira i Virgili University (FLL), Tarragona, Spain; [4]Center of Research in Epidemiology and Statistics, Université Sorbonne Paris Nord - Campus de Bobigny, Bobigny, France; [5]Équipe de Recherche en Épidémiologie Nutritionnelle (EREN), Paris University 13 - Bobigny Campus, Bobigny, France

BACKGROUND AND OBJECTIVES
Smoking has been independently related to an increased risk of type 2 diabetes (T2D). However, controversial RESULTS have been reported for the association between alcohol and T2D onset, while the joint exposure to tobacco and alcohol use has not been explored. Here, we investigated the association of individual and combined tobacco-alcohol exposure with T2D risk.
METHODS

Participants in the NutriNet-Santé web-based cohort (2009-2023) who were free of T2D and had data on alcohol consumption and smoking habits at enrollment were included in these prospective analyses (N = 110,076; mean age 42.9±14.6 years, 79.2% women). Multivariable Cox regression models were fitted to explore the relationships of alcohol consumption (<2 portions/day *vs*. ≥2 portions/day, <10 portions/week *vs*. ≥10 portions/week, and as grams (g) of ethanol/day), tobacco use (never *vs.* former/current smoker), and the combined effect of smoking-alcohol consumption with risk of T2D.

RESULTS

During a median follow-up of 7.5 years (820,470 person-years), 1,175 incident T2D cases were identified. In the fully-adjusted models, no significant differences in T2D risk were detected among categories of alcohol consumption or by alcohol intake (g/day). Compared to never-smokers, former/current smokers showed an increased risk for T2D (HR: 1.36; 1.20 - 1.53). An increased risk of T2D was observed for heavy smokers compared to light/moderate smokers (HR: 2.10; 1.46 – 3.02). Being a former/current smoker with an alcohol consumption ≥10 portions/week was not associated with a higher risk of T2D (HR: 1.11;0.95 – 1.29) compared to having one or neither of these exposures.

CONCLUSIONS

These findings support smoking as an independent risk factor for T2D, and showed that alcohol consumption does not confer any protection against T2D risk. The combined effect of alcohol and tobacco use on T2D risk, and the mechanisms behind this relationship should be further explored.

OAP58_05

THE SULFUR MICROBIAL DIET AND DEMENTIA RISK: INSIGHTS FROM A LARGE-SCALE POPULATION-BASED PROSPECTIVE COHORT STUDY

Jigen Na[1]; Celi Yang[1]; Xiaona Na[1]; Yuefeng Tan[1]; Xiaojin Shi[1]; Ai Zhao[1]
[1]Vanke School of Public Health, Tsinghua University, Beijing, China

BACKGROUND AND OBJECTIVES

Hydrogen sulfide (H2S) produced by gut microbiota has been linked to metabolic disorders, potentially increasing the risk of dementia. However, current evidence remains limited partly due to the high costs of large-scale laboratory studies. To address this gap, we employed the Sulfur Microbial Diet (SMD) score, a novel dietary index based on 43 gut sulfur-metabolizing bacteria, to approximate intestinal H2S production. This study explored the association between this index and incident dementia, as well as potential disease pathways.

METHODS

We analyzed 124,435 participants with at least two 24-hour dietary recalls from the UK Biobank. SMD scores were calculated by summing the products of the β-coefficients and corresponding food serving sizes. Dementia cases, including Alzheimer's disease (AD), vascular dementia (VD), and frontotemporal dementia (FTD), were identified through hospital and death records. Cox proportional hazard models estimated adjusted hazard ratios (HRs) and 95% confidence intervals (CIs), while restricted cubic splines assessed dose-response relationships. Mediation analyses examined five chronic diseases and fourteen serum biomarkers as potential mediators. Stratified analyses were conducted by baseline age, sex, body mass index, and *ApoE ε4* status. Partial correlation coefficients evaluated links between SMD scores and regional grey matter volume changes.

RESULTS

Over a median follow-up of 8.58 years, 676 incident dementia cases were documented. After adjusting for covariates, a U-shaped relationship was observed between SMD scores and risks of dementia and AD. Compared to the middle quintile, the highest quintile group exhibited significantly higher risks of dementia (HR = 1.37, 95% CI: 1.07–1.74) and AD (HR = 1.60, 95% CI: 1.08–2.37), with no significant associations in other quintiles. Diabetes (dementia: 18%; AD: 4%) and hypertension (dementia: 10%; AD: 5%) partially mediated these associations. No significant association was found between SMD scores and VD or FTD. Male sex and older age amplified the impacts of SMD scores on dementia and AD (both p-interaction < 0.05). Positive correlations between SMD scores and decreases in certain regional grey matter volumes were observed but lost significance after multiple testing corrections. Sensitivity analyses yielded consistent RESULTS.

CONCLUSIONS

Our findings suggest a non-linear relationship between gut-derived H2S and risks of dementia and AD, underscoring the adverse effects of excessive H2S. Further studies are warranted to clarify underlying mechanisms and strengthen dietary recommendations.

THE ROLE AND MECHANISM OF HYODEOXYCHOLIC ACID INHIBITED COLORECTAL TUMORS VIA OMICS ANALYSIS

Jialing He[1, 2]; Meng Duan[1, 2, 3]; Yuwen Shi[1, 2]; Simayi Halizere[1, 2]; Ningxin Chen[1, 2]; Congcong Wang[1, 2, 4, 5, 6]; Jinhua Lin[1, 2, 7]; Wei He[1, 2, 3]; Shankuan Zhu[1, 2, 3]; Fei Yang[1, 2, 3]
[1]Department of Nutrition and Food Hygiene, Children's Hospital, Zhejiang University School of Medicine, National Clinical Research Center for Child Health, Hangzhou, Zhejiang, China; [2]Chronic Disease Research Institute, School of Public Health, School of Medicine, Zhejiang University, Hangzhou, Zhejiang, China; [3]Binjiang Institute of Zhejiang University, Zhejiang University, Hangzhou, Zhejiang, China; [4]Metabolic Physiology, Institute for Diabetes and Cancer, Helmholtz Diabetes Center, Helmholtz Zentrum München, German Research Center for Environmental Health, Neuherberg 85758, Germany; [5]German Center for Diabetes Research (DZD), German Center for Diabetes Research (DZD), Neuherberg 85764, Germany; [6]School of Medicine and Health, Technical University of Munich, Munich 80333, Germany; [7]School of Public Health and Medical Technology, Xiamen Medical College, Xiamen, Fujian, China

BACKGROUND AND OBJECTIVES

Studies have shown that obesity contributes to colorectal tumors. Hyodeoxycholic acid has been found to have a therapeutic effect on obesity-related diseases such as NAFLD. However, there are still no studies revealing whether HDCA has effects on tumors, which may suggest new uses for HDCA.

METHODS

C57BL/6 mice fed with high-fat diet supplemented with 0.5% HDCA were injected MC38 cells subcutaneously to construct the subcutaneous metastasis model of colorectal tumors. The trend of body weight and tumor volume were evaluated, and blood metabolism and gut microbiota sequencing were analyzed.

RESULTS

Compared with HFD-fed mice, HDCA-intervened mice had lower body weights and higher fecal HDCA and taurohyodeoxycholic acid levels. After tumor inoculation, the intervened mice had smaller subcutaneous tumor volumes, higher HDCA and THDCA levels in faeces and blood. Blood metabolomics revealed significant enrichment in pathways of bile secretion, arachidonic acid metabolism, primary bile acid metabolism, taurine and hypotaurine metabolism. Analysis of gut microbiota at the completion of obesity modeling revealed the α diversity, the Chao1 index, being lower in the HDCA-intervened mice. The relative abundance of a total of 9 genera were significantly higher and 18 genera were lower. The KEGG RESULTS indicated significant upregulation of 9 metabolic pathways and downregulation of 16 metabolic pathways.

CONCLUSIONS

HDCA intake ameliorates HFD-induced obesity phenotype, inhibiting colorectal tumor growth in mice, and decreases the abundance of gut microbiota. Gut microbiota affected by HDCA may participate in metabolism-related effects through the circulation, which might be one way how HDCA affects colorectal tumors.

SELF-WEIGHING AND DISORDERED EATING AMONG WOMEN: EXPLORING THE MODERATING ROLE OF PSYCHOLOGICAL RESILIENCE AND SELF-COMPASSION

Tugba Turkcan[1]; Duygu Karakus[2]; Yagmur Temiz[2]; Ebru Colak[2]; Pinar Bicaksiz; Burcu Tekes,[2]
[1]Nutrition and Dietetics Department, Istanbul Gelişim University, Istanbul, Türkiye; [2]Department of Psychology, Baskent University, Ankara, Türkiye

BACKGROUND AND OBJECTIVES

Disordered eating behaviours are a significant concern, particularly among women, due to societal pressures related to body image and weight. While self-weighing is often used as a weight management strategy, its psychological effects remain controversial. This study aims to explore the moderating roles of psychological resilience and self-compassion in the relationship between self-weighing frequency and disordered eating behaviours.

METHODS

This cross-sectional study was conducted on 372 women (mean age = 29.27, SD = 7.24). Participants completed a face-to-face questionnaire, including the Self-Compassion Scale, Connor-Davidson Psychological Resilience Scale (CD-RISC), Three-Factor Eating Questionnaire (TFEQ-R21), and a measure of self-weighing frequency. Age and BMI were controlled for in the analyses. Moderated regression analyses were conducted using Model 1 of PROCESS v3.3.

RESULTS

Four significant moderations were identified. The tenacity and competence dimension of psychological resilience moderated the relationship between self-weighing and cognitive restriction ($\Delta R2 = 0.019$, $p = 0.006$). This relationship was positive for participants with low tenacity and competence but was not significant for those with high levels. Total psychological resilience moderated this relationship ($\Delta R2 = 0.015$, $p = 0.016$), with a positive association for those with low resilience. Self-kindness, a sub-dimension of self-compassion, moderated the relationship ($\Delta R2 = 0.015$, $p = 0.014$), with a stronger association for those with low self-kindness. Lastly, total self-compassion moderated the association ($\Delta R2 = 0.011$, $p = 0.042$), with a stronger positive relationship for those with low self-compassion.

CONCLUSIONS

Psychological resilience and self-compassion buffer the impact of self-weighing on cognitive restriction. Women with higher resilience and self-compassion are less affected by the negative effects of frequent self-weighing on disordered eating behaviours. These findings highlight the value of promoting psychological resources like resilience and self-compassion in interventions targeting disordered eating.

REPLACEMENT OF ANIMAL WITH PLANT PROTEIN FOODS REDUCES BLOOD PRESSURE IN INDIVIDUALS WITH PREHYPERTENSION OR HYPERTENSION: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

Zeinab Houshialsadat[1, 2]; Constanca Silva[2, 1]; Diana Ghidanac[2, 1]; Sabrina Ayoub-Charette[1, 2]; Sonia Blanco Mejia[2, 1]; Tauseef Khan[2, 1]; Lawrence A. Leiter[2, 1, 3, 4, 5]; Cyril Kendall[2, 1, 6]; Laura Chiavaroli[1, 2, 5]; John Sievenpiper[1, 2, 3, 4, 5]; David Jenkins[1, 2, 3, 4, 5]

BACKGROUND AND OBJECTIVES

Hypertension remains the top modifiable risk factor for cardiovascular diseases (CVD), the leading cause of global mortality. While diet and lifestyle modification are the cornerstone of hypertension prevention and management, with public health and clinical practice guidelines recommending a shift to plant-based diets, the specific role of replacing animal with plant protein foods on blood pressure (BP) in the context of these diets is unclear. We assessed the effect of this dietary replacement in those with prehypertension or hypertension in a systematic review and meta-analysis of randomized controlled trials (RCTs).

METHODS

MEDLINE, Embase, and Cochrane Library were searched through March 2024 for RCTs ≥3 weeks. Systolic and diastolic BP (primary outcomes) data were extracted by two independent reviewers. Random-effect models were used to estimate pooled mean differences and 95% confidence intervals (CI). Heterogeneity was assessed and quantified using Cochran Q and I^2 statistics. The certainty of evidence was evaluated using GRADE.

RESULTS

The analysis included 7 RCTs, comprising 8 trial comparisons (n=635). Intervention arms featured soy protein powders (n=4) and soy-based foods (n=4) as substitutes for milk protein powder (n=4), animal meat (n=2), and dairy products (n=2). Replacing animal with plant protein foods reduced systolic BP by 4.33 mmHg (95% CI -8.41 to -0.26 mmHg) and diastolic BP by 2.35 mmHg (95% CI -4.50 to -0.21 mmHg), with substantial heterogeneity (I^2=88.94% and 83.75%, respectively, PQ<0.001). Subgroup analyses showed influence by food matrix in both systolic and diastolic BP (P=0.004 and P=0.029, respectively), with whole foods' replacement showing greater reductions in systolic BP (-9.54 mmHg, 95% CI -16.82 to -2.26) and diastolic BP (-4.75 mmHg, 95% CI -8.90 to -0.60). GRADE was moderate owing to downgrades for inconsistency.

CONCLUSIONS

Available evidence suggests that replacing animal with plant protein foods, especially soy-based products, leads to moderate reductions in BP in those with prehypertension or hypertension. This appears to be restricted to the displacement of whole foods. These findings support public health and clinical practice guidelines recommending plant-based dietary patterns for hypertension prevention and management (ClinicalTrials.gov: NCT02037321).

ADIPOSE AND BLOOD DNA METHYLOME OF SOUTH ASIAN INDIANS WITH TYPE 2 DIABETES MELLITUS: RELATIONS WITH GLYCEMIC CONTROL

Nikhil Nadiger,[1]; Nisarga Naik,[1]; Sridar Govindaraj[2]; Anura Kurpad[3]; Arpita Mukhopadhyay[1]
[1]Division of Nutrition, St. John's Research Institute, Bengaluru, India; [2]Department of Surgery, St. John's medical college and hospital, Bangalore, India; [3]Department of Physiology, St. John's Medical College, Bengaluru, India

BACKGROUND AND OBJECTIVES

Adipose *de novo* lipogenesis (*DNL*) preserves insulin sensitivity. This study aims to unravel the epigenetic control of adipose *DNL* in South Asian Indians with type 2 diabetes mellitus (T2DM).

METHODS

Adult normal glucose tolerance (NGT, n=35) and T2DM (n=33) subjects undergoing laparoscopic surgeries for their clinical complications (gall stone, hernia, appendicitis, pancreatitis, splenic cyst, Achalasia cardia) were recruited with written, informed consent. Omental adipose tissue (AT) and fasting venous blood samples was collected and appropriately stored. Epigenome-wide DNA methylation analysis of AT and peripheral blood mononuclear cells (PBMCs) was conducted using Illumina EPIC v2 kit on Illumina iScan instrument. Data was analysed using the ChAMP (v2.29.1) package in R statistical software (v4.4).

RESULTS

The NGT (females: 19, males: 16) and T2DM (females: 20, males: 13) subjects were similar in age (48.6 ± 6.0 and 48.2 ± 6.9 years, respectively, $P = 0.805$) and BMI (27.3 ± 4.5 and 29.1 ± 6.2 kg/m2, respectively, $P = 0.180$). 2356 (False Discovery Rate, FDR corrected $P<0.05$) and 17 (Bonferroni corrected $P<0.05$) differentially methylated probes (DMP) across both sexes in NGT and T2DM subjects in AT and PBMC were identified. Multiple DMPs in *PEG10* and *CCHCR1* were hypermethylated in T2DM across both tissue and sex; except for cg00628211 in *CCHCR1* (hypomethylated in male AT).

CONCLUSIONS

PEG10 and *CCHCR1* were hypermethylated in T2DM AT and PBMCs; except for one hypomethylated *CCHCR1* CpG in male T2DM AT. CCHCR1 is reported to be involved in mRNA metabolism. PEG10 plays a crucial role in early adipocyte differentiation. Their role in glycemic control and maintenance of metabolic homeostasis has not yet been investigated. This is the first epigenome-wide analysis of DNA methylation in AT and PBMCs from South Asian Indian subjects with T2DM. Findings from this study are providing valuable leads for identification of adipose-specific druggable molecular pathways in T2DM.

ASSOCIATION OF NOVEL DIETARY AND LIFESTYLE INFLAMMATION SCORES WITH INCIDENCE OF CARDIOVASCULAR DISEASES AND HEART FAILURE IN MIDDLE-LATE ADULTHOOD

Parto Hadaegh[1, 2]; Azra Ramezankhani[2]; Amir Abdi[2, 3]; Farzad Hadaegh[2]
[1]Faculty of Nutrition Science and Food Technology, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of; [2]Prevention of Metabolic Disorders Research Center, Research Institute for Metabolic and Obesity, Research Institute for Endocrine Sciences, Tehran, Iran, Islamic Republic of; [3]Student Research Committee, School of Medicine, Islamic Azad University Tehran Medical Sciences, Tehran, Iran, Islamic Republic of

BACKGROUND AND OBJECTIVES

We investigated the associations of novel dietary and lifestyle inflammation scores (DIS and LIS) with the incidence of all cardiovascular disease (CVD) events, its different subtypes, including hard CVD, stroke, myocardial infarction (MI), as well as heart failure (HF).

METHODS

We analyzed data from 5866 participants aged ≥45 years from the Multi-Ethnic Study of Atherosclerosis (MESA). DIS and LIS were constructed using food frequency and lifestyle questionnaire data. Multivariable Cox regression models were used to estimate the hazard ratios (HRs) and 95% confidence intervals (95% CIs) of DIS and LIS for CVD outcomes.

RESULTS

Over 14 years, there were 822, 600, 290, 252, and 270 events of all CVD, hard CVD, HF, stroke, and MI, respectively. The highest DIS quintile was associated with an elevated risk of all CVD (HR: 1.28; 95% CI: 1.02-1.61; P-trend=0.067) and hard CVD events (1.47; 1.12-1.92; P-trend=0.013). Additionally, each one-point increase in DIS was associated with a 6% higher MI risk (95% CI: 1.01-1.12). The impact of DIS on all CVD events was more pronounced among overweight participants compared to normal weight or obese counterparts (P-interaction <0.001). Each one-point increase in LIS was associated with a 36% higher HF risk (95% CI: 1.14-1.62). Furthermore, individuals in the highest LIS quintile had a 75% higher risk of HF, compared to those in the lowest quintile (95% CI: 1.18-2.59).

CONCLUSIONS

Diet and lifestyle, through their contributions to inflammation, may be associated with higher risk of CVD, particularly for hard CVD, MI, and HF.

ASSOCIATION BETWEEN MINDFUL EATING AND WEIGHT STATUS IN A FRENCH COHORT

Pauline Paolassini Guesnier; Marion Van Beekum[1]; Rebecca Shankland,[2]; Angélique Rodhain,[3]; Julia Baudry,[1]; Alice Bellicha,[1]; Emmanuelle Kesse-Guyot; Christophe Leys[4]; Serge Hercberg,[1]; Mathilde Touvier; Benjamin Allès[1]; Sandrine Péneau,[1]
[1]Equipe de recherche en épidémiologie nutritionnelle, Université Sorbonne Paris Nord, Bobigny, France; [2]Laboratoire DIPHE, Université Lumière Lyon 2, Lyon, France; [3]Montpellier Research in Management, Université de Montpellier, Montpellier, France; [4]Faculty of Psychology, Educational Sciences, and Speech and Language Therapy, Université libre de Bruxelles, Bruxelles, Belgium

BACKGROUND AND OBJECTIVES

Mindful eating (ME) can be globally defined as paying attention to the eating experience with all the senses, and witnessing the emotional and physical reactions that occur before, during, and after the eating experience without judgment or reaction. This holistic approach to eating may offer a promising alternative to traditional weight management strategies, such as cognitive restraint. However, the relationship between ME and weight status remains underexplored. This cross-sectional study aimed to investigate the association between ME and body mass index (BMI) in a large French population sample and to compare psychological and dietary behavior characteristics across different ME and BMI categories.

METHODS

In 2023, 26,718 participants from a large French web-based cohort study completed the Mind-Eat Scale, which assesses total ME (range: 1-5), and its six sub-dimensions. Height and weight were self-reported. Multivariable logistic regressions were performed to analyze the association between ME (independent variable) and 6 BMI categories (dependent variable). ANCOVA and logistic regression analyses were conducted to compare individual characteristics based on ME level (≤3.32 vs >3.32, median) and weight status (underweight, normal weight, overweight). All analyses were adjusted for socio-demographic and lifestyle characteristics.

RESULTS

Participants were 60.48 ± 13.81 years (74% female) with a mean ME score of 3.32 ± 0.53. Higher ME scores were associated with lower odds of being in the overweight category (excluding obesity) (OR = 0.43; 95% CI: 0.40–0.46), obesity category I (OR = 0.26; 95% CI: 0.24–0.29), or obesity categories II and III (OR = 0.20; 95% CI: 0.17–0.23). Conversely, higher ME scores were linked to greater odds of being in underweight category I (OR = 2.05; 95% CI: 1.80–2.34) or category II (OR = 1.43; 95% CI: 1.16–1.78). Underweight individuals with high ME levels exhibited healthier psychological and dietary behavior characteristics compared to underweight, normal-weight, and overweight individuals with low ME levels.

CONCLUSIONS

ME was associated with lower levels of overweight and obesity suggesting its potential as a preventive tool for these conditions. However, ME was also linked to higher levels of underweight, which was characterized by healthier psychological traits and eating behaviors. Further longitudinal and interventional studies are needed to better understand the relationship between ME and weight status.

CONSUMPTION OF DIFFERENT POTATO PREPARATIONS AND WEIGHT CHANGE IN THE EUROPEAN PROSPECTIVE INVESTIGATION INTO CANCER AND NUTRITION (EPIC) STUDY

Guri Skeie[1]; Jeroen Berden[2, 3]; Reynalda Cordova[4]; Christina C. Dahm[5]; Daniel B. Ibsen[5]; Marie W. Lundblad[1]; Inge Huybrechts[2]; Heinz Freisling[2]
[1]Department of Community Medicine, UiT the Arctic University of Norway, Tromsø, Norway; [2]Nutrition and Metabolism Branch, IARC - International Agency for Research on Cancer, Lyon, France; [3]Department of Food Technology, Safety and Health, Ghent University, Ghent, Belgium; [4]Department of Nutritional Sciences, University of Vienna, Vienna, Austria; [5]Department of Public Health, Aarhus University, Aarhus, Denmark

BACKGROUND AND OBJECTIVES
Potatoes are one of the most important global staple foods, but few studies have examined associations between potato consumption and health outcomes. Studies considering preparation METHODS and employing substitution analyses are lacking. We therefore studied the association between different types of potato preparation and weight change in participants from seven countries in the EPIC-study.
METHODS
We included 289,523 participants who provided sufficient detail on potato preparation METHODS to classify potatoes into boiled (including mashed), fried (including roasted), and French fries, and had available repeated measurements on weight. We used multivariable linear regression and performed substitution analyses using the leave-one-out method to explore associations with weight change. Potatoes were substituted with vegetables and legumes; bread; or rice and pasta. Five-year weight change was calculated as (follow-up weight minus baseline weight/time (years))*5. RESULTS were adjusted for age, sex, centre, all other food groups, baseline weight, BMI, education, physical activity, marital status, and smoking status.
RESULTS

The mean (SD) age at baseline was 52.5 (9.1) years, and the mean time between baseline and follow-up weight assessment was 7.5 (3.5) years. The mean (SD) baseline daily intake of boiled potatoes, fried potatoes, and French fries was 64 (61) g, 5 (10) g, and 14 (23) g, respectively. The mean (SD) weight change was 0.7 (4.3) kg/5 years. No association between intake of boiled potatoes and weight change was observed. A 1-SD higher consumption of French fries and fried potatoes was associated with an additional weight gain of 40 g (95% CI: 10;60 g)/5 years and 50 g (95% CI: 30;70 g)/5 years, respectively. Substitution of 1-SD of fried potatoes with bread was associated with 60 g (95% CI: -70;-40) less weight gain over 5 years. Replacing 1-SD of French fries with an equal amount of rice and pasta was associated with 20 g (-30;-10) g/5 years less weight gain. Substituting 1-SD of boiled potatoes with vegetables and legumes was associated with 30 g (10;50 g)/5 years additional weight gain.

CONCLUSIONS
In a European population, intake of boiled potatoes was not associated with 5-y weight gain. Fried potatoes and French fries were associated with slight weight gain. No clinically meaningful associations with weight change were observed when substituting differently cooked potatoes METHODS with vegetables and legumes, bread, or rice and pasta.

THE ASSOCIATION BETWEEN INDOOR BIOFUEL USE FOR COOKING AND GLUCOSE METABOLISM IN ADULTS: A CROSS-SECTIONAL STUDY

Happyness Kunzi[1]; Mussa K. Nsanya[1]; Kweka Belinda[1]; Evangelista Malindisa,[1]; Bazil Kavishe[1]; Kidola Jeremiah,[1]; Mette Frahm Olsen,[2]; Rikke Krogh-Madsen,[3]; Suzanne Filteau[4]; Henrik Friis,[5]; Daniel Faurholt-Jepsen[6]; George Praygod[1]

BACKGROUND AND OBJECTIVES

The burden of diabetes is rapidly increasing in low- and middle-income countries (LMICs) but determinants are not well-characterized. Household air pollution (HAP) from indoor biofuel for cooking has been associated with non-communicable diseases (NCDs) and may contribute to the increasing burden of diabetes in LMICs but data are limited. We assessed the association between indoor biofuel use for cooking and glucose metabolism in adults.

METHODS

In a cross-sectional analysis among human immunodeficiency virus (HIV) infected and uninfected adults, sociodemographic and NCDs risk factors were collected. The main predictor variable, HAP, established using reported information on where people routinely cooked (outdoor or indoor) and type of fuel used (electricity/gas or biomass fuel) and synthesized as minimal, moderate exposure and high exposure. Outcomes included markers of β-cell dysfunction (HOMA-β, insulinogenic index, oral disposition index) and insulin resistance (HOMA-IR, Matsuda index), prediabetes and diabetes. Logistic regression was used adjusted for age, sex, physical activity, smoking, socioeconomic status, HIV status, and BMI.

RESULTS

There were 1,871 participants, mean age 40.6 years, 59.8% female., Higher odds of low insulinogenic index were seen in, people with moderate (OR=2.13, 95%CI:1.27, 3.57) or high (OR=2.31, 95%CI: 1.39, 3.83) exposure to HAP compared to those with minimal exposure. HAP was not associated with other markers of β-cell function, insulin resistance, pre-diabetes and diabetes.

CONCLUSIONS
HAP is associated with increased risk of β-cell dysfunction among individuals using bio-fuel for cooking indoors. Longitudinal studies are needed to confirm these RESULTS.

THE IMPACT OF NUTRITIONAL, SENSORY AND CULINARY SUPPORT ON IMPROVING THE FOOD-RELATED QUALITY OF LIFE IN CANCER PATIENTS TREATED WITH CHEMOTHERAPY

Anestis Dougkas,[1, 2]; Reisya Rizki Riantiningtyas[1]; Kenza Drareni[1]; Melanie Roche[3]; Amandine Bruyas[4]; Benjamin Riche[5]; Pascale Roux[6]; Hélène Labrosse[7]; Veronique Mourier[8]; Julie-Anne Nazare[2]; Moustafa Bensafi[9]; Agnes Giboreau[10]

BACKGROUND AND OBJECTIVES

Cancer and its treatments significantly affect physical health and overall quality of life (QoL) (1-2), yet the food-related QoL (FR-QoL) remains underexplored. Furthermore, sensory alterations are prevalent among cancer patients and are associated with reduced food enjoyment and intake (3,4). The study aims to assess whether nutritional, sensory and culinary support via consultations and adapting meals to the sensory capacities of each patient could improve the FR-QoL.

METHODS

This randomised, multicentric, prospective interventional study included 209 patients with breast cancer undergoing chemotherapy, divided into control (n=104) and intervention (n=105) groups. Participants were assessed at baseline (V1, before chemotherapy) and after four chemotherapy cycles (V2). Data collected at V1 and V2 included FR-QoL, health-related QoL (EORTC-QLQ C30), anthropometric measures, chemosensory assessments using taste strips and scratch and sniff tests, nutrient intake, and food consumption using 24-hour dietary recalls. The intervention group received a CANUT guide, a booklet with sensory-adapted culinary advice and 35 recipes, along with two dietary consultations. Meanwhile, the control group received standard care without the CANUT guide or dietary consultations. Mixed regression modelling was performed to investigate the effects of time (V1 vs V2) and intervention (control vs intervention groups) on FR-QoL and other measures

RESULTS

The findings revealed a significant decline over time in FR-QoL ($p < 0.001$) and health-related QoL ($p < 0.001$) in cancer patients undergoing chemotherapy. Olfactory measures also deteriorated, with reduced odour identification ($p < 0.001$) and pleasantness ($p < 0.001$), alongside heightened odour intensity ($p = 0.012$). However, no significant changes were observed in taste, anthropometric measures, nutrient intake, or food consumption over time. While the intervention offering nutritional, sensory, and culinary support showed potential, its effects on FR-QoL and other measures were comparable to the control group ($p > 0.05$).

CONCLUSIONS

These findings highlight the complex challenges associated with managing the nutritional, sensory, and QoL impacts of chemotherapy and emphasise the need for innovative strategies to better support patients.

EVALUATION OF THE EFFECTIVENESS OF 5A-5R COUNSELING SERVICES FOR TOBACCO CESSATION, A MAJOR RISK FACTOR FOR NONCOMMUNICABLE DISEASES

Sabrina Ahmed[1]; Ali Ahsan[2]; Tanmoy Sarker[3]; Malay Kanti Mridha[4]
[1]Department of Public Health, North South University, Dhaka, Bangladesh; [2]Centre for Non-communicable Diseases and Nutrition, BRAC JPGSPH, BRAC University, Dhaka, Bangladesh; [3]Centre for Non-communicable Disease and Nutrition, BRAC JPGSPH, BRAC University, Dhaka, Bangladesh; [4]James P Grant School of Public Health, BRAC University, Dhaka, Bangladesh

BACKGROUND AND OBJECTIVES

Tobacco use remains a significant public health challenge globally and a major risk factor for noncommunicable diseases and premature deaths. The 5A-5R counseling model, endorsed by the World Health Organization (WHO), is effective for tobacco cessation in diverse settings, but its application in LMICs remains underexplored. This study aims to evaluate the effectiveness of culturally adapted 5A-5R counseling services alone or with mobile phone-based remote support in reducing tobacco consumption among adults in a primary healthcare setting.

METHODS

A randomized control trial was conducted over eight months in Birganj, Dinajpur district, Bangladesh. The study included 668 adult participants who were current daily tobacco users and were randomly assigned to three arms: (1) conventional 5A-5R counseling, (2) 5A-5R counseling with mobile phone based remote support, and (3) a control group receiving usual care. Data were collected through interviewer-administered questionnaires and were facilitated by trained community health workers. Interventions were delivered by community health care providers. We performed descriptive analysis on continuous and categorical variables to compare changes in primary and secondary outcomes in the end line compared to the baseline. Statistical significance was determined using p-values (<0.05) and 95% confidence intervals. Data were analyzed using Stata version 17.0.

RESULTS

Among smoking tobacco users, the multicomponent arm showed a reduction in tobacco use from 30% to 18%, with a 12% quitting rate (P<0.01) in end-line analysis. In the 5A-5R-only arm, smoking tobacco use decreased from 50% to 27%, resulting in a 23% quitting rate (P<0.01) while the control arm showed no significant difference. Again, for smokeless tobacco users, the multicomponent arm demonstrated a significant reduction from 85% to 41%, corresponding to a 44% quitting rate (P<0.01), while the 5A-5R-only arm reduced use from 67% to 34%, with a 33% quitting rate (P<0.01) in end line survey. In terms of reduction if not quitted, only the 5A-5R-only arm led to a significant decrease in cigarette consumption (7.4±4.5 sticks/day, P<0.01) and smokeless tobacco consumption (5.9±1.4 times/day, P<0.01), no significant reductions were observed in the other arms.

CONCLUSIONS

The study found that the 5A-5R counseling model, particularly when delivered in-person through the health care providers, was highly effective in promoting tobacco cessation and reducing tobacco consumption in a primary health care setting.

OAP63_07

CARDIOMETABOLIC HEALTH EFFECTS OF DIETARY COUNSELING ON A HIGH-QUALITY, FIBER-RICH DIET IN ADULTS WITH TYPE 2 DIABETES: A RANDOMIZED CONTROLLED TRIAL

Iris van Damme[1]; Eva Van Veldhuisen[1]; Renate Winkels[1]; Marianne Geleijnse[1]
[1]Division of Human Nutrition and Health, Wageningen University & Research, Wageningen, Netherlands

BACKGROUND AND OBJECTIVES

Individuals with type 2 diabetes are at increased risk for developing cardiovascular disease (CVD). A healthy diet is pivotal in effective management of CVD risk factors. We assessed how dietary counseling on a high-quality, fiber-rich diet influenced the cardiometabolic health profile of patients with type 2 diabetes.

METHODS

In this six-month trial, 121 patients with type 2 diabetes (age 67 ± 8.7 years, 68% men, mean body mass index 27.8 kg/m2) were randomly assigned to counseling by a dietitian (n=61) or to a control group that continued with standard care and usual diet (n=60). The counseling included 4-7 individual sessions with the dietitian, aimed at improving diet quality by focusing on increasing the intake of fiber-rich foods. As primary outcome, a composite cardiovascular risk score was used to estimate ten-year CVD risk. Secondary outcomes included changes in diet quality, assessed by the Dutch Healthy Eating Index-2015 (DHD15-index), changes in individual risk factors (HbA1c, LDL-cholesterol, blood pressure, and body weight), and changes in medication use. As objective markers of dietary intake, folic acid status and 24-hour urinary sodium and potassium excretion were measured.

RESULTS

Predicted ten-year CVD risk at baseline was 2.2 ± 1.4% in the control group and 2.3 ± 1.4 in the intervention group and did not change during the trial period (difference in change between groups -0.1%, 95%CI: -0.2; 0.1). The mean diet quality score (DHD15-index) at baseline was 115 ± 26 out of 160 and was similar across groups. Over the six months, the intervention group improved their DHD15-index score by 4.5 points (95%CI: -0.2; 9.1) more than the control group. No statistically significant differences between groups over time were found for HbA1c (-1.1 mmol/mol, 95%CI: -4.4; 2.3), LDL-cholesterol (0.0 mmol/l, 95%CI: -0.1; 0.1), blood pressure (-1 mmHg, 95%CI: -6; 4), body weight (-0.1 kg, 95%CI: -1.2; 1.1), or medication use (change in medication effect score 0.1, 95%CI: -0.5; 0.7). Urinary sodium-to-potassium ratio was 1.8 at baseline, did not change over time and no differences between the two groups were found. Folic acid status did not differ between the groups at 6 months.

CONCLUSIONS

Dietary counseling for six months slightly improved self-reported adherence to a high-quality, fiber-rich diet in patients with type 2 diabetes but did not significantly impact cardiometabolic health or medication use.

ADAPTATIONS OF MUSCLE STRENGTH AND QUALITY IN MALE AND FEMALE OBESE OLDER ADULTS AFTER 12 WEEKS OF CITRULLINE SUPPLEMENTATION COMBINED WITH HIGH-INTENSITY INTERVAL TRAINING

Philippe Noirez[1]; Layale Youssef[2]; Vincent Marcangeli[3]; José A Morais[4]; Pierrette Gaudreau[5]; Guido Kroemer[6]; Gildas Bertho[7]; Gilles Gouspillou[3]; Mylène Aubertin-Leheudre[3]
[1]PSMS, University of Reims Champagne Ardenne Campus Red Cross, Reims, France; [2]CRIUGM, University of Montreal, Montréal, Canada; [3]Science de l'activité physique, University of Quebec in Montreal, Montréal, Canada; [4]Division of Geriatric Medicine, McGill University, Montreal, Canada; [5]Centre de Recherche du CHUM, University of Montreal, Montréal, Canada; [6]Centre de Recherche des Cordeliers, Université paris cité, Paris, France; [7]NMR biomedical platform, Université paris cité, Paris, France

BACKGROUND AND OBJECTIVES

In our previous research (PMID:35257499), a 12-week High-Intensity Interval Training (HIIT) combined with citrulline (CIT) supplementation enhance the health status of obese older adults (OOA). However, it remains unclear if these health benefits are sex-dependent. We aim to assess sex differences in muscle and biological adaptations following a 12-week intervention combining HIIT with CIT in OOA.

METHODS

Eighty-one OOA completed a 12-week HIIT intervention (3 times/week) combined with either a citrulline [HIIT-CIT: n=45 (men=20, women=25)] or a placebo [HIIT-PLA: n=36 (men=18, women=18)] supplementation. Body composition (DXA/QPCT), absolute muscle S (AMS) and quality (AMS relative to body mass or specific lean mass) and serum metabolites were compared pre (T0) and post (T12) intervention (3-way-anova with repeated measures; $p<0.05$: significant). Pearson's correlations between S parameters and metabolites were also performed.

RESULTS

We observed sex-divergent health adaptations following the intervention. Only Men increased significantly their lean mass compared to women after the intervention (M: T0=54±9 - T12=55±7 vs. W: T0=41±5 - T12=41±5). Specifically, HIIT-CIT women exhibited a higher increase (+15%) in leg extension S (N; HIIT-CIT: T0=277±64 - T12=320±70 vs. HIIT-PLA: T0=272±62 - T12=270±55) than HIIT-CIT men (+11%). Only HIIT-CIT women exhibited a higher significant increase in leg extension S relative to leg lean mass (N.kg-1; HIIT-CIT: T0=9.4±2.2 - T12=10.6±1.9 vs. HIIT-PLA: T0=9.6±2.0 – T12=9.6±1.7). In men, total lean mass was significantly positively correlated to ceramide (18:1/16:0) ($r2 = 0.43$; $p <0.01$). In women, leg extension S was significantly positively correlated to carnitine C80:1 ($r2 = 0.42$; $p <0.01$) and to acetylputrescine ($r2 = 0.46$; $p<0.01$). Additionally leg extension S relative to leg lean mass was negatively correlated to glycodeoxycholic acid ($r2 = -0.45$ $p< 0.01$).

CONCLUSIONS

Although previous research has concluded that HIIT-CIT is beneficial for OOA, it appears that women and men don't adapt in the same way. This raises the question of how to consider strength to determine sarcopenia and sarcopenic obesity: should we use absolute strength or muscle quality? These findings underscore the importance of assessing sex differences in adaptations to address specific recommendations.

REPLACING DIETARY RED MEAT WITH NON-SOY LEGUMES HAS NO EFFECT ON SYSTEMIC INFLAMMATION VIA GUT BARRIER FUNCTION OR CHOLINE METABOLISM IN 6-WEEK RCT WITH HEALTHY MEN

Tuulia Kreetta Pietilä[1]; Elisabetta Cantini,[1]; Tiina Pellinen[1]; Essi Päivärinta[1]; Anne Salonen,[2]; Anne-Maria Pajari[1]
[1]Department of Food and Nutrition, University of Helsinki, Helsinki, Finland; [2]Faculty of Medicine, Human Microbiome Research Program, University of Helsinki, Helsinki, Finland

BACKGROUND AND OBJECTIVES

While the health burden of high red and processed meat intake has been acknowledged in observational studies, evaluation of the effects of unprocessed red meat intake and relevant underlaying mechanisms in healthy participants have generated mixed findings. Our aim was to see whether in apparently healthy men a partial replacement of unprocessed and processed red meat (from 760 g/week to 200 g/week) with non-soy legume foods yields beneficial effects on plasma markers of systemic inflammation through changes in gut barrier function and choline metabolism.

METHODS

This study was a 1:1 randomized, partly controlled, 6-week parallel trial (age 37.9 y, BMI 25.5 ± 3.3 kg/m2, mean ± SD) with two groups following either a diet supplemented with unprocessed and processed red meat (Meat group, n = 51) or with non-soy legumes and meat (Bean group, n = 51). Between-group differences in markers of inflammation as primary outcomes, and white blood cell counts, markers of barrier function, choline metabolism and body fatness as secondary outcomes were tested at 6 weeks using ANCOVA model adjusted with the baseline. This trial is registered at clinicaltrials.gov as NCT04599920.

RESULTS

We report no differences in circulating levels of high sensitivity CRP (Meat 0.85 mg/L (95%CI 0.61, 1.08) and Bean 0.79 mg/L (0.55, 1.02), P=0.54), glycoprotein acetyls (Meat 0.71 mmol/L (0.70, 0.73) and Bean 0.70 mmol/L (0.69, 0.72), P=0.39), cytokines and other immune modulators between the groups. Although a lower percentage of eosinophils, concentration of plasma total choline and higher urine dimethylamine excretion (g/day) in the Bean group were observed, no differences in urine trimethylamine-N-Oxide (TMAO) excretion (g/day) or lipopolysaccharide Binding Protein (LBP), a marker of gut barrier, occured. Interestingly, the Bean group losing more weight did not translate to between group differences. But we identified BMI, hip-waist ratio and LBP as important factors explaining individual/overall variance within the markers of Olink Inflammation panel. In addition to confirming previously reported associations between certain cytokines and BMI, we were able to identify others linked to TMAO and/or LBP and fiber independently of BMI.

CONCLUSIONS

It is known that a large variation between individuals exist in the function immune system. More attention should be paid in separating the effects in the context of red meat intake in healthy individuals.

THE INTERINDIVIDUAL VARIABILITY OF ADIPOSE TISSUE PROVITAMIN A CAROTENOID CONCENTRATIONS IS LINKED TO COMBINATIONS OF SINGLE NUCLEOTIDE POLYMORPHISMS

Mark Pretzel Zumaraga[1]; Patrick Borel; Charles Desmarchelier[1]
[1]Center for CardioVascular and Nutrition Research (C2VN), AMU/INSERM/INRAE, Marseille, France

BACKGROUND AND OBJECTIVES

Carotenoids are a group of lipophilic pigments of plant origin. In the human body, some can be converted to vitamin A (VA) and are thus referred to as proVA carotenoids, with β-carotene (BCAR), α-carotene (ACAR), and β-cryptoxanthin (BCRY) being the main ones in our diets. Adipose tissue serves as their primary storage site, accounting for 80-85% of total body BCAR, where they are involved in several processes, including oxidative stress and inflammation. The determinants of their concentrations in adipose tissue are not well characterized and this study thus aimed to identify single nucleotide polymorphisms (SNPs) associated with them.

METHODS

Periumbilical adipose tissue samples were collected on 6 occasions in 43 healthy adult males, who had their whole genome genotyped, and proVA carotenoid concentrations were measured by HPLC. Following the selection of 44 candidate genes assumed to be involved in adipose tissue or blood proVA concentrations, the association of the corresponding 2398 SNPs on the DNA chips with adipose tissue proVA concentrations were assessed by partial least squares regression.

RESULTS

ProVA carotenoid concentrations in adipose tissue ranked as follows: BCAR > ACAR > BCRY. Adipose tissue proVA concentration exhibited an interindividual variability ranging from 54 to 66% (CV). A PLS regression model including fasting BCAR concentrations and 10 SNPs in 8 genes (*BCO1*, *CAPN2*, *CXCL8*, *IRS1*, *LIPC*, *MGLL*, *PPARG*, *PTPRT*) explained 69% (adjusted R^2) of the variability in adipose tissue BCAR concentrations. Another model including fasting ACAR concentrations and 12 SNPs (same genes and 7 SNPs in common) explained 59% of the variability in adipose tissue ACAR concentrations. For BCRY, a PLS regression model including 14 SNPs in 9 genes (*ABCA1*, *CAPN8*, *CXCL8*, *INSIG2*, *IRS1*, *ISX*, *MC4R*, *PPARG*, *PTPRT* and 3 SNPs in common with BCAR and ACAR) explained 67% of the variability in adipose tissue BCRY concentrations. RESULTS from canonical correlation analysis and multivariate PLS regression to explore the relationships between datasets will also be presented.

CONCLUSIONS

The interindividual variability in adipose tissue proVA carotenoid concentrations is, at least partly, due to combinations of SNPs in genes involved in carotenoid and lipid metabolism.

ALMONDS AND THEIR IMPACT ON THE IMMUNE RESPONSE FOLLOWING INFLUENZA VACCINATION: A RANDOMISED CONTROLLED TRIAL OF A VACCINATION MODEL OF IMMUNE RESPONSE IN HEALTHY ADULTS

Alice van der Schoot[1]; Alice Creedon[1]; Esperanza Perucha,[2]; Wendy L. Hall[1]; Victor Turcanu,[3]; Kevin Whelan,[1]; Eirini Dimidi,[1]
[1]Department of Nutritional Sciences, King's College London Waterloo Campus, London, United Kingdom; [2]Centre for Inflammation Biology and Cancer Immunology, King's College London, Guy's Campus, London, United Kingdom; [3]School of Immunology and Microbial Sciences, King's College London, Strand Campus, London, United Kingdom

BACKGROUND AND OBJECTIVES

Some nutrients and food supplements have been shown to optimise the immune response to influenza vaccination, however, no studies have assessed the impact of a whole food. Almonds may benefit immune function due to their immunoregulatory nutrients and fibre content, the latter known to interact with the immune system via the microbiome. This study aimed to investigate the effect of whole almonds on the immune response following influenza vaccination.

METHODS

In this randomised controlled trial, healthy adults (40-64 years) were randomised to consume almonds (56 g/d) or isocaloric control (pretzels; 86 g/d) for 8 weeks (NCT05515263). At week 4, both groups received seasonal influenza vaccine (quadrivalent). Blood samples were collected at 4 (immediately pre-vaccination) and 8 (4 weeks post-vaccination) weeks to quantify antigen-specific antibody titres using the hemagglutination inhibition assay. The primary outcome was the proportion of participants achieving seroconversion for ≥1 of the four vaccine strains. Participants reported upper respiratory symptoms during the intervention and follow-up (2 and 3 months post-vaccination) using the Wisconsin Upper Respiratory Symptom Survey.

RESULTS

Ninety participants were randomised. In the almond group, 38/41 (93%) participants achieved seroconversion for ≥1 strain, which was not significantly different to the control group (37/39 participants, 95%). Seroconversion rates did not differ between the almond and control groups for any vaccine strain: AH1N1 subtype (68% *vs* 74%), AH3N2 subtype (59% *vs* 62%), B/Victoria lineage (71% *vs* 59%) or B/Yamagata lineage (78% *vs* 62%). Incidence of upper respiratory symptoms (participants with ≥ 1 episode) did not differ between groups for common cold (almonds: 24%, control: 31%; p=0.52) or influenza-like illness (almonds: 27%, control: 18%; p=0.34).

CONCLUSIONS

While almonds are rich in nutrients supporting immune function, they may not offer additional benefits in enhancing seroconversion in a healthy population, where the influenza vaccine is already highly effective. Future studies using different immune response models, or in those with weaker immune responses, such as older people, may better elucidate the role of almonds in improving immune response.

MULTI-TISSUE, MULTI-OMICS STUDY TO UNDERSTAND THE BIOLOGICAL SIGNATURE OF CHILDHOOD EDEMATOUS SEVERE MALNUTRITION (KWASHIORKOR)

Gerard Bryan Gonzales[1]; On Behalf Of The Kwashiorkor Omics Collaboration,[2]
[1]Department of Public Health and Primary Care, Faculty of Medicine and Health Sciences, Ghent Uni, University of Ghent, Gent, Belgium; [2]Collaboration with MSF, Epicentre, University of Cambridge, University of Ghent, Gent, Belgium

BACKGROUND AND OBJECTIVES

Edematous malnutrition, aka kwashiorkor, is a phenotype of childhood severe malnutrition comprising oedema, fatty liver, and skin and hair changes. Despite high fatality, the etiology and pathophysiology of kwashiorkor remain enigmatic. This study aimed to understand the molecular pathophysiology of kwashiorkor to provide insights into its potential etiological mechanisms.

METHODS

We recruited children aged 6 to 59 months with kwashiorkor (n = 60), marasmus (n = 60) and non-acutely malnourished children (n = 60) matched on sex, age and clinical severity at a hospital and several health centres supported by Médecins Sans Frontières in Niger from 2018 - 2019. Blood plasma, urine and stool samples were collected at admission to the hospital or at a community feeding or health center for in-depth biochemical profiling. Blood plasma was additionally obtained at discharge from the hospital and at the end of the ambulatory nutritional rehabilitation. Using a multi-omics, multi-tissue approach, we integrated plasma lipidomics, metabolomics, and proteomics, urine metabolomics, and gut microbiome data to identify pathways specific to kwashiorkor.

RESULTS

Our RESULTS demonstrate that kwashiorkor is characterized by increased extracellular matrix (ECM) remodeling and impaired lipid transport, particularly of cholesterol-related lipids. No significant (plasma or urine) metabolomic or gut microbiome signatures were specifically linked to kwashiorkor.

CONCLUSIONS

These findings suggest that kwashiorkor is an inflammatory syndrome leading to ECM degradation-related edema. Further research on the role of inflammatory triggers that contribute to kwashiorkor development is needed and can potentially point to more effective therapeutic strategies for children with oedematous malnutrition.

INFLUENCE OF VITAMIN D-RELATED GENE GENOTYPES (VDR, GC, AND CYP2R1) ON THE RESPONSE TO DIETARY INTAKE CHANGES. THE MYFOOD4SENIOR PROJECT

María Benavent[1]; Cristina Alvarez-Martin[1]; Angela García-González[1]; María Achón[1]; Natalia Ruiz[1]; Violeta Fajardo[1]; Natalia Ubeda[1]; María Purificación González[1]; Elena Alonso-Aperte[1]; Rocío de la Iglesia González[1]
[1]Departamento de Ciencias Farmacéuticas y de la Salud, CEU San Pablo University, Madrid, Spain

BACKGROUND AND OBJECTIVES

Vitamin D is a critical nutrient in bone health, yet deficiency states are frequently reported. This study investigates the interaction between VDR, GC, and CYP2R1 and vitamin D intake, as well as its biochemical values, in Spanish individuals aged 65 and older. The study was conducted before and after a 6-month nutritional education intervention.

METHODS

Blood samples from 120 volunteers were analysed for plasma 25-OH vitamin D and genotyped for: rs2228570 (FokI), rs2282679, and rs10741657. A genetic risk score for vitamin D deficiency, depending on the three genotypes, was estimated based on scientific evidence. Each participant was asked for vitamin D supplement use and completed two three-day food records, at baseline and after 6-months of intervention.

RESULTS

A statistically significant difference was observed in plasma 25-OH vitamin D levels between individuals taking supplements and those who did not (22 ng/ml *vs.* 37 ng/ml, $p < 0.001$), despite a higher dietary vitamin D intake in the non-supplemented group (4.15 µg/day *vs.* 2.06 µg/day, $p = 0.04$). In the supplemented group, significant differences in baseline plasma 25-OH vitamin D levels between genotypes were observed only for rs2228570 (AA + AG: 43.7 ng/ml *vs.* GG: 29.5 ng/ml, $p = 0.04$). In the non-supplemented group, significant differences based on genotype were observed for rs2282679 (GG: 16.6 ng/ml *vs.* GT: 20.8 ng/ml *vs.* TT: 24.23 ng/ml $p = 0.02$) and for the genetic risk score (High risk: 21.52 ng/ml *vs.* Intermediate risk: 19.09 ng/ml *vs.* Low risk: 26.17 ng/ml; $p = 0.04$). After 6 months of nutritional intervention, there was no significant change in vitamin D intake or serum 25-OH vitamin D levels. However, in non-supplemented individuals, biochemical responses varied significantly according to the overall genetic risk score ($p = 0.05$), with the intermediate risk score being the most sensitive, and the highest risk score the least sensitive to increasing biochemical values with increasing vitamin D intake ($p = 0.03$).

CONCLUSIONS

When vitamin D supplemented, individuals carrying the A allele for rs2228570 (FokI) reach higher plasma 25-OH Vitamin D levels. In non-supplemented individuals, mutations in rs2282679 are associated with lower levels. Moreover, targeting the three genes at a time may help identify responsive individuals at dietary levels of intake. The identification of genotypes with different sensitivity to vitamin D intakes and supplementation is important in tailoring personalized treatments for individuals at risk for deficiency.

GENETIC PREDISPOSITION AND HEALTH BEHAVIORS OF LIFE'S ESSENTIAL 8, ON CORONARY HEART DISEASE RISK AND CORONARY ARTERY CALCIUM

Xiang Jun Wang[1]; Marinka Steur[2]; Bos Daniel[1]; Kavousi Maryam[1]; Ghanbari Mohsen[1]; Trudy Voortman[1]
[1]Epidemiology, Erasmus University Medical Center, Rotterdam, Netherlands; [2]Division of Human Nutrition and Health, Wageningen University & Research, Wageningen, Netherlands

BACKGROUND AND OBJECTIVES

Life's Essential 8 (LE 8) recommends DASH- and Mediterranean-style eating patterns as being most consistent with optimal cardiovascular health. Plant-based diets have also been shown to benefit cardiovascular health and prevent coronary heart disease (CHD). However, no prior studies have investigated its additive effect in combination with other ideal health behaviors included in LE 8 on CHD prevention. Furthermore, limited attention has been given to interactions with genetic predisposition, which may add personalized health behavior recommendations. Therefore, we developed a combined lifestyle score, the healthy plant-based diet index-lifestyle (hPDI-Lifestyle) score, including a healthy plant-based diet index as dietary component, evaluated its association with CHD incidence and atherosclerosis development, and investigated potential effect modification with genetically predicted CHD risk.

METHODS

A total of 7,764 participants from the population-based Rotterdam Study were included in the analysis. Multivariable Cox proportional hazard models were used to estimate hazard ratios (HRs) and 95%-confidence intervals (CIs) for CHD according to categories of the hPDI-Lifestyle score, stratified by polygenic risk score of CHD. Generalized linear modelling (GLM) was used to assess associations of hPDI-Lifestyle score and log-transformed coronary artery calcium score plus 1 (log [CAC+1]).

RESULTS

We documented 918 CHD cases during 116,324 person-years of follow-up. Ideal adherence to the hPDI-Lifestyle was associated with a 20% lower CHD risk among participants at low genetic risk (HR 0.80, 95% CI 0.71-0.90), and a 44% lower CHD risk among those at high genetic risk (HR 0.56, 95% CI 0.49-0.63), compared with participants at high genetic risk but with poor adherence to the hPDI-Lifestyle (p for interaction < 0.001). No significant associations were observed between hPDI-Lifestyle adherence and genetic risk with log [CAC+1] (βs [95% CI], per SD, hPDI-Lifestyle score: -0.10 [-0.27-0.06]), but a decreasing trend in reverse-transformed CAC scores was observed among participants with higher adherence to the hPDI-Lifestyle, within each genetic risk subgroup.

CONCLUSIONS

Our findings support recommendations to adopt a healthful plant-based dietin combination with non-smoking, adequate physical activity and moderate sleep duration. Potential differences by genetic predisposition and the role of lifestyle on subclinical CHD prevention warrants further investigation.

ASSOCIATION OF SERUM 25-HYDROXYVITAMIN D LEVELS WITH INFLAMMATORY MARKERS AND LUNG FUNCTION IN UK BIOBANK PARTICIPANTS WITH INFLAMMATORY BOWEL DISEASES

Chiu-Li Yeh[1]; Hsien-Yu Fan[1]; Yih-Jong Chern[2]; Hsin-Yin Hsu[3]; Po-Jui Lai[4]; Ming-Chen Tasi[5]; Chih-Jun Lai[6]
[1]School of Nutrition and Health Sciences, College of Nutrition, Taipei Medical University, Taipei, Taiwan; [2]Division of Colon and Rectal Surgery, Department of Surgery, Chang Gung Memorial Hospital, Taoyuan, Taiwan; [3]Department of Family Medicine, Mackay Memorial Hospital, Taipei, Taiwan; [4]School of Medicine, College of Medicine, National Taiwan University, Taipei, Taiwan; [5]Department of Internal Medicine, Mackay Memorial Hospital, Taipei, Taiwan; [6]Department of Anesthesiology, National Taiwan University Hospital, Taipei, Taiwan

BACKGROUND AND OBJECTIVES

Previous studies have established a relationship between serum 25-hydroxyvitamin D (25(OH)D) levels and lung function. However, the role of inflammatory markers in the relationship among patients with inflammatory bowel disease (IBD) is still unclear. This study aimed to identify which inflammatory biomarkers significantly influence the relationship between serum 25(OH)D levels and lung function in patients with IBD.

METHODS

The UK Biobank study included 497,134 participants recruited between 2006 and 2010. Among them, 4,088 participants had IBD. The serum of 25(OH)D levels (nmol/L) was measured and classified into quintiles: Q1 (<29), Q2 (29~41), Q3 (41~53), Q4 (53~67), and Q5 (>67). Q1 served as the reference group, and linear regression analysis was used to examine the differences in inflammatory marker levels and lung function across Q2 to Q5, using Q1 as the reference. This analysis adjusted for sex, age, education, income, ethnicity, current smoking status, energy intake, body mass index, health score, moderate metabolic equivalents, and alcohol frequency. Additionally, a counterfactual-based mediation analysis was performed to identify which inflammatory biomarkers significantly influence the relationship between serum 25(OH)D levels and lung function in patients with IBD.

RESULTS

After adjustments, the levels of blood glucose (mmol/L), white blood cells (WBCs) (10^9 cells/L), and neutrophils (10^9 cells/L) were lower in Q2 to Q5 compared to Q1. Significant reductions were observed in blood glucose for Q2 (-0.15, standard error [SE] = 0.07, $p = 0.04$) and Q5 (-0.15, SE = 0.08, $p = 0.04$), WBCs were notably lower in Q3 (-0.23, SE = 0.09, $p = 0.01$) and Q5 (-0.36, SE = 0.10, $p < 0.01$). Neutrophil counts were also significantly reduced in Q3 and Q5 ($p < 0.01$). In contrast, lung function parameters, measured in liters, were higher in Q2 to Q5 compared to Q1. Forced expiratory volume in 1 s (FEV1) significantly increased in Q2 (0.07, SE = 0.03, $p = 0.02$), Q3 (0.11, SE = 0.03, $p < 0.01$), Q4 (0.06, SE = 0.03, p=0.04), and Q5 (0.07, SE = 0.03, $p = 0.02$). Forced vital capacity (FVC) also increased significantly in Q2 (0.10, SE = 0.04, $p = 0.01$), Q3 (0.11, SE = 0.04, $p < 0.01$), and Q5 (0.09, SE = 0.04, $p = 0.02$).

CONCLUSIONS

Blood glucose levels, white blood cell counts, and neutrophil counts may be critical factors linking serum 25(OH)D levels to lung function in the IBD population within the UKB.

CHANGES DURING SYSTEMIC THERAPY IN COMPUTED TOMOGRAPHY-EVALUATED BODY COMPOSITION PREDICT LONG-TERM SURVIVAL IN COLORECTAL CANCER

Erin Stella Sullivan[1, 2]; Clodagh Scannell[2]; Samantha Cushen[2]; Derek Power; Aoife Ryan[2]
[1]Department of Nutritional Sciences, King's College London, London, United Kingdom; [2]School of Food & Nutritional Sciences, University College Cork, Cork, Ireland

BACKGROUND AND OBJECTIVES

Low muscle mass is associated with poor clinical outcomes in colorectal cancer, however the impact of body composition changes has rarely been explored. This study aimed to evaluate the prognostic value of body composition changes during systemic anti-cancer treatment (SACT) for colorectal cancers (CRC).

METHODS

A prospective study was conducted in an ambulatory SACT centre. Chart review and patient survey were used to record clinical, anthropometry, laboratory and quality of life variables. Routine computed tomography scans were analysed at L3 using OsiriX MD to determine muscle and adipose tissue body composition measures at baseline and follow-up within a year. Changes between scans were normalised over 100 days. Validated cut-offs were used to diagnose low muscle mass (1), low muscle attenuation (MA)(1) and cachexia (CC)(2). Median survival follow-up was 121.5 months and 60% were deceased at the censoring date. Multivariate Cox regressions stratified by treatment intent examined changes in MA, skeletal muscle index (SMI) and total adipose tissue index (TATI) as predictors of overall survival.

RESULTS

Of 1018 patients enrolled, 182 had CRC and 2 evaluable scans. At baseline, 40% had CC, 31% had low SMI and 39% had low MA. At follow-up, 39% had CC, 37% had low SMI and 41% had low MA. At baseline, 6% had BMI <20 kg/m² while 61% had BMI ≥25 kg/m². In patients undergoing SACT with palliative intent (n=91), MA increase by >5% over 100 days was associated with worse survival than stable MA [HR: 3.7 (95% CI: 1.4-9.3), p=0.006] and decreased TATI (>5%/100 days) was associated with worse survival than stable TATI (±5%) [HR: 1.9 (95% CI: 1.1-3.5), p=0.027], independent of changes in SMI, which were not significant. Body composition changes were not significant predictors on multivariate analysis for those treated with curative intent.

CONCLUSIONS

In the palliative CRC cohort, the negative impacts of fat loss and increased MA may represent a deterioration from the insulin resistant/metabolic syndrome phenotype commonly observed in CRC, toward a fat-wasting phenotype associated with advancing cachexia. Larger prospective studies are needed to control for the impact of dietetic care and SACT exposure on body composition, considering dynamic changes in all body composition compartments.

GUT MICROBIOME AS A PREDICTOR FOR POSITIVE YOUTH DEVELOPMENT TRANSITION FROM CHILDHOOD TO EARLY ADOLESCENCE

Yujie Xu[1]; Xiaoyu Wang[1]; Guo Cheng[1]; Jingyuan Xiong[2]
[1]Maternal & Child Nutrition Center, West China Woman's and Children's Hospital, Sichuan University, Chengdu, China; [2]West China School of Public Health and West China Fourth Hospital, Sichuan University, Chengdu, China

BACKGROUND AND OBJECTIVES

Growing evidence highlights the important role of the gut microbiome in mental health, underscoring the potential for leveraging this insight to promote positive youth development (PYD). This study aims to characterize the transition of PYD profiles from childhood to adolescence and explore the predictive value of the gut microbiome in shaping these developmental trajectories.

METHODS

This cohort study used two waves of data from the Chinese Adolescent Cohort study (children aged 8 to 11 years at baseline). Stool samples were collected at wave 1 and analyzed using 16s rRNA sequencing to profile the gut microbiota. Children were assessed for PYD at both time points and categorized into profiles by latent profile analysis. Stability and change between these profiles over the 2-year follow-up period were examined via latent transition analysis. A Light Gradient Boosting Machine model was developed to link the gut microbiota with PYD transition type, and model prediction was further validated using multinominal logistic analysis.

RESULTS

Among 1061 participants with 2-year follow-up, three PYD profiles were identified at both waves: limited development, average development, and considerable development. Fifteen microbial genera were identified as significant predictors of PYD transitions, such as *Sarcina*, *Lachnospiraceac_UCG.001*, *Eubacterium_eligens_group*, or *Ruminococcus_torques_group*. Children with higher abundance of these taxa were more likely transitioned to a stable or promoted class rather than a downgraded class (odd ratio ranging from 2.03 to 5.45) from childhood to adolescence. Notably, children in earlier stages of puberty were found to be more sensitive to the microbiome-PYD transition association. This predictive model for PYD transition type demonstrated excellent performance, with an area under the curve of 0.91.

CONCLUSIONS

The gut microbiome presents predictive value in the substantial transition of PYD from childhood to adolescence. Targeting specific gut taxa may inform future health promotion programs to optimize child development, particularly during the critical pubertal transition.

IMPACT OF PREOPERATIVE MEDIUM-CHAIN TRIGLYCERIDE (MCT) SUPPLEMENTATION WITHIN ENHANCED RECOVERY AFTER SURGERY (ERAS) PROTOCOLS ON PERIOPERATIVE OUTCOMES IN COLORECTAL CANCER PATIENTS

Jinran Yang[1]; Zhang Xinsheng[1]; Yun Tang[2]; Chaojun Zhang[2]; Canrong Lu[2]; Na Liu[2]; Xinpu Yuan[2]; Ziwei Zhuang[2]; Dachuan Sun[2]; Xiangrong Liu[1]; Yetong Ma[1]; Yinghua Liu[1]
[1]Department of Nutrition, The First Medical Center, Chinese People's Liberation Army General Hospital, Beijing, China; [2]Department of Surgery, The First Medical Center, Chinese People's Liberation Army General Hospital, Beijing, China

BACKGROUND AND OBJECTIVES

Preoperative oral carbohydrate (CHO) solutions are known to improve patient comfort and facilitate postoperative recovery; however, evidence on their perioperative impact remains limited. This study aimed to evaluate the effects of preoperative supplementation with medium-chain triglyceride (MCT)-CHO solution on postoperative insulin resistance, perioperative stress responses, and nutritional status in colorectal cancer patients, while exploring the underlying mechanisms.

METHODS

1.A total of 120 patients undergoing colorectal surgery were randomized into two groups: the experimental group (MCT-CHO solution) and the control group (CHO solution). Primary outcomes included blood glucose, insulin levels, and insulin resistance, measured preoperatively, 3 hours postoperatively, and on POD 1 and 3. Secondary outcomes involved WBC, IL-6, CRP levels, VAS scores for thirst, hunger, and fatigue, as well as time to first flatus. Gut microbiota and metabolomic profiles were also assessed.

2.In an animal study, 40 male Sprague-Dawley rats were assigned to MCT-CHO, CHO, saline, or fasting groups. Blood glucose, insulin, leucine levels, and insulin-related indices were evaluated pre- and post-surgery. mRNA and phosphorylated protein levels of mTOR, IRS-1, PI3K, AKT, and GLUT4 in liver tissue were analyzed using PCR and Western blotting.

RESULTS

1.In patients, blood glucose, insulin levels, and insulin resistance showed no significant differences between groups preoperatively, 3 hours postoperatively, or on POD 3. However, these metrics were significantly lower in the MCT-CHO group on POD 1 ($P < 0.05$). Additionally, WBC, IL-6, CRP, and VAS scores for thirst, hunger, and fatigue were significantly reduced in the MCT-CHO group both preoperatively and on POD 1 and 3 ($P < 0.05$). Time to first flatus did not differ significantly between groups ($P = 0.411$).

2.In the rat model, postoperative blood glucose levels were significantly lower, and phosphorylated IRS-1, PI3K, and AKT levels were markedly higher in the MCT-CHO group compared to other groups ($P < 0.05$).

CONCLUSIONS

Preoperative supplementation with MCT-CHO solution improves postoperative insulin resistance and reduces perioperative stress responses more effectively than CHO solution alone, offering a novel approach to enhanced recovery after surgery (ERAS). Mechanistically, MCT-CHO exerts its effects by decreasing postoperative hepatic insulin resistance and enhancing insulin sensitivity via the PI3K/AKT/mTOR signaling pathway.

MULTI-METABOLITE PLASMA SIGNATURE AS A ROBUST PREDICTOR OF LONG-TERM MORTALITY: A MULTI-COHORT STUDY

Fernandez-Duval Gonzalo[1]; Razquin Cristina; Fenglei Wang[2]; Huan Yun[3]; Jie Hu[3]; Rexrode M. Kathryn[4, 5]; Balasubramanian Raji[4, 5]; Group Predimed[1]; Clary Clish[6]; Frank B. Hu[2]; Miguel A. Martínez-González[1]; J. Alfredo Martinez[7, 8]

BACKGROUND AND OBJECTIVES

Metabolomics represent a powerful approach to understand biological pathways related to aging and mortality. While several plasma metabolites have been associated with all-cause mortality, their independence, replicability, and clinical utility beyond conventional risk factors remain unclear. This study aimed to identify and validate a plasma metabolite profile independently associated with all-cause mortality in a Mediterranean dietary intervention trial and replicate findings in independent cohorts.

METHODS

Among 1,878 participants from a dietary intervention trial (2003-2019), 337 plasma metabolites were measured at baseline and after one year. Using elastic net penalized Cox regression, metabolites associated with all-cause mortality were identified at baseline in the discovery cohort. The resulting multi-metabolite signature was validated using one-year follow-up samples and replicated in four independent cohorts.

RESULTS

Thirty-eight plasma metabolites were identified as mortality predictors. GABA, homoarginine, serine, creatine, 1-methylnicotinamide, and specific sphingomyelins, plasmalogens, phosphatidylethanolamines and cholesterol esters showed inverse associations with mortality. Conversely, DMGV, choline, short and long-chain acylcarnitines, 4-acetamidobutanoate, pseudouridine, 7-methylguanine, N6-acetyllysine, phenylacetylglutamine and creatinine were associated with higher mortality. The multi-metabolite signature strongly predicted mortality in both the 1-y data from the discovery cohort and four independent cohorts.

CONCLUSIONS

This novel plasma multi-metabolite signature demonstrated robust predictive capability for all-cause mortality across diverse populations, suggesting potential applications in risk stratification and providing new insights into metabolomic pathways associated with survival.

ASSOCIATION OF DIETARY INTAKE WITH BODY CELL MASS, CLINICAL OUTCOMES AND QUALITY OF LIFE IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKAEMIA

Deepa Puttaswamy[1, 2]; Aaminah Kausar[1]; Sumithra Selvam[3]; Tony Raj[4, 5]; Kishor G Bhat[1]; Anand Prakash[6]; Vandana Bharadwaj[6]; Anura Kurpad[5]; Sumathi Swaminathan[1]; Rebecca Kuriyan[1, 5]
[1]Nutrition, St. John's Research Institute, Bengaluru, India; [2]Research Scholar, Manipal Academy of Higher Education, Manipal, India; [3]Epidemiology and Biostatistics, St. John's Research Institute, Bengaluru, India; [4]Medical Informatics, St. John's Research Institute, Bengaluru, India; [5]Physiology, St. John's Medical College, Bengaluru, India; [6]Pediatric Oncology, St. John's Medical College Hospital, Bengaluru, India

BACKGROUND AND OBJECTIVES

In children with Acute lymphoblastic leukaemia (ALL), tailored dietary interventions can be planned if associations between diet and the functional and clinical outcomes are known. Diet in terms of dietary diversity has been associated with better immune function and reduced risk for certain types of cancers. This study aimed to evaluate the association of dietary intakes with body cell mass (BCM), clinical outcomes, and quality of life (QOL) during treatment, in children with ALL.

METHODS

A longitudinal study was carried out in children with ALL, aged 2 to 8 y recruited at time of diagnosis, and followed up during induction, consolidation and completion of delayed intensification phase (~6 m from diagnosis). Diet was estimated using 24-hour recalls collected over 3 non-consecutive days at each time point and dietary diversity score (DDS) calculated using the food group data obtained. Anthropometry, BCM using whole-body potassium counter and QOL using a validated questionnaire were assessed. At delayed intensification phase associations between dietary intake and the outcomes were analysed using multiple linear regression and logistic regression model adjusted for the sex, energy intake per kg body weight and baseline DDS.

RESULTS

At diagnosis, the mean age of the children (n = 32, 62.5% boys) was 4.6 ± 1.9 y. Clinically, 71.8% and 21.8% were identified as intermediate and high-risk ALL category respectively. The mean energy, protein intake per kg body weight and DDS were 76.5± 18.6 kcal, 2.53 ± 0.59g and 8.8 ± 1.4 respectively. The % BCM was 30.9 ± 4.6 %, BCM Index (BCMI, BCM/height (m)2) 4.6 ± 0.7 kg/m2. Across visits, dietary intakes were similar ($p>0.05$). At delayed intensification phase, higher DDS had significant associations with increased BCMI (β: 0.202; 95% C.I. (0.035, 0.368), p=0.019) and QOL score (β: 7.78; 95% C.I. (1.19, 13.6), p=0.01) and % BCM (β: 0.693; 95% C.I. (-0.139, 1.524), p=0.09). Similarly, higher DDS was significantly associated with lesser number of infections (Adjusted odds ratio: 0.650; 95% C.I. (0.420, 1.00), p=0.05).

CONCLUSIONS

Incorporating diverse diets may reduce treatment related complications in children with ALL.

A RANDOMIZED, PLACEBO CONTROLLED, CROSSOVER CLINICAL TRIAL TO EVALUATE THE EFFECT OF A TURMERIC FORMULATION ON MUSCLE SORENESS AND FUNCTION RECOVERY IN MODERATELY ACTIVE ADULTS

Katja A. Schönenberger[1]; Julie Laval[2]; Trevor Woods[3]; Romain Truillet[4]; Sandra Naranjo-Modad[2]; Samuel Mettler[5]; Pascale Fança-Berthon[2]
[1]Taste & Wellbeing, Givaudan International AG, Kemptthal, Switzerland, Switzerland; [2]Taste & Wellbeing, Givaudan France Naturals, Avignon, France; [3]Human Performance Laboratory, Department of Sport and Physical Activity, University College Cork, National University of Ireland, Cork, Ireland; [4]Biostatistics, ATLANSTAT SA, Rezé, France; [5]Department of Health, Bern University of Applied Sciences, Bern, Switzerland

BACKGROUND AND OBJECTIVES

Turmeric may alleviate exercise-induced, delayed onset muscle soreness and function loss due to the strong anti-inflammatory and antioxidant activities of its active compounds, the curcuminoids. The primary objective of this trial was to evaluate the effect of a highly bioavailable turmeric formulation (TF) on delayed onset muscle soreness in male adults. The bioavailability of curcuminoids in this TF is not negatively affected by food matrices and can even be increased when administered with lipids, such as in a sports nutrition bar.

METHODS

In a randomized, placebo-controlled, crossover trial (ClinicalTrials.gov NCT04946981), 44 moderately active adults (34 males, 10 females) ingested a TF (300 mg/day, thereof 90 mg curcuminoids) or placebo for five days. On the second day, muscle damage was induced with exercise (30 min downhill run at 70% VO_2 max). Immediately before and 0, 24, 48, and 72 h post-exercise, muscle soreness during squat on quadriceps (visual analog scale), muscle function (knee extension dynamometer), muscle power (vertical jump test), muscle damage (creatine kinase), range of motion (knee flexion), and perceived wellness and wellbeing (questionnaire) were assessed. During exercise, exhaustion was assessed using the Borg Rating of Perceived Exertion. The primary trial population consisted of the male participants, outcomes in females were considered exploratory.

RESULTS

There were no significant differences between the TF and placebo in muscle soreness AUC from pre-exercise to 72 h post-exercise and at all timepoints, except for a trend observed in males at 72 h (adjusted mean difference (AMD) [SE] = -4.8 [2.7] mm, $p = 0.0776$). Muscle soreness recovery (difference between 72 h and maximum post-exercise) was significantly improved with the TF compared to placebo (AMD [SE] = -10.7% [4.3%], $p = 0.0184$ for the males, and -7.9% [3.6%], $p = 0.0346$ for the total sample). Furthermore, in males the decrease from pre-exercise to 24 h after exercise in isokinetic peak torque was significantly lower with the TF (AMD [SE] = 11.0 [4.9] Nm, $p = 0.0275$), as was the decrease in isokinetic max rep work (AMD [SE] = 11.6 [4.9] J, $p = 0.0195$), while vertical jump peak power at 24 h after exercise was higher (median [IQR] with the TF vs. placebo = 931.1 [825.9; 1001.1] W vs. 916.5 [824.8; 989.5] W, $p = 0.0445$).

CONCLUSIONS

Supplementation with the TF can accelerate exercise-induced muscle soreness recovery and could attenuate muscular function loss and improve performance 24 h after unaccustomed exercise in young, moderately active, male adults.

MODULATORY EFFECTS OF FOOD ON THE GUT MICROBIOTA AND GUT RESISTOME

Ze Liang[1]; Zijian Liang[1]; Zhongxiang Fang[1]; Kate Howell[1]; Hangwei Hu[1]; Pangzhen Zhang[1]
[1]School of Agriculture, Food and Ecosystem Sciences, The University of Melbourne, Parkville, Australia

BACKGROUND AND OBJECTIVES

The increasing prevalence of antibiotic-resistant bacteria and resistance genes (collectively, the gut resistome) poses a global health challenge. This study investigates how dietary phytochemicals, particularly anthocyanins from blueberries and Lycium berries, influence the gut microbiota and resistome, with a focus on their antibacterial and resistance gene modulation effects.

METHODS

Phytochemicals were extracted from blueberries and Lycium berries and identified using HPLC-DAD-ESI-QTOF-MS/MS. The additice effects of the plant extracts combined with antibiotics on inhibiting antibiotic-resistant bacteria were evaluated, and their regulatory impacts on antibiotic resistance mechanisms were investigated. The modulation of bacterial gene expression was analyzed via qPCR and transcriptomics, and molecular docking evaluated interactions between phytochemicals and bacterial proteins.

RESULTS

The blueberries and Lycium berries extracts demonstrated additive effects combined with gentamicin against *Acinetobacter baumannii* BAA-1605. The additive combination inhibited β-lactamase activity and reduced efflux pump activity. Transcriptomic analysis revealed additive combination downregulated key resistance-related genes (*mecA* and *NorA*), and molecular docking suggested strong binding affinities of phytochemicals (querctin, rutin) to bacterial efflux pump proteins (PBP2a, beta-lactamase, *NorA*).

CONCLUSIONS

Dietary phytochemicals, particularly anthocyanins, show promising potential for mitigating the spread of antibiotic resistance within the gut microbiota. These findings highlight the role of food-based interventions in addressing antibiotic resistance and improving gut health.

APPETITE TEST PLUS: ADAPTING THE STANDARD APPETITE TEST FOR ENHANCED CLINICAL APPLICATION IN CHILDREN WITH SEVERE ACUTE MALNUTRITION

Alemayehu Toni[1, 2]; Tsinuel Girma[3]; Hetherington Marion[4]; Gonzales Bryan,[5, 2]; Ciaran Forde[2]
[1]Department of Pediatrics and Child Health, University of Gondar, Gondar, Ethiopia; [2]Human Nutrition and Health, Wageningen University & Research, Wagen, Netherlands; [3]Pediatrics and Child Helath, Jimma University, Jimma, Ethiopia; [4]School of Psychology, University of Leeds, Leeds, United Kingdom; [5]Public Health and Primary Care, Ghent University, Ghen, Belgium

BACKGROUND AND OBJECTIVES

Severe acute malnutrition (SAM) treatment guidelines recommend using the appetite assessment through the "appetite test" as a tool for classification, and a criterion for hospital admission, treatment follow-up, and discharge. However, the existing scarce literature highlights the test's subjectivity and time-consuming nature. Therefore, this study aims to develop a new appetite assessment tool by adapting the standard "appetite test" to enhance its clinical utility for use in severely malnourished children.

METHODS

We conducted a cross-sectional study with observational method at two health facilities. Infants and children aged 6-59 months with SAM were included. Ten eating behaviors were identified from previous studies, comprising four positive eating behaviors(approach): opening mouth, leaning body forward, swiping/grabbing, and turning head toward Ready-to-Use Therapeutic Feeding (RUTF); and six negative behaviors(avoidance): refusing to open mouth, arching back, crying, pushing, turning head away, and spitting out RUTF. A total of 328 video extracts from 30 "appetite test" procedures were coded by four trained medical doctors and the study team. Additionally, 60 randomly selected videos were re-coded by the same coder after two weeks. Inter-observer reliability was evaluated using the Fleiss' kappa, while intra-observer reliability was measured with Cohen's kappa. Internal consistency was assessed using Cronbach's alpha, and associations among eating behaviors were analyzed using Spearman's Rho correlation.

RESULTS

Two positive behaviors, opening mouth (k=0.89, 95%CI:0.84,0.93) and swiping RUTF (k=0.79, 95%CI: 0.74,0.83), and all negative behaviors demonstrated moderate to high inter-observer reliability with acceptable agreement(k>0.60). Intra-observer reliability was also above the acceptable threshold for all negative and positive behaviors, except leaning forward(k=0.02). The internal consistency of negative behavior subscale(α=0.78) was higher than that of positive behavior subscale(α=0.56). The overall scale retained a Cronbach's alpha greater than 0.7, even when the last half of the RUTF feeding observations were excluded. All positive behaviors were positively correlated with each other, while all negative behaviors, except spitting out, exhibited a positive correlation with other negative behaviors.

CONCLUSIONS

Eating behavior cues expressed during the "appetite test" provides a reliable method with acceptable agreement in shorter observation durations. However, further validation studies are required before the clinical implementation of this newly developed tool.

WILD BLUEBERRIES IN THE CONTEXT OF METABOLIC SYNDROME: PRELIMINARY FINDINGS FROM THE BLUMET DIETARY INTERVENTION STUDY

Cristian Del Bo'[1]; Marco Rendine[1]; Samuele Venturi[1]; Mirko Marino[1]; Francesca Menichetti[1]; Alessandro Leone[2]; Alberto Battezzati[2]; Daniela Martini[1]; Patrizia Riso[1]; Dorothy Klimis-Zacas[3]
[1]Department of Food, Environmental and Nutritional Sciences (DeFENS), University of Milan, Milano, Italy; [2]International Center for the Assessment of Nutritional Status, DeFENS, University of Milan, Milano, Italy; [3]School of Food and Agriculture, University of Maine, Orono, United States of America

BACKGROUND AND OBJECTIVES

The Metabolic Syndrome (MetS) represents a constellation of metabolic abnormalities including an impairment of vascular function. Blueberries, sources of polyphenols and other bioactive constituents, may positively influence MetS representing a possible alternative or coadjutant to drug therapy. Few human studies have been conducted evaluating the effect of blueberries on MetS (1-2). This study attempts to test the hypothesis that wild blueberries (WB) can normalize MetS risk factors, improve endothelial function and permeability, and reduce inflammation.

METHODS

Twenty-six subjects with risk factors for MetS are enrolled for an 8-week, randomized, double-blind, placebo-controlled, crossover trial (BLUMET study). Subjects consumed 240 ml/day of a WB drink (providing at least 560 mg of anthocyanins and 200 mg of chlorogenic acid) or a placebo drink. Each treatment is separated by an 8-week washout period. At the beginning and at the end of each intervention measurement of blood pressure, body composition, together with analyses of markers of cardiometabolic health, vascular and intestinal permeability, inflammation, and oxidative stress, is performed by routine laboratory assessment or by ELISA kits, while reactive hyperemia index and arterial stiffness, as markers of vascular function, are measured by plethysmography (Endo-PAT2000).

RESULTS

The RESULTS related to 10 out of 26 subjects have shown a significant reduction in insulin response (-15.6%; $p<0.05$), total cholesterol (-9.2%; $p<0.05$), and ratio of total cholesterol/HDL-cholesterol (-8.4%; $p<0.05$) following the WB drink compared to placebo. In addition, a trend to decrease systolic blood pressure (-6.65%; $p=0.061$) and increase adiponectin (+23.7%; $p=0.055$) has been documented. No effect has been observed for the rest of the markers under study.

CONCLUSIONS

The preliminary RESULTS obtained from the BLUMET study seem to suggest a possible contribution of WB in the management of MetS mainly through an improvement of lipid and glucose profile. The analysis of the full group of subjects will be crucial for providing a clear understanding of the positive role of wild blueberries in the context of MetS.

BACKGROUND AND OBJECTIVES

Continuous glucose monitors are increasingly used to characterise glycaemic responses to foods, yet the validity of continuous glucose monitors to quantify the glycaemic index of foods is unclear. The ability of continuous glucose monitors to accurately quantify glycaemic indices may also depend on properties of the foods ingested. The objective of this study was to compare glucose responses to different test drinks when measuring using capillary sampling *versus* continuous glucose monitoring of interstitial fluid.

METHODS

Fifteen healthy adults (9 female) completed 7 laboratory visits in randomised crossover design with at least 48 h washout between visits. During each visit, participants consumed a test drink/food which comprised of either 50 g glucose (CONTROL), a commercially available fruit smoothie containing 50 g available carbohydrate (PRODUCT), equivalent carbohydrate ingested as whole fruits (WHOLE), or as blended fruits (BLEND), the commercial product ingested over 30 min (SLOW), the commercial product ingested with 5 g inulin (FIBRE), and the commercial product ingested in a typical serving size providing 30 g carbohydrate (DOSE). Capillary (duplicate) and interstitial glucose were recorded every 15 min for 120 min and expressed as the incremental area under the curve (iAUC). For test drinks meeting glycaemic index (GI) testing guidelines, the GI was calculated relative to CONTROL.

RESULTS

The GI for PRODUCT was higher with interstitial (84±54), compared with capillary sampling (60±35; P=0.05), and was also higher for FIBRE with interstitial (80±41), compared with capillary sampling (56±25; P=0.05). In contrast, no evidence was observed for differences in the GI for WHOLE or BLEND with interstitial (62±38 and 65±17, respectively), compared with capillary sampling (57±38 and 55±29; P=0.26 and 0.18, respectively). Furthermore, there the difference between interstitial versus capillary fasting glucose concentrations varied by participant (main effect participant, p=0.001).

CONCLUSIONS

Continuous glucose monitoring can overestimate the glycaemic index drinks and there is evidence of inter-individual heterogeneity of the accuracy of continuous glucose monitors to estimate fasting glucose concentrations. Caution should be applied when interpreting absolute or relative glycaemic responses using continuous glucose monitors, and capillary sampling should be used when accurate quantification of glycaemic response is the priority.

IMPACT OF MORE PLANT-BASED DIETS ON GUT MICROBIOTA COMPOSITION AND FUNCTION: A 1-MONTH RANDOMIZED CROSS-OVER TRIAL IN MEN AT CARDIOMETABOLIC RISK

Gaïa Lépine[1]; Anne-Marie Davila[2]; Gwendal Cueff[1]; Florence Thirion[3]; Laura Desnouveaux[4]; Caroline Perreau[5]; Catherine Lefranc-Millot[5]; Didier Rémond[1]; François Mariotti[2]; Marion Courrent[6]; Hélène Fouillet[2]; Sergio Polakof[1]

BACKGROUND AND OBJECTIVES

More plant-based diets, which are lower in animal protein (AP) and higher in plant protein (PP) sources, have been associated with lower cardiometabolic risk but also differences in gut microbiota that may contribute to those health benefits. This study aimed to characterize the effects of a partial substitution of AP by PP on fecal microbiota composition and activity.

METHODS

We conducted a 1-month randomized cross-over trial with high dietary control in 19 men at cardiometabolic risk who consumed a flexitarian diet higher in PP (FL, 63% PP, all food groups, low in animal products) and an isocaloric control diet (CON, 34% PP). As previously reported, the intervention improved some cardiometabolic risk factors independently of the diet, with a trend towards greater improvement after FL. In this ancillary study, fecal microbiota composition and function were assessed by shotgun metagenomic sequencing followed by gene ontology analysis and a targeted metabolomics approach (LC-MS) on feces collected before and at the end of each diet arm. Data were analyzed using a non-parametric analysis (nparLD, R) testing the effect of time, diet and their interaction.

RESULTS

The evolution of the fecal metabolite profile was mostly similar after both diets, with only linoleic acid decreasing more after FL than CON. α and β diversity were unchanged but, irrespective of the diet, bacteria degrading complex carbohydrates (e.g., Lachnospira pectinoschiza, Bifidobacterium adolescentis) increased, possibly due to the high fiber intake in both diets (28 g/d in CON and 36 g/d in FL, compared to 21 g/d at baseline). 52 species changed with time differently according to the diet (p-diet*time <0.05), but only two remained significant after multiple-testing correction (q<0.1): Dysosmobacter segnis and Lactococcus cremoris decreased after FL while increasing after CON. Among those 52 species, Flavonifractor plautii showed the strongest decrease after FL and no change after CON, in line with its reported negative correlation with plant-based diets and positive correlation with cardiometabolic risk factor [1]. At the functional level, FL induced decreased potential bacterial capacities for indole production and increased potential for methanogenesis.

CONCLUSIONS

This study reveals subtle shifts in fecal microbiota after 1 month of a flexitarian diet with diversified PP sources in a tightly controlled dietary setting. To explore the cross-talk between changes in the gut microbiota and the host metabolic status, a multi-omic data integration including fecal metagenomic, and fecal and plasma metabolomics is underway.

BACKGROUND AND OBJECTIVES

The increasing rate of cancer survivorship highlights the need for high-quality care that addresses factors beyond cancer recurrence, such as diet, lifestyle, and other behaviors that may influence quality of life (QoL) and prognosis. There is a lack of validated screeners to assess these factors in cancer survivors. The aim was to develop and validate a screening tool to be used in both clinical and research settings.

METHODS

An international expert panel participated in a two-round e-Delphi to develop the screener. A face validity study was conducted with cancer survivors (n=12) to assess comprehension, construct interpretation, time to complete, and acquiescence of the screener. Construct validity was assessed in cancer survivors (n=103) (inclusion criteria <5 years since surgery or finishing chemotherapy and/or radiotherapy). Participants answered the screener, and validated diet, lifestyle, and mental health questionnaires. Body composition (InBody), physical activity (accelerometer), strength (dynamometer and 30-s chair test) and cortisol (saliva) were assessed. Data from these validated assessments will be compared to data obtained with the screener (ongoing) using Spearman and Intraclass correlations. All participants answered the screener 7-10 days later for reproducibility analysis.

RESULTS

The screener considers six domains (body composition, physical activity, diet and alcohol, smoking, sleep behavior, and psychosocial distress) which include 58 items. It is self-administered and available in English and Spanish. Participants of the face validity study (75% women; age: 51.9 ±9.6 years; 42% breast cancer) provided feedback on the screener and took 10.5 ±4.8 min to complete it. Refinements were made, leading to the final version of the screener. The validation study was carried out in 103 participants: 64% women; age: 58.1±12.2 years; the most common cancer being: 39.8% breast, 28.1% colorectal, 15.5% lymphoma. A total of 30.9% are still receiving hormonal or immunological treatment and the other 69.1% received the last treatment 2.6±1.9 years ago. Participants took 13.3 ±5.3 min to complete the screener. Data cleaning and statistical analyses are currently ongoing.

CONCLUSIONS

Validation of the screener is necessary for its application in clinical practice, which will allow for the early detection of health and wellness issues in cancer survivors, who could benefit from extra support, thereby enhancing QoL.

EGG WHITE-DERIVED PEPTIDES REDUCED BLOOD GLUCOSE IN HIGH-FAT-DIET AND LOW-DOSE STREPTOZOTOCIN-INDUCED TYPE 2 DIABETIC MICE VIA REGULATING THE HEPATIC GLUCONEOGENIC SIGNALING AND METABOLIC PROFILE

Wang Liao[1]; Xinyi Cao,[1]
[1]School of Public Health, Southeast University, Nanjing, China

BACKGROUND AND OBJECTIVES

Food proteins are considered an ideal source for the identification of bioactive peptides with the potential to intervene in nutrition-related chronic diseases such as cardiovascular disease, obesity, and diabetes. Egg white-derived peptides (EWPs) have been shown to improve glucose tolerance in insulin-resistant rats. However, underlying mechanisms are to be elucidated.

METHODS

The young male mice were randomly divided into the normal-diet group and high-fat diet (HFD) group. The mice in the high-fat-diet (HFD) group were fed with 60% HFD, while the normal diet group mice were given a normal diet for 7 weeks. In the fifth week, the mice fed the high-fat diet were treated with 40 mg kg−1 streptozotocin (STZ) dissolved in 0.1 mol L−1 citrate buffer for a consecutive 5 days, while the normal-diet mice received the vehicle solution only. To confirm the induction of DM, 7 days after the last STZ injection, the fasting blood glucose (FBG) levels of the mice were measured using a glucometer and blood glucose test strips (ROCHE, Germany). After 3 weeks of the STZ injections, the mice with blood glucose level >11.1 mmol L−1 together with manifestations of polydipsia, polyuria, and polyphagia were considered diabetic. The diabetic mice were randomly subdivided into three groups: T2DM, T2DM + EWP-low-dose (EWP-L, 500 mg per kg body weight) and T2DM + EWP-high-dose (EWP-H, 1000 mg per kg body weight). Mice in the EWP-L group and EWP-H group were given 500 mg kg−1 or 1000 mg kg−1 peptides by gavage daily for 7 weeks, while mice in the control and T2DM groups were given the same volume of distilled saline. The body weight, fasting blood glucose (FBG), and random blood glucose (RBG) of the mice were recorded weekly. The tissues were collected at the end of the protocol for the downstream analyses.

RESULTS

The RESULTS showed that 7 weeks of EWP treatment reduced the fasting blood glucose in T2DM mice and the inhibition of the liver gluconeogenic pathway was involved in the mechanisms of actions. In addition, the EWP treatment also altered the hepatic metabolic profile in T2DM mice, in which, the role of fatty acid esters of hydroxy fatty acids in mediating the hypoglycemic effect of EWPs might be pivotal.

CONCLUSIONS

The chronic treatment of EWP exerts a hypoglycemic effect in HFD-fed and low-dose STZ-induced T2DM mice. Potential molecular mechanisms include the inhibition of gluconeogenic signaling and the regulation of metabolic dis orders through FAHFAs metabolism. The RESULTS of this study suggest that EWP is a potential candidate for T2DM intervention.

INVESTIGATING SYMPTOM VARIABILITY AND TREATMENT RESPONSE IN PERNICIOUS ANAEMIA: A LONGITUDINAL SYMPTOM TRACKING STUDY

Alfie Thain[1]; Kathryn Hart[1]; Petra Visser[2]; Kourosh Ahmadi[1]
[1]Faculty of Health and Medical Sciences, University of Surrey, Guildford, United Kingdom; [2]Chief Officer, The Pernicious Anaemia Society, Bridgend, UK, United Kingdom

BACKGROUND AND OBJECTIVES

Pernicious anaemia (PA) is characterised by vitamin B12 (B12) deficiency due to autoimmune-mediated loss of gastric parietal cells and intrinsic factor (1). The current treatment guidelines for PA recommend one intramuscular B12 injection every 2–3 months (2). However, many patients, report needing more frequent injections to ameliorate symptom recurrence or severity (3–5), suggesting a need for a precision medicine approach to PA management. This study aimed to track daily symptoms in PA patients to examine day-to-day symptom variation and response to different treatment modalities.

METHODS

UK-dwelling adults with PA were recruited to a longitudinal study from the PA society membership. Participants self-reported their daily symptoms and severity (scale of 1–10) and recorded any B12 treatments received over a three-month period via an online survey. Descriptive statistics and pre- and post-treatment comparisons were used to assess symptom variability and treatment response. A favourable Ethical Opinion was received from the University Ethics Committee (EGA ref: FHMS 22-23 030).

RESULTS

The survey was distributed to 381 people, of whom 83 enrolled, and 68 completed the study (female: 82%, mean age: 63 [SD 11]) years old, range: 27–85 years). Tiredness was the most prevalent symptom (97%, overall mean severity 6.34, [SD 1.97]), followed by muscle pain (85%, 5.85, [SD 2.06]) and poor concentration (82%, 5.62, [SD 1.77]). Treatment frequencies varied and were categorised into 2–3 monthly (44%), monthly (26%), weekly (15%), and more than weekly (15%). Symptom severity decreased post-treatment across all symptoms, with tiredness reducing by 28.1% (mean pre: 5.38 [SD 2.55, range 1–10] to post: 3.87 [SD 2.96, range 0–10], $p < 0.001$), muscle pain by 31.41% (4.42 [SD 2.42, range 0.67–10] to 3.03 [SD 2.47, range 0–9.67], $p < 0.001$), and poor concentration by 40.47% (3.55 [SD 2.30, range 0.67–9.67] to 2.11 [SD 2.22, range 0–9], $p < 0.001$). Some participants experienced immediate relief post-treatment, while others reported delayed improvement, with response times ranging from 1.6 to 5 days.

CONCLUSIONS

This study highlights the large degree of heterogeneity of symptom experiences and treatment responses in PA patients, emphasising the need for personalised management strategies. Daily symptom tracking captured individual patterns, and future research should explore wearable tools like smartwatches to enable real-time monitoring, provision of individualised care, and improved symptom management and quality of life for PA patients.

BACKGROUND AND OBJECTIVES

The SWEET Beverages trial was a multi-centre intervention across Spain, Denmark and UK examining the acute effects of three Sweeteners & Sweetness enhancers blends compared to sucrose on satiety, consumer preference, safety & health. We present here the RESULTS related to food intake behaviour after acute consumption of S&SE blends delivered in beverage format.

METHODS

Double-blind randomised crossover study with 60 healthy participants (47% female; mean±SD age 31±10 y; BMI 29±3 kg/m2). At each visit participants consumed 330 ml of a beverage containing either a blend of two S&SEs (0 kcal) or 8% sucrose (106 kcal), followed by a standardised breakfast served 7 min later (400-600 kcal). The blends were stevia RebM 80% purity with mogroside V 50% purity; stevia RebA 95% purity with thaumatin; and sucralose with acesulfame-K. Appetite and gastro-intestinal sensations were measured for three hours post intake, alongside food hedonics (20 min post-consumption), and food cravings (end of the day). Data were analysed with mixed effects linear regression. TRIAL REGISTRATION: ClinicalTrials.gov NCT04483180.

RESULTS

There was no impact of blend on any of the food preference/reward scores for fat or sugar biases (i.e. explicit liking; explicit wanting; implicit liking; choice frequency for high-fat relative to low-fat, and for sweet relative to savoury foods) (all $p>0.05$). In adjusted models, end of day craving control scores were lower after the sucralose-containing blend vs. any of the other blends and vs. sucrose (adjusted 0-100 pt mean score±SE: 55.8.1±3.5 vs. 65.1 to 66.2±3.5, respectively; $p<0.01$) while craving for sweet scores were higher vs. sucrose (40.6±3.4 vs. 33.5±3.4; $p<0.05$). Craving for savoury and positive mood did not differ by blend. Irrespective of blend, compared with older participants (46-60 y), younger ones (18-45 y) showed higher implicit wanting (14.9±4.9 vs. -14.9±11.9, $p<0.05$), and higher choice frequency for high-fat foods (5.1±1.7 vs. -4.8±4.2, $p<0.05$). BMI, sex, beverage liking or desire, and appetite did not modulate food behaviour responses.

CONCLUSIONS

Two novel stevia-containing blends plus a known sucralose-containing blend elicited comparable food hedonic responses in a sample of individuals with overweight and obesity, after acute consumption, but a sucralose/acesulfame K-containing blend showed reduced craving sensations vs. sucrose.

CHANGES IN SERUM 25(OH)D, ZONULIN, BODY MASS INDEX, AND DIETARY INTAKE LEVELS AFTER SUPPLEMENTATION OF PROBIOTICS AND VITAMIN D AMONG OVERWEIGHT AND OBESE HEALTHCARE WORKERS: A RANDOMIZED TRIAL DURING COVID-19 PANDEMIC

Rina Agustina[1]; Alfi R. Putri,[2]; Chaula P. Rizkia,[1]; Natasha D. Devana,[1]; Yani Kurniawan,[3]; Endang S. Rahayu,[4]; Wahyu I. Wardhani,[1]; Hario Baskoro,[5, 6]; Erfi Prafiantini,[1, 2]
[1]Department of Nutrition, Faculty of Medicine, Universitas Indonesia – Dr. Cipto Mangunkusumo General Hospital, Jakarta, Indonesia; [2]Human Nutrition Research Center, Indonesian Medical Education and Research Institute (IMERI), Faculty of Medicine, Universitas Indonesia, Jakarta, Indonesia; [3]Departement of Biochemistry, Faculty of Medicine, Universitas Indonesia, Jakarta, Indonesia; [4]Food and Agricultural Product Technology, Universitas Gadjah Mada, Yogyakarta, Indonesia; [5]Universitas Indonesia Hospital, Universitas Indonesia Hospital, Depok, Indonesia; [6]COVID-19 Emergency Hospital, Jakarta, Jakarta, Indonesia

BACKGROUND AND OBJECTIVES

Overweight or obese frontline healthcare workers (HCWs) face an increased risk of COVID-19 infection due to vulnerabilities linked to their nutritional status and eating habits. We examined the changes in serum 25(OH)D levels, zonulin (a marker of gut integrity), body mass index (BMI), body weight (BW), waist circumference (WC), and dietary intake after a 3-month supplementation with combined probiotics and vitamin D among healthcare workers during the COVID-19 pandemic.

METHODS

We conducted a 12-week randomized controlled trial with 81 healthcare workers (HCWs) who frequently interacted with COVID-19 patients at three Jakarta and West Java referral hospitals. Participants were assigned to receive daily supplementation of either probiotic *Lactobacillus plantarum* Dad-13 combined with 1000 IU of vitamin D (ProD; n=39) or a placebo (n=42) and counselling on healthy diets and lifestyles. We employed analysis of covariance to compare changes in serum 25(OH)D and zonulin levels as the primary outcomes during the intervention. Additionally, we examined changes in dietary intake and anthropometric measurements at baseline, one month, two months, and three months as secondary outcomes. This analysis was adjusted for specific covariates between the groups.

RESULTS

Eighty-one HCWs participated in a three-month intervention, with 39 assigned to the ProD group and 42 to the placebo group. The baseline characteristics, including age, BW, BMI, WC, IgG antibody response, working hours, demographic factors, and the history of COVID-19 vaccinations and infections, were similar across both groups. After adjusting for age, gender, health care, work duration, multivitamins consumption, COVID history, and BW, serum 25(OH)D levels increased significantly in the ProD group compared to the placebo group (MD of 5.8 ng/mL (95% CI: 3.3 to 8.3; p=0.000). Additionally, the ProD group (n=37) exhibited a greater decrease in zonulin levels than the placebo group (n=36) (MD of -5.5 ng/mL (95% CI: -11.5 to 0.4; p=0.067). These mean anthropometric assessment and dietary intake changes were not statistically significant between groups.

CONCLUSIONS

Combined probiotics and Vitamin D supplementation improve 25(OH)D levels and intestinal integrity, potentially reducing COVID-19 infection risk in overweight and obese healthcare workers, but no effect on dietary intake and anthropometric indicators.

FUSARIUM VENENATUM DERIVED B-GLUCANS ENHANCE INTESTINAL BARRIER INTEGRITY BY MODULATING TIGHT JUNCTION PROTEINS, IMMUNE RECEPTOR ACTIVATION, AND TRANS-EPITHELIAL RESISTANCE

Mohammed Salama[1]; Daniel Commane,[1]; Hannah Walden,[1]; Louise Durrant[2]
[1]Health and Life Sciences, Northumbria University, Newcastle, United Kingdom; [2]Nutrition Comms Manager, Quorn Foods, Stokesley, United Kingdom

BACKGROUND AND OBJECTIVES

A dysfunctional gut barrier is associated with inflammation and susceptibility to infection. Dietary 1-3,1-6 β-glucans may optimise innate immune surveillance and attenuate inflammatory status (Del Cornò et al., 2020) through interaction with Dectin-1 and other molecular pattern receptors (Herre et al., 2004). Additionally, they may enhance epithelial barrier function by modulating the expression and assembly of tight junction proteins, contributing to overall gut health (Qiao et al., 2022). We aim to determine whether 1-3,1-6 β-glucans derived from *F. venenatum* promote a healthy intestinal barrier.

METHODS

1-3, 1-6 glucans were isolated from several sources including mycoprotein, a food derived from the filamentous fungus *Fusarium venenatum*. Isolated glucans were applied to cultured intestinal epithelial cells, outcomes included cell viability; expression, localisation and functionality of tight junction proteins via q-PCR, immunofluorescence and transepithelial electrical resistance (TEER) respectively. Immune cells were studied for the induction of glucan receptors and downstream inflammatory pathways

RESULTS

The expression of tight junction protein 3 and Claudin 1 were elevated by 1-3,1-6 β-glucans. Increased tight junction integrity was observed in the TEER assay dependent on glucan source. Glucans were dose dependently associated with Dectin-1 induction in immune cells, further studies will determine whether improved tight junction integrity was linked to dectin-1 activation.

CONCLUSIONS

F. venenatum derived myco-glucans improve intestinal barrier integrity *in vitro*, suggesting postbiotic benefit. I*n vivo* studies are needed to confirm whether dietary fungi are effective at improving barrier function in consumers

INCREASING THE PROPORTION OF SLOWLY DIGESTIBLE STARCH IN THE DAILY DIET IMPROVES GLYCEMIC VARIABILITY AND CONTROL IN TYPE 2 DIABETIC PATIENTS

Maeliss Chisbert[1, 2]; Anne-Laure Castell[1, 3]; Laurie Van Den Berghe[1]; Nathalie Feugier[1]; Charlotte Cuerq[2, 4]; Olivier Brack[5]; Martine Laville[3]; Alexandra Meynier[6]; Sophie Vinoy[7]; Julie-Anne Nazare[1, 2]
[1]Centre de Recherche en Nutrition Humaine Rhône-Alpes, CarMeN Laboratory, Oullins-Pierre-Bénite, France; [2]CarMeN Laboratory, Universite Claude Bernard Lyon1,INSERM, INRAE, Oullins-Pierre-Bénite, France; [3]Endocrinology Department, Diabetes and Nutrition, Hospices Civils de Lyon - HCL, Chemin du Grand Revoyet, Oullins-Pierre-Bénite, France; [4]Biochemistry Department, Hospices Civils de Lyon - HCL, Chemin du Grand Revoyet, Oullins-Pierre-Bénite, France; [5]Société K.S.I.C, (Statistique Industrielle-Kh2 Consulting), Esches, France; [6]Nutrition Research, Mondelez France R&D, Saclay, France; [7]Nutrition Research, Mondelez R&D, Paris Saclay Tech Centre, Saclay, France

BACKGROUND AND OBJECTIVES

Diet plays a crucial role in managing Type 2 Diabetes (T2D), with starchy foods being the main carbohydrate source. The degree and speed of starch digestibility are influenced by several factors and may be characterized into 3 types: Rapidly Digestible Starch (RDS), Resistant Starch (RS), and Slowly Digestible Starch (SDS) the latter modulating glycemic peaks. Increasing the SDS content in the diet seems to be a relevant strategy to manage postprandial hyperglycemia in T2D. Glycemic variability (GV) has arisen as a component of T2D dysglycemia, which was associated to cardiovascular complications. This study investigates the impact of increasing SDS in the daily diet on GV, glycemic control, and the cardiometabolic profile of T2D patients.

METHODS

In a 12-week randomized, controlled and parallel trial, 51 T2D patients followed either a high-SDS (H-SDS) or low-SDS (L-SDS) diet, guided by specific dietary and culinary advice, and supply of commercial starchy products, selected for their SDS content. GV parameters were assessed using Continuous Glucose Monitoring System (CGMS) with the Mean Amplitude of Glucose Excursions (MAGE) as the primary outcome. Biological glycemic control and cardiometabolic parameters were also measured.

RESULTS

Compared to L-SDS diet (17.2 ± 1.0g SDS/day), H-SDS diet (63 ± 1.0g SDS/day) significantly reduced the intraday GV after 3 months: MAGE (-11.5% vs +9.4%, $p=0.0005$), SD (Standard Deviation ($p=0.0021$), CV (Coefficient of Variation) ($p=0.0056$), CONGAs (Continuous Overall Net Glucose Action) ($p<0.001$) and MIME (Meal Indices of Meal Excursions) Glycemic Delta ($p=0.0013$). Also, lower interday GV, represented by IQR50 ($p=0.0007$) and MODD (Mean of Daily Differences, $p=0.0515$) and risk of hyperglycemia (HBGI, $p=0.0863$; ADRR, $p=0.0506$) were obtained with the H-SDS diet. HbA1c and C-peptide levels significantly decreased ($p<0.05$). Fasting glucose, insulin, glucagon, HOMA-IR and cardiometabolic parameters remained unchanged.

CONCLUSIONS

Increasing the SDS content in daily diet with simple culinary and dietary advice on starchy products choices and cooking significantly improved GV and glycemic control in T2D, to achieve HbA1c targets (<7%). Modulating starch digestibility appears as a relevant nutritional strategy to improve glycemic management in T2D.

PERSONALIZED DIETARY FIBRE MIXTURES BASED ON IN VITRO MICROBIAL SCFA PRODUCTION REDUCE INSULIN RESISTANCE (HOMA-IR) IN INDIVIDUALS WITH PREDIABETES AND OVERWEIGHT/OBESITY

Gillian Larik[1]; Nouhaila Hamari,[1]; Monica Maurer Sost[2]; Colin Van Kalkeren[1]; Jens Holst,[3]; Ellen Blaak[1]; Emanuel Canfora[1]
[1]Department of Human Biology, Maastricht University, Maastricht, Netherlands; [2]Centre for healthy eating and food innovation, Maastricht university, maastricht, Netherlands; [3]Novo Nordisk Foundation Center for Basic Metabolic Research and Department of Biomedical Science, University of, Copenhag, Denmark

BACKGROUND AND OBJECTIVES

The gut microbiota ferments dietary fibres into short-chain fatty acids (SCFAs), which can improve the host metabolism. However, long-term supplementation of isolated single dietary fibres showed no consistent metabolic benefits, emphasizing the role of individual differences in the microbial fermentation capacity. Post-hoc analyses suggest that microbial SCFA producing taxa may predict response to dietary fibre intervention, but prospective evidence is largely lacking. This study aimed to investigate the effects of a personalized fibre mixtures (PFM), designed to enhance gut microbial SCFA production, on insulin sensitivity.

METHODS

This randomized, placebo-controlled, double-blind parallel study included 44 individuals with overweight/obesity (body mass index (BMI) 28–40 kg/m², age 35–70 y) with prediabetes and/or insulin resistance. Anaerobic fecal samples were collected from each individual to screen for a fibre mixture that produces the highest amount of SCFAs using an *in vitro* colon model. Participants were randomized into two groups: 22 subjects received 24g of the *in vitro* defined PFM, and 22 received a single fibre control (galacto-oligosaccharides) for 12 weeks. Insulin sensitivity, the primary outcome determined by hyperinsulinemic-euglycemic clamp, was assessed alongside indirect calorimetry, body composition, and analyses of blood hormones, metabolites and inflammation markers. Additionally, microbial metabolites in faeces and blood were measured before and after the intervention.

RESULTS

No differences in the change in peripheral insulin sensitivity (M-value) was observed between groups. However, PFM decreased fasting insulin (Δ -0.98 ± 2.48 vs 0.90 ± 2.96 u*U*/mL, P=0.037), HOMA-IR (Δ -0.27 ± 0.65 vs Δ 0.22 ± 0.76, P=0.036), body weight (Δ -0.28 ± 2.3 vs Δ 1.37 ± 1.5 kg, P=0.014), and BMI (P=0.017) with a trend toward reduced body fat mass (P=0.073) compared to control. The PFM increased both plasma and faecal branched-chain fatty acid isovalerate (P<0.05) and showed a trend toward increased isobutyrate levels (P<0.1) compared to control. No differences were observed in energy expenditure, substrate oxidation, blood lipids, inflammatory markers, gut-derived hormones, or plasma and faecal SCFAs levels between the groups.

CONCLUSIONS

Compared to the control, PFM supplementation did not affect peripheral insulin sensitivity but slightly decreased body weight and reduced HOMA-IR (marker of insulin resistance), suggesting a benefit for hepatic insulin sensitivity. Personalized fibre approaches may help improve metabolic health in individuals at high risk for type 2 diabetes.

GUT MICROBIAL CLUSTERS IN CHILDREN SHOW DIFFERENT CARDIOMETABOLIC RESPONSES TO WHOLEGRAINS – A POST-HOC ANALYSIS OF THE KORN RANDOMIZED TRIAL

Marie B. M. Madsen[1]; Lars H. Christensen[1]; Dennis S. Nielsen[2]; Yichang Zhang[2]; Henrik M. Roager[1]; Lotte Lauritzen[1]; Rikard Landberg[3]; Camilla T. Damsgaard[1]
[1]Department of Nutrition, Exercise and Sports, University of Copenhagen, Frederiksberg Campus, Frederiksberg, Denmark; [2]Department of Food Science, University of Copenhagen, Frederiksberg Campus, Frederiksberg, Denmark; [3]Department of Life Sciences, Food and Nutrition Science, Chalmers University of Technology, Gothenburg, Sweden

BACKGROUND AND OBJECTIVES

The beneficial effects of wholegrain intake on cardiometabolic risk may be mediated by the gut microbiota. In adults, there are indications that cardiometabolic responses to diet, including wholegrains, depend on the gut microbiome ecosystem structure. However, this has not been investigated in children. We aimed to identify gut microbial clusters among Danish children and explore their role in the cardiometabolic response to high wholegrain intake.

METHODS

We used data from a randomized cross-over study involving 51 Danish children aged 8-13 years with high BMI, who received *ad libitum* breads, pasta and cereal products with wholegrain oats and wholegrain rye (WG) and refined grain (RG) for 8 weeks in random order. Anthropometry, body composition, blood pressure, blood lipids and markers of glucose metabolism and inflammation as well as short-chain fatty acids in blood and feces were assessed at 0, 8 and 16 weeks. Fecal microbiota composition was determined by 16S rRNA gene amplicon sequencing and microbial clusters were identified by partitioning around medoid clustering. We used linear mixed models to investigate potential modifying effects of baseline microbial cluster on the cardiometabolic effects of WG *vs* RG.

RESULTS

Children consumed 108±38 and 3±2 g/d wholegrain in the WG and RG period, respectively (P<0.001) (Madsen et al. 2024). We identified two clusters dominated by Faecalibacterium, Bacteroides, Ruminococcus and Lachnospiracae (Cluster 1, n=25), and Bifidobacterium and Clostridium and lower α-diversity (Cluster 2, n=26), respectively. Cluster modified the effect of WG on the children's BMI z-score, fat mass index, and waist circumference (all, P-interaction≤0.002), which were reduced among children in Cluster 1 and increased in Cluster 2. Cluster also modified the effect of the intervention on plasma HDL cholesterol (P-interaction=0.03), which was increased by 0.09 (0.03, 0.15) mmol/L with WG vs. RG in Cluster 2 only.

CONCLUSIONS

Two distinct gut microbial clusters were identified which appeared to influence the effectiveness of wholegrain intake in reducing children's fat mass and increasing HDL cholesterol. We speculate that Cluster 2 reflects a less mature gut microbiota, but this needs further investigation.

MACHINE LEARNING-IDENTIFIED HABITUAL DIETARY PATTERNS ARE ASSOCIATED WITH HOST METABOLISM THROUGH GUT MICROBIOTA MEDIATION

Heyjun Park[1, 2]; Xiaotao Shen[2]; Dalia Parelman[2]; Pranav Berry[2]; Rachel Battersby[2]; Alessandra Celli[2]; Caroline Bejikian[2]; Michael Snyder[2]
[1]International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, United States of America; [2]Genetics, Stanford University, Stanford, United States of America

BACKGROUND AND OBJECTIVES

Diet influences the gut microbiome and host metabolism, yet the underlying mechanisms remain unclear. Using multi-omics tools combined with an autoencoder machine learning approach, this study aimed to identify latent dietary patterns and their associations with plasma metabolites, gut microbiota, and potential causal pathways.

METHODS

We analyzed plasma (n=139) and stool (n=109) samples along with food records surveys (n=151) from 71 healthy adults (mean 53.4y). Participant data were longitudinally collected for approximately one year (averaging 335d). Latent dietary patterns were identified using nutrient and food group data with an autoencoder approach (deep learning neural network architecture). Plasma metabolomics and gut microbiome profiling were performed using untargeted liquid chromatography-mass spectrometry and 16S rRNA sequencing, respectively.

RESULTS

Two distinct dietary patterns were identified: DP0, a “meat-dominant” pattern with high meat and poultry intake, and DP1, a “balanced meal” pattern emphasizing mixed meals of protein and vegetables (e.g., sandwiches and wraps). Compared to DP0, DP1 was associated (*P*BH<0.25) with different levels of 35 metabolites, after adjusting for age and sex. Additionally, DP1 was linked to higher abundances of 6 gut microbial taxa relative to DP0, including *Parabacteroides* (coefficient=0.32, *P*BH=0.09) and *Butyricimonas* (coefficient=0.28, *P*BH=0.13). Mediation analysis revealed 9 significant mediation effects (*P*medi<0.05), indicating that 5 out of these 6 microbial taxa mediated the relationship from dietary patterns to the metabolites across 5 metabolic pathways: benzoate, food component/plant, leucine, isoleucine, and valine, monoacylglycerol, and androgenic steroids metabolism. For instance, *Butyricimonas* mediated the relationship between DP1 and cinnamoylglycine (βmedi=0.14) as well as DP1 and 3-phenylpropionate levels (βmedi=0.14).

CONCLUSIONS

Overall, habitual balanced dietary patterns were associated with significant differences in gut microbiome and metabolome profiles compared to meat-dominant patterns. These findings also highlight the potential mediating role of the microbiome in dietary influences on host metabolism.

IN SILICO GUT MICROBIOME METABOLIC MODELING IDENTIFIES METABOLITES THAT ARE ASSOCIATED WITH METABOLIC HEALTH AND ARE MODIFIABLE BY DIETARY INTERVENTIONS

Timothy Swartz[1]; Gianluca Galazzo[1]; Rafael Patiño-Navarrete[2]; Nouredine Farah[1]; Metacardis Consortium[3]; Karine Clément[2]
[1]Research and Development, Integrative Phenomics, Paris, France; [2]Nutrition and Obesities: Systemic Approaches, NutriOmics, Research Unit, Sorbonne Université, INSERM, Paris, France; [3]7th Framework Program, European Union, Brussels, Belgium

BACKGROUND AND OBJECTIVES

Obesity and diabetes are associated with alterations in the human gut microbiome composition and function, which in turn influence how the gut microbiome interacts with dietary factors and host tissues. *in silico* gut microbiome metabolic modeling provides a method to elucidate diet-microbiome community functional and mechanistic relationships underlying the production of metabolites that influence both gut barrier and host health. In two large-scale national and European cohorts, we evaluated 1) the ability of *in silico* human gut microbiome community metabolic modeling to delineate human metabolic health phenotypes , 2) the validity of identified *in silico* signatures using metabolomics, and 3) the effect of dietary interventions to drive predicted metabolites toward signatures reflective of improved metabolic health.

METHODS

In the EU MetaCardis Cohort (n = 2000 subjects) and the French GutInside weight loss cohort (n= 1855 subjects), we used shotgun stool metagenomics data to perform compartmentalized constraint-based *in silico* gut microbiome community metabolic modeling. Predicted metabolites were then analyzed in relation to obesity and metabolic health. Cardiometabolic diseases and heterogeneous obesity phenotypes were defined clinically, and metabolic health was defined with a data-driven score. *In silico* predicted metabolites were evaluated for their association with serum metabolomics. Finally, we used dietary interventions to determine if diet significantly modifies predicted metabolites.

RESULTS

The modeling approach identified 62 predicted metabolites associated with obesity-related phenotypes independently of usual dietary habits. A total of 19 identified metabolites were common across Class I to Class III obesity. A further 14 predicted metabolites were associated with the metabolic health score. A sub-population of predicted metabolites were significantly correlated with serum metabolomics, which included metabolites related to human metabolic health. Using dietary pattern interventions and nutrient compositions, we found diet shifted predicted metabolites in both diet- and individual-dependent manners.

CONCLUSIONS

in silico gut microbiome metabolic models provide clinically relevant predicted metabolite signatures stratifying host obesity- and metabolic health and identify functional interactions that reflect human health. Collectively, this work paves the way for the use of this modeling approach in precision or personalized nutrition interventions for human metabolic health.

OAP57_06

THE INTERACTION OF SEX AND THE CHEESE MATRIX ON THE CHOLESTEROL RESPONSE TO DAIRY FAT IN MIDDLE-AGED ADULTS

Martina Rooney[1]; Eileen Gibney[2]; Emma Feeney[2]
[1]Co-Centre for Sustainable Food Systems, University College Dublin, Dublin, Ireland; [2]Institute for Food and Health, University College Dublin, Dublin, Ireland

BACKGROUND AND OBJECTIVES

Despite being a source of saturated fat, cheese has been shown to lower total and LDL cholesterol concentrations compared to butter (1,2). The dairy matrix is thought to be responsible for this effect. While diet can influence disease rise in a sex-specific manner (3), the interaction between sex and the cheese matrix in the cholesterol response to dairy fat is largely unexplored, which this study aims to investigate.

METHODS

The present work is secondary analysis of pooled data from two parallel-arm randomised controlled trials with similar protocols (4,5). Participants (*n* 197, 41.6% male) received either 120g, full-fat cheddar cheese (*n* 104) or deconstructed cheese (49g butter, 30g calcium caseinate and a calcium supplement, *n* 93) for 6-weeks. Each arm provided ~40g dairy fat per day.

RESULTS

In the group as a whole, full-fat cheese was shown to lower total and LDL cholesterol compared to deconstructed cheese (-0.21 ± 0.69 mmol/L vs 0.01 ± 0.68 mmol/L, P=0.002). No sex x treatment interactions were observed, although within-sex analysis found males and females to respond differently. Within males, cholesterol concentrations decreased in response to cheese (-0.23 ± 0.57 mmol/L) and butter (-0.11 ± 0.61, P=0.189). Within the female group, full-fat cheese lowered total (-0.19 ± 0.77 mmol/L) and LDL cholesterol (-0.19 ± 0.61 mmol/L) concentrations, whereas deonstructed cheese was found to increase the same lipid markers (0.10 ± 0.73 mmol/L, P=0.004; 0.03 ± 0.58 mmol/L, P=0.001) No sex x treatment interactions were observed for LDL (P=0.619) or HDL (P=0.678) particle size, or for large (P=0.146) or small (P=0.658) LDL particle concentrations.

CONCLUSIONS

Full-fat cheese was found to lower cholesterol concentrations in the cohort as a whole, while males and females were found to respond differently to dairy fat. Females appear to respond more favourably to full-fat cheese comapred to deconstructed cheese, indicating that the cheeese matrix may have a stronger role in females, which may play a role in personalised nutrition.

ASSOCIATION BETWEEN DIETARY LIVE MICROBES AND FATIGUE MEDIATED BY FOLATE: FINDINGS FROM A CROSS-SECTIONAL STUDY OF THE U.S. NATIONAL SURVEY IN OLDER ADULTS

Galya Bigman[1]; Amber S. Kleckner[2]; Elizabeth A Dennis[3]; Alice S. Ryan[4]; John D Sorkin[5]
[1]Epidemiology, University of Maryland, Baltimore, Baltimore, United States of America; [2]Department of Pain and Translational Symptom Science, University of Maryland, Baltimore, Baltimore, United States of America; [3]Physical Therapy and Rehabilitation Science, University of Maryland, Baltimore, Baltimore, United States of America; [4]Department of Medicine, University of Maryland, Baltimore, Baltimore, United States of America; [5]Department of Epidemiology and Public Health, University of Maryland, Baltimore, Baltimore, United States of America

BACKGROUND AND OBJECTIVES

Fatigue is a debilitating condition in older adults and can reduce independence. A deficiency in folate, a vital nutrient for energy metabolism, is strongly linked to more severe fatigue [3]. The gut microbiome plays a vital role in folate metabolism, with microbes such as Lactobacillus converting dietary precursors into tetrahydrofolate, a bioactive form of folate [4,5]. Thus, the consumption of live microbes, found in fermented foods and fresh produce, may help alleviate fatigue by improving folate bioavailability and metabolism via the gut [2]. This study examines the association between dietary live microbe intake and fatigue, emphasizing folate as a mediator, and provides insights into microbiota-targeted nutritional strategies to mitigate fatigue.

METHODS

We analyzed data from 2,353 older U.S. adults (≥60 years) in NHANES (2021–2023) [6]. Fatigue, assessed via a single-item question from the PHQ-9 “Feeling tired or having little energy” divided as Low ("Not at all/Several days") or Moderate-Severe ("More than half of days/Nearly every day"). Red blood cell folate, measured through standardized assays, served as a biomarker of long-term folate status. Dietary data from 24-hour recalls classified live microbe intake across 9,388 food codes into Low ($<10^4$ CFU/g), Medium (10^4–10^7 CFU/g), or High ($>10^7$ CFU/g) [7]. Covariates included demographics, comorbidities, and energy intake. Multivariable weighted logistic and multinomial logistic regression models decomposed the effects of live microbe on fatigue, mediated through folate, while accounting for complex survey design.

RESULTS

The mean age was 69.4 years (SD = 6.3), with 46.1% male. Live microbe intake was low (28.3%), medium (45.5%), or high (26.5%), and 15.4% reported moderate-severe fatigue. Multivariable analysis indicated that higher live microbe intake was associated with reduced odds of fatigue (ORHvs.L=0.52, 95% CI: 0.34–0.79, p=0.005), as was a higher level of folate (ORHvs.L=0.60, 95% CI: 0.40–0.92, p = 0.021). Higher live microbe intake was associated with increased odds of elevated folate levels (ORHvs.L=1.40, 95% CI: 1.09–1.80, p = 0.012). Mediation analysis showed that folate partially mediated this relationship, accounting for 26% of the effect.

CONCLUSIONS

A diet rich in live microbes may help alleviate fatigue, partly by enhancing folate levels. However, the cross-sectional design of this study limits causal interpretations, underscoring the need for longitudinal studies or intervention trials.

NOVEL POPULATION-SPECIFIC GENETIC VARIANTS ASSOCIATED WITH VITAMIN B12 BIOAVAILABILITY IN HEALTHY INDIANS

Ambily Sivadas[1]; Sarita Devi[2]; Roshni Pasanna[2]; Ujjaini Dutta[2]; Harshpal Singh Sachdev[3]; Anura Kurpad[4]
[1]Division of Molecular Biology and Genetics, St. John's Medical College Hospital, Bengaluru, India; [2]Division of Nutrition, St. John's Research Institute, Bengaluru, India; [3]Pediatrics, Sitaram Bhartia Institute of Science and Research, New Delhi, India; [4]Physiology, St. John's Medical College, Bengaluru, India

BACKGROUND AND OBJECTIVES

Vitamin B12 deficiency is a prevalent health concern that can lead to hematological and neurological disorders. Despite adequate dietary intake, inter-individual variability in B12 absorption and metabolism, influenced by genetic and environmental factors, can result in insufficiency/deficiency. While previous studies have explored the genetic basis of circulating vitamin B12 levels, they have not validated these findings using precise measurements of B12 bioavailability. This study aimed to measure the plasma bioavailability of an oral dose of [13C]-labelled B12 (cyanocobalamin) in a cohort of 104 healthy Indian individuals using pharmacokinetic modelling and examine its associations with genetic variants in key genes involved in B12-related pathways.

METHODS

Oral B12 bioavailability was measured over 10 h after administration of [13C]-cyanocobalamin tracer (~2.5 μg) in healthy participants (n=104) aged 18-40 years with BMI < 25 kg/m². The plasma B12 bioavailability was estimated from the kinetics of the tracer appearance in plasma using a 2-compartment model. Functional B12 markers including plasma total B12 and active B12 (HoloTC) were measured. Genotyping was conducted using Illumina GSA array, with quality control and imputation performed to yield SNPs for association analysis with B12-related traits. Polygenic risk score (PRS) was calculated, with cross-validation and positive predictive value (PPV) was used to evaluate predictive performance for supplementation needs.

RESULTS

The mean measured B12 bioavailability was 52% ± 16%, demonstrating significant 4.4-fold variability. A total of 54 SNPs in or near 10 genes were significantly associated with plasma total B12 bioavailability, including 5 previously reported SNPs for B12-related traits and 49 novel variants from known B12 pathway genes. PRS was computed, explaining more than 70% of the variance in B12 bioavailability in the same cohort, and 43% in a 3-fold cross validation test. At the 1st quartile threshold, the PRS identified individuals requiring supplementation with a PPV of 0.40.

CONCLUSIONS

These findings provide insights into the genetic determinants of vitamin B12 absorption and homeostasis, emphasizing the potential of genetic markers for personalized nutritional strategies. This is particularly critical for identifying populations who are susceptible to B12 deficiency despite adequate dietary intake, highlighting the need for precision nutrition using precise functional measurements of B12 bioavailability in specific populations.

ASSOCIATION BETWEEN COMPOSITE DIETARY ANTIOXIDANT INDEX AND RISK OF HEPATIC STEATOSIS AND FIBROSIS AMONG CHOLECYSTECTOMY ADULTS: EVIDENCE FROM NHANES 2017-2020

Shuyao Hua[1]; Zhong Wen[2]; Ge Sheng[1]
[1]Clinical nutrition, Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China; [2]General Surgery, Tongren Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China

BACKGROUND AND OBJECTIVES

Cholecystectomy increases the incidence of metabolic associated fatty liver disease and fibrosis. Antioxidants protect the liver from oxidative stress and inhibit the development of metabolic dysfunction-associated steatotic liver disease (MASLD), yet the epidemiological evidence that links dietary antioxidants to hepatic steatosis and fibrosis in patients who underwent cholecystectomy is not available. Therefore, the present study aimed to investigate the association of dietary composite dietary antioxidant index (CDAI) with the risk of hepatic steatosis and fibrosis in the cholecystectomy population.

METHODS

Data of 773 participants from the National Health and Nutrition Examination Survey (NHANES) 2017-2020 were analyzed. Intake of dietary antioxidants were collected to calculate CDAI. The controlled attenuation parameter (CAP) and liver stiffness measurement (LSM) assessed by the vibration controlled transient elastography (VCTE) were used to identify hepatic steatosis and hepatic fibrosis, respectively. Weighted multivariate logistic regression and restricted cubic spline (RCS) regression were conducted to analyze the association.

RESULTS

Weighted multivariate logistic regression analysis with full adjustment for confounding variables showed a negative association between CDAI and hepatic fibrosis in individuals underwent cholecystectomy [OR (95%CI) = 0.87 (0.79, 0.94), *P*=0.010], while non-significant association was found between CDAI and MASLD. Moreover, compared to the lowest quartile, the highest quartile of CDAI was associated with a lower risk of hepatic fibrosis [OR (95%CI) = 0.28 (0.13, 0.60), *P*=0.007]. The RCS analysis further indicated a linear negative relationship between intake of CDAI and the risk of hepatic fibrosis (*P* overall<0.001).

CONCLUSIONS

Our findings suggest that higher dietary antioxidants intake may be associated with lower risk of hepatic fibrosis among individuals underwent cholecystectomy, whereas there was no evident association between CDAI intake and the risk of hepatic steatosis. Further studies are needed to validate current findings and explore the underlying mechanisms.

ENRICHMENT OF THE DIET OF BLACK SOLDIER FLY (HERMETIA ILLUCENS) LARVAE WITH ERGOSTEROL FOLLOWED BY UV-B EXPOSURE PRODUCES LARVAE VERY RICH IN VITAMIN D

Lisa Morand-Laffargue[1]; Florence Charles[2]; Damien Sabatier[3]; Patrick Borel[1]
[1]Center for CardioVascular and Nutrition research, Aix-Marseille Université: Faculté de Médecine, Marseille, France; [2]SQPOV, Inra, Avignon, France; [3]Biomimetic R&D, Biomimetic, Boulbon, France

BACKGROUND AND OBJECTIVES

Vitamin D (VD) is essential for humans and many animals. It comes either from food or from skin synthesis under the action of UV-B rays. Two molecules have almost equivalent VD activity. VD3, or cholecalciferol, is the form synthesized by humans and animals in the skin under the action of UV-B rays. Its precursor is 7-dehydrocholesterol. VD2, or ergocalciferol, is synthesized by UV-B exposure of ergosterol, a molecule found mainly in mushrooms. Edible insects, and more particularly the black soldier fly, which are known to be interesting sources of proteins, are not particularly rich in this vitamin. We have nevertheless shown that they can bioaccumulate high concentrations of carotenoids and vitamin E (1-3). It is in this context that we aimed to investigate whether black soldier fly larvae (BSFL) can bioaccumulate high concentrations of ergosterol and whether this ergosterol can be converted into VD2 by exposing the larvae to UV-B light.

METHODS

BSFL were reared on mushrooms for 2 wks and then exposed, before killing them, to UV-B light (2.7 mW/cm2/s for up to 5h). Following this experiment, ergosterol and VD (VD2 and VD3) were quantified by HPLC in the larvae.

RESULTS

These analyses allowed the following observations to be made: larvae non-exposed to UV-B did not contain any detectable amount of VD2 or VD3. Larvae reared on mushrooms and not exposed to UV-B contained a high concentration of ergosterol (702 ± 95 mg/Kg FW) and did not contain any detectable amount of VD2 or VD3. Larvae reared on mushrooms and then exposed to UV-B for 1h contained high concentrations of VD2 and VD3 (46 ± 2 and 10.9 ± 0.5 mg/Kg FW, respectively).

CONCLUSIONS

We concluded that 1) BSFL do not naturally contain VD2 or VD3, or their content are below the detection limits of our method of analysis. 2) BSFL bioaccumulate ergosterol when reared on a substrate rich in this compound. 3) Exposure of BSFL to UV-B allows the conversion of ergosterol present in these larvae into VD2 and the production of VD3, likely from 7-dehydrocholesterol naturally present in the larvae as in other animals. Note that the concentration of VD2 + VD3 in the larvae was about 23 times higher than that reported for the richest natural source of VD, i.e. cod liver oil. Thus, the concentration of VD found in the larvae classify them as a food, intended for animal feed, rich in VD. This procedure has been patented (PCT/EP2024/074854).

MICROALGAE AS MORE SUSTAINABLE AND AFFORDABLE MICRONUTRIENT-RICH SOURCES FOR HUMAN NUTRITION AND HEALTH

Fengzheng Gao[1]; Michael Zimmermann[2]; Ferdinand Von Meyenn[1]; Alexander Mathys[1]
[1]Department of Health Sciences and Technology, ETH Zürich, Zürich, Switzerland; [2]Weatherall Institute of Molecular Medicine, John Radcliffe Hospital, The University of Oxford, Oxford, United Kingdom

BACKGROUND AND OBJECTIVES

Micronutrient deficiencies remain common global nutritional problems. Iron-deficiency anaemia (IDA) is the most common global nutritional deficiency, affecting >1 billion people. Dietary intervention is the best strategy to overcome IDA. Animal-based foods with high amounts of highly bioavailable iron are expensive and poorly consumed by vegetarians/vegans. Iron absorption from conventional plant-based food is low due to overall low (bioavailable) iron and commonly present iron-uptake inhibitors. Novel food formulations or sources with high contents of bioavailable iron are urgently needed to prevent IDA and its adverse consequences. Microalgae are small unicellular microorganisms that could contain high amount of minerals but are poorly studied in micronutrient deficiencies treatment.

METHODS

At ETH Zurich, we are building a joint strategic research line in Microalgae in Human Nutrition and Health with two laboratories to investigate the bioaccessibility, bioavailability, and bioactivity of minerals from different microalgae using *in vitro*, *ex vivo*, and *in vivo* methodologies. Different processing techniques are applied to increase iron bioaccessibility. Absorption trials in humans will be designed and performed based on the RESULTS from the above experiments.

RESULTS

Microalgae are rich in minerals such as iron, zinc, and calcium. For instance, microalgae could contain hundred times more iron (~2000 ppm) compared to beef, a commonly accepted iron-rich food. In addition, microalgae are rich in ascorbic acid, which is an important iron absorption enhancer. The bioaccessibility of microalgae iron could reach 83% based on *in vitro* assessment. Microalgae-derived iron can be absorbed well in human cell and animal models. Iron from the microalga *Spirulina* could have a higher bioavailability compared to ferrous sulfate.

CONCLUSIONS

Microalgae are promising in IDA treatment as more sustainable and affordable sources. The outcome of this research will provide insight on using microalgae as mineral supplements or protein-rich novel foods with highly bioavailable iron to control anaemia.

ANALYSIS OF NUCLEOTIDE CONCENTRATION TRAJECTORIES OVER LACTATION IN HUMAN MILK AND INFLUENCING FACTORS

Haitao Yu,[1]; Song Ni,[1]; Motong Liu,[1]; Yan Han,[1]; Xinhong Jiang,[1]; Hua Pan,[1]; Shuping Ren[1]; Li Guo,[1]; Lin Ye,[1]; Xiaomei Liu,[1]; Wenhui Xu,[1]; Lin Xie,[1]
[1]Department of Nutrition and Food Science, Jilin University, Changchun, China

BACKGROUND AND OBJECTIVES

Nucleotides play a crucial role in the growth and development of infants. The study of nucleotide concentration trajectories in human milk and the factors that influence them can provide insights into the nutritional management of breastfeeding mothers.

METHODS

A total of 1517 lactating mothers were enrolled, and 2235 human milk samples were collected from 0 to 400 days postpartum. Among these, 216 lactating mothers provided longitudinal milk samples at three stages: 0-5 days (colostrum milk, CM), 10-15 days (transitional milk, TM), and 40-45 days (mature milk, MM1). In addition, a further 347 mature milk samples were collected at 40-45 days, 641 at 200-240 days (MM2) and 599 at 300-400 days (MM3) as part of a cross-sectional study. The levels of human milk nucleotides, including cytidine monophosphate (CMP), uridine monophosphate (UMP), guanosine monophosphate (GMP) and adenosine monophosphate (AMP), were determined at different stages of lactation using HPLC, and the total potentially available nucleosides (TPAN) were calculated.

RESULTS

Maternal parity history, mode of delivery and pre-pregnancy BMI had no effect on human milk nucleotides, but lactation period and dietary pattern had an effect on human milk nucleotide concentrations. GMP and AMP decreased over time, while UMP, CMP and TPAN decreased during the TM stage, and then increased in MM1. Factorial analysis showed that lactation time affected all human milk nucleotides, and an interaction between lactation time and dietary pattern was observed for GMP and AMP. Further analysis showed that dietary patterns influenced nucleotide levels in later stages of lactation (MM2 and MM3), whereas nucleotide levels in CM were unaffected by diet. Mothers who consumed the Beans-Nuts dietary pattern exhibited the highest nucleotide levels in their mature milk, followed by those who consumed the Potato-Vegetable dietary pattern.

CONCLUSIONS

There was an interaction between dietary pattern and lactation time on human milk nucleotide. The Beans-Nuts dietary pattern resulted in increased nucleotide levels in late-term milk, but not in colostrum or early maturing milk.

HEPATIC GPCPD1 ACTIVITY-DRIVEN CHOLINE UTILIZATION LINKS TO ENERGY METABOLISM

Siyi Chen[1]; Kou Nakayama[1]; Abigael Edeh[1]; Minako Nakamura[1]; Noriyasu Ohshima[2]; Yoshiko Nakagawa[3]; Tetsushi Sakuma[1]; Thanutchaporn Kumrungsee[1]; Takashi Yamamoto[1]; Noriyuki Yanaka[1]
[1]Graduate School of Integrated Sciences for Life, Hiroshima University, Higashihiroshima, Japan; [2]Graduate School of Medicine, Gunma University, Gunma, Japan; [3]Center for Animal Resources and Development (CARD), Kumamoto University, Kumamoto, Japan

BACKGROUND AND OBJECTIVES

Choline is an essential nutrient for cellular function such as phosphatidylcholine (PC) synthesis, neuronal development, and one-carbon metabolism. Choline can be obtained through dietary intake or synthesized endogenously via the PC hydrolysis pathway. The liver, as the central organ of choline metabolism, is pivotal in maintaining systemic choline homeostasis. Gpcpd1 was previously identified as an intracellular enzyme that converts glycerophosphocholine (GPC) to choline *in vitro*, however, its potential role in endogenous choline production remains poorly understood. In this study, we generated liver-specific Gpcpd1-deficient mice (LKO) and investigated the regulatory roles of Gpcpd1 for choline and one-carbon metabolisms in liver and its impact on energy homeostasis.

METHODS

LKO mice were generated by crossing Gpcpd1-floxed mice, produced using the CRISPR-Cas9 system, with mice expressing Cre recombinase specifically in hepatocytes. Primary hepatocytes were isolated from LKO mice to investigate the impact of Gpcpd1 on choline metabolism. Liver tissue from LKO mice was analyzed using DNA microarray and metabolomics to assess its metabolite changes. Male LKO mice were subjected to fasting model (24h and 48h fasting) and refeeding model (24h fasting followed by 6h refeeding) to evaluate feeding behavior and metabolic alterations.

RESULTS

Liver of LKO mice showed GPC accumulation, betaine depletion, and reduced methylation potential as indicated by decreased SAM/SAH ratio and increased fgf21 mRNA level. Although there is no change in hepatic choline level between wild-type (WT) and LKO mice, primary hepatocytes from LKO mice showed lower choline levels compared with those of WT mice. During fasting, hepatic Gpcpd1 expression of WT mice increased accompanied by hepatic GPC degradation. In the fasting experiment, LKO mice exhibited reduced levels of branched-chain amino acids (BCAAs) and elevated levels of dihydroxyacetone phosphate (DHAP) and glycerol-3-phosphate (G3P), along with reduced blood ALT and AST levels. Notably, LKO mice gained more body weight than WT mice during refeeding.

CONCLUSIONS

These findings suggest Gpcpd1 activity regulates choline metabolism, one carbon metabolism, and energy metabolism, offering insights into the mechanistic crosstalk between these metabolisms and metabolic adaptations to energy deprivation.

THE MECHANISM OF SULFORAPHANE TARGETING CALCIUM ION-GSN SIGNALING AXIS TO REGULATE MITOCHONDRIAL HOMEOSTASIS AND IMPROVE LIPID METABOLISM DISORDERS

Sicong Tian[1]; Lihua Liu[1]; Guanqiong Na[1]; Zhipeng Liu[1]; Yujuan Shan[1]
[1]School of Public Health, Wenzhou Medical University, Wenzhou, China

BACKGROUND AND OBJECTIVES

Mitochondria are the sites of lipolysis and their ability to take up Ca2+ regulates mitochondrial dynamic balance. In our previous study, sulforaphane (SFN) could reduce triglyceride (TG) content. The mechanism of SFN targeting Ca2+-Gelsolin (GSN) signaling axis to regulate mitochondrial homeostasis to improve lipid metabolism was studied.

METHODS

The associations of serum Ca2+ level with the prevalence of non-alcoholic fatty liver disease (NAFLD) was examined using the National Health and Nutrition Examination Survey (NHANES). The causal relationship between Ca2+ and NAFLD was detected by two-sample Mendelian Randomization. A double-blind, randomized controlled trial using broccoli seed extract tablets rich in SFN on NAFLD patients was conducted and plasma proteomics was analyzed. The NAFLD mice model was established with methionine-choline deficient (MCD) diet. ALM12 hepatocytes was induced by mixed fatty acids (FA) and GSN Ca2+-binding site mutant cell lines were constructed and treated with 10 μmol/L SFN.

RESULTS

The serum Ca2+ was positively associated with higher risk of NAFLD. Genetically predicted high levels of serum Ca2+ were consistently associated with increased risk of NAFLD. Glutamyltransferase, alanine transaminase and serum Ca2+ levels decreased in NAFLD patients treated with SFN. Ca2+ has mediating effect on the association between SFN and TG. After SFN intervention in NAFLD patients, the levels of Ca2+-gated channel proteins decreased; mitochondrial fusion proteins and actin increased by plasma proteomics. SFN increased the number of tubular mitochondria and mitochondria fusion protein expression, while decreased fission protein in MCE mice; improved fatty acids oxidation (FAO) capacity. The differential proteins after SFN intervention were mainly concentrated in the actin and mitochondrial outer membrane protein in crude mitochondria; GSN was more prominent. SFN decreased mitochondrial Ca2+ level, the colocalization coefficient of mitochondria and GSN, and mitochondrial fission protein, while increased fusion protein. The cleavage F-actin mitochondrial skeleton wave disappeared in GSN overexpression cell, resulting in the accumulation of fused mitochondria. After GSN-G6 Ca2+-binding site mutation, the activity of cleaved F-actin was enhanced and the mitochondrial kinetic cycle was inhibited.

CONCLUSIONS

High levels of serum Ca2+ may be a potential risk factor for NAFLD and SFN intervention could effectively improve NAFLD. SFN targets the Ca2+ binding site of GSN to activated the cleavage of F-actin, thereby regulating the mitochondrial dynamic balance to promote FAO.

EFFECTS OF DIETARY GERANYLGERANIOL SUPPLEMENTATION ON PAIN-ASSOCIATED BEHAVIORS, MITOCHONDRIAL HOMEOSTASIS, AND NEUROINFLAMMATION, BUT NOT GUT MICROBIOME, IN STREPTOZOTOCIN-INDUCED DIABETIC RATS

Chwan-Li Shen[1]; Moamen Elmassry[2]; Xiaobo Liu[1]; Volker Neugebauer[3]
[1]Pathology, Texas Tech University Health Sciences Center, Lubbock, TX, United States of America; [2]Molecular Biology, Princeton University, Princeton, NJ, United States of America; [3]Pharmacology and Neuroscience, Texas Tech University Health Sciences Center, Lubbock, TX, United States of America

BACKGROUND AND OBJECTIVES

Growing evidence highlights the links between diabetic neuropathy (DNP), gut microbiota, mitochondrial homeostasis and neuroinflammation in colon and spinal cord. Geranylgeraniol (GG) shows neuroprotective capacity. We examined the effects of GG on pain-associated behaviors, gut microbiota, and mitochondrial homeostasis in DNP rats.

METHODS

33 male rats were randomly divided into 3 groups: control group (low-fat diet), DPN group (high-fat diet plus single dose of streptozotocin), and DPN+GG at 800 mg/kg in diet for 6 weeks. Von Frey test and elevated plus maze were used to assess nocifensive responses and anxiety-like behavior, respectively. Fecal samples were collected for microbiota composition analysis using 16S rRNA gene sequencing and analyzed by QIIME 2. The mRNA expression levels of tight junction protein, mitochondrial homeostasis, and neuroinflammation were measured in the colon and spinal cord using qRT-PCR. Data were analyzed statistically.

RESULTS

At the end of the study, GG supplementation mitigated mechanical hypersensitivity and anxiety-like behavior of rats with DNP. There were no significant differences in the alpha-diversity and beta-diversity of gut microbiome among all three groups. Relative to the control group, the DNP group had increased abundance of *Clostridium sensu stricto 1*, but decreased abundance of *Peptococcaceae*. GG supplementation into the diet did not influence any abundance of gut microbiome composition in the DNP rats. Relative to DNP group, the DNP+GG group had (i) increased claudin-3 (tight junction protein) and (ii) decreased mitochondrial fusion-1 mRNA expression in the colon, but not in the spinal cord. Relative to the DNP group, the DNP+GG group had (i) increased peroxisome proliferator-activated receptor-γ coactivator-1α (mitochondrial biogenesis and energy metabolism) and (ii) decreased mitochondrial fission protein 1 mRNA expression in the spinal cord, but not in the colon. GG increased glial fibrillary acidic protein (mitochondrial function/biogenesis), while it did not affect PTEM-induced kinase 1 (mitophagy) mRNA expression in the colon and spinal cord of DNP rats. GG suppressed TNF-α mRNA expression levels in the colon and NFkB mRNA expression in the spinal cord of DNP rats.

CONCLUSIONS

GG supplementation reduced DNP pain-associated behaviors, improved intestinal integrity, favored mitochondrial homeostasis, and suppressed neuroinflammation in the animals without affecting the gut microbiome.

MAPPING THE DISPARITIES: SEVERE AND EXTREME CHILD GROWTH FAILURE ACROSS SOUTH AND SOUTHEAST ASIA

Md Mehedi Hasan,[1]; Abdullah Al Mamun,[1]
[1]Poche Centre for Indigenous Health, The University of Queensland, Brisbane, Australia

BACKGROUND AND OBJECTIVES

The elimination of child growth failure (CGF), encompassing stunting, wasting, and underweight, is a global target to be achieved by 2030. Identifying vulnerable geographic regions and populations within these areas is essential for the development and delivery of targeted interventions to mitigate CGF. This study investigated disparities in overall, severe, and extreme CGF between and within countries in South and Southeast Asia (SSEA).

METHODS

We utilized population-based, nationally representative Demographic and Health Survey (DHS) data collected between 2014 and 2021 from eight SSEA countries: Bangladesh, Cambodia, India, Maldives, Myanmar, Nepal, Pakistan, and Timor-Leste. The analysis included data from 243,805 children under five years of age from both sexes. Absolute and relative inequalities were quantified, and concentration indices were computed to assess disparities.

RESULTS

Between 2014 and 2021, 34.8% of children in SSEA were stunted, 13.7% were severely stunted, and 4.5% were extremely stunted. Additionally, 15.5% of children were wasted, 4.3% were severely wasted, and 1.5% were extremely wasted. Underweight prevalence was 30.4%, with 8.8% classified as severely underweight and 1.8% as extremely underweight. Timor-Leste exhibited the highest prevalence of CGF across all severity categories. Within-country disparities were evident, with the highest prevalence of extreme stunting observed in the Ainaro division of Timor-Leste (18.7%). Children from poorer socioeconomic backgrounds and rural areas consistently experienced higher rates of CGF across all countries, with the exception of the Maldives. Socioeconomic and geographic inequalities in CGF were more pronounced at sub-national levels.

CONCLUSIONS

Substantial variability in CGF was observed between and within countries in SSEA. The implementation and reinforcement of targeted nutrition interventions are imperative, particularly in high-risk regions and among vulnerable populations, to address the persistent disparities in child growth outcomes.

EXPLORING NUTRITION AND AGRI-FOOD EDUCATORS' KNOWLEDGE OF FOOD SUSTAINABILITY: INSIGHTS TO ADDRESS CLIMATE CHANGE AND SUSTAINABILITY CHALLENGES

Maria McDonagh[1]; Aisling Moran,[1]; Lisa Ryan[1]
[1]Sport, Exercise and Nutrition, Atlantic Technological University, Galway, Ireland

BACKGROUND AND OBJECTIVES

Education is pivotal in shaping a future geared toward achieving climate neutrality and cultivating agents of change capable of addressing current sustainability challenges. The depth of educators' understanding of food sustainability significantly influences how effectively they integrate it into programs and the emphasis placed on its importance. The objective of this study was to examine the knowledge and understanding of food sustainability among nutrition and agri-food educators in Europe. This study was part of a joint European-funded project (2023-1-IE01-KA220-VET-00156916: Train to Sustain – upskilling educators on food sustainability priorities).

METHODS

Following ethical approval, a survey was distributed to nutrition and agri-food educators across the project partner countries of Ireland, Slovenia, Poland, and Italy. Data were collated and analysed using both qualitative and quantitative methodologies to gain a comprehensive understanding of the educators' knowledge of food sustainability.

RESULTS

A total of 123 nutrition and agri-food educators participated in the survey. 81% (n=100 participants; 68 females) of respondents strongly agreed or agreed that they fully understood the term "food sustainability." 97% of respondents believed it was either extremely important (52%) or somewhat important (45%) to include food sustainability in educational programs. Despite this, only 62% of the programs taught by these respondents currently incorporate food sustainability into their curricula. This disparity highlights a gap between perceived importance and actual implementation in education. The data also offered insights into educators' perceptions of food sustainability. Two primary themes were identified: 1 environmental sustainability and 2 social sustainability. Participants referred to producing food in an environmentally friendly way, linking this to achieving zero waste. The qualitative analysis also highlighted the significance of ensuring societal access to healthy food, focusing on food security. However, there was limited mention of economic and cultural sustainability, highlighting a potential gap in educators' understanding of these areas.

CONCLUSIONS

This study highlights the importance of ensuring that nutrition and agri-food educators possess a comprehensive understanding of food sustainability. This foundational knowledge is crucial for adapting and advancing food and nutrition education, which can have a significant impact on climate change mitigation and addressing sustainability challenges.

PROTEIN INTAKE AND QUALITY AMONG NEW ZEALAND VEGANS: INSIGHTS FROM BASELINE ASSESSMENTS AND TEMPORAL MEAL PATTERNS

Bi Xue Patricia Soh[1]; Nick Smith[1]; Matthieu Vignes[1]; Hurst, Pamela Von[2]; Warren Mcnabb,[1]
[1]Sustainable Nutrition Initiative, Riddet Institute, Massey University, Palmerston North, New Zealand; [2]School of Sport, Exercise and Nutrition, Massey University, Auckland, New Zealand

BACKGROUND AND OBJECTIVES

The restrictive nature of a vegan diet is associated with risks of indispensable amino acid (IAA) deficiencies, as plant-based proteins provide lower utilisable IAAs. Since IAAs cannot be synthesized endogenously and excess is oxidized in the presence of limiting AAs, evenly distributed protein with synchronised delivery of all IAAs in meals is crucial for optimal metabolism. This study aims to quantify digestibility-adjusted protein and IAA intake, compared to body requirements, and evaluate the temporal distribution across the day.

METHODS

Dietary intake data was obtained through a four-day food diary from adult vegans in New Zealand, who have followed a vegan diet for at least two years (Ethics: HDEC 2022 EXP 12312). Protein and IAA composition of all foods were matched to food composition data from New Zealand FoodFiles and the USDA, and adjusted for True Ileal Digestibility. Time-series clustering was used to objectively classify vegan dietary data into specific clusters and analysed for protein and amino acid distribution as a function of time.

RESULTS

Mean protein intakes for males and females were 0.99 and 0.81 g/kg of body weight /day, respectively, but a quarter from each group were below the Estimated Average Requirement for protein. When adjusted to individual body weight, average IAA intakes were above daily requirements, but lysine just met requirements at 31.2 mg/kg of body weight/day (reference: 30 mg/kg/d). Mean total protein per eating occasion (EO) is 11.1g, with 93.5% of the cohort consuming below 20g of total protein per EO. Higher protein and IAA intake occurred at later parts of the day. Clustering produced three distinct groups, segregated mainly by total protein intake (cluster 1 = 8.2g of protein, cluster 2 = 15.9g, cluster 3 = 30.0g). Among the IAAs, lysine and leucine were at least 4x higher in cluster 3 than cluster 1. Legumes and pulses contributed the largest proportion of total protein and lysine intake in clusters 2 and 3 while cluster 1 had more balanced contribution from different food groups.

CONCLUSIONS

Protein and IAA intake were unevenly distributed throughout the day in this vegan cohort and generally below selected protein reference values of 20 g per EO, particularly for cluster 1. Lysine was the most limiting IAA supplied from the overall vegan diet of the cohort, but just met daily requirements when adjusted to individual body weight. Increasing the intake of legumes and pulses could increase total protein and IAA quantities but must be balanced within the context of other micronutrients. Further exploration of plant protein combinations in cluster 3 could inform recommendations to optimise protein quality in vegan diets.

POLYPHENOLS AS MODULATORS OF THE BMP SIGNALING PATHWAY TO COUNTER COLORECTAL CANCER INITIATION

Emma Cogo[1]; Edwin Fouché[1]; Jacques Dupuy[1]; Fabrice Pierre[1]; Françoise Guéraud[1]; Pascale Plaisancié[1]
[1]Prevention and Promotion of Carcinogenesis by Food, INRAe Toxalim (Research Centre in Food Toxicology), University of Toulouse, Toulouse, France

BACKGROUND AND OBJECTIVES

The Bone Morphogenetic Protein (BMP) signaling pathway is today known as playing a crucial role in inhibiting the initiation/promotion of colorectal cancer (CRC) (*1,2*). In the colon, subepithelial fibroblasts and colonocytes represent the main BMP ligand-producing cells (*1,3,4*). To date, polyphenols are the only nutritional factors known to modulate the BMP pathway, but related to bone metabolism (*5,6*). The aim of our study was to determine (a) whether certain polyphenols were able to modulate the BMP pathway at the intestinal level and (b) whether they could prevent colonocyte transformation induced by 4-hydroxynonenal (HNE), a product of lipid peroxidation suspected to be involved in CRC development.

METHODS

Ten polyphenols were tested on normal colonocytes (Co) and fibroblasts (nF) from the same mouse colon. Expression of BMP pathway players was analyzed by immunofluorescence and RT-qPCR. We then assessed the ability of a selected polyphenol to inhibit colonocyte transformation induced by HNE using a soft agar assay that evaluates the ability of Co cells to grow without anchoring, a characteristic of transformed cells. For this purpose, we treated Co and nF cells both in mono and coculture during three weeks with HNE (5 µM) and/or the selected polyphenol (10 µM) continually.

RESULTS

Apigenin, a flavonoid present in fruits, spices and vegetables, was selected for its ability to increase BMP4 ligand production in nF cells (+650% vs. control, $p < 0.0001$) and to decrease gene expression of GREM1, a BMP antagonist. The soft agar assay showed that pretreatment with apigenin protected colonocytes from HNE-induced transformation ($p < 0.0001$). A similar result was observed with Co cells pretreated in coculture with fibroblasts. The use of a potent inhibitor of the BMP type I receptor (K02288; 500 nM) on monocultured Co cells demonstrated the involvement of the BMP pathway in the protective effect of apigenin. It is very interesting to note that the soft agar assay performed in the presence of fibroblasts pretreated with apigenin, HNE and K02288 also amplified the anchorage-independent growth ability of colonocytes compared to the presence of fibroblasts pretreated only with apigenin and HNE.

CONCLUSIONS

All these data suggest that apigenin, via its action on the BMP signaling pathway, could play a major protective role in the initial stages of colorectal carcinogenesis. This polyphenol, present in our diet, therefore represents a particularly relevant molecule that could lead to the development of new nutritional strategies for the prevention of CRC.

REINFORCING INTEGRATED MANAGEMENT OF ACUTE MALNUTRITION

Ranjan Kapali[1]; Ojaswi Acharya[2]; Lila Bikram Thapa[3]
[1]Nutrition and Health, Action Against Hunger | ACTION CONTRE LA FAIM (ACF), Lalitpur, Nepal; [2]Country Director, Action Against Hunger | ACTION CONTRE LA FAIM (ACF), Lalitpur, Nepal; [3]Family Welfare Division, Department of Health Services, Kathmandu, Nepal

BACKGROUND AND OBJECTIVES

Severely acute malnourished children face a mortality risk 5 to 20 times higher than well-nourished peers. Despite a decline in wasting prevalence in Nepal from 15% to 8%, provincial disparities persist. The IMAM program, reaching only 30% of those in need, requires updates to address these gaps and improve child health outcomes.

This project seeks to restress the importance of quality IMAM program among different stakeholders engaged at the province level. The specific objectives include: (1) identification of the gaps in implementation of IMAM services at the province level, (2) development of provincial level recommendations for ensuring quality of IMAM program nationally, and (3) supporting the Government for updating the existing National IMAM Guideline based on the key findings from the gap analysis and the recently released WHO guidelines 2023.

METHODS

The gap analysis employed a tool adapted from the Health System Strengthening (HSS) diagnosis tool, developed by ACF at the global level. This was implemented across all seven provinces in Nepal. KII were conducted to complement the gap analysis findings, and information was triangulated through desk reviews of national policies, research reports, and health data (e.g., NDHS 2016 and 2022, HMIS, MSNP II). The findings were aligned with WHO guidelines on the prevention and management of acute malnutrition in children under 5 years.

RESULTS

The analysis identified significant issues across seven provinces, categorized by six health system building blocks and 22 sub-building blocks. Major challenges were found in service delivery, human resources, and health information systems. Governance was generally adequate, except in Madhesh and Koshi Provinces, where policy formulation and assessment capacities were weak. Financial resources were sufficient in most provinces, but Koshi struggled with both financial and human resources. Supply chain adequacy varied, with Sudurpashchim and Karnali performing well, while others faced shortages. Short, medium, and long-term action plans were developed, along with detailed recommendations to support the revision of the IMAM guidelines.

CONCLUSIONS

The gap analysis underscores the need for a multisectoral approach to the IMAM program, emphasizing comprehensive policy revisions and targeted interventions to address identified gaps. These findings will inform the update of the IMAM guidelines, ensuring more effective implementation and contributing to better health outcomes for children across Nepal.

QUALITY ASSESSMENT OF EFFERVESCENT FOOD SUPPLEMENTS ON THE SLOVENIAN MARKET: COMPLIANCE WITH DECLARED NUTRIENT CONTENT

Maša Hribar[1]; ŠPela Goljuf[2]; Igor Pravst[1]
[1]Public health, Institute for Nutrition, Ljubljana, Slovenia; [2]Food and Nutrition, Biotehnical Faculty, Ljubljana, Slovenia

BACKGROUND AND OBJECTIVES

The popularity of food supplements has grown significantly in Slovenia, where they are increasingly used to meet daily nutrient needs. However, concerns arise regarding their quality, safety, and labeling accuracy. Effervescent tablets (ET) are a food supplement known for their convenience and palatability. This study aimed to evaluate the compliance of declared contents of selected micronutrients (vitamins D, B12, C, and minerals zinc, calcium, magnesium, and iron) in ET with actual composition determined through laboratory analysis.

METHODS

A detailed review of the packaging for 71 samples was conducted, focusing on declared ingredients, chemical forms of micronutrients, and the use of nutrition and health claims. Laboratory analyses were used to evaluate nutrient content.

RESULTS

The analysis revealed discrepancies in nutrient content, with 11% of samples exceeding permitting tolerance limits (80-150 %). Vitamin D showed the highest non-compliance, with 24% of samples outside the acceptable range. Furthermore, 55% of ET samples contained at least one micronutrient exceeding the reference daily intake, while 18% surpassed the upper tolerable intake level, raising potential safety concerns. Most ET samples (86%) declared the chemical forms of added micronutrients, which is compliant with EU regulations, whereas 14% failed to specify these forms. Additionally, 79% of samples featured health claims, yet 13% of these claims did not meet regulatory requirements, indicating potential issues in labeling practices.

CONCLUSIONS

The findings highlight gaps in the quality control and labeling accuracy of food supplements in the Slovenian market, particularly among effervescent tablets. These gaps underscore the need for more stringent oversight and improved regulatory frameworks to ensure that product labeling accurately reflects nutrient content and complies with established safety standards. Transparent and precise labeling practices are essential to prevent consumer misinformation and support public health. Addressing these issues requires regular and systematic testing of food supplement products, adherence to legislative standards, and enhanced quality monitoring processes.

DOES LACTIC ACID-RICH SOURDOUGH BREAD IMPROVE APPETITE REGULATION COMPARED TO YEAST BREAD? A RANDOMIZED, DOUBLE-BLIND CONTROLLED TRIAL

Georgia Chatonidi[1]; Inés Pradal[2]; Luc De Vuyst[2]; Christophe Courtin[3]; Kristin Verbeke[1]
[1]Translational Research in GastroIntestinal Disorders, KU Leuven, Leuven, Belgium; [2]Research Group of Industrial Microbiology and Food Biotechnology, Vrije Universiteit Brussel, Brussels, Belgium; [3]Laboratory of Food Chemistry and Biochemistry, KU Leuven, Leuven, Belgium

BACKGROUND AND OBJECTIVES

Sourdough bread has been linked to better glucose and appetite regulation, potentially due to the organic acids produced during fermentation. This study aimed to compare the effects of wholemeal sourdough bread (WSB), rich in lactic acid, on energy intake, satiety, gastric emptying, and glucose and C-peptide responses, with wholemeal yeast bread (WYB).

METHODS

Forty-four normal-weight participants (age: 30 ± 10 years; BMI: 23 ± 2 kg/m²) took part in a double-blind, randomized crossover trial. The trial consisted of two study visits, each separated by one week. During each visit, gastric emptying, subjective appetite, and glucose and C-peptide concentrations were measured over a four-hour period. Afterward, ad-libitum energy intake was assessed.

RESULTS

Although there was no significant difference in ad-libitum energy intake after bread consumption ($p = 0.068$), WSB led to significantly lower hunger ($p < 0.001$), higher fullness ($p < 0.001$), reduced desire to eat ($p < 0.001$), and lower prospective food consumption ($p < 0.001$) compared to WYB. WSB also resulted in slower gastric emptying rate ($p = 0.002$), reduced glucose response between 15-30 minutes ($p < 0.05$), and lower C-peptide response between 15-90 minutes ($p < 0.05$) after consumption compared to WYB.

CONCLUSIONS

Consumption of WSB, rich in lactic acid, led to a slower gastric emptying rate, lower early glucose and C-peptide responses, and a slight increase in satiety compared to WYB. However, it did not impact ad-libitum energy intake at the next meal, compared to WYB.

NUCLEOTIDES AS AN ANTI-AGING SUPPLEMENTATION IN OLDER ADULTS（TALENTS）: A RANDOMISED CONTROLLED TRIAL

Meihong Xu[1]; Shuyue Wang[1]; Lixia Song[1]; Rui Fan[1]; Qianqian Chen[1]; Mei You[1]; Ruisheng Fu[1]; Yuxiao Wu[1]; Meng Cai[1]; Li Yong[1]
[1]Department of Nutrition and Food Hygiene, School of Public Health, Peking University, Beijing, China

BACKGROUND AND OBJECTIVES

Aging impairs nutrient metabolism and accelerates biological aging, negatively affecting health and longevity. The targeting Aging and Longevity with Exogenous Nucleotides (TALENTs) trial aimed to explore whether nucleotides supplementation (NTs) could delay biological aging and improve health outcomes in older adults.

METHODS

The trial was a 19-week, double-blind, randomized, placebo-controlled study in Chengdu, China, with 121 elderly participant (60-70 years). Participants were randomly assigned in a 1:1 ratio to receive either NTs (1.2 g/day) or a placebo group by an independent researcher applying a computer-generated sequence. Primary outcomes included DNA methylation median age (Median DNAmAge) and leukocyte telomere length (LTL). Secondary outcomes assessed metabolic health and aging biomarkers. Other observational data, such as body composition and comprehensive geriatric questionnaire assessment were also collected. Safety was assessed through monitoring adverse events and routine clinical markers. Data were collected at baseline, week 11, and week 19. The study is registered with ClinicalTrials.gov, NCT05243108.

RESULTS

The mean age of the participants was 65.65 ([SD] 2.59) years and 82 (67.21%) of them were women. NTs significantly reduced Median DNAmAge compared to placebo (β = -3.08 years, 95% CI: -5.07 to -1.10, P = 0.0023), suggesting an anti-aging effect. LTL showed no significant difference between groups (β =0.11, 95% CI: -0.06 to 0.28, P = 0.19). Insulin sensitivity improved in NTs group, with a significant reduction in HOMA-IR (β =-0.45, 95% CI: -0.86 to -0.04, P = 0.033). There were no significant changes in any of the other secondary outcomes between groups. Observational data indicated an increase in skeletal muscle mass (β = 0.50 kg, CI: 0.01 to 1.00, P = 0.046) as well as reductions in trunk fat mass (β = -0.33 kg, CI: -0.64 to -0.01, P = 0.044) and visceral fat grade (β = -0.40, CI: -0.73 to -0.08, P = 0.015). No severe adverse events were reported. No significant changes in liver or kidney function, nor tumor markers.

CONCLUSIONS

NTs supplementation is safe and may promote healthy aging by reducing DNAmAge and improving insulin sensitivity with a well-tolerated safety profile. Observed changes in body composition, such as increased muscle mass and reduced trunk and visceral fat, support potential benefits. Further research is needed to confirm these findings and assess long-term effects.

EX VIVO STUDY ON THE PREBIOTIC EFFECTS OF CITRUS PECTIN IN HEALTHY ADULTS

Frederique Respondek[1]; Sune Petersen[2]; Pieter Van Den Abbeele[3]
[1]Innovation, CP Kelco, Levallois-Perret, France; [2]Innovation, CP Kelco, Lille-Skensved, Denmark; [3]Scientific Affairs, Cryptobiotix, Gent, Belgium

BACKGROUND AND OBJECTIVES

Upcycled citrus pectin, derived from citrus peels, is a complex polysaccharide formed of a linear chain of galacturonic acid (homogalacturonan) and branched chains (rhamnogalacturonan I and II), that is mostly known for its functional properties in foods. Recent literature also highlights an interesting prebiotic potential in humans (Pascale et al, 2022; Gu et al, 2023). Due to the complexity of the molecule, more studies are needed to fine-tune the structure-function relationship, including variations of its molecular weight, and better estimate the efficient dose in healthy adults.

METHODS

The *ex vivo* SIFR® fermentation technology (Van den Abbeele et al, 2023) was used to study the effects of 5g/L citrus pectins with various molecular weight in comparison to chicory inulin. Faecal samples from 6 healthy adult donors (BMI between 20-25, no antibiotic use for the past 3 months, no use of pre- and probiotics) were used as inoculum in a single-donor study design. The fermentative parameters were evaluated after 48h along with gut microbiome composition (16SrRNA gene) and the gut metabolome (untargeted metabolomics). Samples collected after 48h were also applied to a Caco-2 epithelial layer to measure barrier integrity (TEER) and to THP-1 cells to evaluate cytokine/chemokine response of upon LPS treatment.

RESULTS

Similarly to inulin, all tested pectins induced a significant production of SCFA with a critical role of the molecular weight. Fermentation of pectin was highly oriented towards the production of acetate but also propionate and butyrate, yet slightly lower than inulin. All pectins promoted barrier integrity (higher TEER in absence and presence of LPS) and modulated the immune system (slight increase in IL-6, like inulin). Pectin particularly stimulated the growth of the *Ruminococcaceae* and *Bacteroidaceae* families whereas inulin stimulated *Bifidobacteriaceae* and *Coriobacteriaceae*. Both fibres increased the concentration of various acetylated amino acids. With pectin, *Bacteroidaceae* were also positively correlated with tryptophan-derived and phenolic compounds.

CONCLUSIONS

This *ex vivo* study confirmed that citrus pectin-derived fibres have a prebiotic potential in humans at similar doses as inulin and also have complementary effects as illustrated by a higher acetate production and other bacterial metabolites that may have health benefits. Modulating the molecular weight of pectin can impact its fermentation properties and help to optimize its efficacy in humans and facilitate its use in food and beverage.

EXAMINATION OF MEASUREMENT CONDITIONS FOR EVALUATING THE DIGESTIBILITY OF CARBOHYDRATES IN FOODS USING THE GR METHOD

Yukiko Nakanishi[1, 2]; Takako Ikeda[3, 1]; Hiroko Nakamura[1]; Mika Kimura[2]; Hajime Sasaki[2]
[1]Institute for Women's Health Science, Showa Women's University, Tokyo, Japan; [2]GR Project, International Life Sciences Insitute Japan, Tokyo, Japan; [3]Faculty of Food and Health Science, Showa Women's University, Tokyo, Japan

BACKGROUND AND OBJECTIVES

The Glycemic Index (GI) is an in vivo method for predicting postprandial blood glucose levels. However, GI measurement requires blood sampling, posing challenges such as mental stress, high costs, and time constraints. To address these issues, the Glucose Releasing Rate (GR) method was developed by the ILSI Japan GR Project as a simpler screening method to predict glycemic response. This study examines factors influencing the variability of GR measurements, particularly the impact of food moisture content.

METHODS

The GR method involves in vitro simulations of mastication, gastric digestion, pancreatic enzyme activity, and disaccharide breakdown in the small intestine. GR values are expressed as the ratio of glucose concentration at 20 minutes to that at 16 hours. This study reevaluated experimental procedures and investigated the effects of soaking time and water addition during sample preparation.

RESULTS

Variations in GR measurements were influenced by shaking water bath conditions, including temperature and shaking distance, as well as fluctuations in measurements before and after the 16-hour time point.

For low-moisture foods, samples were previously soaked at 37°C for 10 minutes to simulate mixing with saliva. Reducing the soaking time to 1 minute, to account for mastication time before swallowing, yielded RESULTS that were either comparable to or lower than those with 10 minutes of soaking.

CONCLUSIONS

This study identified factors affecting the variability of GR measurements, emphasizing the importance of clearly defined conditions to minimize variability. The GR method mimics mastication by grinding samples, with pre-grinding preparations simulating mixing with saliva. Variations in GR values were observed depending on the amount of saliva simulated and the mastication time.

OAP28_06

THE SYSTEMIC AVAILABILITY OF SHORT-CHAIN FATTY ACIDS: IMPACT OF SMALL INTESTINAL VERSUS COLONIC DELIVERY

Riet Rosseel[1]; Tessa Dehau[1]; Greet Vandermeulen[1]; Kristin Verbeke[1]
[1]Translational Research in GastroIntestinal Disorders, KU Leuven, Leuven, Belgium

BACKGROUND AND OBJECTIVES
Fermentation of dietary fibers in the human colon generates short-chain fatty acids (SCFA), which potentially mediate the health benefits associated with fiber intake. The fraction of SCFA that bypasses metabolism in colonocytes and liver and enters unchanged the systemic circulation, is called the systemic availability. Unlike colonic cells, small intestinal enterocytes do not primarily use SCFA as energy source. Therefore, we hypothesized that small intestinal delivery of SCFA RESULTS in a higher systemic availability than colonic delivery.
METHODS

In a randomized, crossover trial with healthy subjects (n=11; age: 28 years; BMI: 22 kg/m²), 13C-labeled SCFA (400 mg 13C-acetate, 300 mg 13C-propionate, 800 mg 13C-butyrate) were administered in the small intestine or the colon using standard capsules or capsules with a colon-delivery coating, respectively. A primed, continuous intravenous infusion containing ²H-labeled SCFA ([$^2H_3$]-acetate: 10 µmol/kg + 20 µmol/kg/h; [$^2H_5$]-propionate: 1 µmol/kg + 2 µmol/kg/h; [$^2H_7$]-butyrate: 0.5 µmol/kg + 1 µmol/kg/h) was administered for 12 hours to assess the clearance of SCFA from the circulation. Postprandial serum samples were collected at regular timepoints for 12 hours. All samples were analyzed for total (labeled + unlabeled) SCFA using gas chromatography-mass spectrometry (GC-MS) after derivatization with 2,4-difluoroanilin. ²H- and 13C-abundances were measured in ether extracts of the serum samples using GC-MS or GC-combustion-isotope ratio mass spectrometry, respectively. The clearance (L/h) was calculated by dividing the ²H-SCFA infusion rate by the ²H-SCFA steady state concentrations. The systemic availability was calculated from the area under the curve of 13C-SCFA concentration over 12 hours, multiplied with the clearance and divided by the administered dose of 13C-SCFA.

RESULTS

13C-SCFA concentrations peaked after 30 min after small intestinal delivery, while colonic delivery resulted in peaks between 200 and 400 min. The systemic availability was not different between small intestinal and colonic delivery (Wilcoxon signed rank test) for acetate (median [IQR]): 41.6 [34.3-51.5%] vs. 37.0% [27.9-49.2%], p = 0.6377), propionate (5.46 [4.91-7.52%] vs. 4.29% [3.65-6.84%], p = 0.2783) and butyrate (1.68% [1.48-1.88%] vs. 1.82 [1.22-2.22%], p = 0.7646).

CONCLUSIONS

The lack of difference does not exclude that a higher fraction of SCFA entered the portal circulation after small intestinal administration and was compensated by increased liver extraction. Thus, the site of administration does not influence the systemic availability.

OAP28_07

MATH ADVANCES NUTRITION RESEARCH: THE CHALLENGE OF DESIGNING MENUS FOR CONTROLLED FEEDING TRIALS

Johanna C Gerdessen[1]; Karin Borgonjen-van den Berg[2]; Monique Daanje[2]; Jacintha Domić[2]; Els Siebelink[2]
[1]Operations Research & Logistics, Wageningen University & Research, Wageningen, Netherlands; [2]Division of Human Nutrition and Health, Wageningen University & Research, Wageningen, Netherlands

BACKGROUND AND OBJECTIVES

Controlled feeding trials are an important method for establishing cause-effect relationships between dietary intake and metabolic parameters, risk factors, or health outcomes. In controlled feeding trials, participants are provided with full-day menus for a specified period. These menus must adhere to the trial's nutritional and operational standards. Levels of nutrients under investigation should differ sufficiently between intervention groups, while being consistent across different energy levels within each group. Levels of other key nutrients should be as similar as possible for all participants. Additionally, menus must be both diverse and manageable. Designing these menus is both a nutritional and a computational challenge, heavily reliant on the skills of the research dietitian. The process is highly time consuming, and managing last-minute disruptions poses significant challenges.

METHODS

We developed a mixed integer linear programming model to support the design of menus for controlled feeding trials. The model is demonstrated for a trial that involved consumption of individualized, isoenergetic menus with either a low or a high protein content (1). The model was used in the design of several trials, focusing on e.g. variation in postprandial glucose responses during a fully controlled dietary intervention, during which the participants had to comply with strict 30-minute time windows for food intake during nine weeks (2) and the muscle protein synthetic response in older adults to a vegan diet for which the protein intake had to be very precisely allocated to six meal moments (3).

RESULTS

All menus generated by the model fully comply with the trials' standards. The model accommodates strict nutrient composition ranges and supports the incorporation of complex design features. It is particularly effective in managing contrasts and similarities in key nutrient intake levels across groups and energy levels, even when dealing with numerous nutrients and energy levels. Additionally, the model facilitates the generation of multiple alternative menus and helps to tackle last-minute disruptions. Its flexibility allows for easy adaptation to trials involving different components or nutritional requirements.

CONCLUSIONS

The model helps to design menus for controlled feeding trials in a fast, objective, transparent, and reproducible manner. It significantly facilitates the menu design process, reducing both time and development costs. As such, it advances nutrition research.

THE IMPACT OF UVB RADIATION ON ACETYLCHOLINESTERASE INHIBITORY POTENTIAL IN VARIOUS MUSHROOM SPECIES: AN IN VITRO STUDY

Aybike Cebeci[1]; Turgut Taşkın[2]; ŞUle Aktaç[3]
[1]Department of Nutrition and Dietetics, Faculty of Health Sciences, Balıkesir University , Balıkesir, Türkiye; [2]Department of Pharmacognosy, Faculty of Pharmacy, Marmara University, İstanbul, Türkiye; [3]Department of Nutrition and Dietetics, Faculty of Health Sciences, Marmara University, İstanbul, Türkiye

BACKGROUND AND OBJECTIVES

This study aims to investigate the effects of UVB radiation on the acetylcholinesterase (AChE) inhibitory potential of three mushroom species: white button, shiitake, and king oyster.

METHODS

Mushrooms were exposed to three levels of UVB radiation (none, moderate, and high). AChE inhibitory activity was measured using an in vitro enzyme inhibition assay. Data were analyzed to determine the influence of UVB radiation and species-specific responses.

RESULTS

UVB radiation significantly enhanced AChE inhibitory activity in all mushroom species. The highest inhibition levels were observed under high UVB exposure, with shiitake mushrooms showing the most pronounced response. UVB-treated mushrooms demonstrated superior AChE inhibition compared to untreated controls, suggesting increased anti-Alzheimer potential.

CONCLUSIONS

UVB exposure is a promising method for enhancing the neuroprotective properties of edible mushrooms. These findings highlight the potential of UVB-treated mushrooms as functional food ingredients in dietary strategies for neurodegenerative diseases such as Alzheimer's. Further research is recommended to elucidate underlying mechanisms and assess clinical applications.

ANALYSIS OF THE MICROBIOME AND METABOLOME IN HUMAN BREAST MILK FROM HEALTHY AND DIABETIC MOTHERS IN THE COFFEE-GROWING REGION OF COLOMBIA

Sandra Yolanda Valencia Castillo[1, 2]; Martha Viviana Zuluaga Rojas[3]
[1]Biotechnology Research Department, BIOS Colombia, BIOS, Manizales, Colombia; [2]Department of Basic Sciences, Faculty of Health Sciences, Caldas University, Manizales, Colombia; [3]Academic Direction, Universidad Nacional de Colombia Sede La Paz, Los Robles La Paz, Colombia

BACKGROUND AND OBJECTIVES

Human breast milk (HBM) contains diverse metabolites and microbiomes essential for infant nutrition. Its composition and microbial abundance are influenced by physiological factors, including gestational diabetes mellitus (GDM), which disrupts both the microbiome and metabolome, affecting infant nutrition. This study compared the microbiome and metabolome profiles of HBM from healthy mothers and those with GDM to identify features influencing dysregulation in the mother-infant dyad.

METHODS

We analyzed biological samples from 20 healthy and 16 GDM mothers, including maternal and infant feces and HBM. Microbiome analysis involved DNA purification, 16S rRNA sequencing of the V3–V4 region, quality filtering, and classification using the SILVA database. For metabolomics, metabolites were extracted, derivatized, and analyzed via GC/MS QTOF, with identification based on retention indices.

RESULTS

Significant differences in gut bacterial abundances were observed between groups. GDM mothers showed reduced Bifidobacterium, Serratia, and Sutterella in their gut, while HBM had lower levels of Sutterella, Serratia, and Lactococcus. Infants of GDM mothers exhibited reduced Bifidobacterium, Lactobacillus, Sutterella, Serratia, Streptococcus, and Veillonella. Metabolomic analysis revealed alterations in glycolysis, gluconeogenesis, valine, leucine, and isoleucine biosynthesis, the citrate cycle (TCA), and pyruvate metabolism pathways in GDM-affected milk.

CONCLUSIONS

These findings suggest that GDM significantly impacts the gut and HBM microbiomes and metabolomes, potentially influencing infant health through disrupted metabolic pathways and microbial profiles.

ACCURACY OF BODY COMPOSITION ESTIMATION USING BIOELECTRICAL IMPEDANCE ANALYSIS (BIA) – COMPARISONS BETWEEN SEVEN MODELS WITH DUAL ENERGY X-RAY ABSORPTIOMETRY (DXA) –

Masaharu Kagawa[1]; Ikki Mineshima,[2]; Satoshi Oda,[2]; Keiko Kamachi,; Maki Tamura,; Osamu Ishihara,[3, 1]
[1]Institute of Nutrition Sciences, Kagawa Nutrition University, Sakado, Japan; [2]Measurement Department, TOYO MEDIC Co., Ltd, Chiyoda City, Japan; [3]Nutrition Clinic, Kagawa Nutrition University, Toshima City, Japan

BACKGROUND AND OBJECTIVES

An accurate estimation of body composition is important to better understand one's health and nutritional status. Bioelectrical impedance analysis (BIA) is one of the techniques widely used to estimate body composition due to its convenient, time-efficient and non-invasive nature. However, due to its popularity, a wide range of devices of different levels of accuracy is available today. The present study aimed to investigate an accuracy of different BIA devices that vary in numbers of frequencies and electrodes using a dual energy x-ray absorptiometry (DXA) as the reference technique.

METHODS

A total of 52 young Japanese female university students (median age: 20.0 years old, stature: 158.4 ± 5.8 cm, body mass: 52.6 ± 8.1 kg) underwent body composition assessment using DXA (Horizon, Hologic) and seven BIA devices. The BIA devices include 1) hand-to-hand single frequency BIA [SFBIA], 2) foot-to-foot SFBIA, 3) hand-to-foot SFBIA, 4) hand-to-foot dual frequency BIA [DFBIA], 5) hand-to-foot DFBIA with a prediction equation derived from the four-compartment model [DFBIA-4C], 6) a research-use hand-to-foot multi-frequency BIA [MFBIA-R], and 7) a home-use hand-to-foot MFBIA [MFBIA-H]. Assessments by DXA were conducted within one week of assessments using BIA devices.

RESULTS

Participants had percentage body fat (%BF), fat mass (FM) and fat-free mass (FFM) of 31.9 ± 4.8%, 16.6 ± 4.5 kg, and 34.8 ± 4.3 kg respectively from DXA. All BIA devices underestimated %BF compared with DXA. Devices with minimum estimation errors of %BF, FM and FFM were MFBIA-H, MFBIA-R, and DFBIA-4C. These devices had narrower limits of agreement than other devices for %BF (2.0 – 3.1% overestimation and 7.5 – 8.0% underestimation), FM (1.4 – 1.9 kg overestimation and 3.6 – 3.9 kg underestimation), and FFM (4.7 – 5.6 kg overestimation and 0.7 – 1.8 kg underestimation).

CONCLUSIONS

Present study observed differences in accuracy of body composition assessment between different BIA devices, indicating that RESULTS obtained from different BIA devices are not interchangeable. While MFBIA and DFBIA-4C devices showed smaller estimation error, these devices still showed approximately 10% error for %BF and approximately 6 kg for FM and FFM respectively, suggesting a need of caution to interpret the RESULTS.

CONFLICTS OF INTERESTS

One of the BIA devices used in the present study was supplied by TOYO MEDIC Co., Ltd. However, I. K. and S. O. did not involve in data analysis and interpretation of the RESULTS.

ALISTIPES INDISTINCTUS WITH POTENTIAL PROBIOTIC CHARACTERISTICS PREVENTS LIPOPOLYSACCHARIDE-INDUCED INTESTINAL BARRIER INJURY

Xu Yingxi[1]; Zhu Jiangyuan[2]; Liu Ludi[1]; Xia Min[1]; Liu Yan[1]
[1]School of Public Health, Sun Yat-sen University, GuangZhou, China; [2]School of Public Health, Sun Yat-sen University, Guang Zhou, China

BACKGROUND AND OBJECTIVES

Alistipes indistinctus (A. indistinctus) has demonstrated a beneficial effect on metabolic disorders, such as hyperglycemia, hyperuricemia, and fatty liver disease, suggesting that it has the potential to be a next-generation probiotic.[1-3] However, whether A. indistinctus meets the criteria of probiotics proposed by International Scientific Association for Probiotics and Prebiotics remains unclear. [4]

METHODS

Germ-free mice were gavaged with live and heat-killed A. indistinctus for one month to determine its colonization and potential effect on mucin production. Differentiated Caco-2 cells, an intestinal monolayer epithelium model, was employed to determine the protective effect of A. indistinctus on intestinal barrier function and amelioration in LPS-induced inflammation.

RESULTS

The survival rate of A. indistinctus in gastric and intestinal fluid was 77.3% and 73.0%, respectively, comparable to most well-known probiotics, such as Bifidobacterium. [5] Similar to other well-known probiotics, A. indistinctus was capable of encoding bile acid hydrolase (BSH), and showed strong BSH activity. [6] Besides, live A. indistinctus could colonize in the mucus layer for one week after single gavage, while long-term treatment of A. indistinctus exerted no adverse effect on liver and kidney function. Moreover, colonization of A. indistinctus led to a 1.8-fold increase in the number of goblet cells, which in turn boosted the formation of thickness of mucus layer. Additionally, co-culture with A. indistinctus enhanced the trans-epithelial electrical resistance value by 12.5%, and substantially reduced the paracellular permeability in Caco-2 cells exposed to LPS. Such an increase in intestinal barrier was accompanied by a 56.5% increase in the expression of zonula occludens-1 and occludin. Mechanistically, A. indistinctus treatment downregulated the expression of pro-inflammatory cytokines, including IL-1β, IL-6, and TNF-α, through suppressing the activity of NF-κB.

CONCLUSIONS

Though more investigations in humans are warranted, our findings provide evidence that A. indistinctus meets the criteria of probiotics and holds potential to be a next-generation of probiotics.

CHRONIC ELECTROACUPUNCTURE (EA) TREATMENT IN OBESE MINIPIGS MODIFIED GENE EXPRESSION AND BOLD FMRI BRAIN FUNCTIONAL RESPONSES TO FURTHER EA AND SWEET GUSTATORY STIMULATION IN THE CORTICO-LIMBIC-STRIATAL CIRCUITS

David Val-Laillet[1]; Yann Serrand[1]; Sylvie Guerin[1]; Youenn Launay[1]; Véronique Rome[1]; Nicolas Coquery[1]; Xuwen Zhang[1, 2, 3, 4]
[1]NuMeCan, INRAE, INSERM, Univ Rennes, Rennes, France; [2]Department of Acupuncture, Guangzhou University of Chinese Medicine, Guangzhou, China; [3]Chinese Medicine Clinic, Guangzhou Rui Xingtang, Guangzhou, China; [4]Praxis Dr. Zhang, GmbH, Sörenberg, Switzerland

BACKGROUND AND OBJECTIVES

Electroacupuncture (EA), a modern derivative of Chinese traditional acupuncture, is increasingly used for treating various diseases and especially gastrointestinal disorders. We previously showed in healthy minipigs that acute EA modulated physiological and metabolic parameters of the gut-brain axis compared to basal, sham and control conditions, with promising effects on brain fMRI responses, especially for the Sanwan/Dafengmen (S/D) acupoints (corresponding to human acupoints Shangwan, Zhongwan, Xiawan and Baihui). Here, we investigated the effects of a chronic EA on the brain functions of obese minipigs.

METHODS

Sixteen adult Yucatan minipigs were subjected to a 2-month obesogenic high-fat/high-sucrose diet before either a control (N=8) or chronic EA treatment composed of 12 20-min EA sessions (N=8, S/D stimulation) under general anesthesia. All animals were then subjected to *in vivo* whole-brain BOLD functional magnetic resonance imaging (fMRI) in response to acute EA stimulation or oral sucrose stimulation, as well as to *post mortem* brain tissue gene expression (80 genes) microarray analyses in four regions of interest (prefrontal cortex, striatum, hippocampus, hypothalamus).

RESULTS

Chronic EA in obese minipigs, compared to control, led to different brain responses to further EA or oral sucrose stimulation ($p<0.05$) in the prefrontal cortex (cognitive control), orbitofrontal cortex (hedonic evaluation), dorsal striatum (pleasure, motivation), cingulate cortex (decision making, attention) and hippocampus (learning, memory). Gene expression microarray revealed a region-dependent effect ($p<0.05$) of EA compared to control, with a decreased expression for genes involved in tight junction (CLDN5), fatty acid transport (FATP3) and brain development/maturation (CTNNB1), as well as an increased expression for genes involved in eating and thermogenesis control (NPY, MFSD2A), brain cell communication, survival and differentiation (SYP, GRIN2B, NTF3).

CONCLUSIONS

This study is the first to describe, in a large animal obesity model, the effects of chronic EA on the brain responses to sweet taste and gene expression in relation with brain plasticity and metabolism. Perspectives include the analysis of behavioral and physiological data already acquired. This opens the way to a better understanding of the (electro)acupuncture mechanisms, as well as their clinical use to fight against obesity and its comorbidities.

A NOVEL PROTOCOL FOR EXTRACTING DIETARY DERIVED MICRORNAS FROM GASTROINTESTINAL DIGESTA

Miguel Cifuentes Acebal[1]; Yvan Devaux[1]; Torsten Bohn[1]
[1]Department of Precision Health, Luxembourg Institute of Health, Strassen, Luxembourg

BACKGROUND AND OBJECTIVES

Recent years have shown multiple reports of dietary derived miRNAs surviving gastrointestinal digestion (1). These have later been detected in diverse body compartments, as well as in the circulatory system and feces (2,3). Considering the relevance of these reports, we have optimized an existing method of RNA extraction to enable researchers to purify and study miRNAs present in the gastrointestinal digesta as assessed by spike-ins and naturally occurring miRNAs.

METHODS

Using the bioaccessible phase of gastrointestinal digesta obtained from the INFOGEST 2.0 method (4), we have developed a miRNA purification protocol (5). This new method is based on a combination of lysis and precipitation buffers with the addition of a novel step, which decreases cross reactivity of the gastrointestinal digesta with downstream processes. This step consists in the addition of a reagent prior to RNA extraction that reduces RNAse activity from the digesta and chelates ions that would otherwise precipitate with RNA. The RNA is then further purified using a silica column. In the following, we benchmarked our protocol with other METHODS available. This included using a combination of spiked-in miRNAs and native miRNA from food matrices to validate the protocol. Assessment of miRNA extraction quality was done through qPCR.

RESULTS

The optimized protocol purifies miRNAs from gastrointestinal digesta in a reproducible manner (SD= 0.8 and 1.5 cycles respectively for spike-ins and native miRNAs), while allowing a relative large input volume (600 µl). Furthermore, it overcomes limitations observed with other commonly used techniques, such as cross reactivity derived from the gastrointestinal digesta composition or degradation of samples caused by RNAses present within the GID. The method, which allows for downstream applications such as RT-qPCR is significantly better in preserving RNA from the gastrointestinal digesta (i.e. recovery, $p<0.05$) than existing METHODS for miRNA extraction, even at low concentrations (ca. 100 copies / µl).

CONCLUSIONS

The current method provides a tool for researchers to study dietary derived miRNAs as novel food bioactives and biomarkers of food intake in a quick (<2 h) and reliable manner.

VALIDATION OF THE INTERVIEWER-BASED 24-H DIETARY RECALL APP 'CATCH-24' FOR DIETARY ASSESSMENT IN LMIC

Karin Borgonjen-van den Berg[1]; Desiree Lucassen[1]; Taonga Chirwa-Moonga[2]; Edith Feskens[1]; Elise Talsma[1]
[1]Division of Human Nutrition and Health, Wageningen University & Research, Wageningen, Netherlands; [2]Food Science and Nutrition, The University of Zambia, Lusaka, Zambia

BACKGROUND AND OBJECTIVES

Dietary assessment in low- and middle-income countries (LMIC) is difficult due to the unavailability of effective tools and population specific databases, making the preparation and execution time consuming and burdensome for both researchers and participants. Catch-24, an interviewer-based 24-h dietary recall (24hR) tablet app, is specifically developed for use in small-scale studies in LMIC as it can easily be adapted to new study areas and requires minimal data preparation. This study aimed to evaluate the intake of energy and nutrients assessed with Catch-24, against traditional pen-paper 24hRs and independent urinary recovery markers.

METHODS

Dietary intake was assessed in a cross-sectional study in urban and rural areas of two districts in Zambia. In total, 357 women (18-49 year) completed 6 non-consecutive 24hRs on randomly non-consecutive days, over a period of 3 weeks (3x 24hRs with Catch-24, 3x 24hRs with pen-paper). A subgroup of 52 women completed 24-h urine collection to determine urinary nitrogen excretion. Perceived usability of Catch-24, by the interviewers, was assessed using an evaluation questionnaire.

RESULTS

According to the interviewers, Catch-24 was easy-to-use and the app supported the structure of the interview. Average intakes of energy and nutrients (except alcohol) were slightly lower when assessed with Catch-24 24hRs compared to pen-paper 24hRs (energy 2974±951 kcal vs 3173±1072 kcal, nutrients e.g. protein 78.3±28.8 g vs 84.8±29.7 g; fat 77.7±34.3 g vs 85.0±35.6 g; carbohydrates 460±156 g vs 484±180 g). Urinary protein was lower than dietary protein intake assessed with pen-paper 24hRs. Correlation coefficients between 24hR METHODS ranged from 0.40 to 0.70 for energy and macro nutrients and from 0.29 to 0.51 for micro nutrients, except for calcium (0.23). Reproducibility for intake of energy and nutrients was comparable for both 24hR METHODS.

CONCLUSIONS

Dietary intake assessed with Catch-24 was slightly lower for energy and almost all nutrients, compared to pen-paper 24hRs with predominantly acceptable to good correlations. Subsequently, pen-paper 24hRs seem to overestimate compared to urinary protein, which may suggest that Catch-24 24hRs are more accurate than pen-paper 24hRs. Overall, Catch-24 was easy-to-use and guided the interview process, and therefore supported the overall estimation of dietary intake. Catch-24 has the potential to significantly reduce the researcher burden in diet-related studies in LMIC and is a valid tool to assess dietary intake.

ENHANCEMENTS TO THE NATIONAL SCHOOL NUTRITION PROGRAMME (NSNP) TO DIVERSIFY MENUS AND IMPROVE MEAL QUALITY, SERVICE, AND FACILITIES IN SOUTH AFRICA

Imana Pal[1, 2]; Anjellah Reddy[1]
[1]Food and Nutrition Consumer Sciences, Durban University of Technology, Durban, South Africa; [2]School of Health Sciences and Technology, UPES, Dehradun, India

BACKGROUND AND OBJECTIVES

In South Africa, the National School Nutrition Program (NSNP) targets food insecurity while enhancing learners' health and performance in school. Even with its success, challenges, including inadequate menu diversity, inconsistent meal quality, and poor infrastructure, still exist. As part of UNICEF's initiative to enhance the school food environment (SFE), an intervention of diversifying NSNP menus was piloted in six public schools. The goal of the intervention was to increase menu variety, improve nutritional content, and utilise more locally sourced, affordable, nutrient-dense ingredients that didn't require much storage space to promote a healthier, sustainable, and efficient school food environment.

METHODS

A mixed-METHODS approach was employed. Stakeholders' perceptions offered qualitative insights into the limitations of NSNP at the baseline, while sensory evaluations collected quantitative data on the developed recipes at the endpoint. Recipes were designed based on expert recommendations, utilising seasonal, local, and indigenous resources to enhance environmental sustainability and reduce reliance on processed ingredients. Recipes were developed to be scalable, economical, and appropriate for educational institutions with limited kitchen resources. Schools received support to establish kitchen gardens so they could utilise the produce in their kitchens. The training of Voluntary Food Handlers (VFHs) and the provision of promotional materials facilitated implementation.

RESULTS

The sensory evaluation of the fifteen newly produced recipes was positively received by professional panellists and learners. Furthermore, four out of six schools are successfully operating their kitchen gardens and utilising the produce to improve the quality of the NSNP meals. The identified barriers include insufficient kitchen facilities, restricted food storage, logistical difficulties in procuring fresh, local products, learner aversion to unfamiliar foods, cultural preferences, and insufficient parental involvement.

CONCLUSIONS

Improving the NSNP by diversifying the menu and incorporating nutritious, locally sourced foods enhances meal quality and satisfaction among learners. The ease of preparation and scalability of recipes provide accessibility for schools with low resources. Capacity-building activities for key stakeholders, collaborations with local farmers, and the development of school gardens can provide a consistent supply of ingredients and enhance the sustainability of programs over the long term.

BACKGROUND AND OBJECTIVES

The contacts between mitochondria and the endoplasmic reticulum referred as mitochondria-associated membranes (MAMs), have a crucial role in the control of liver metabolic homeostasis. Recent studies have shown that MAMs are decreased in the liver of obese mice. Metabolic dysfunction-associated steatotic liver disease (MASLD) is related to a disruption of methionine cycle, characterized by altered metabolite levels and methylation processes in the liver. We explored the effect of MASL (MASLD first stage) on the hepatic MAM proteome and methylproteome to determine whether these two elements could be connected.

METHODS

C57BL/6JOlaHsd male mice were fed either a standard diet (SD) or a high fat high sucrose diet (HFD) for 14 weeks. Liver MAMs were analyzed by transmission electron microscopy (TEM) and proximity ligation assay (PLA, VDAC1-IP3R1 close contact). Hepatic MAM fractions were isolated by differential ultracentrifugation and their proteome and methylproteome were characterized by liquid chromatography coupled to tandem mass spectrometry (LC-MS/MS). The functional analysis was performed using the Ingenuity Pathway Analysis software. The levels of liver methionine cycle metabolites were assessed by LC-MS/MS.

RESULTS

Both betaine and methionine levels were lower in HFD livers, whereas the ratio between S-adenosylmethionine and S-adenosylhomocysteine, which reflects the methylation capacity, was unchanged. The reduced number of MAMs in HFD livers was confirmed using MET and PLA. The MAM proteome analysis revealed that 163 proteins were differentially abundant (127 upregulated and 36 downregulated proteins). The functional analysis of these data showed a strong enrichment of proteins related to translation (eIF4A1, RL10A) and a decrease in proteins involved in cholesterol biosynthesis (LSS, CP51A) and xenobiotic metabolism (EST1). Interestingly, methionine cycle-related enzymes were localized to MAMs (BHMT1, MATα1, GNMT) but with a similar content. Finally, the MAM methylproteome was composed of 95 methylated proteins, including 8 proteins that were methylated either on a lysine or arginine residue with a Variable Importance in Projection (VIP) score > 1,5, which enabled identification of proteins potentially involved in the regulation of MAM integrity.

CONCLUSIONS

Alteration of methionine cycle and MAM disruption occurred concomitantly in MASL, potentially through altered methylation processes at the MAM interface. The dysregulation of key cellular pathways such as translation and cholesterol biosynthesis in hepatic MAMs reinforces the fact that MAMs are important regulatory hubs for hepatocyte function.

AKKERMANSIA MUCINIPHILA ALLEVIATES DIABETIC COGNITIVE IMPAIRMENT BY INHIBITING BRAIN NLRP3 INFLAMMASOME ACTIVATION AND HIPPOCAMPAL SYNAPTIC DEFECTS

Yanhui Lu[1]; Du Yage[1]; An Yu[2]; Cao Zhaoming[1]; Zheng Jie[1]; Xu Guangyi[1]; Wang Jingya[1]
[1]School of nursing, Peking University, Beijing, China; [2]Department of Endocrinology, Beijing Chao-Yang Hospital, Beijing, China

BACKGROUND AND OBJECTIVES

Diabetic cognitive impairment (DCI) is a chronic complication of diabetes. *Akkermansia muciniphila* (*A. muciniphila*) is a next-generation probiotic with significant development potential, shown to improve metabolic diseases, neurodegenerative disorders, and neuroinflammation. This study aims to explore the neuroprotective effects of *A. muciniphila* by inhibiting brain *NLRP3* inflammasome activation in DCI mice.

METHODS

A total of 36 healthy controls and 27 patients with DCI were enrolled to investigate the differences in the relative abundance of *A. muciniphila* in fecal samples. We established a DCI mouse model in male C57BL/6J and *NLRP3* knockout (*NLRP3*−/−) mice to investigate the effect of *A. muciniphila* intervention on neurobehavioral deficits and the underlying mechanisms.

RESULTS

The relative abundance of *A. muciniphila* was significantly reduced in patients with DCI compared to healthy controls. Supplementation with either live or pasteurized *A. muciniphila* (5×10^9 CFU/200 μL) in DCI mice improved learning and memory ability, neuroinflammation, neuronal damage, and synaptic ultrastructure. Mechanistically, either live or pasteurized *A. muciniphila* significantly reduced the ratio of *Firmicutes* to *Bacteroidetes*, the relative abundance of *Adlercreutzia* and *Desulfovibrio*, and increased the relative abundance of *A. muciniphila*, *Bifidobacterium*, *Prevotella*, and *Paraprevotella*. Further studies have shown that either live or pasteurized *A. muciniphila* significantly inhibited the activation of the *NLRP3* inflammasome in the hippocampus. *NLRP3*−/− mice showed no significant improvement in learning and memory ability, neuronal damage, and synaptic ultrastructure by live *A. muciniphila* intervention, and could not significantly inhibit the activation of the *NLRP3* inflammasome in the hippocampus.

CONCLUSIONS

Collectively, our study found that *A. muciniphila* can alleviate DCI by inhibiting brain *NLRP3* inflammasome activation and hippocampal synaptic defects, which may be one of the underlying mechanisms of neuroprotection.

BACKGROUND AND OBJECTIVES

The intestinal microbiota is recognized as a key player in developing and maintaining obesity (1). While the small intestine is a critical site for nutrient sensing and absorption, its specific alterations in obesity have been underexplored. The small intestine microbiota can significantly influence its functions, and its alteration is observed in people suffering from obesity (2). However, it remains unclear whether obesity leads to changes in the microbiota, or whether the microbiota can be modulated by dietary modifications, leading to metabolic changes (3). Studies on these issues are mainly based on mouse models. We therefore sought to investigate the role of diet in metabolomic and metagenomic changes along the digestive tract using a non-coprophagic model, pig.

METHODS

Our study involved 40 Iberian pigs, fed either a control diet or a medium fat diet (MFD), not obesogenic. After 12 weeks, the pigs were sacrificed, and bile and duodenojejunal fluid metabolomic analyses were conducted. Illumina sequencing was performed on luminal content from three segments of the small intestine and two of the large intestine. The Metaphlan4 pipeline was used to profile microbial communities. Multivariate and multidimensional models were performed to identify significant differences between diets and correlations between morphometric, biological, and “omics” data.

RESULTS

Our RESULTS reveal sex-dependent diet-induced shifts in bile and duodenojejunal fluid metabolite levels. These metabolites include p-cresol, stachydrine, or indole derivatives. These metabolic changes were associated with changes in the gut microbiota. While α-diversity (microbial diversity within groups) remained similar across the dietary groups, β-diversity (differences between groups) showed significant variation ($p \leq 0.001$). In particular, we observed a decrease in *Lactobacillus johnsonii* and an increase in *Streptococcus alactolyticus* in the 5 segments studied in pigs fed the MFD.

CONCLUSIONS

These findings underscore the interplay between dietary fat, sex-specific metabolomic responses, and intestinal microbiota composition. Diet is a key driver of metabolic and genomic changes in the gut and bile, and influences key bacterial species, highlighting the need for further analyses to explore the potential mediating role of diet in shaping male and female pig phenotypes through bile and metagenomic changes. These findings offer promising insights into the role of nutrition in metabolic disease development.

IMBALANCED VITAMIN B6 INTAKE SUPPRESSES MUSCLE HYPERTROPHY

Chanikan Bumrungkit[1]; Weizhen Zhang[1]; Noriyuki Yanaka[1]; Thanutchaporn Kumrungsee[1, 2]
[1]Food and AgriLife Science, Graduate School of Integrated Sciences for Life, Hiroshima University, Higashihiroshima, Japan; [2]Smart Agriculture, Graduate School of Innovation and Practice for Smart Society, Hiroshima University, Higashihiroshima, Japan

BACKGROUND AND OBJECTIVES

Sarcopenia is an age-related decline in skeletal muscle mass and function. Currently, no medical treatments exist for sarcopenia, with management strategies limited to nutritional and exercise interventions. Maintaining muscle mass is crucial for preventing sarcopenia, making muscle hypertrophy a key strategy. Human studies in Europe and Japan have shown an association between low vitamin B6 (B6) status and sarcopenia. Recently, we found that B6 deficiency impairs satellite cell (SC) activity and muscle regeneration. In this study, we investigated impact of B6 status on muscle hypertrophy.

METHODS

Eight-week-old male ICR mice were fed a basal diet with 1 mg (deficient), 7 mg (recommended), or 35 mg (supplemented) pyridoxine HCl per kg of diet for 8 weeks. The left tibialis anterior (TA) muscles were injured via cardiotoxin (CTX, 10 μM) injections, followed by a 28-day recovery for muscle regeneration and growth. This injury-recovery cycle was repeated to induce muscle hypertrophy. TA muscles were then isolated, weighed, and preserved for cryosections, while gastrocnemius (GAS) muscles were used for RNA extraction. Hematoxylin and eosin staining and immunofluorescence analysis assessed muscle morphology, myofiber types, and SC numbers.

RESULTS

All B6 diets had no effects on resting (uninjured) muscles. In regenerating (CTX-injured) muscles, muscle hypertrophy was significantly induced, as evidenced by a 1.4-fold increase in muscle mass; however, no significant differences were observed across all B6 groups. As compared to the 7 mg group, the 1 and 35 mg groups significantly decreased regenerating myofiber size. Additionally, the 1 and 35 mg groups significantly increased the number of small myofibers (< 1000 μm², $p < 0.01$) and decreased the number of large myofibers (> 4001 μm², $p < 0.05$). The 1 and 35 mg groups decreased type IIb myofiber percentage and increased type IIx myofiber percentage. The significant lower number of SCs was observed in the 1 mg and 35 mg groups. A significant upregulation of Atrogin1, a muscle atrophy-related gene, was observed in the 1 mg group.

CONCLUSIONS

This study suggests that both B6 deficiency and supplementation suppress muscle hypertrophy and reduce fast-twitch myofibers, possibly partly due to decreased SCs and Atrogin1 upregulation. An optimal intake of B6 is crucial for promoting muscle hypertrophy. Further work is needed to clarify the underlying mechanisms.

CERAMIDE-ENRICHED CHYLOMICRONS DERIVED FROM THE ABSORPTION OF MILK SPHINGOMYELIN INHIBIT PLATELET AGGREGATION

Catherine Calzada[1]; David Cheillan,[2, 1]; Thomas Soulié,[1]; Nina Ritsch,[1]; Marie-Caroline Michalski,[1]; Armelle Penhoat[1]

BACKGROUND AND OBJECTIVES

Dietary milk sphingomyelin (SM) showed beneficial effects on cardiometabolic health in women by decreasing serum triglycerides and some deleterious ceramide (Cer) species in intestine-derived chylomicrons. The intestinal absorption of SM implies its hydrolysis into Cer, and further into sphingosine (SPH) and fatty acids (FA), varying in chain length and degree of saturation. There is clear evidence that the digestion and the biological activities of sphingolipids depend on their acyl chains. Our objective was to study the metabolism of digestion products of SM in enterocytes and subsequently to determine the impact of secreted chylomicrons on platelet aggregation.

METHODS

Caco-2/TC7 cells cultured on permeable inserts served as a model to assess the intestinal uptake and trafficking of hydrolyzed products of SM. Mixed micelles containing different lipids and taurocholate were prepared without or with deuterated SPH (SPH-d9) and/or different FA, and applied twice to the apical side of cells. Targeted analyses of sphingolipids were performed by tandem mass spectrometry. The effects of chylomicrons, isolated from the basolateral media of cells, on the aggregation of platelets from human volunteers were investigated.

RESULTS

The enrichment of mixed lipid micelles with SPH-d9 and C23:0, one of the most abundant FA in milk SM, and their apical supply to Caco-2/TC7 cells led to increased SPH-d9, sphingosine-1-phosphate-d9 and Cer-d9 concentrations in cells, and to preferential synthesis of C23:0 Cer-d9 and its secretion in basolateral media. Resulting chylomicrons decreased collagen-induced aggregation of isolated platelets. Chylomicrons secreted from cells incubated with micelles enriched with SPH-d9 and C22:0, another abundant milk SM FA, also displayed anti-aggregant effects on platelets while those secreted from cells loaded with (SPH-d9+C16:0)-enriched micelles did not.

CONCLUSIONS

Our data indicate that micelles enriched with SPH and milk specific FA, mimicking postprandial micelles formed after milk SM ingestion, impacted enterocyte sphingolipid metabolism and Cer composition of chylomicrons, which inhibited platelet aggregation and may favorably influence metabolic health.
