PREDICTION OF GESTATIONAL DIABETES MELLITUS USING CONTINUOUS GLUCOSE MONITORING METRICS

Ling-Wei Chen[1, 2]; Chee Wai Ku[3]; Jerry Kok Yen Chan[3]; Fabian Yap; See Ling Loy[3]
[1]Institute of Epidemiology and Preventive Medicine, National Taiwan University College of Public Health, Taipei, Taiwan; [2]Master of Public Health Program, National Taiwan University College of Public Health, Taipei, Taiwan; [3]Department of Reproductive Medicine, KK Women's and Children's Hospital, Singapore, Singapore

BACKGROUND AND OBJECTIVES

Advances in continuous glucose monitoring (CGM) offer potential for early hyperglycemia detection, yet research in Asian pregnant women is scarce. We evaluated CGM metrics for predicting gestational diabetes (GDM) in this population.

METHODS

Data were from a prospective cohort of 167 participants in Singapore with ≥3 days of CGM data (18–24 weeks gestation) and GDM diagnosis via oral glucose tolerance tests (24–28 weeks gestation). Predictive performance of the CGM metrics was assessed using the area under the receiver operating characteristic (AUROC) curve, sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) in logistic regressions (20 repetitions of 5-fold cross-validation; optimal cut-points determined using Youden's index).

RESULTS

There were 30 diagnosed GDM cases (prevalence of 18%) in this study. According to the AUROC, the best-performing CGM metric was %time above 140 mg/dl (%TA140) [AUROC (95% CI): 0.86 (0.78, 0.95); cut-point: 1.23%; sensitivity: 0.80; specificity: 0.85; PPV: 0.49; NPV: 0.96]. The second and third best-performing metrics were J-index [AUROC (95% CI): 0.84 (0.75, 0.94); cut-point: 11.05; sensitivity: 0.77; specificity: 0.88; PPV: 0.55; NPV: 0.95] and standard deviation (SD) [AUROC (95% CI): 0.83 (0.75, 0.91); cut-point: 1.12 mmol/L; sensitivity: 0.77; specificity: 0.80; PPV: 0.42; NPV: 0.95]. The predictive performance of these three metrics was stronger in lean women (body mass index (BMI) <23 kg/m2; n=89) (AUROC for %TA140, J-index, SD: 0.88, 0.85, 0.86) than in women with overweight (BMI >=23 kg/m2; n=78) (AUROC for %TA140, J-index, SD: 0.74, 0.73, 0.73). AUROC for %TA140 and J-index remain >0.80 in analyses restricted to ethnically Chinese participants (n=142), whereas SD emerged as the best-performing metric for non-Chinese participants (AUROC: 0.85), albeit based on small number (n=25). In the overall population, adding CGM metrics individually to a baseline model including maternal age, BMI, job status, and ethnicity improved the AUROC from 0.62 to 0.89 (%TA140), 0.86 (J-index), and 0.86 (SD). Including all the metrics in the model simultaneously did not further improve the AUROC (0.88).

CONCLUSIONS

CGM-derived glycemic metrics, particularly %TA140, J-index, and SD, show promise as early predictors of GDM, highlighting the potential of CGM for earlier detection and management of adverse glycemic profiles during pregnancy. The observed variations in predictive performance by weight status and ethnicity warrant replication in larger, diverse populations.

REAL-WORLD CONSUMER OUTCOMES IN INDIVIDUALS SUBSCRIBED TO A PERSONALIZED NUTRITION MEAL DELIVERY PROGRAM IN FRANCE

Timothy Swartz[1]; Nouredine Farah[1]; Laurent Gendron[2]; Vincent Guillet[2]; Karine Clément[3]
[1]Research and Development, Integrative Phenomics, Paris, France; [2]Dietbon, Aliive, Neuilly-sur-Seine, France; [3]Nutrition and Obesities: Systemic Approaches, NutriOmics, Research Unit, Sorbonne Université, INSERM, Paris, France

BACKGROUND AND OBJECTIVES

Weight loss meal delivery programs are a solution offered to individuals looking for weight loss and convenience. Evidence-based personalized nutrition, using individual preferences and biological factors, provides a means to improve individual outcomes through informing consumers and recommending tailored dietary plans. Beyond clinical trials, real-world of evaluation of commercial offers using personalized nutrition is scant. Our objective was to assess the effectiveness of the first commercial offer of a weight loss meal delivery program using personalized nutrition recommendations in cardiometabolic health released in France in 2021.

METHODS

We performed retrospective analyses on real-world data from 2021 and 2022 in a subset (n = 2034) of clients with body weight data that were subscribed to a standard (n = 554) or personalized (n = 1480) weight loss meal delivery program throughout France. After centering and scaling baseline body weights, we used Linear Mixed Models to evaluate body weight trajectories over time between personalized and standard programs for men and women. Linear Mixed Models were also used to evaluate time to reach 5% body weight lost. Cox proportional hazards were used to assess the probability of achieving 5% weight loss between programs across the duration body weight data available.

RESULTS

Subscription to the personalized program was associated with significantly more weight loss over a period of 120 days compared to subscription to the standard program (significant time*program interaction, $P<0.05$ for men, $P<0.001$ for women). Complementing these findings, the average time to reach 5% body weight loss was significantly faster in the personalized group vs standard group (43.7 ± 3.3 vs 53.4 ± 3.0 days, respectively, $P < 0.05$). In both programs, weight loss measurements were available for 2 months on average (personalized: 62.2 ± 2.3 days, standard: 60.8 ± 1.4 days). Across all longitudinal body weight data available, individuals in the personalized program were 40% more likely to reach 5% weight loss compared to standard subscribers (HR: 1.40, CI: 1.03-1.91, $p < 0.05$).

CONCLUSIONS

Personalized nutrition recommendations are associated with superior short-term weight loss outcomes, which provides promise for these personalized nutrition algorithms in real-world populations and cardiometabolic disease prevention. Future analyses will focus on individual-reported outcomes, such as quality of life measurements and factors related to acceptability, which are equally important outcomes, similar to long-term weight-loss sustainability

SOAP11_07

TAILORED FOOD AS MEDICINE PROGRAM AS AN EFFECTIVE APPROACH TO IMPROVE CLINICAL OUTCOMES AMONG LOWER RESOURCE ADULTS EXPERIENCING FOOD INSECURITY AND HYPERTENSION

Alison Gustafson[1]; Carolyn Lauckner[1]
[1]Dietetics and Human Nutrition, University of Kentucky, Lexington, United States of America

BACKGROUND AND OBJECTIVES

Food is medicine programs have shown to be effective at reducing blood pressure among adults experiencing food insecurity and have gained increased attention as a way to address social determinants of health. However, many of the studies have focused on comparing food is medicine programs to either standard of care or to another program offering while not considering the user experience, preferences, and resource constraints of the participant. Our study developed a screening decision tool which allocates participants based on preferences and resource constraints and allows for the user to be part of the decision-making process. The aims of this study are to: 1) Examine the use of a screening decision tool for allocation into food is medicine programs; 2) Determine effect of the FIM program on primary outcomes of blood pressure (systolic and diastolic); and 3) Determine effect of FIM programs on secondary outcomes of quality of life, dietary intake, nutrition security, and food security.

METHODS

Two large hospital systems in Kentucky, one rural and one urban, screened patients for food insecurity over 45-days. Patients who met eligibility criteria of being food insecure, ages 18-64, and having a diagnosis of hypertension were referred to the team for informed consent and baseline survey. After consent a further screening decision tool was given to patients related to preferences and resource constraints. A total of =N159 completed enrollment; N= 115 allocated into grocery Rx programs and N=43 allocated to medically tailored meals and N=1 allocated to grocery Rx online.

RESULTS

Among those who participated in the medically tailored meal program there was a reduction in systolic blood pressure (-9.82mmHg) and diastolic (-6.82mmHg) from pre and post intervention. Among those who participated in the grocery prescription program there was a reduction in systolic blood pressure (-6.72mmHg) and diastolic (-2.34mmHg) from pre and post intervention. Secondary outcomes indicated an overall reduction in food security, increased intake of 1 serving size of fruits and vegetables combined, and increase in quality of life.

CONCLUSIONS

Tailoring a food is medicine program to user preferences and constraints is a preferred method to improve clinical outcomes among food insecure adults. Clinical and community partners conducting food is medicine programs need to tailor efforts based on user preferences and needs for clinically meaningful RESULTS.

NAVIGATING DIETARY ADVICE AND ILEOSTOMY: INSIGHTS FROM PATIENTS AND HEALTHCARE PROFESSIONALS

Niamh Magee[1]; Ellen E.a. Simpson[2]; Kirsty Pourshahidi[1]; Pauline Douglas[1]; Chris Gill[1]
[1]NICHE, School of Biomedical Sciences, Ulster University, Coleraine, United Kingdom; [2]School of Psychology, Ulster University, Coleraine, United Kingdom

BACKGROUND AND OBJECTIVES

Ileostomy surgery is a life-changing operation which impacts approximately 64 000 people in the UK (1) and necessitates significant dietary change in the first 6-8 weeks post-surgery (2). Dietary restrictions are often sustained for many months, or even years after an ileostomy (3, 4). Challenges with accessibility and inconsistency of dietary support often contribute to this (5). Consequently, this study aimed to understand the provision and implementation of dietary advice for ileostomates.

METHODS

A qualitative study using semi-structured interviews. Ileostomates (>8 weeks post-surgery) and healthcare professionals (HCPs) (stoma nurses and dietitians) were eligible to take part. People and Public Involvement informed the interview structure; questions covered experiences of pre- and post-operative (short and long-term) advice. Interviews were audio/ video recorded, and transcribed verbatim prior to thematic analysis (6).

RESULTS

For the ileostomate group (n=13), inflammatory bowel disease was the most common reason for surgery (n = 8) and post-operative duration ranged from 4 months – 30 years. HCP participants (n=12) were predominantly dietitians (n=7, 58%) and / or based in an acute hospital setting (n=9, 75%). From a pre-operative perspective, emergent themes demonstrated the need for increased support at this timepoint. This was emphasised by both groups and echoed post-operatively where follow-up was lacking. HPCs identified staffing shortage and limited finances as major barriers to improving services and patient care. Dietary advice emphasises “foods to avoid,” which is reflected in the dietary restrictions implemented by ileostomates in the weeks, months, and years post-surgery. During the first 6-8 weeks post-operative, reassurance from HCPs and support from family were crucial for ileostomates in adapting their diet. Following the early post-operative period, where external support was absent, peer support (from other ileostomates) and self-discovery were imperative in coping with dietary management of their stoma. Conflicting advice regarding symptom management – particularly management of high output stoma – was a major barrier to dietary reintroduction and a source of distress for ileostomates and HCPs.

CONCLUSIONS

This study provides a comprehensive understanding of the dietary support available to ileostomates from a dual perspective and highlights a need for improvements in the services offered. These findings will contribute to evidence-based practices for HCPs and offer practical solutions to optimise person-centred care.

SOAP11_13

ADULTS WITH COELIAC DISEASE LIVING GLUTEN FREE: INFLUENTIAL SOURCES OF DIETARY INFORMATION

Humayun Muhammad[1]; Ruksar Nishat[1]; Katie Kennedy[2]; Cristian Costas-Batlle[3]; Nick Trott[4]; Yvonne Jeanes[5]
[1]School of Life and Health Sciences, University of Roehampton, UK, London, UK, United Kingdom; [2]Dietitian, Dr Schär UK Ltd, Birchwood Park, United Kingdom; [3]Nutrition and Dietetics Department, Bradford Teaching Hospitals NHS Foundation Trust, Bradford, United Kingdom; [4]Gastroenterology, Sheffield Teaching Hosptitals NHS Foundation TRust, sheff, United Kingdom; [5]School of Life and Health Sciences, University of Roehampton, UK, London, United Kingdom

BACKGROUND AND OBJECTIVES

Coeliac disease (CD) affects 1% of the global population [1]. Gluten Free (GF) diet is the only treatment for people living with CD, widely recognised to be challenging, especially when eating out of the home environment [2]. Access to healthcare professionals (HCPS) is limited and alternative sources of information are used to enable people to live GF [3].

Study Aim: Determine key sources of dietary information beyond healthcare professionals.

METHODS

A survey was designed to collect patient demographics and key GF dietary information sources, the online survey link (Jisc) was distributed by email and social media during Summer 2024. SPSS software was used for data analysis.

RESULTS

Data from 675 adults with CD completed the online survey (82% female; 95% white; 98% living in the UK). The majority (88%) report symptoms on gluten ingestion, 84% were diagnosed for >1year and 51% were current members of coeliac patient support charity [5]. The majority (84%) reported following a strict gluten-free diet.

Sources of useful information and misinformation on gluten free diet.

Information Source	Very/ Extremely useful	Received/ Accessed missinformation
Coeliac UK charity	74%	4%
Person with CD	61%	20%
Cookbooks	55%	7%
Internet	52%	32%
Socia media	48%	31%
Healthcare professionals		
Dietitian	51%	9%
Gastroenterologist	35%	8%
General Doctor	15%	18%

Half of participants (n=356) used social media at least 1/week, of these 64% found it to be very/ extremely useful for providing information on new GF foods, 61% for GF recipes and 59% for travelling or eating out GF.

CONCLUSIONS

https://doi.org/10.1017/jns.2026.10126 Published online by Cambridge University Press

The internet and social media is widely used by adults with CD to live well GF, however there is a high proportion of misinformation. HCPs need to continue creating high quality digital content to support instantly accessible dietary information for living gluten-free.

CONFLICTS OF INTERESTS

KK is employed by a company that manufactures gluten free products.

SOAP11_14

IMPACT OF MEDITERRANEAN DIET ON PROCOAGULANT ACTIVITY OF ENDOTHELIAL MICROPARTICLES

Rosa Casas[1]; Ana Maria Ruiz-León,[1]; Dolors Tassies[2]; Emilio Sacanella[1]; Cristina Sierra[1]; Jose Naval[1]; Olga Rodriguez[1]; Ramon Estruch[1]
[1]Internal Medicine, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [2]INST.CL.MALALTIES HEMATO-ONCOLÒGIQUES, Hospital clinic de Barcelona, Barcelona, Spain

BACKGROUND AND OBJECTIVES

Microparticles play a role in vascular injury observed in cardiovascular disease. The Mediterranean diet (MedDiet) pattern is increasingly considered due to its cardioprotective effects because of the bioactive compounds contained in of this pattern (e.g., olive oil or its polyphenols). The aim was to investigate the impact of an intensive weight loss intervention with an energy-reduced Mediterranean diet (eMedDiet) and physical activity promotion in preventing cardiovascular disease in adults with metabolic syndrome (MetS) on microparticle procoagulant properties.

METHODS

One hundred thirty-two older adults with overweight/obesity and MetS (49% females, mean age 67.8 ± 4.2 years) were studied in the framework of the PREDIMED-Plus study. At baseline and after 1-year intervention, microparticle procoagulant activity was determined using ZymuphenTM MP-ACTIVITY according to the manufacturer's protocol. Thrombin activity was measured by absorbance at 405 nm on a spectrophotometer following cleavage of a specific substrate. Plasma microparticle concentration was expressed in nM of phosphatidylserine (PS) equivalent.

RESULTS

After 12-months, microparticle concentration (nM PS) increased from 15.7 ± 1.0 to 24.7 ± 2.5 ($p < 0.001$) and from 17.1 ± 1.1 to 29.5 ± 1.5 ($p < 0.001$) in eMedDiet and control group, respectively. The difference between changes was lower in the eMedDiet group (-4.8 ± 2.2) with a significant P-interaction (Pint=0.042).

CONCLUSIONS

Increases in eMedDiet microparticle release and its procoagulant activity were significantly lower than those observed in the control group after 12 months of intervention.

SOAP 17 - PRECISION AND CLINICAL NUTRITION

SOAP17_02

EFFECT OF A LOW CHO/HIGH PROTEIN BREAKFAST COMPARED TO A CONTROL BREAKFAST ON GLYCEMIC RESPONSE IN PREGNANT WOMEN WITH GESTATIONAL DIABETES: A RANDOMIZED CROSSOVER STUDY

Lissette Duarte[1]; Veronica Sambra[1]; Nathalie Llanos[1]; Gladys Gonzalez[2]; Jeannette Cornejo[2]; Ana Claudia Villarroel[2]; Ignacia Castro[3]; Stefania Castillo[3]
[1]Departamento de Nutricion, Universidad de Chile, Santiago, Chile; [2]Endocrinologia, Clinica Santa Maria, Santiago, Chile; [3]Escuela de Nutricion, Universidad de Chile, Santiago, Chile

BACKGROUND AND OBJECTIVES

Gestational diabetes mellitus (GD) is a glucose intolerance leading to hyperglycemia that is diagnosed during pregnancy (1). The amount and type of carbohydrate (CHO) ingested affects glycemia; the current recommended amount of CHO in GD is 175 g, or ~35% of a 2000 kcal diet (2). There is no evidence on how CHO intake should be distributed throughout the day. One of the meals with the highest postprandial hyperglycemia is breakfast, due to more pronounced insulin resistance at this time of day. Whether a low CHO but high protein intake at breakfast is beneficial has not yet been studied.

Objective: to compare the effects of a breakfast low in CHO and high in protein (10% of daily CHO and 30% of daily protein) with a control breakfast (25% of daily CHO and 15% of daily protein) on postprandial glycemia in women with GD.

METHODS

Randomized crossover clinical trial with 7 women diagnosed with GD with normal nutritional status, overweight or obese and without pharmacological treatment for GD. Each participant was her own control, receiving two different types of breakfasts: a low CHO/high protein breakfast (10% of the day's CHO and 30% of the day's protein) and a control breakfast (25% of the day's CHO and 15% of the day's protein). Each breakfast was consumed in two independent but continuous 3-day periods, with a 1-day washout period in between. Participants remained on continuous glucose monitoring throughout the trial and performed capillary glycemia measurement at fasting and at 30, 60, and 120 min after breakfast intake. Data were analyzed by Paired T test and repeated measures ANOVA test.

RESULTS

Participants were on average 37 +/-3.8 years old and had a BMI of 27.7 +/-5.4 kg/m². The control breakfast caused statistically higher glycemia at 30 and 60 minutes ($p<0.05$). None of the breakfasts exceeded the glycemic range of 63 -140 mg/Dl recommended for pregnant women with GD. The low CHO/high protein breakfast showed a statistically lower area under the incremental glycemic curve than the control breakfast ($p<0.05$).

CONCLUSIONS

A low CHO/high protein breakfast significantly reduced glycemia at 30 and 60 minutes. These RESULTS suggest that adjusting the macronutrient distribution at breakfast could be an effective strategy to improve glycemic control in these women, especially in the prevention of postprandial hyperglycemia.

SOAP17_03

IMPROVING NUTRITIONAL STATUS AMONG HIV-POSITIVE CAMBODIAN CHILDREN: IMPACT OF A FISH-BASED READY-TO-USE THERAPEUTIC FOOD ON WEIGHT GAIN AND MICRONUTRIENT AND POLYUNSATURATED FATTY ACID STATUS

Sanne Sigh[1]; Nanna Roos[1]; Chamnan Chhoun[2]; Arnaud Laillou[3]; Frank T. Wieringa[4]
[1]Department of Nutrition, Exercise, and Sports, University of Copenhagen, Frederiksberg Campus, Frederiksberg, Denmark; [2]Department of Fisheries Post-Harvest Technologies and Quality Control, Fisheries, Phnom Cambodia; [3]Department of Child Survival and Development, UNICEF Cambodia, Phnom Penh, Cambodia; [4]UMR-204, Institut de Recherche pour le développment/Université Montpellier/SupAgo, IRD, Montpellier, France

BACKGROUND AND OBJECTIVES

Severe acute malnutrition (SAM) in children with human immunodeficiency (HIV) is common, due to higher requirements and reduced intakes, but data on the impact of ready-to-use therapeutic foods (RUTFs) on anthropometry and nutrient status are scarce. We aimed to assess effectiveness of RUTFs in the treatment of SAM among 0.5-18-year-old HIV-positive Cambodian children.

METHODS

The present study is a secondary analysis using a sub-sample (35 HIV-positive children) from a larger trial on the impact on nutritional status of a locally produced fish-based RUTF (NumTrey) or standard milk-based RUFT (BP-100TM) consumed over an 8-week period. During a single-blinded randomised intervention, nutritional status and health markers were assessed through anthropometric assessment and serum biomarkers for inflammation and micronutrient biomarkers. Whole-blood fatty acids were analysed using dried blood spots. The trial was conducted at the National Paediatric Hospital, Phnom Penh, Cambodia.

RESULTS

Mean age of the children was 11.4 years, who received on average 56 days of treatment. *In the intention-to-treat analysis the estimated weight gain with BP-100T*M *was 4.78 g/kg/day;* 95% CI (-6.9, 16.4), while for *NumTrey, the weight gain was 3.71 g/kg/day*; 95% *CI* (-13.0, 20.4) (*P<0.05)*. Haemoglobin (*p*=0.029), CRP (*p*= 0.047), and AGP (*p*=0.002) concentrations were significantly lower at discharge than at admission. There was no statistical change over the treatment period in ferritin, sTfR, body iron, or RBP concentrations, although the prevalence of iron and vitamin A deficiency declined from 3% to 0% and from 6% to 4% respectively (P<0.05). On the contrary, statistically significant increases in marginal vitamin A deficiency and anaemia prevalence were found (P<0.05). Whole-blood Mead acid was significantly reduced to 0.06±0.03 FA% (*p*=0.001). Total n-6 PUFA's remained the same, while a significant reduction in DPA (22:5n-6) was found (from 0.3 FA% to 0.2 FA%, *p* = 0.010). A minor non-significant increase in total n-3 PUFA was found, while non-statistically significant reduction was found for DPA n-6/DHA, n-6/n-3 PUFA ration and EPA+DHA.

CONCLUSIONS

This sub-sample analysis show positive effects on weight gain for both RUTFs during SAM treatment of HIV-positive children, but the limited impact on micronutrients and fatty acids status requires further investigation.

CONFLICTS OF INTERESTS
The authors have no conflict of interest.

BACKGROUND AND OBJECTIVES

The management of chronic constipation remains challenging, with high rates of treatment dissatisfaction. Current clinical guidelines offer limited dietary recommendations, and there is a lack of evidence-based guidelines for the dietary management of chronic constipation. The aim of this project was to develop the first comprehensive evidence-based dietary guidelines for the management of chronic constipation in adults.

METHODS

The scope of the guidelines included dietary supplements, foods, drinks, and whole diets in adults with chronic constipation. Four systematic reviews and meta-analyses were performed to identify eligible randomised controlled trials (RCTs) (1-4). The findings generated from the meta-analysis of RCTs were then used to develop guideline statements using the Grading of Recommendations, Assessment, Development and Evaluation (GRADE) approach and a Delphi consensus survey among a multi-disciplinary expert steering committee. Recommendation statements were produced for treatment response, stool output, gut symptoms, adverse events, and quality of life, and only based on the findings where ≥2 RCTs contributed to the meta-analysis. The “strength of recommendation” was assessed using the GRADE approach. Consensus voting amongst the expert steering committee was performed using a modified Delphi survey approach.

RESULTS

The four systematic reviews included a total of 75 RCTs (1-4). Fifty-nine dietary recommendation statements were generated and accepted through the Delphi survey. In terms of dietary supplements, 15 recommendation statements related to fibre supplements, 20 related to probiotics, 2 to synbiotics, 5 to magnesium oxide, 2 to senna, and 3 to kiwifruit supplements. In terms of foods, 3 recommendation statements related to kiwifruits, 2 to prunes, and 2 to rye bread. In terms of drinks, 5 recommendation statements related to high mineral-containing water. No recommendations were made for whole diet approaches due to lack of evidence. Ten statements had a very low level of evidence, 41 had low level of evidence, and 8 had moderate evidence. Twenty-seven statements were strong recommendations and 32 were qualified recommendations.

CONCLUSIONS

These are the first comprehensive evidence-based dietary guidelines for the management of constipation based upon robust systematic review and GRADE processes. Recommendations were made for dietary supplements, foods and drinks that have never been previously included in clinical guidelines, and can now be rapidly implemented into clinical practice.

EATING HABITS AND SPECIFIC FOODS AND THEIR ASSOCIATION WITH GASTROINTESTINAL SYMPTOMS IN PATIENTS WITH FUNCTIONAL DYSPEPSIA AND IRRITABLE BOWEL SYNDROME

Sanna Nybacka[1]; Esther Colomier,[1]; Ines Trindade[2]; Joost Algera[1]; Hans Törnblom[1]; Stine Störsrud[1]; Magnus Simren[1]
[1]Department of Molecular and Clinical Medicine, University of Gothenburg, Gothenburg, Sweden; [2]Center for Health and Medical Psychology (CHAMP), Örebro Universitet, Örebro, Sweden

BACKGROUND AND OBJECTIVES

Among patients with functional bowel disorders (FBD), food intake is a known symptom trigger and dietary modifications are encouraged as a first line treatment. Here, we aimed to explore if certain eating habits are associated with gastrointestinal (GI) symptoms, and which specific foods are identified as triggers of GI symptoms among participants with functional dyspepsia (FD), irritable bowel syndrome (IBS), and a control group without bowel symptoms.

METHODS

An online survey was conducted including n=825 Swedish women and men aged 18-70 years who had at least one bowel symptom at the frequency threshold (Rome IV criteria) for defining an FBD. An age- and sex-matched control group without bowel symptoms was recruited from the general Swedish population (n=1738). The survey included questions on demographics, dietary preferences, eating speed, liquid intake during meals and meal frequency per day. An in-house created food frequency questionnaire that assesses intakes of 38 commonly consumed food items was used. For each food, participants had to answer whether they considered the specific food to be a trigger for GI symptoms. IBS symptom severity was assessed with the IBS severity scoring system (IBS-SSS).

RESULTS

In total, n=159 fulfilled Rome IV criteria for FD and n=136 for IBS, hereafter referred to as patients. Adhering to any special diet was more common in patients compared to controls ($p<0.001$). The controls reported drinking less liquids during mealtime compared to patients with FD ($p=0.027$). Among patients, neither eating speed, liquid intake during meals, nor the number of eating occasions per day was significantly associated with IBS symptom severity. Foods that were least commonly reported to cause GI symptoms in patients included hard bread, fish, berries, and seeds. The most frequently reported food triggers include pizza, crisps, ice cream, white bread, and dairy. Having overlapping IBS and FD increased the prevalence of foods that were considered to cause symptoms.

CONCLUSIONS

In this cross-sectional study, no associations with eating patterns and GI symptoms were noted. In patients with FD and IBS, food items associated with a healthy Nordic diet were less commonly reported to cause GI symptoms, whereas junk foods were more commonly reported to cause GI symptoms. Promoting healthy food choices seems compatible with dietary treatment of patients with FD and IBS.

HOW DOES THE USE OF BIOELECTRICAL IMPEDANCE SPECTROSCOPY VS CALF-CIRCUMFERENCE IMPACT THE MALNUTRITION DIAGNOSIS ACCORDING TO THE GLOBAL LEADERSHIP INITIATIVE ON MALNUTRITION (GLIM) IN PATIENTS WITH CHRONIC KIDNEY DISEASE?

Mikaela Dietrichson[1]; Ylva Orrevall,[2, 3]; Karin Windahl,[4, 5]; Jenny Stenberg,[6]; Harriët Jager-Wittenaar,[7, 8, 9]; Sandra Einarsson,[1]
[1]Department of Food, Nutrition and Culinary Science, Umeå University, Umeå, Sweden; [2]Clinical Nutrition, Medical Unit Women's Health and Allied Health Professionals Theme, Karolinska University Hospital, Solna, Sweden; [3]Department of Medicine, Karolinska Institutet, Huddinge, Sweden; [4]Division of Renal Medicine, Department of Clinical Intervention and Technology, Karolinska Institutet, Stockholm, Sweden; [5]Division of Clinical Nutrition and Dietetics, Department of Orthopedics, Danderyds Hospital, Stockholm, Sweden; [6]Department of Medical Sciences, Uppsala University, Uppsala, Sweden; [7]Research Group Healthy Ageing, Allied Health Care and Nursing, Hanze University of Applied Sciences, Groningen, Netherlands; [8]Department of Gastroenterology and Hepatology Dietetics, Radboud university medical center, Nijmegen, Netherlands; [9]Department Physiotherapy, Human Physiology and Anatomy, Vrije Universiteit Brussel, Brussels, Belgium

BACKGROUND AND OBJECTIVES

Malnutrition is considerably prevalent in chronic kidney disease (CKD), with higher prevalence in later stages of CKD. The Global Leadership Initiative on Malnutrition (GLIM) is a framework designed to diagnose malnutrition in adults. Since its release in 2019, the framework has gained broad acceptance both in research and clinical practice. Studies that address how the five criteria of GLIM should be applied in different populations, with special attention to the phenotypic criterion ‘reduced muscle mass’, are needed. The aim was to investigate how different ways of operationalizing and measuring the phenotypic criterion reduced muscle mass influence the GLIM diagnosis in patients with CKD treated with hemodialysis.

METHODS

This is a cross-sectional study where recruitment of patients with CKD was conducted at a university hospital in Sweden during August-September of 2024. Patients who were ≥18 years of age, with hemodialysis treatment >3 months and who were able to understand and give written consent were included. Collection of data is ongoing and will be available in the spring of 2025. Data are collected from medical records and from the Swedish Renal Registry. All five GLIM criteria will be assessed for all participants: weight loss, low BMI, reduced muscle mass (phenotypic criteria), as well as reduced food intake/assimilation and inflammation/disease burden (etiologic criteria). Presence of at least one phenotypic and at least one etiologic criterion will set the diagnosis. Muscle mass will be assessed by bioelectrical impedance spectroscopy (BIS) and calf circumference.

RESULTS

In total, 97 patients were screened for eligibility and 69 of 74 eligible patients (43 men and 26 women, mean age 66.6 ±14.6 years) gave their written consent and were included. Mean time on dialysis was 48.9 ± 48.1 months (min 3.7, max 198.8). RESULTS on how the prevalence of malnutrition according to GLIM differs per muscle assessment method will be presented at the congress.

CONCLUSIONS

The findings will contribute to increased understanding on how the phenotypic criterion reduced muscle mass should be applied when using GLIM in patients with CKD treated with hemodialysis.

GINSENOSIDE RB1 DECREASES TOTAL CHOLESTEROL AND APOLIPOPROTEIN A IN PATIENTS WITH HYPERCHOLESTEROLEMIA: A RANDOMIZED DOUBLE-BLIND PLACEBO CONTROLLED TRIAL

Jiazhi Lu[1]; Huiyu Luo[1]; Fei Xiong[2]; Xin Li[1]; Xiangyi Zheng[3]; Qing Li[4]; Longying Zha[1]
[1]Department of Nutrition & Food Hygiene, School of Public Health, Southern Medical University, Guangzhou, China; [2]Department of Clinical Nutrition, Zhujiang Hospital, Southern Medical University, Guangzhou, China; [3]Department of Health Management Medicine, Guangzhou Panyu District Rehabilitation Hospital, Guangzhou, China; [4]Department of Clinical Nutrition, Nanfang Hospital, Southern Medical University, Guangzhou, China

BACKGROUND AND OBJECTIVES

Ginsenoside Rb1 is one of the major bioactive ingredients of ginseng and exhibits a variety of bioactivities. However, the lipid-lowering efficacy of ginsenoside Rb1 in human remains controversial. This study aimed to investigate the effect of ginsenoside Rb1 on lipid profiles in patients with hypercholesterolemia by using a randomized double-blind placebo controlled trial (RCT).

METHODS

A total of 124 patients diagnosed with hypercholesterolemia (total cholesterol (TC)≥5.2 mmol/L) were recruited in the 8-week RCT (Registration number: ChiCTR2400086584). Participants were randomly assigned to the placebo (starch and cellulose) and ginsenoside Rb1 (oral ingestion of 200 mg/d) group (n=62 each) with maintaining double blind to both researchers and participants. The primary outcome measure TC and the secondary outcome measures including triglycerides (TG), high-density lipoprotein cholesterol (HDL-C), low-density lipoprotein cholesterol (LDL-C), apolipoprotein A (APOA), apolipoprotein B (APOB), fasting blood glucose (FBG), fasting insulin (FINS), and liver and kidney function indicators in blood were determined at baseline, 4w and 8w.

RESULTS

At baseline and 4 w, there was no significant difference (p>0.05) in any lipid or glucose metabolism parameters between the two groups. At 8 w, TC was significantly reduced by 0.24 mmol/L (95% CI: -0.44 to -0.04; p=0.019) and APOA decreased by 0.06 mmol/L (95% CI: -0.11 to -0.01; p=0.023) in the ginsenoside Rb1 group. No difference (p>0.05) was found in TG, HDL-C, LDL-C, APOB, FBG or FINS between the two groups. In addition, no liver or kidney damage was observed during the trial period.

CONCLUSIONS

Ginsenoside Rb1 supplementation for 8 w reduces TC and APOA in patients with hypercholesterolemia, suggesting its efficacy in lowering cholesterol.

SOAP17_12

CROSS-SECTIONAL ASSOCIATIONS BETWEEN SATURATED FAT INTAKES FROM MEAT, DAIRY AND DESSERTS AND BIOMARKERS AND METABOLITES OF CARDIOMETABOLIC RISK IN THE UK BIOBANK COHORT STUDY

Lourdes Chavez-Alfaro[1]; Jennifer Carter[2]; Carolina Carvalho[3]; Marta Guasch-Ferre[4]; Aurora Perez-Cornago[5]; Carmen Piernas[1]
[1]Department of Biochemistry and Molecular Biology II, University of Granada, Granada, Spain; [2]Nuffield Department of Population Health, University of Oxford, Nuffield, United Kingdom; [3]Public Health Department, Federal University of Maranhão, Maranhão, Brazil; [4]Department of Public Health, Section of Epidemiology, Novo Nordisk Foundation Center for Basic Metabolic Research, University of Copenhagen, Copenhagen, Denmark; [5]Joint Research Centre (JRC), European Commission, Ispra, Italy

BACKGROUND AND OBJECTIVES

Red and processed meats are significant sources of saturated fatty acid (SFA), which compared with other food sources of SFA, can have potentially negative impacts on cardiometabolic (CM) health. This study aimed to classify participants in the UK Biobank based on their consumption of three primary dietary sources of SFA – dairy, red/processed meats, and desserts – and examine cross-sectional associations with biomarkers and metabolites of CM risk.

METHODS

Detailed dietary data from at least two 24-h online dietary assessments was used for a sample of n=107,758 participants. Participants were classified using their average daily consumption (g/day) of food groups as mostly consuming 1) Dairy (n=10,516), 2) Red/processed meat (n=26,438), 3) Desserts (n=46,425) or 4) combinations of those (n=24,379). CM related biomarkers, such as LDL-C, HDL-C, triglycerides (TAG), apolipoprotein A (ApoA), apolipoprotein B (ApoB), lipoprotein(a), glucose, HbA1c, C-reactive protein (CRP), as well as metabolomic analyses were determined using fasting blood samples. Multivariable linear regressions were used to estimate geometric means (95% CIs) of biomarkers according to SFA group, adjusted for demographic, lifestyle, and dietary confounders.

RESULTS

Participants in the red/processed meat group showed significantly higher levels of LDL-C (3.64 mmol/L, 95%CI 3.63 to 3.65), compared with the dairy (3.56 mmol/L, 95%CI 3.55 to 3.58) or the desserts group (3.62 mmol/L, 95%CI 3.62 to 3.63). Similar patterns were observed in other biomarkers, with significant lower levels of HDL-C and ApoA, and significantly higher levels of TAG, ApoB and CRP in the red/processed meat group compared with the dairy group. People in the desserts group also showed significantly positive associations with TAG and CRP compared with the dairy group.

CONCLUSIONS

Intake of different food sources that contribute the most to dietary SFA show small albeit significantly different levels of several cardiometabolic biomarkers. Whilst people consuming more dairy foods show favorable or neutral associations with HDL-C and ApoA, people consuming more red/processed meat and desserts show significantly higher levels of lipid, glycemic, and inflammatory markers which reflect a more adverse CM profile. These findings emphasize the importance of targeting specific SFA sources in dietary recommendations to improve cardiometabolic health.

SOAP17_13

ASSOCIATIONS BETWEEN DIETARY PATTERNS, GUT MICROBIOME DIVERSITY, AND ITCH SEVERITY IN PRESCHOOL AGED CHILDREN WITH ATOPIC DERMATITIS: A CROSS-SECTIONAL STUDY

Jing Yan[1, 2]; Jisu Park[1, 2]; Soo Jin Lee[1]; Hyemee Kim[1]; Minyoung Jung[3]
[1]Department of Food Science and Nutrition, Pusan National University, Busan, Korea, Republic of; [2]BK21 FOUR Program : Precision Nutrition Program for Future Global Leaders, Pusan National University, Busan, Korea, Republic of; [3]Department of Pediatrics, Kosin University Gaspel Hospital, Busan, Korea, Republic of

BACKGROUND AND OBJECTIVES

Atopic dermatitis (AD) is a common chronic inflammatory skin disease that significantly affects the quality of life, physical health, and psychological well-being of young children. In recent years, diet-gut microbiota-disease hypothesis for AD has been studied in infancy, but its implications for preschool-aged children remain less understood. This study aims to investigate the relationships among dietary patterns, gut microbiota, and disease severity in Korean preschoolers.

METHODS

This study included 97 Korean preschool children aged 3–6 years, comprising 46 with atopic dermatitis (AD) and 51 healthy controls. Dietary intake was assessed using a validated Food Frequency Questionnaire (FFQ), and dietary patterns were analyzed through factor analysis of the FFQ. AD severity was assessed using EASI, SCORAD and CDLQI scores. Gut microbiota composition was characterized using 16S rRNA sequencing. Spearman correlation analysis was conducted to examine the relationships between dietary patterns, nutrient intake, gut microbiota, and AD symptoms.

RESULTS

Through factor analysis of food group, Q1 (Traditional Korean Diet Pattern) and Q2 (Processed Food and Snack Pattern) were identified. AD-Q2 diet had lower vitamin C intake compared to those on the AD-Q1 diet (p=0.011). *Dorea* and *Anaerostipes* were more prevalent in the AD-Q2 group (LDA score: 3.4 and 3.9, respectively). The AD-Q2 group also reported significantly poor CDLQI and high nighttime itching compared to the AD-Q1 group (p=0.032 and 0.041, respectively). Insufficient intake of vitamin C was significantly associated with increased EASI and SCORAD (r=-0.52, p=0.03; r=-0.41, p=0.045, respectively), whereas the presence of *Dorea* and *Anaerostipes* also positively correlated with itching.

CONCLUSIONS

In preschool children with AD, the Processed Food and Snack dietary pattern was associated with increased disease severity, potentially mediated by *Dorea* and *Anaerostipes* abundance and vitamin C deficiency, impacting the gut environment and inflammation pathways.

SOAP17_14

EFFECTS OF A HIGH-FIBER DIET AND MODERATE-INTENSITY EXERCISE ON THE GUT MICROBIOTA OF CHILDREN: A RANDOMIZED CONTROLLED TRIAL

Zhengxiao Zhang[1]; Mingyue Yang,[1]; Edward C. Deehan,[2]; Eytan Wine[3]; Karen L. Madsen,[4]; Chenxi Cai,[5]
[1]College of Ocean Food and Biological Engineering, Jimei University, Xiamen, China; [2]Department of Food Science and Technology, University of Nebraska, Lincoln, United States of America; [3]Department of Pediatrics, University of Alberta, Edmonton, Canada; [4]Department of Medicine, University of Alberta, Edmonton, Canada; [5]School of Public Health, Xiamen University, Xiamen, China

BACKGROUND AND OBJECTIVES

Altering lifestyle behaviors to modulate gut microbiota has emerged as a potential strategy for preventing chronic diseases including obesity. However, several clinical findings have shown that the regulating effects of lifestyle on gut microbiota were inconsistent and challenging to sustain. This study aimed to evaluate the synergistic regulatory effects of nutrition and exercise on the gut microbiota in children, and to determine the factors influencing the personalized microbial response.

METHODS

We conducted a 14-weeks four-arm randomized controlled trial with 205 children aged 7-11 years, to assess the effects of a diet high in dietary fiber (HFD, n = 49, 15 g/day), moderate-intensity interval training (MIIT, n = 46, 75 min/week), and the combination of MIIT and HFD (MED, n = 50) on gut microbiota composition and SCFAs production, compared to the control group without treatment (Control, n = 49).

RESULTS

Compared to the Control and the single treatment groups (HFD and MIIT), the MED group consistently and significantly elevated the levels of fecal acetate and butyrate by 14 weeks treatment ($p < 0.05$). The subjects' baseline microbiota compositions and physical activity status could predict acetate (ROC-AUC = 0.72) and butyrate (ROC-AUC = 0.78) individualized response in MED group. Subgroup analysis further found that high-fiber diet and exercise interventions exert different modulatory impact on gut microbiota in overweight and obese children compared to normal weight children. For instance, the *Prevotella*/*Bacteroides* ratio in overweight and obese children significantly increased in all three treatments ($p < 0.05$). For normal weight children, the autoimmune diseases associated taxon *Sutterella* dramatically decreased in the MED group ($p < 0.0001$).

CONCLUSIONS

This study confirmed the synergistic effects of exercise and high-fiber diet on gut microbiota functional improvements, as well as identified the key factors contributing to the individualized regulatory efficacy of distinct lifestyle interventions. Thus, providing evidence for the development of precise lifestyle strategies to beneficially modulation the gut microbiota in children.

SOAP 44 - PRECISION AND CLINICAL NUTRITION

SOAP44_01

DEVELOPMENT OF A MINIMAL INVASIVE METHODOLOGY FOR DIABETYPING DURING THE TRADITIONAL ORAL GLUCOSE TOLERANCE TEST (OGTT) AND A MODIFIED OGTT TO PERSONALIZE TYPE 2 DIABETES TREATMENT

Kristel Kamstra[1]; Sanne Haanstra[1]; Dagmar Smid[1]; Tim Van Den Broek[1]; Willem Van Den Brink[1]; Suzan Wopereis[1]
[1]Healthy Living & Work, TNO - Locatie Leiden, Leiden, Netherlands

BACKGROUND AND OBJECTIVES

Research shows that different tissue-specific insulin resistant phenotypes exist in persons with type 2 (pre)diabetes ((pre)T2D). These diabetypes have different efficacy to nutritional interventions, requiring a precision nutrition strategy [1,2]. Simultaneously, digital-first strategies are gaining traction to reduce participant burden, speed up recruitment, increase study population diversity and capture real-world data. Diabetyping, the methodology to subtype persons with (pre)T2D, is based on an extended oral glucose tolerance test (OGTT), which is invasive, often causing nausea, and needs to take place in a clinical setting. Therefore, we aim to develop minimally invasive alternatives of diabetyping.

METHODS

In this observational study, 17 out of the expected 57 people with overweight/(pre)T2D used a continuous glucose monitor (CGM) for 20 days and underwent three mornings of measurements: one traditional OGTT (sugar water solution drink) and two times a modified OGTT in which a standardized snack (two pieces of a gingerbread based snack, ‘Snelle Jelle’, naturel 65 gram) after an overnight fast were consumed. Continuously measured subcutaneous glucose, as well as glucose, insulin, and c-peptide via venous as well as via capillary at home sampling was collected. Agreement analyses were used to compare the different measurement methods, and the traditional and modified OGTT. Interim analysis of CGM as alternative sampling method during the traditional and modified OGTT was evaluated.

RESULTS

Preliminary RESULTS of glucose, insulin, and c-peptide venous and CGM glucose values of the traditional and modified OGTT all showed a large deviation for all timepoints (MARD > 10%). This also RESULTS in a significantly poor agreement between CGM and venous diabetyping during the traditional OGTT (κ=0.206, z=2, p=0.046) and modified OGTT (k=0.325, z=3.06, p=0.002). However, a significant moderate agreement between the traditional OGTT and the modified OGTT with venous sampling was found (κ=0.432, z=3.95, p=7.89e-05).

CONCLUSIONS

Based on preliminary RESULTS the modified OGTT with venous sampling shows potential as an alternative to the traditional OGTT. With the use of the modified OGTT complaints such as nausea, caused by the sugary drink, could be prevented. Current diabetyping cut-off values, based on traditional OGTT venous measurements, may require adaptation for CGM use. Further analysis on multiday CGM data for diabetyping as minimally invasive alternative are planned.

SOAP44_02

A REAL-WORLD ANALYSIS OF CLINICAL OUTCOMES IN PATIENTS USING SEMAGLUTIDE 2.4 MG FOR 12 MONTHS

Melissa Akerib[1]; Aleksandrina Ruseva[2]; Wojciech Michalak[2]; Anthony Fabricatore[2]; Briain O Hartaigh[2]; Zhao Zhenxiang[2]; Devika Umashanker[3]
[1]Medical Affairs, Novo Nordisk, Puteaux, France; [2]Novo Nordisk, Novo Nordisk, Plainsboro Township, United States of America; [3]Hartford, Hartford HealthCare Medical Group, Hartford, United States of America

BACKGROUND AND OBJECTIVES

Real-world effectiveness data for semaglutide 2.4 mg are limited. Changes in weight and cardiovascular risk factors among US patients with obesity or overweight treated with semaglutide 2.4 mg compared to those not treated with any anti-obesity medications (AOMs) were assessed.

METHODS

This retrospective study used the Komodo Research dataset and included adults with obesity or overweight, with ≥1 obesity-related comorbidity, who initiated semaglutide 2.4 mg after June 15, 2021, escalated to 2.4 mg and remained on treatment for 12 months. Reductions in weight and improvement in cardiovascular risk factors, such as systolic blood pressure (SBP), diastolic blood pressure (DBP), glycated hemoglobin (HbA1c), triglycerides (TG), low-density lipoprotein cholesterol (LDL-C) and high-density-lipoprotein cholesterol (HDL-C) were assessed compared to the non-treated cohort in the same period. Outcomes were compared between 1:4 propensity-score matched cohorts using generalized linear models adjusted for any residual imbalance.

RESULTS

At 12 months, patients treated with semaglutide 2.4 mg (n=410) had a greater reduction from baseline in weight vs non-treated cohort (n=1708) (estimated treatment difference [ETD]: −15.11%), and a greater odds of achieving weight reductions of ≥5% (odds ratio [OR]: 44.7), ≥10% (OR: 59.9) and ≥15% (OR: 48.9); all p<0.001. From baseline to 12 months, ETD (semaglutide 2.4 mg vs non-treated cohorts) was: −4.4 kg/m2 (n=1000 vs n=3351) for BMI; −6.0 mmHg (n=349 vs n=1477) for SBP; −2.7 mmHg (n=348 vs n=1480) for DBP; −0.6% (n=86 vs n=481) for HbA1c; −33.6 mg/dL (n=57 vs n=273) for TG; all p<0.001. Changes in LDL-C (n=53 vs n=252) and HDL-C (n=59 vs n=284) were −3.4 mg/dL and 0.4 mg/dL, respectively, with no statistical significance. Sample size for each biomarker varied based on availability.

CONCLUSIONS

Compared to the non-treated cohort, treatment with semaglutide 2.4 mg was associated with a greater reduction in body weight and in some cardiovascular risk factors at 12 months.

CHICORY INULIN REDUCES SYMPTOMS OF FUNCTIONAL CONSTIPATION AND IMPROVES SOCIAL AND EMOTIONAL WELL-BEING OUTCOMES OF QUALITY OF LIFE IN A RANDOMIZED CONTROLLED TRIAL

Marie-Luise Puhlmann[1]; Carrie A. M. Wegh[1]; Sofie Van Der Zalm[2]; Veerle Dam[3]; Doolan Doolan[4]; Diederick Meyer[3]; Clara Belzer[1]; Elaine Vaughan[3]; Marc A. Benninga[5]; Hauke Smidt[1]
[1]Laboratory of Microbiology, Wageningen University & Research, Wageningen, Netherlands; [2]Division of Human Nutrition and Health, Wageningen University & Research, Wageningen, Netherlands; [3]Health Science & Regulatory Affairs, Sensus (Royal Cosun), Roosendaal, Netherlands; [4]Atlantia Clinical Trials, Atlantia Clinical Trials, Cork, Ireland; [5]Emma Children's Hospital, Amsterdam UMC, Amsterdam, Netherlands

BACKGROUND AND OBJECTIVES

Functional constipation is a disorder of the gut-brain interaction (DGBI) characterized by infrequent bowel movements and hard stools, a diagnosis based on patients reported symptoms, and their interference with daily life. This disorder substantially affects patients' quality of life, who also seek non-pharmacological treatment. Thereby this study investigated supplementation with gut microbiome-targeted inulin which may be a promising alternative based on its documented impact on bowel habit1 and microbiota, and potentially the brain2.

METHODS

In a randomized, double-blind, placebo-controlled, cross-over trial, we investigated the effect of four-week daily 12g inulin intake compared to a placebo maltodextrin in 39 individuals with functional constipation according to Rome III Criteria. We assessed stool frequency and consistency, constipation-related quality of life (PAC-QOL) and symptoms (PAC-SYM)3, and stool microbiota composition using 16S rRNA gene sequencing.

RESULTS

In the cross-over analysis we observed that inulin intake increased stool frequency with 0.53 (0.26) p=0.046 defecations per week compared to placebo, though not stool consistency. This was concurrent with improvements in PAC-QOL (-0.41 (0.15), p=0.007) and PAC-SYM (-0.35 (0.15), p=0.022), compared with placebo. There was an increase in the relative abundance of known butyrate-producing bacterial genera in the stool microbiota. Further investigation indicated a carry-over effect, whereby half of those receiving inulin in the first period had a remarkable placebo response in the second period. These participants had the largest improvements in all outcomes during inulin intake, and higher baseline and wash-out relative abundances of butyrate producing bacteria, and lower but more responsive *Bifidobacterium* spp.. To address this carry-over bias, we analyzed only the first period as a parallel trial which confirmed the positive effect of inulin on bowel habit, PAC-QOL, PAC-SYM, and affirmed its bifidogenic effect. Improvement in social and emotional well-being scores were consistent across both the cross-over and first period analyses while absent during placebo for both sequences, indicating a genuine effect of inulin intake.

CONCLUSIONS

This cross-over study confirmed inulin as promising nonpharmacological treatment for functionally constipated patients by increasing stool frequency and modifying microbiota. It improved constipation-related quality of life, social-emotional well-being and abdominal symptoms. Future trials targeting the gut microbiome should consider the carry-over effect.

SOAP44_06

ASSOCIATION BETWEEN MILK CONSUMPTION AND THE PREVALENCE OF SARCOPENIA FROM NHANES 2011-2018

Ao Shen[1]; Xin Yu[1]; Wenghao Wan[1]; Hengyu Zhou[1]; Ying Cai[1]
[1]School of nursing, Chongqing Medical University, Chongqing, China

BACKGROUND AND OBJECTIVES

Sarcopenia has the potential to result in a deterioration in quality of life. It has been determined that nutrition plays a critical role in both the prevention and treatment of the condition. However, most people find it difficult to accurately measure the nutrients in their daily diet and therefore prefer nutrient-rich foods such as milk, which may contribute to the maintenance of healthy bones and muscles. Nevertheless, the optimal choice of milk, whether whole, low-fat, or skimmed, for individuals with sarcopenia remains unclear and requires further investigation.

METHODS

We used the data from the National Health and Nutrition Examination Survey (NHANES) 2011-2018 and included participants with complete milk questionnaire data and who underwent dual-energy X-ray absorptiometry (DXA) scans. Meanwhile, we employed the definition and diagnostic criteria for sarcopenia as established by the Foundation for the National Institutes of Health (FNIH). Three statistical METHODSwere used to assess the correlations, including weighted multivariate logistic regression, subgroup analysis and cox proportional hazards models.

RESULTS

A total of 8292 participants were included in this study, and 750 (9.0%) people were classified as having sarcopenia with aged 43±11.5. To avoid overfitting, least Absolute Shrinkage and Selection Operator (Lasso) was used before logistic regression. We observed that 1% fat milk was significantly linked with the lower risk of sarcopenia (OR 0.68, 95% CI 0.03-0.75, P=0.037< 0.05). According to subgroup analysis stratified by gender, body mass index (BMI), and age, the significant relationship between 1% fat milk and sarcopenia remained in the age (≥40 years) group, and the BMI (＞24.9 kg/m2) group ($p < 0.05$). Among individuals with sarcopenia, 19 experienced all-cause mortalities. Following adjustment for confounding variables, it was observed that soy milk consumption was associated with an increased all-cause mortality rate among sarcopenia patients ($p < 0.05$).

CONCLUSIONS

Moderate fat intake is necessary to maintain muscle health, while a high-fat diet can trigger chronic inflammation, which is a risk factor for sarcopenia. And our study indicates that patients with sarcopenia should take in 1% or lower-fat milk instead of whole milk and soy milk.

SOAP44_07

CAGRISEMA TARGETS AND ACTIVATES KEY CNS REGIONS INVOLVED IN APPETITE REGULATION IN RATS

Melissa Akerib[1]; Sofia Lundh[2]; Anna Secher[3]; Rune Kuhre Ehrenreich[2]; Wouter Hogendorf[4]; Joakim Holck Andersen[4]; David Ipsen[2]; Marina Kjærgaard Gerstenberg[5]; Kirsten Raun[2]
[1]Medical Affairs, Novo Nordisk, Puteaux, France; [2]Global Drug Discovery, Novo Nordisk A/S - site Måløv, Måløv, Denmark; [3]Global drug discovery, Novo Nordisk, Søborg, Denmark; [4]Global Research Technologies, Novo Nordisk A/S - site Måløv, Måløv, Denmark; [5]Global Translation, Novo Nordisk A/S - site Måløv, Måløv, Denmark

BACKGROUND AND OBJECTIVES

CagriSema, a combination of long-acting analogues of GLP1 (semaglutide) and amylin (cagrilintide), is in clinical development for treatment of obesity and type 2 diabetes. CagriSema leads to a greater weight loss than either monotherapy, both believed to contribute to central nervous system (CNS)-mediated suppression of appetite. To explore the actions of CagriSema in CNS, we investigated drug distribution in whole rat brains using 3D imaging, followed by more detailed analyses on regional distribution and neuronal activation.

METHODS

Chow fed male rats were dosed with fluorescently labelled semaglutide or cagrilintide (VT750 and AF488; 100 nmol/kg I.V) and euthanized at several different timepoints after administration. Drug distribution was visualized and quantified in whole rat brains using 3D imaging of direct fluorescence, or in 2D brain sections using indirect anti-AF488 immunohistochemistry (IHC) to allow for combined *in situ* hybridization and IHC of target receptors. Acute neuronal activation was assessed in dorsal vagal complex (DVC) using cFos IHC after administration of unlabelled drug alone or in a combination (10 nmol/kg each, S.C).

RESULTS

Labelled cagrilintide and semaglutide distributed in a time dependent manner to similar regions of the CNS, such as the circumventricular organs, the mediobasal hypothalamus, the DVC in the hindbrain, and the septum. The drug distribution overlapped largely with receptor expression of the respective targets (Glp1r and Calcr) in areas of access, but the spatial expression pattern of the receptors differed slightly. Distribution of cagrilintide and semaglutide to DVC was associated with drug induced neuronal activation in this region.

CONCLUSIONS

Cagrilintide and semaglutide target key regions in the rat CNS that regulate appetite. Both Glp1r and Calcr are expressed in the regions directly targeted by either drug but display some notable differences in expression pattern. This highlights the potential complimentary mechanisms and the value of targeting both biological systems simultaneously with CagriSema.

SOAP44_09

GASTROINTESTINAL INFLAMMATION IS ASSOCIATED WITH SYSTEMIC INFLAMMATION AND GUT SYMPTOMS IN FEMALE UNIVERSITY TEAM SPORT PLAYERS

Marlizé Louw[1]; Arista Nienaber,[1]; Yolandi Willemse[2]; Jana Storm[2]; Zuma Zoleka[1]; Lize Havemann-Nel[1]; Mary A. Uyoga[1]; Linda Malan[1]
[1]Centre of Excellence for Nutrition, North-West University, Potchefstroom, South Africa; [2]Centre for Health and Human Performance, North-West University, Potchefstroom, South Africa

BACKGROUND AND OBJECTIVES

Female high-performance athletes frequently experience exercise-induced gastrointestinal syndrome (EIGS) which is characterised by gastrointestinal (GI) and systemic inflammation with unwanted GI symptoms, affecting health, quality of life, and sport performance (1,2). Data on the GI inflammatory markers used to identify EIGS and the related GI symptoms are lacking in high-performance female team sport players. This study aimed to measure GI inflammation and integrity markers and to determine their association with systemic inflammation, GI symptoms, and fitness levels in female university team sport players.

METHODS

This cross-sectional study included 69 university female team sport players from soccer (23%), netball (31%), and hockey (44%) teams. Plasma GI and systemic inflammatory markers at rest were analysed with the Q-Plex Human Environmental Enteric Dysfunction Quansys immunoassay including intestinal fatty acid binding protein (I-FABP), fibroblast growth factor-21 (FGF-21) and cluster of differentiation 14 (sCD14), alpha-1-acid glycoprotein (AGP), and C-reactive protein (CRP). Fitness level was determined with a three-minute aerobic test (VO2 max). GI symptoms in the seven days before the study were determined and categorised using a five-point severity Lickert scale. Associations between GI and systemic inflammatory markers, symptoms, and fitness level were tested with a partial Pearson correlation, Spearman correlation, multivariable linear regression, and independent t-tests. Ethical clearance was obtained from the Health Research Ethics Committee.

RESULTS

Of the players, 32%, 23%, and 96% had a resting plasma I-FABP, FGF-21 and sCD14 respectively above the average 90th percentile reported in other athletic populations (3-8). AGP was above the reference range of 1 g/L in 78% of players. Resting sCD14 positively correlated with CRP ($p = 0.048$) and AGP ($p < 0.001$). 48% of players reported at least one GI symptom in the 7 days before data collection, most frequently bloating (29%), abdominal noise (23%), flatulence (15%), and eructation (13%). Resting sCD14 was higher in players with heartburn ($p = 0.049$) and positively correlated with heartburn severity ($p = 0.028$). The player's VO2 max did not significantly correlate with resting GI inflammation markers.

CONCLUSIONS

Resting sCD14 was elevated and associated with chronic low-grade systemic inflammation (elevated AGP) and heartburn in high-performance university female team sport players. Strategies to lower GI inflammation and associated systemic inflammation and GI symptoms can be investigated to contribute to female athlete health.

SOAP44_10

ISOTOPIC MEASUREMENT OF IRON ABSORPTION AND LOSS AND THE EFFECT OF IRON SUPPLEMENTATION WITH AND WITHOUT PREBIOTICS IN SOUTH AFRICAN CHILDREN WITH VIRALLY-SUPRESSED HIV: FINDINGS FROM THREE PROSPECTIVE STUDIES

Jeannine Baumgartner,[1]; Renée Blaauw[2]; Nadja Mikulic[3]; Charlene Goosen[2]; Shaun Barnabas[4]; Mark Cotton[4]; Michael Zimmermann,[5]
[1]Department of Nutritional Sciences, King's College London, London, United Kingdom; [2]Division of Human Nutrition, Stellenbosch University, Cape Town, South Africa; [3]Laboratory of Human Nutrition, ETH Zurich, Zurich, Switzerland; [4]Family Centre for Research with Ubuntu (FAMCRU), Stellenbosch University, Cape Town, South Africa; [5]RDM Investigative Medicine, MRC Weatherall Institute of Molecular Medicine (Oxford University & John Radcliffe Hospital), Oxford, United Kingdom

BACKGROUND AND OBJECTIVES

Children living with HIV are often iron-deficient. This may be due to impaired iron absorption, which could increase dietary iron requirements and blunt efficacy of iron interventions. We compared iron absorption from different iron interventions and the habitual diet between children with and without HIV. We further determined whether providing prebiotic galacto-oligosaccharides (GOS) as adjunct treatment to oral iron supplementation improves efficacy and safety of oral iron in iron-deficient children with HIV.

METHODS

We performed three prospective studies in South Africa. In Study 1, we compared fractional iron absorption (FIA) from isotopically-labelled iron-fortified maize porridge, a lipid-based nutrient supplement (LNS) and an oral iron supplement in iron-deficient children with (n=43) vs without (n=45) HIV. In Study 2, using a novel isotope dilution method, we quantified habitual dietary iron absorption and losses over 6 months in children with (n=29) and without (n=36) HIV. Study 3 was a 12-week randomised, double-blind trial of oral iron (50mg/day) given with 7.5g GOS or placebo in iron-deficient children with HIV (n=86), with serum ferritin as primary outcome.

RESULTS

Comparing children with vs without HIV: in Study 1, median (IQR) FIA from porridge, LNS and oral iron were 7.6% (3.8,12.8) vs 10.5% (6.1,13.1) (P=0.23), 5.6% (3.6,10.2) vs 6.4% (4.3,9.1) (P=0.92) and 26.0% (16.0,33.3) vs 24.8% (19.2, 30.3) (P=0.82); in Study 2, dietary iron absorption (mg/d) was 1.09 (0.82,1.32) vs 1.44 (0.85,2.06) (P=0.041), iron losses were 0.80 (0.43,1.13) vs 0.78 (0.58,1.57) (P=0.089), and iron gains were 0.33 (-0.01,0.71) vs 0.41 (0.04,0.89) (P=0.773). In Study 3, children receiving iron with GOS had 33% higher ferritin (P=0.053) and greater gut integrity (P=0.088), and a lower incidence of fever (P=0.058) and rhinorrhoea (P=0.018) but no significant differences in gut inflammation or abundances of enteropathogens.

CONCLUSIONS

Compared to children without HIV, children with virally-suppressed HIV have low-level inflammation and lower habitual dietary iron absorption. However, their ability to absorb iron from supplements and fortificants is comparable to children without HIV, and they do not show increased gastrointestinal iron losses. Therefore, oral iron should be effective in iron-deficient children with HIV, and providing iron with GOS may improve its efficacy and safety.

BACKGROUND AND OBJECTIVES

Semaglutide, a glucagon-like peptide-1 (GLP-1) receptor agonist, reduced the rates of cardiovascular (CV) death, myocardial infarction and stroke in patients with high CV risk and overweight or obesity but without diabetes. We sought to determine the impact of semaglutide on total hospital admissions and duration of hospital stay, in any indication.

METHODS

SELECT compared the effect of treatment with semaglutide 2.4 mg and placebo weekly on CV events in 17,604 patients aged ≥45 years with established CV disease, with body mass index (BMI) ≥27 kg/m2 and without diabetes. Hospital admissions and days in hospital, for any indication, in both treatment groups were evaluated.

RESULTS

Patients (age 61.6±8.9 years, 72.3% male, BMI 33.3±5.0 kg/m2) were followed for a mean of 39.8±9.4 months. The percentage of patients with a first hospital admission was lower in the semaglutide group for any indication (33.4 vs 36.7%, hazard ratio [HR] 0.89 [0.84, 0.93], p<0.0001) and for serious adverse events (30.3 vs 33.4%, HR 0.88 [0.84, 0.93], p<0.0001). The number of total hospitalisations was lower in the semaglutide group for all indications (18.3 vs 20.4 admissions per 100 patient years, HR 0.90 [0.85, 0.95], p=0.0002) and for serious adverse events (15.2 vs 17.1 admissions per 100 patient years, HR 0.89 [0.84, 0.94], p<0.0001). The number of days hospitalised per 100 patient years was lower in the semaglutide group for all hospitalisations (157.2 vs 176.2 days, risk ratio [RR] 0.89 [0.82, 0.98], p=0.01) and hospitalisations for serious adverse events (137.6 vs 153.9 days, RR 0.89 [0.81, 0.98], p=0.02). No statistical treatment heterogeneity was observed for the reduction in hospital admissions with semaglutide on selected subgroups including BMI, age and gender.

CONCLUSIONS

This cohort had a high rate of admissions. Treatment with semaglutide 2.4 mg once weekly resulted in significant reductions in hospital admissions and overall time spent in hospital, extending the benefits beyond those of CV events.

CALCIUM METABOLISM IN HEALTHY MEN AND WOMEN IN RESPONSE TO DIETARY SALT: A RANDOMIZED CROSSOVER TRIAL

Sisi Cao[1]; Christina Vialva,[1]; Shirin Hooshmand[1]; Mark Kern[1]; Gina Woods[2]; Scott Roesch[3]; Connie Weaver[1]
[1]School of Exercise and Nutritional Sciences, San Diego State University, San Diego, United States of America;
[2]School of Bone Densitometry, University of California, San Diego, San D, United States of America;
[3]Department of Psychology, San Diego State University, San Diego, United States of America

BACKGROUND AND OBJECTIVES

Previous research showed that Black adolescent girls retain more calcium and excrete less urinary sodium compared to their white counterparts when consuming a high sodium diet. However, the influence of dietary salt on calcium absorption efficiency and excretion across racial, sex, and age groups remains poorly understood. This study's objective was to compare subgroup differences in fractional calcium absorption, as well as 48-hour urinary sodium and calcium excretion in response to a low- and high-salt diet in healthy young diverse adults.

METHODS

This 2-phase crossover trial included 64 healthy persons aged 18-35, equally distributed among four race groups (White, Black, Hispanic/Latino, and Asian) with an equal number of men and women in each group (n=16 per race). Participants were randomly assigned to consume controlled diets for two days, with either low (2300 mg/Na/day) or high salt levels (3700 mg/Na/day). Fractional calcium absorption was assessed using dual calcium isotopes (Ca-44 oral and Ca-43 intravenous) measured by Inductively Coupled Plasma-Mass Spectrometry (ICP-MS). Two twenty-four-hour urine samples were collected on each diet and urinary calcium and sodium excretion was quantified using ICP-Optical Emission Spectrometry (ICP-OES). Data were analyzed using a mixed-model ANOVA by SPSS.

RESULTS

Salt intake increased urinary sodium excretion but did not alter calcium metabolism on average. No sex differences were found, but Black adults excreted less urinary calcium than White adults.

CONCLUSIONS

These findings suggest that the racial differences in calcium and sodium retention in response to dietary salt previously reported in the Black and White adolescent girls was not explained by differences in calcium absorption in racially diverse young adults.

SOAP07_01

ENHANCED BIOACCESSIBILITY AND ANTI-INFLAMMATORY EFFECTS OF PHLOROTANNINS FROM ECKLONIA CAVA THROUGH IN VITRO DIGESTION AND FERMENTATION

Qunzhe Wang[1, 2]; Hyemee Kim[1]
[1]Department of Food Science and Nutrition, Pusan National University, Busan, Korea, Republic of; [2]BK21 FOUR Program : Precision Nutrition Program for Future Global Leaders, Pusan National University, Busan, Korea, Republic of

BACKGROUND AND OBJECTIVES

Phlorotannins (PTs), a class of polyphenols known for their notable anti-inflammatory properties, remain underexplored in terms of bioaccessibility. This study utilized an in vitro digestion and fermentation model to investigate the transformation of phlorotannins in *Ecklonia cava* (EC) and their associated anti-inflammatory effects.

METHODS

In vitro static digestion models simulated human gastrointestinal processes, followed by anaerobic fermentation using gut microbiota-derived from human fecal samples. LC-MS/MS quantified phenolic extracts from different digestive stages. Effects of PT-derived metabolites were evaluated using RAW 264.7, Caco-2, and Jurkat cells through ELISA, RT-PCR, and Western blotting to analyze changes in anti-inflammatory properties across digestive stages and assess modulation of the AhR pathway. Gut microbiota composition was examined using PCR.

RESULTS

RESULTS demonstrated that free PTs exhibited the highest retention in the stomach, which decreased to 10.75% after small intestinal digestion but increased to 25.34% following colonic fermentation. In contrast, the release of bound PTs declined during digestion but increased 2.6-fold after fermentation compared to digestion alone. LC-MS/MS analysis revealed that dieckol was the dominant phenolic compound in undigested EC and gastric digestion stages, whereas phlorofucofuroeckol A and eckstolonol were prevalent during intestinal digestion and colonic fermentation. Bound PTs exhibited superior bioactivity due to microbial conversion into smaller, bioactive compounds and significantly enhanced the abundance of Lactobacillus and Bifidobacterium, demonstrating strong prebiotic effects. Comparative experiments between raw PT extracts and PT-derived metabolites revealed that the metabolites significantly enhanced the expression of tight junction proteins ZO-1, Occludin, and Claudin in Caco-2 cells. Additionally, the metabolites more effectively reduced anti-inflammatory markers in RAW 264.7 cells. In Jurkat cells, the metabolites activated the AhR/IL-22/STAT3 pathway, further confirming their superior bioactivity.

CONCLUSIONS

These findings highlight that bound forms of PT enhance bioaccessibility and underscore the pivotal role of microbial fermentation in amplifying the anti-inflammatory effects of PTs. This study provides insights for developing functional foods and supplements targeting anti-inflammatory benefits and gut health.

SOAP07_03

EFFECTS OF WHOLE MEAL SOURDOUGH BREAD WITH OR WITHOUT BAKER'S YEAST ON APPETITE, ENERGY INTAKE, AND POSTPRANDIAL METABOLIC RESPONSES: A RANDOMIZED, BLINDED, CROSS-OVER STUDY

Georgia Chatonidi[1]; Riet Rosseel[1]; Boushra Dalile[2]; Dina Satriawan[1]; Greet Vandermeulen[1]; Bram Van Holm[3]; Luke Comer[4]; Piet Maes[3]; Nadia Everaert[4]; Christophe Courtin[5]; Kristin Verbeke[1]
[1]Translational Research in GastroIntestinal Disorders, KU Leuven, Leuven, Belgium; [2]Laboratory of Biological Psychology, Research Unit Brain & Cognition, KU Leuven, Leuven, Belgium; [3]Laboratory of Clinical and Epidemiological Virology, Rega Institute, Leuven, Belgium; [4]Nutrition and Animal Microbiota Ecosystems Lab, KU Leuven, Leuven, Belgium; [5]Laboratory of Food Chemistry and Biochemistry, KU Leuven, Leuven, Belgium

BACKGROUND AND OBJECTIVES

Bread is a staple carbohydrate source in Europe, and wholemeal varieties may provide better metabolic responses and greater satiety compared to white bread. This study aimed to evaluate the effects of wholemeal bread leavened with either baker's yeast (WYB), sourdough (WSB), or a combination of both (WSYB) on appetite control and metabolic outcomes in healthy individuals.

METHODS

In a double-blind, randomized crossover trial, 44 healthy participants (25 ± 4 years, BMI: 22 ± 2 kg/m²) consumed 180 g of each type of bread daily for two weeks, separated by a 2-week washout period. Participants reported their usual food intake and provided faecal samples for microbiota analysis. On the final day of each intervention, participants ate 100 g of the test bread for breakfast. Measurements included oral processing, gastric emptying, postprandial glucose, C-peptide, appetite, and hormonal responses. The primary outcome was ad-libitum energy intake at the following lunch.

RESULTS

There were no differences in ad-libitum energy intake at lunch following the consumption of the test breads. However, WYB and WSYB were consumed more slowly than WSB, leading to slightly higher satiety ($p < 0.05$). WSYB increased C-peptide levels, WYB elevated PYY, and both WSB and WYB stimulated higher GLP-1 release ($p < 0.05$). No significant differences were observed in gastric emptying, glucose responses, ad-libitum energy intake, habitual energy intake, cholesterol levels, or gut microbiota composition ($p > 0.05$).

CONCLUSIONS

Although there were small differences in some metabolic responses, the findings suggest that wholemeal bread leavened with baker's yeast and/or sourdough have similar effects on appetite regulation.

SOAP07_04

THE IMPACT OF OMEGA-3 FATTY ACIDS ON MESENTERIC AND PERIPANCREATIC ADIPOSE TISSUE DEPOTS DURING MURINE PANCREATIC CARCINOGENESIS

Aya Ead,[1]; Joanna Wirkus[1]; Gerardo Mackenzie[1]
[1]Nutrition, University of California, Davis, Davis, United States of America

BACKGROUND AND OBJECTIVES

Preclinical and epidemiological studies have shown that high-fat diets (HFD), high in saturated fatty acids (FA), can promote pancreatic cancer development. However, the type of fat is crucial in modulating tumor growth. Since adipose tissue is recognized as a significant contributor to cancer growth, we examined the impact of HFDs with different omega-6 to omega-3 FA ratios on pancreatic cancer development and analyzed the roles of mesenteric adipose tissue (MAT) and peripancreatic adipose tissue (PPAT)

METHODS

To study the impact of early high omega-3 FA diet intervention, we conducted an initial short-term study on cohorts of male and female *KrasLSL-G12D/+; Ptf1aCre/+* (KC) mice that were randomly assigned to a high-fat diet (HFD) with an omega-6: omega-3 FA ratio of 10:1 or a high fat, high omega-3 fatty acid diet (HFHO) with an omega-6: omega-3 FA ratio of 1:1 (matched at 60% kcals from fat), and fed their diets during eight weeks. Then, to study the effects of a dietary switch in the context of obesity, cohorts of male and female KC mice were fed a HFD with an omega-6: omega-3 FA ratio of 10:1 during 8 weeks. Then, half the of the mice remained on the HFD while the other half underwent a dietary switch to a HFHO diet. Mice were fed these diets for an additional 13 weeks.

RESULTS

KC mice fed a HFHO diet early on, during the first eight weeks, showed significant reductions in pancreas and MAT weights, pancreatic acinar-to-ductal metaplasia, cell proliferation, and adipocyte size. They also had increased MAT M2 macrophage populations compared to mice fed a HFD. When a diet high in omega-3 FA was introduced after obesity induction and continued for 13 weeks, we observed significant differences in body weight gain, fat mass, and increased serum adiponectin, in HFHO-fed mice compared to HFD-fed mice. Additionally, HFHO diet induced sex-dependent changes in PPAT metabolites, with female KC mice showing significant differences in saturated and monounsaturated FAs. Furthermore, HFHO-fed mice exhibited reduced pancreatic acinar-to-ductal metaplasia compared to mice fed a HFD throughout the entire period. However, no differences in cell proliferation or cancer incidence were observed between the HFD and HFHO groups.

CONCLUSIONS

Omega-3 FA can only partially counteract the effects of a HFD on the pancreas and adipose tissue. This mitigating effect is more pronounced in mice before they develop obesity. Further studies are needed to understand how specific metabolites in adipose tissue might prevent or promote pancreatic cancer.

SOAP07_05

INVESTIGATION OF THE EFFECTS AND MECHANISMS OF LYCOPENE ON NON-ALCOHOLIC FATTY LIVER DISEASE BASED ON THE FXR/FGF21-MEDIATED HEPATIC-ADIPOSE AXIS

Jing Sui[1, 2]; Beijia Zhou[1]; Wang Ying[1]; Guiju Sun[1]; Hui Xia[1]
[1]Department of Nutrition and Food Hygiene, School of Public Health, southeast university, Nanjing, China; [2]Research Institute for Environment and Health, Nanjing University of Information Science and Technology, nanjing, China

BACKGROUND AND OBJECTIVES

Non-alcoholic fatty liver disease (NAFLD) is associated with lipid metabolism disorders that primarily occur within the hepatic-adipose axis. Lycopene may regulate hepatic and adipose lipid synthesis and fatty acid oxidation pathways through the Farnesoid X Receptor (FXR)/Fibroblast Growth Factor 21 (FGF21) signaling, improving lipid deposition in both the liver and adipose tissues, and thereby slowing the progression of NAFLD.

METHODS

This study investigates the effects and underlying mechanisms of lycopene on NAFLD from a nutritional perspective, with a focus on the maintenance of lipid metabolic homeostasis within the hepatic-adipose axis. Using high-fat diet-induced C57BL/6J mice, a fatty acid-induced NAFLD model, and a co-culture system of hepatic and adipose cells, this research systematically explores the regulatory impact of lycopene on lipid metabolism in the hepatic-adipose axis via the FXR/FGF21 pathway.

RESULTS

The RESULTS show that lycopene intervention significantly improves serum and hepatic lipid metabolism in NAFLD mice, with histopathological analysis revealing a marked reduction in hepatic lipid accumulation following lycopene treatment. Lipidomic analysis indicates that lycopene primarily downregulates the levels and types of triglycerides (TG) and diglycerides (DG) in the liver. Lycopene upregulates the expression of FXR, FGF21, PPAR-α, and AMPK in the livers of NAFLD mice, while downregulating the gene and protein expression of SREBP-1C and FAS. Additionally, lycopene increases the expression of FGF21 and PPAR-γ in adipose tissues. In vitro co-culture studies further reveal that lycopene enhances the expression of FGF21, PPAR-γ, and ADIPO proteins in AmL12 cells, with protein levels increasing in a dose-dependent manner. This effect is mediated through the modulation of FGF21, PPAR-γ, and ADIPO expression in adipocytes, which in turn elevates FGF21 levels in AmL12 cells and decreases CD36, SREBP-1, and FAS protein levels. Transfection with SiFXR RESULTS in a significant reduction in FXR and FGF21 protein expression, demonstrating that downregulation of FXR expression in AmL12 cells reduces FGF21 protein levels.

CONCLUSIONS

Overall, this study confirms that lycopene improves NAFLD through the interaction of FXR and FGF21 within the hepatic-adipose axis.

SUGAR SWEETENED BEVERAGE INTAKE, PHYSICAL ACTIVITY AND NUTRITIONAL STATUS OF SCHOOL CHILDREN IN KAMPALA, UGANDA

Robert Fungo[1]
[1]Food Technology and Nutrition, Makerere University , Kampala, Uganda

BACKGROUND AND OBJECTIVES

Despite the increase in non-communicable diseases (NCDs), there is increased production and consumption of sugar sweetened beverages (SSBs) among school going children making them susceptible to develop NCDs leading to early onset of morbidity which is of public health concern.

METHODS

This cross sectional study investigated SSB consumption, nutritional status, physical activity level and correlates of SSB intake among primary school children age 9-13 year in Kampala city. The association between variables were established via Chi-square.

RESULTS

Overweight and obesity are on the rise and account for 26.4% among the respondents. RESULTS showed a significant association ($P \leq 0.05$) between dietary diversity and nutritional status. More than half of the pupils did not meet the WHO recommended vigorous physical activity level of at least 75 minutes per week. About 63% and 94% of the respondents respectively had consumed soda and locally sweetened beverages at least once in 24 hours. For the majority of the pupils, parents/guardians were responsible for buying the SSB consumed (55.2%) and deciding on the type of SSB to be carried to school (56.3%). There were also significant associations ($p \leq 0.05$) between consumption of SSBs and nutritional status, physical activity and parents buying the SSBs and influence.

CONCLUSIONS

Most pupils did not achieve the levels of physical activity recommended. Consumption of SSBs is positively associated with overweight and obese, physical activity and parents influencey. Efforts should be made to promote physical activity participation and good dietary practices within school and home environments.

SOAP07_07

NUTRITIONAL EFFECTS OF SPIRULINA LIQUID EXTRACT ON PLASMA PARAMETERS AND FATTY ACID AND GLUCOSE LIVER METABOLISMS IN SEDENTARY AND MODERATE RUNNING MALE WISTAR RATS

Jordi Vignaud[1]; Céline Loiseau[1]; Martine Côme[1]; Isabelle Martin[1]; Josiane Hérault[1]; Claire Mayer[1]; Olivier Lépine[2]; Lionel Ulmann[1]
[1]BiOSSE - Biologie des Organismes, Stress, Santé, Environnement, Le Mans University, Laval, France; [2]Algosource, Algosource, Guérande, France

BACKGROUND AND OBJECTIVES

It is well-recognized that moderate physical activity is a beneficial factor in the prevention of lipid and carbohydrate metabolism disorders (Myers et al., 2019). Another way to prevent the onset of diseases such as diabetes or obesity is to use food supplements rich in hypolipidemic or antioxidant molecules (Bonetti et al., 2022). The use of *Spirulina*extracts, rich in phycocyanin which is an antioxidant molecule has been able to show its effectiveness on the regulation of lipid and glucose metabolism parameters (Kasbi-Chadli et al., 2021). The objective of this work was to combine the effects of a *Spirulina* liquid extract (SLE) with moderate running activity in order to search a potentiation of these two factors on plasma and hepatic parameters related with fatty acid and glucose metabolisms.

METHODS

Three week-old male Wistar rats were fed a control diet (SAFE A04). Four groups were determined: a sedentary control group (C), a sedentary group supplemented with SLE (SLE), a group with moderate activity (T) and a group with moderate activity and supplemented with SLE (T-SLE). After 8 weeks of nutritional monitoring and treadmill running, rats were euthanized and plasma and liver were collected. In plasma, triglyceride (TG), cholesterol (Chol) and glucose concentrations were determined as well as insulinemia. At the 7th week, a glucose tolerance test (GTT) has been conducted. The expression of the liver genes IRS1, Gys1, CD36, and PPAR-alpha, was followed to observe the combined effects of SLE and training.

RESULTS

At the end of the 8th week, a lower bodyweight was observed in the T and T-SLE groups by comparison with the C and SLE ones respectively. Concerning GTT, even if no training effect has been observed, SLE has been shown to decrease glycemia (SLE vs C; T-SLE vs T). Concerning plasma lipid profile, only a training effect has been reported while no effect of SLE was observed. Training has also been shown to decrease TG and Chol concentrations, and the atherogenic index (AIP), with an even higher reduction in AIP observed in the T-SLE group. Finally, concerning the expression of genes involved in glucose and lipid metabolisms, only Gys1 and PPAR-alpha gene expressions were upregulated while CD36 one was downregulated in the T-SLE group, by comparison with the control one.

CONCLUSIONS

This study has reported that SLE supplement combined with moderate training activity was able to improve AIP value and glycemia. In the liver, it seemed that this combination was able to improve balance between fatty acids transport and glycogen synthesis.

SOAP07_08

LYCIUM BARBARUM POLYSACCHARIDES REGULATED HIGH-FAT DIET INDUCED METABOLIC ASSOCIATED FATTY LIVER DISEASE (MAFLD) THROUGH HEPATIC-ADIPOSE AXIS

Hui Xia[1]; Jing Sui[2, 1]; Beijia Zhou[1]; Ying Wang[1]; Guiju Sun[1]
[1]Department of Nutrition and Food Hygiene, School of public health, Southeast University, Nanjing, China; [2]Institute of Environment and Health, Nanjing University of Information Science and Technology, Nanjing, China

BACKGROUND AND OBJECTIVES

The global prevalence of Metabolic associated fatty liver disease (MAFLD) is high and on the rise, while the pathogenesis of NAFLD has not yet been clarified and effective treatment measures are lacking. *Lycium barbarum* polysaccharides (LBP) intervention has been found to exert anti-MAFLD lipid metabolism disorders, but there is a lack of systematic studies on organ interactions, especially on the liver-fat axis. Therefore, there is an urgent need to explore effective prevention and treatment strategies and novel targets for MAFLD.

METHODS

Animal experiments were carried out using 6-week-old C57BL/6J male mice fed 60% high-fat chow to construct a mouse MAFLD model, and different doses of LBP (50mg/kg, 100mg/kg, 150mg/kg) were added to the model for 12 weeks. At the end of the intervention, relevant indexes were detected by HE staining, RT-qPCR and Western Blot to explore the organ interaction of the liver-fat axis.

RESULTS

The RESULTS of animal experiments showed that the livers of MAFLD model mice showed obvious fat accumulation and morphological changes, LBP intervention had no obvious effect on the body weight of mice, but it could significantly improve the body shape and pathological characteristics of mice, reduce the area and number of hepatic fat vacuoles, improve the inflammatory reaction of adipose tissue, and the high-dose LBP intervention group was able to reduce the serum free fatty acid level. Lipidomics test RESULTS showed that LBP intervention may have some up-regulation effect on glycerophospholipid level, able to up-regulate the LPC and PC species and quantity in glycerophospholipid class, in which the regulation of lipid metabolism was more obvious in the high-dose group. Through WB, it was found that LBP intervention was able to up-regulate the expression of FXR, FGF21, AMPK and ADIPO proteins in the livers of MAFLD mice, down-regulate the expression of CD36 proteins, and significantly elevate the levels of FGFR and FGF21 protein expression in the adipose tissues of the mice, and the protein level of ADIPO was significantly elevated in the adipose tissue of the mice in the LBP-M and LBP-H groups.

CONCLUSIONS

The present study elucidated the mechanism and targets of LBP in regulating lipid metabolism disorders in the hepatic-fatty axis of MAFLD mice by affecting the FXR/FGF21 pathway, which provides a new nutritional intervention strategy and potential therapeutic target for the prevention and treatment of metabolic diseases.

THE IMPACT OF SUCRALOSE EXPOSURE ON TESTICULAR DAMAGE AND MALE INFERTILITY: ROLE OF OXIDATIVE STRESS AND AUTOPHAGY

Yi-Fen Chiang[1]; Ko-Chieh Huang[1]; Tzong-Ming Shieh[2]; Yin-Hwa Shih[3]; Shih-Min Hsia[1]
[1]School of Nutrition and Health Sciences, Taipei Medical University, Taipei, Taiwan; [2]School of Dentistry, China medical university Yincai Campus, Taichung, Taiwan; [3]Healthcare Administration, Asia University, Taichung, Taiwan

BACKGROUND AND OBJECTIVES

The effects of non-nutritive sweeteners (NNS) on male reproductive health, particularly at the cellular level, remain inadequately understood. Sucralose, a widely used artificial sweetener, is highly stable and resistant to degradation in wastewater treatment, raising concerns about its environmental and physiological impacts. However, there is a lack of evidence regarding the modulation role of NNS and the impact of sucralose exposure on male infertility. In this study, for the sake of food safety, we investigated the relationship between sucralose consumption and male reproductive function, as well as the related modulation sites affected by sucralose exposure. This study aimed to investigate the impact of sucralose on male reproductive health by examining its effects on cellular proliferation, autophagy, and oxidative stress, as well as on reproductive physiology in animal models.

METHODS

In vitro experiments were conducted using TM3 (Leydig) and TM4 (Sertoli) cell lines to assess sucralose's effects on cell proliferation and survival. Autophagy disruption and oxidative stress pathways were examined. Additionally, male Sprague-Dawley (SD) rats were exposed to sucralose via oral gavage for two months to evaluate its impact on sperm viability, steroidogenesis, and overall reproductive health.

RESULTS

In vitro findings revealed that sucralose significantly reduced cell survival by disrupting autophagy through inhibition of autophagosome formation and lysosome fusion, leading to increased oxidative stress and DNA damage. In vivo, sucralose exposure in SD rats resulted in suppressed sperm viability, reduced testosterone levels, and impaired reproductive health. These effects were mediated by oxidative stress, autophagy disruption, and suppressed steroidogenesis.

CONCLUSIONS

These findings enhance our understanding of sucralose's adverse effects on male reproductive physiology and provide insights into the underlying mechanisms. Additionally, the environmental persistence of sucralose and its potential leakage into wastewater systems underscore broader implications for public health and ecosystem stability. This research highlights the need for cautious utilization of non-nutritive sweeteners and informs food safety policies and wastewater management practices aimed at mitigating the release of sucralose into the environment.

INVESTIGATING THE THERAPEUTIC POTENTIAL OF HINOKITIOL IN SUPPRESSING UTERINE LEIOMYOMA PROLIFERATION AND EXTRACELLULAR MATRIX ACCUMULATION

Yi-Fen Chiang[1]; Ko-Chieh Huang[1]; Tzong-Ming Shieh[2]; Yin-Hwa Shih[3]; Shih-Min Hsia[1]
[1]School of Nutrition and Health Sciences, Taipei Medical University, Taipei, Taiwan; [2]School of Dentistry, China medical university Yincai Campus, Taichung, Taiwan; [3]Healthcare Administration, Asia University, Taichung, Taiwan

BACKGROUND AND OBJECTIVES

Uterine leiomyomas are prevalent benign tumors associated with high recurrence and treatment resistance, primarily due to their proliferative characteristics, stem cell-like properties, and extracellular matrix (ECM) accumulation. Current treatments, including surgery and hormonal therapies, often fail to prevent recurrence. Hence, alternative therapies utilizing natural compounds are being explored. Hinokitiol, a compound with documented antitumor properties, has been proposed to target various aspects of tumor biology, including proliferation, apoptosis, and autophagy. Our study aims to determine whether hinokitiol can effectively reduce uterine leiomyoma proliferation and ECM accumulation.

METHODS

Uterine leiomyoma cells and normal myometrial cells were cultured under standard conditions and treated with hinokitiol. The MTT assay was used to assess cell proliferation and viability. Cell cycle distribution and apoptosis levels were analyzed by flow cytometry. The expression of autophagy and ECM-related proteins was quantified through western blotting and immunohistochemistry. In vivo studies were performed by injecting female mice with uterine leiomyoma cells and treating them with hinokitiol via oral gavage, followed by measurement of tumor size and ECM-related protein expression after treatment.

RESULTS

Treatment with hinokitiol significantly suppressed the proliferation of uterine leiomyoma cells while sparing normal myometrial cells. This suppression correlated with a G1/S phase cell cycle arrest and increased apoptosis. Hinokitiol also enhanced autophagic activity, which is crucial for regulating ECM accumulation. In vivo, hinokitiol treatment led to reduced tumor growth and lower expression of ECM-related proteins, suggesting its potential in mitigating ECM accumulation associated with tumor progression.

CONCLUSIONS

The study highlights hinokitiol's efficacy in inhibiting uterine leiomyoma proliferation, promoting apoptosis, and reducing ECM accumulation through autophagy modulation. These findings support the potential of hinokitiol as a novel, natural therapeutic option for uterine leiomyoma management.

HISPIDIN IS A NUTRITIOUS FOOD INGREDIENT FOR ENHANCING WOUND HEALING

Yi-Shan Liu[1]; I-Min Liu[2]
[1]Dermatology, E-DA Hospital, Kaohsiung, Taiwan; [2]Department of Pharmacy and Master Program, College of Pharmacy and Health Care, Tajen University, Kaohsiung, Taiwan

BACKGROUND AND OBJECTIVES

Hispidin, a polyphenol component mainly derived from the medicinalmushroom species Phellinus and Inonotus, shows promise for biomedical applications, yet its potentialin wound healing remains largely unexplored. This research investigates the wound healing effects ofhispidin through in vitro and in vivo experiments, while also evaluating its antimicrobial propertiesand safety profile.

METHODS

In vitro scratch assays were conducted to evaluate the impact of hispidinon the migration of NIH-3T3 cells. The wound healing potential of hispidin was assessed in rats usingexcision wounds, dead space wounds, and linear incisions, treated with various topical ointmentsincluding a simple ointment, 2.5% (w/w) and a 5% (w/w) hispidin ointment, and a 0.2% (w/w)nitrofurazone ointment, administered at 0.2 g daily for 14 days.

RESULTS

Hispidin demonstratedantimicrobial properties and was particularly effective against Staphylococcus epidermidis. Hispidinenhanced NIH-3T3 cell viability, and promoted wound closure in scratch assays, correlating withincreased levels of FGF21, TGF-β1, EGF, and VEGF.

CONCLUSIONS

These findings highlight hispidin’s potential in wound care, demonstratingits antimicrobial, regenerative, and safety properties.

BUGS GOT MILK? EXPLORING THE POTENTIAL OF LACTOSE AS A PREBIOTIC INGREDIENT FOR THE HUMAN GUT MICROBIOTA OF LACTOSE TOLERANT INDIVIDUALS

Mathilde Guerville[1]; Rita De Cassia Pessotti[2]; Laira Lorraine Agostinho[2]; Cristina Stewart Bittencourt Bogsan[3]; Mateus Kawata Salgaço[2]; Amandine Ligneul[1]; Miller Nunes De Freitas[2]; Cristiano Ruch Werneck Guimarães[2]; Katia Sivieri[2]

[1]Nutrition Department, Lactalis Research & Development, Retiers, France, Retiers, France; [2]., Nintx- Next Innovative Therapeutics, São Paulo, Brazil; [3]Biochemical and Pharmaceutical technology, School of Pharmaceutical Sciences - USP, São Paulo, Brazil

BACKGROUND AND OBJECTIVES

Milk consumption is important to help meet daily nutrient requirements. Emerging studies have demonstrated an additional benefit from regular dairy consumption: improvement of gut health. Lactose, present in dairy products, has been associated with digestive discomfort in individuals who are lactose intolerant or have inadequate lactase activity. Yet, a new perspective on this dietary component has emerged – its potential as a prebiotic for lactose tolerant population. The objective of this study is to assess the acute impact of lactose ingestion on the gut microbiota of adults.

METHODS

We employed a short-duration *in vitro* batch colonic model and a long-duration *in vitro* dynamic multi-vessel colonic model to evaluate the effects of chronic ingestion of lactose on the gut microbiota. In both cases, a mixture of lactose/galactose/glucose was administered in a defined proportion to mimic lactose metabolism and galactose/glucose absorption in the small intestine in lactose tolerant adults.

RESULTS

A modulatory prebiotic effect was revealed on the structure and metabolism of the microbiota upon treatments simulating the ingestion of three doses of lactose, equivalent to the consumption of half, one, and two glasses of cow's milk. The long-duration model confirmed this potential, leading to an increase in the relative abundance of the beneficial genera *Lactobacillus*, *Akkermansia*, and *Faecalibacterium*, while the usually detrimental genus *Clostridium* decreased. Additionally, an increase of health-promoting microbial metabolites was observed, such as acetate, propionate, and lactate.

CONCLUSIONS

Therefore, the lactose ingestion could positively modulate the gut microbiota in healthy lactose tolerant adults promoting gut health, shedding light on the dietary benefits of consuming milk.

IMPACT OF NON-NUTRITIVE SWEETENERS CONTENT IN JUICES ON CHILDREN

Emilia Aliaga[1]; Consuelo Bassi[1]; Martín Garrido[2]; Sebastián Cofré[1]; Monserrat Toloza[1]; Rudy Carolina Alvarez Vega[3]

[1]Facultad de Ciencias de la Salud, Universidad Católica del Maule, Curicó, Curicó, Chile; [2]Facultad Ciencias de la Salud, Universidad Católica del Maule, Curicó, Curicó, Chile; [3]Facultad de Ciencias de la Salud, Universidad Católica del Maule, Curico, Chile

BACKGROUND AND OBJECTIVES

Malnutrition due to excess in children is a multifactorial public health problem with a complex approach. Studies show that an inadequate food intake occurs mainly in the educational environment, where schoolchildren carry out their daily workday. In this context, in Chile the Law No. 20,606 (2016) was implemented, regulating the content of critical nutrients harmful to health (e.g. sugar) through front labeling. Consequently, the food industry has had to reformulate a large part of the food matrices, using non-nutritive sweeteners (NNS) instead to guarantee the sweet taste of packaged food products. However, recently the World Health Organization (2023) has suggested limiting the consumption of NNS due to the scarce evidence on its long-term benefits, especially its recommendation to avoid consumption in children. The objective of this research project is to analyze the content of NNS (sucralose and steviol glycosides) frequently consumed in juices from Chile (individual portion).

METHODS

This study was carried out through a descriptive cross-sectional design. The content of sucralose (SU) content and steviol glycosides (SG) was collected from nutritional labeling information of juices available from a Jumbo supermarket (Chile). The data was recorded using a database, specifying: brand, flavour, SU and SG content in one regular portion of consume (200 mL). Then it was calculated the acceptable daily intake (ADI) of SU and SG limits according FDA agency, and per average weight of children (6-10 years old) according The WHO Child Growth Standards.

RESULTS

Information was collected from the nutritional labeling of a total of 26 juices present on the shelves of a supermarket, which 60% of have at least SU or/and SG. The brands highlight for their high content: Valle” and “Vivo” with 40 mg and 35 mg of SU, respectively. While in content of SG, it spotlights the brands “Vivo” and “Watts” with 12 mg and 5 mg respectively. The highest content of SU and SG in juices was presented by 5 juices, obtaining 10,4 – 14,1 % of ADI children of 6 years old.

CONCLUSIONS

Among the juices studied, some presented a mixture of sweeteners. While a single serving does not pose a health risk to school children, indiscriminate consumption (several portions) of these juices together with other foods with sweeteners can represent a risk to children health.

SOAP07_15

HEPATIC GENDER DIFFERENCES IN ONE CARBON AND CHOLINE METABOLISM DURING FASTING

Abigael Edeh[1]; Siyi Chen[1]; Rahmawati Aisyah[1]; Yoichi Mizukami[2]; Thanutchaporn Kumrungsee[1]; Noriyuki Yanaka[1]
[1]Food and AgricLife Science, Graduate School of Integrated Sciences for Life, Hiroshima University, Higashihiroshima, Japan; [2]Institute of Gene Research, Yamaguchi University Science Research Center, Yamaguchi, Japan

BACKGROUND AND OBJECTIVES

The liver plays a central role in metabolic homeostasis; however, sex chromosomes and hormones have been discussed to influence hepatic metabolism with gender-specific differences. Furthermore, research has shown sexual disparities in the development and prevalence of a variety of liver diseases, such as nonalcoholic fatty liver disease, and a disorder of one-carbon metabolism in this disease progression. This study aims to investigate the hepatic adaptive response to fasting, with a focus on one-carbon metabolism, to elucidate the molecular mechanisms of sexual disparities in disease progression.

METHODS

Eight-week-old C57BL/6 male and female mice were subjected to 48 hours of fasting. Liver tissue were subjected to whole transcriptome analysis by RNA-seq and metabolomics to access metabolite changes by the LC-MSMS method.

RESULTS

Transcriptome analysis identified hepatic 1,673 and 2,773 genes upregulated in male and female fasted mice, respectively. Among the identified genes, the gene group involved in one-carbon metabolism was regulated differently in a gender-specific manner. Next, choline metabolites, glycerophosphocholine (GPC), choline, and betaine levels were investigated, and notably, the GPC level decreased in males, resulting in a significant increase in choline levels to supply methyl groups for betaine synthesis and the methionine cycle. In contrast, GPC level increased in females while betaine level decreased. Furthermore, the mRNA level of GPC hydrolyzing enzyme, glycerophosphodiesterase 1 (Gpcpd1), is increased in males, demonstrating a gender-specific regulation of choline metabolism in response to fasting. The increased expression of Gpcpd1 in males is possibly related to an increased one-carbon metabolism for methylation processes, accompanied by active *S*-adenosylmethionine (SAM) consumption. However, in females, the Fgf21 level in the liver and the serum increased sevenfold compared to males, suggesting DNA hypomethylation in females. Taken together, our findings reveal distinct adaptive crosstalk between one-carbon metabolism and the Fgf21 pathway in response to fasting, which varies by gender.

CONCLUSIONS

This study identified Gpcpd1, a regulator of one-carbon metabolism, and Fgf21, a liver hormone, as drivers of sex differences in fasting-induced liver adaptation. These highlight the distinct hepatic responses related to gender that maintain metabolic homeostasis during fasting, paving the way for personalized, sex-specific nutritional approaches.

SOAP 13 - BASIC RESEARCH IN NUTRITION

SOAP13_02

THE RELATIVE VALIDITY OF 24-HOUR DIETARY RECALLS CONDUCTED VIA TELEPHONE AGAINST A 4-DAY FOOD RECORD TO ESTIMATE FOOD GROUP INTAKES IN A CONVENIENCE SAMPLE OF ADULTS IN IRELAND

Hannah Al-Sehaim[1]; Laura Kehoe[1, 2]; Breige Mc Nulty[3]; John Kearney[4]; Albert Flynn[2]; Janette Walton[1]
[1]Department of Biological Sciences, Munster Technological University, Cork, Ireland; [2]School of Food & Nutritional Sciences, University College Cork, Cork, Ireland; [3]Institute of Food and Health, University College Dublin, University, Dublin, Ireland; [4]School of Biological, Health & Sport Sciences, Technological University Dublin, Dublin, Ireland

BACKGROUND AND OBJECTIVES

In Ireland, the National Adult Nutrition Survey (NANS) (2008-10) collected dietary data using a 4-day weighed food record(1), however, the more recent NANS II (2021-22) used 2x24hour dietary recalls(2) (via telephone due to the Covid-19 pandemic restrictions). The aim of this study was to investigate the relative validity of 2x24-hour dietary recalls (via telephone) against a 4-day weighed food record to estimate food group (FG) intakes in a convenience sample of adults to ascertain comparability between the two methods.

METHODS

Forty participants (19-64 years; 55% female) were equally randomised (to complete the food record first or to complete one dietary recall first, followed by the food record & 2nd dietary recall). Participants were trained in completing the food record using a food scales provided. The researcher-led 24-hour dietary recalls were conducted via telephone (at least 7 days apart) (with a photographic food atlas provided to participants). For both methods, there was a high level of researcher interaction (3 visits) with detailed dietary data collected at brand level. All foods/drinks consumed were mapped to one of 18 predefined FGs (with further disaggregated subgroups). FG intakes were estimated as mean daily intakes (g/d). Differences between METHODSwere assessed using a seven-criteria validity analysis(3).

RESULTS

The RESULTS indicated good/acceptable agreement between the two METHODSfor estimating FG intakes. Of the 18 predefined FGs, eight had all good/acceptable outcomes (‘bread/bread products’, ‘breakfast cereals’, ‘biscuits/ cakes/pastries’, ‘cheese’, ‘butter/spreads/oils’, ‘vegetables/vegetable dishes’, ‘meat/meat products’ & ‘soups/sauces/misc. foods’), seven FGs had 6/7 good/acceptable outcomes (‘grains/rice/pasta/savouries’, ‘milk/yogurt’, ‘eggs/egg dishes’, ‘potatoes/potato products’, ‘fruit/fruit juices’, ‘fish/fish dishes’ & ‘beverages’) while three FGs had 5/7 good/acceptable outcomes (‘creams/ice-creams/chilled desserts’, ‘sugars/confectionery/preserves/savoury snacks’ & 'nuts/seeds'). Disaggregation of FGs into subgroups generally resulted in a similar/higher number of good/acceptable outcomes except for ‘other savouries’, ‘boiled/baked/mashed potatoes’ & ‘fish discrete’ which had just 4/7 good/acceptable outcomes from the seven-criteria validity analysis.

CONCLUSIONS

These findings suggest that 2x24-hour dietary recalls (via telephone) may be comparable with a 4-day weighed food record for estimating FG intakes in adults. However, the protocols employed in this study (high researcher involvement, brand level data & gold standard food quantification methods) are important for accuracy and may have improved comparability.

SOAP13_03

MINDFUL EATING AND PERCEIVED STRESS: INSIGHTS FROM AN ADULT POPULATION STUDY

Şeyma Kalkuz[1]
[1]Nutrition and Dietetics, Kırklareli University Kayali Campus, Kırklareli, Türkiye

BACKGROUND AND OBJECTIVES

Mindful eating is characterized by heightened awareness of physical and psychological hunger and satiety signals, promoting healthier eating behaviors. It is hypothesized to aid in the development of sustainable dietary habits and support body weight management. Additionally, stress and body weight are believed to be related. This study aimed to evaluate the levels of mindful eating and perceived stress among adults.

METHODS

The study was conducted as an online survey between September and November 2024, targeting adults aged 18–65 years. Data were collected through a structured questionnaire encompassing sociodemographic characteristics, dietary habits, body weight, and height. Mindful eating was assessed using the Mindful Eating Inventory, while stress levels were measured via the Perceived Stress Scale.

RESULTS

A total of 200 participants were enrolled, of whom 73.5% were female and 80% were single. The mean mindful eating score was 3.56±0.42, while the mean perceived stress score was 2.92±0.47. Females had significantly higher stress scores (3.04±0.43) compared to males (2.78±0.54) ($p=0.003$). However, no significant association was observed between gender and mindful eating scores. Single (3.03±0.44) participants had higher stress scores than married (2.73±0.53) participants ($p=0.002$), although there was no significant relationship between mindful eating and marital status. Participants with a body mass index (BMI) over 30 had the lowest stress scores ($p=0.005$), and mindful eating scores ($p>0.05$). While mindful eating scores were negatively correlated with stress scores, this relationship was not significant ($r=-0.120$; $p=0.091$).

CONCLUSIONS

Stress levels were influenced by gender and marital status, while mindful eating showed no significant associations. Interestingly, higher BMI was associated with lower stress levels. These findings emphasize the need for more comprehensive research to explore the interplay between stress, mindful eating, and body weight in promoting sustainable dietary and psychological well-being.

The study was supported by TÜBİTAK (The Scientific and Technological Research Council of Türkiye).

SOAP13_04

MALNUTRITION INDICATORS AND NUTRITIONAL FACTORS INFLUENCING FRAILTY IN MALAYSIAN OLDER ADULTS

NURUL FATIN MALEK RIVAN[1]; Hanis Mastura Yahya[1]; Suzana Shahar[2]; Devinder Kaur Ajit Singh[3]
[1]Nutritional Sciences Programme and Centre for Healthy Ageing and Wellness (H-CARE), Malaysia National University Kuala Lumpur Campus, Kuala Lumpur, Malaysia; [2]Dietetic Programme, Centre for Healthy Ageing and Wellness (H-Care), Faculty of Health Sciences, Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia; [3]Physiotherapy Programme & Centre for Healthy Ageing and Wellness (H-CARE), Universiti Kebangsaan, National University of Malaysia, Kuala Lumpur, Malaysia

BACKGROUND AND OBJECTIVES

Frailty, a condition that increases vulnerability to health-related negative events, is particularly significant among older adults when faced with internal or external stressors. Despite its importance, the role of malnutrition indicators and nutritional determinants in frailty remains underexplored. This study addresses this critical gap by investigating the nutritional factors linked to frailty among community-dwelling older adults in Malaysia.

METHODS

This cross-sectional study included 1000 older adults aged >60 years old and interviewed for sociodemographics, health status, depression, functional performance, food intake using a structured dietary history questionnaire, activity lifestyle, and disability. Anthropometric and frailty assessments based on Fried's criteria were assessed. The predictive value of malnutrition indicator and nutritional factors was evaluated using binary logistic regression (BLR) in SPSS software.

RESULTS

Of the participants, 13.9%, 72.5%, and 13.6% were categorised as robust, pre-frail and frail, respectively. Participants with obesity (Adj OR=3.219; 95% CI: 1.415–7.324; $p<0.05$) and high waist circumference (Adj OR=1.032; 95% CI: 1.006–1.058; $p<0.05$) had a higher risk of frailty after controlling for confounding factors. Low intake of energy (Adj OR = 0.971; 95% CI: 0.948–0.995; $p<0.05$), protein (Adj OR=0.987; 95% CI: 0.976–0.998; $p<0.05$), carbohydrate (Adj OR = 0.976; 95% CI: 0.963–0.990; $p<0.05$), fibre (Adj OR=0.884; 95% CI: 0.794–0.985; $p<0.05$) and riboflavin (Adj OR=0.239; 95% CI: 0.091–0.630; $p<0.05$) increased the risk of frailty.

CONCLUSIONS

This study indicates that older adults with abdominal obesity and who had a lower intake of energy, carbohydrate, and fibre are at higher risk of frailty. These findings highlight the need for targeted nutritional interventions and obesity management strategies to prevent frailty, emphasizing the importance of promoting balanced diets while addressing abdominal obesity to support healthy aging in older populations.

CONFLICTS OF INTERESTS

SOAP13_05

COMPARATIVE IN VIVO AND IN VITRO PROTEIN AND AMINO ACID DIGESTIBILITY FOR DIFFERENT PLANT-BASED FOODS AND INGREDIENTS

Cristina Gómez-Marín,[1]; Natalia S. Fanelli,[2]; Hans Stein,[2]; Beatriz Miralles[1]; Isidra Recio[1]
[1]CIAL, Institute of Food Science Research, CSIC, Madrid, Spain; [2]Department of Animal Sciences, University of Illinois, Urbana, United States of America

BACKGROUND AND OBJECTIVES
Protein nutritional quality refers to the ability of dietary proteins to fulfil the amino acid requirements of the human body. Research protocols currently recommended to determine the digestible amino acid score (DIAAS) require human or animal studies. The METHODSbased on ileal digestibility in humans or pigs are the reference in protein quality evaluation, but they are affected by ethical limitations. Therefore, there is interest in the development of rapid and reproducible *in vitro* METHODSto evaluate protein digestibility. In this context, the aim of this work was to determine the *in vitro* protein and amino acid digestibility of foods and protein ingredients and to compare RESULTS with the standardized ileal digestibility values determined in ileal-cannulated growing pigs.
METHODS

An *in vitro* method based on the internationally harmonized protocol INFOGEST (Sousa et al., 2023) was used to digest 16 foods and protein concentrates with previously measured protein and amino acid digestibility in ileal cannulated pigs. The digestible and non-digestible fraction were determined by precipitation with MeOH.

RESULTS

The *in vitro* protocol provided comparable crude protein digestibility values (differences ≤ 5 %) to *in vivo* data except for rapeseed protein isolate, which contained trypsin inhibitors, corn flakes, whole meal bread, and wheat bagel. The discrepancy in the wheat-based products was attributed to the different matrix tested *in vivo* (fresh product) and *in vitro* (freeze-dried powder), resulting in a greater protein digestibility of the latter form. *In vitro* amino acid digestibility was also similar to *in vivo* values, and observed differences were ascribed to the analytical procedure, e.g. total lysine *vs* reactive lysine determination.

CONCLUSIONS

The *in vitro* digestion protocol reproduced to a good extent the in vivo protein and amino acid digestibility determined in ileal cannulated pigs except for samples containing trypsin inhibitors, indicating that the *in vitro* method was less sensitive to antinutritional factors. In comparative studies, it is important to evaluate digestibility of identical food matrices, since mild treatments, such as freeze drying, can affect protein digestibility, as occurred in the cereal products.

THE ROLE OF PECTIN IN MODULATING BETA-CAROTENE BIOACCESSIBILITY UNDER VARIOUS GASTROINTESTINAL DIGESTION CONDITIONS

Anushka Shukla[1]; Aziliz Rolland,[1]; Thomas Schleeh[2]; Patrick Borel[3]; Charles Desmarchelier[3]; Torsten Bohn[1]
[1]Department of Precision Health, Luxembourg Institute of Health, Strassen, Luxembourg; [2]ERIN Department, Luxembourg Institute Science Technology, Sanem, Luxembourg; [3]Center for CardioVascular and Nutrition Research (C2VN), Aix marseille University, Marseille, France

BACKGROUND AND OBJECTIVES

Carotenoids are naturally occurring lipophilic phytochemicals. Their health benefits [1] and low bioavailability have sparked interest in understanding the factors and interactions that influence their absorption. Some dietary fibers have been shown to have inhibitory effects on carotenoid bioavailability [2].They may inhibit carotenoid bioaccessibility by inhibiting enzymes, binding occluding carotenoids, or bile salts, changing physico-chemical aspects such as viscosity and surface tension during digestion [3]. In this study, we investigated the impact of pectin on β-carotene bioaccessibility under various gastrointestinal conditions.

METHODS

β-Carotene bioaccessibility was assessed by the INFOGEST static in vitro gastrointestinal digestion model with slightly modified gastrointestinal digestion conditions. Combinations of pancreatin/bile were employed to achieve various ratios of 100 U/mL (pancreatin) with 3.4 mg/mL (bile extract, suboptimal digestive conditions), 200 U/mL with 6.8 mg/mL (physiological digestive conditions), and 300 U/mL with 10.3 mg/mL (high enzyme levels). Shear forces (100 vs. 140 RPM of the water bath) were modified. All conditions were also tested with the addition of glass beads to evaluate the effects of additional sheer forces on micellization in the presence and absence of pectin. The samples were tested for bioaccessibility along with various physico-chemical properties.

RESULTS

Overall, pectin reduced β-carotene bioaccessibility from 29.9±10.8% to 24.0±7.6% ($p<0.001$), pooling all other factors. Enzyme concentration significantly impacted bioaccessibility, with the lowest observed at 23.1±7.2% under incomplete digestive conditions (low bile/pancreatin), compared to 33.6±11.1% under physiological enzyme conditions and 27.3±9.1% at high enzyme levels. Glassbeads increased bioaccessibility from 25.5±8.6% to 30.0±11.09% ($p < 0.001$). Interestingly, increasing RPM from 100 to 140 reduced bioaccessibility from 30.0±9.4% to 24.7±9.8% ($p < 0.001$).

CONCLUSIONS

Pectin's impact varied with digestive conditions, with bioaccessibility being lowest under marginal enzyme conditions, 140 RPM, and with the presence of glass beads/additional sheer forces, 14.9±1.9%, and highest under physiological enzyme conditions, 140 RPM, and no glass beads, 33.1±6.0%.The findings highlight the variability of carotenoid-fiber interactions depending on gastro-intestinal digestions conditions, which could be relevant for persons with digestion disorders such as irritable bowel syndrome.

SOAP13_08

ABSORPTION, UTILIZATION AND METABOLIC MECHANISM OF SIALYLLACTOSE, A HUMAN MILK OLIGOSACCHARIDE

Bing Wang[1]; Bowen Jiang[2]; Jianjun Li[2]; Yuguang Du[2]; Zhuo Wang[2]
[1]School of Agricultural, Environmental and Veterinary Sciences, Charles Stuart University, Wagga Wagga, Australia; [2]State Key Laboratory of Biochemical Engineering, Institute of Process Engineering, Chinese Academy of Sciences, Beijing, China

BACKGROUND AND OBJECTIVES

The predominant sialylated human milk oligosaccharides (HMOs) are 6'sialyllactose (6'SL) and 3'sialyllactose (3'SL). In early human milk (0-3 month), the 6'SL concentration is 2-3 times higher than 3'SL (1,2). Sialic acid is a key a component of SL playing many critical roles to strengthen the infant immune function and neurodevelopment (3). Despite this important role, the absorption, transportation and utilization of sialyllactose (SL), and the underlying mechanisms of metabolism in living organisms, remain largely unknown. There is no information on whether these processes differ between 3'SL and 6'SL and why the concentration of 6'SL in early human milk is higher than that of 3'SL.

METHODS

We explored the absorption, transport and metabolic fate of exogenous 6'SL in weaning mice using in vivo and ex vivo optical/fluorescence imaging (Cy7 labeled 6'SL) and stable isotope-labeled 13C-6'SL. We compared the differences in metabolism and mechmisims between 6'SL and 3'SL in weaning mice and neuronal cell cultures. The experimental protocol was approved by the Animal Ethic Committee of Beijing Association for Science and Technology (License No. SYXK-2019-0004).

RESULTS

Orally administered labelled 6'SL-Cy7 reached the brain intact within 0.5 h, with a cumulative amount of ~0.3% of the oral dose in female weaning mice, and 1.54% in male weaning mice. This was followed by a sharp decline by 1.5 h with about 0.05% of the oral dose of 6'SL-Cy7 retained at 12 h. Since the colon show no 6'SL cumulation within 30 minutes, the intact oral 6'SL crossing the BBB during this time is independent of colonic fermentation.

A stable isotope-labelled 13C-6'SL can cross the BBB in weaning mice. About 0.25% of intact 13C-6'SL was detected in the brain 1 h after oral administration. Most of this remained in the brain at 3 h (66%), but very little was present at 6 h (0.01%).

Dietary sources of 6'SL is primary donor of Sia, which directly promotes the synthesis of polysialic acid (polySia) and gangliosides in neuronal cells of brain, thereby promoting neurodevelopment.

CONCLUSIONS

Intact oral 6'-SL rapidly crosses the BBB, acting as a primary sialic acid donor that enhances polySia and ganglioside expression in neuronal cells, promoting neurodevelopment in weaning mice independently of colonic fermentation. Its metabolic process is more effective than that of 3'-SL. These findings are novel and previously undescribed.

SOAP13_10

EVALUATING THE PROTECTIVE ROLE OF FISH OIL AGAINST CHRONIC ALCOHOL-INDUCED BRAIN DAMAGE

Qian Xiao[1]; Suh-Ching Yang[1]
[1]School of Nutrition and Health Sciences, Taipei Medical University, Taipei, Taiwan

BACKGROUND AND OBJECTIVES

Chronic alcohol abuse leads to extensive systemic harm. In addition to hepatic damage due to the metabolism process, excessive consumption of alcohol significantly raises the risk of developing dementia. One of the major causes of alcohol related brain damage (ARBD) is oxidative stress. As key regulator of antioxidant system, Nrf2 activates transcription of antioxidant genes such as NAD(P)H-quinone oxidoreductase 1 (NQO1) and heme oxygenase-1 (HMOX1), while enhancing glutathione, superoxide dismutase and catalase. GSK3β has been identified as the proposed communicator to Tauopathies, prolonged binge drinking exacerbates tau pathology, leading to neurodegeneration. Recent research indicates omega-3 fatty acids can balance cellular redox via NRF2. Fish oil, abundant in omega-3 fatty acids, is well studied for its antioxidant and anti-inflammatory protections. Our previous studies elaborated its protective effect against alcoholic liver disease. Therefore, this study aims to evaluate the protective effects of fish oil on ARBD.

METHODS

Male Wistar rats were fed either a control liquid diet (C) or the Lieber-Decarli alcohol diet (E), with 25% or 57% of fish oil substituted (F25 and F57, respectively) for 8 weeks.

RESULTS

After 8 weeks, the liver damage parameters, including plasma AST, ALT activities, hepatic lipids accumulation, and inflammation scores, were elevated in the E group, while EF25 and EF57 ameliorated these effects. Histopathological analysis using H&E staining revealed more condensed pyramidal cells in the hippocampus of the E group, whereas the EF25 and EF57 groups exhibited reduced damage. Increased GFAP and Iba-1 expression were observed in E group, while EF25 and EF57 showed less. Additionally, spatial memory, assessed by the spontaneous Y-maze test, was impaired in the E group. Phosphorylated NRF2 protein expression, mRNA expression of NQO1 and activities of antioxidant enzymes in prefrontal cortex were suppressed in E group. However, phosphorylated Tau (Thr231) remained unchanged in this study. Other phosphorylation sites should be explored in future study.

CONCLUSIONS

These findings suggest that chronic alcohol consumption impairs the brain with spatial memory function loss. Fish oil may offer protection against alcohol-induced damage by preserving hippocampus integrity. The modulation of NRF2 activation and tau phosphorylation should continue to be explored.

BACKGROUND AND OBJECTIVES

Although peanuts are a high-calorie food, several studies have highlighted their beneficial effects due to their rich profiles of fatty acids, proteins, fiber, vitamins, minerals, and bioactive compounds with potential antioxidant properties, as well as their high satiety value. However, the impact of peanut consumption on anthropometric parameters in preadolescents has not been fully explored. This study aims to investigate the effects of daily peanut consumption on weight management in preadolescents.

METHODS

A two-arm parallel cluster-randomized controlled trial was conducted with 83 healthy preadolescents in Barcelona. Schools were randomly assigned to intervention or control group and both arms received an educational intervention designed to promote healthy dietary habits. The intervention group consumed 25g of whole skin roasted peanuts for six months. Anthropometric and adiposity measurements, were taken during baseline, follow-up and final visits.

RESULTS

The findings revealed significant differences between the two groups at six months of the intervention (p=0.01). A significant increase in body weight (p=0.01) and body fat (p=0.02), as well as a significant decrease in muscle mass (p=0.024), was observed in the control group; however, these adverse effects were not observed in the intervention group. Moreover, waist circumference, an indicator of adiposity, showed a significant increase in the control group after six months (p=0.01). In contrast, this increase was not observed in the intervention group, which displayed a marked difference compared to the control group at six months (p=0.001).

Regarding the BMI z-score, adjusted for age and sex, there was a trend towards improvement in the intervention group, but it was not significant (p=0.07). In terms of peanut consumption, a significant difference was observed at 6 months (p=0.01). Additionally, the KIDMED questionnaire on adherence to the Mediterranean diet showed a significant decrease in scores in the control group at 6 months, with a significant difference between groups (p=0.03). This trend was not observed in the intervention group, where adherence remained the same or even improved in the girls.

CONCLUSIONS

Daily peanut consumption was associated with a smaller increase in body fat and less muscle mass loss compared to the control group. These RESULTS suggest that peanuts may positively influence weight management in preadolescents.

SOAP13_12

INTESTINAL FUNCTION MODULATION OF DAIRY PHOSPHOLIPID BY-PRODUCTS FOLLOWING IN VITRO STATIC DIGESTION

Marion Lemaire[1]; Benjamin Choque[1]; Julie Pourprix[2]; Gwenal Broudic[1]; Eléonore Lepvrier[1]; Prescilia Hakmeh[3]; Isabelle Le Huerou-Luron[3]; Sophie Blat[3]
[1]Research and Innovation Center, Sodiaal, Rennes, France; [2]Eurosérum, Sodiaal, Port-sur-Saône, France; [3]Institut NUMECAN, INRAE, INSERM, Rennes University, Rennes, France

BACKGROUND AND OBJECTIVES

The gut barrier plays an important role in human health. Milk is naturally rich in many active constituents that contribute to beneficial functions. Some dairy by-products providing milk fat globule membrane (MFGM) could modulate intestinal digestive, barrier, endocrine and immune functions. We previously demonstrated in vitro the benefits of dairy ingredients providing MFGM on gut physiology, both in basal and inflammation states. Our objective was to further decipher their effects in an experimental protocol approaching better the intestinal physiology i.e. after incorporation in a food matrix model and in vitro static digestion.

METHODS

Three dairy ingredients were used: Buttermilk, a natural source of MFGM, and MFGM-Buttermilk and MFGM-Whey, two MFGM-enriched ingredients. They were studied using an in vitro model of the human intestinal epithelium, in an inflammatory state that mimicks the one encountered in elderly. Ingredients, studied either alone or incorporated in a dairy drink, were subjected to a first step of in vitro static digestion prior to evaluate their impact on a quadricellular model of intestinal epithelium. When studied alone, MFGM-enriched ingredients were standardized at 0.15 mg/mL phospholipids whereas buttermilk was used at a lower concentration of PL (0.031 mg/mL) to investigate dose-dependent effects. Due to solubility issues, phospholipid concentration was lower when using the dairy drink model (0.045 mg/mL and 0.009 mg/mL respectively). Digestion was adapted from the INFOGEST 2.0 protocol. Inflammation was induced using TNFα. Cytoxicity was evaluated by lactate-dehydrogenase release and barrier integrity by trans-epithelial electrical resistance. Expression of genes of interest was quantified by RT-qPCR using a SmartChip device.

RESULTS

All MFGM-ingredients had no effect on cytotoxicity. The digestion fluid alone (i.e. 1/40 diluted product of the digestion protocol without ingredient) impaired gut barrier integrity, which was restored by MFGM-ingredients.

A MFGM-dose dependent effect on cell viability was observed when MFGM-ingredients were incorporated in the dairy drinks, with a significant higher cell viability for MFGM-enriched ingredients than for Buttermilk. Multivariate analysis including gene expressions is underway to better characterize the underlying mechanisms and investigate intestinal functions.

CONCLUSIONS

These RESULTS add to the body of evidence of MFGM benefits especially in intestinal disorders which could occur for the elderly.

REIMAGINING ANTHROPOMETRIC MEASUREMENTS: AI-POWERED HEIGHT PREDICTION AND MALNUTRITION CLASSIFICATION – A PILOT STUDY IN NEPAL

Miriam Kahraman[1]; Anupama Vadyadagaya; Simone Welte[2]; Shivangi Kaushik[3]; Ankit Gupta[4]; Tara Nath Paudel[5]; Deependra Chaudhari[6]; Deepak Mandal
[1]Innovation Unit, Deutsche Welthungerhilfe e.V., Bonn, Germany; [2]Sector Strategy Knowledge and Learning Unit, Deutsche Welthungerhilfe e.V., Bonn, Germany; [3]Innovation Unit, Deutsche Welthungerhilfe e.V., New Delhi, India; [4]Head of Product Child Growth Monitor, Indiviual Consultant, Mumbai, India; [5]MEAL, Deutsche Welthungerhilfe e.V., Kathmandu, Nepal; [6]Nutrition, Deutsche Welthungerhilfe e.V., Saptari, Nepal

BACKGROUND AND OBJECTIVES
Accurate anthropometric measurements are critical for monitoring child growth and identifying malnutrition. With traditional METHODSdemonstrating significant limitations, emerging technologies, like AI, show promise for more reliable and accurate solutions. Deutsche Welthungerhilfe e.V. (WHH) developed a smartphone-based AI application, the Child Growth Monitor (CGM). In March 2023, WHH conducted a study together with FORWARD Nepal, to evaluate CGM's potential to accurately assess children's height and screen for stunting and wasting status. The study aimed to assess CGM's accuracy as a height measurement, and as a stunting and wasting screening tool (utilizing manual weight) for children aged 24-59 months in the community setting.
METHODS

Data from 292 children aged 24-59 months was collected in March 2023. Village Health Volunteers (VHV) collected manual anthropometric measurements, and enumerators, trained using SMART methodology, collected expert manual measurements and CGM scans with the smartphone. The performance of the CGM application was assessed by comparing height measurement and stunting and wasting classification metrics derived from scan-based data to those from VHV measurements, with enumerator's measurements being the reference.

RESULTS
The height accuracy comparison revealed that the scan-predicted measurement consistently outperformed the VHV manual measurement, and the screening RESULTS across all evaluated metrics, with a significantly lower Mean Absolute Error (MAE) (0.9194cm) compared to VHV (2.025cm). The stunting screening RESULTS analysis demonstrated that the CGM scans outperformed VHV manual measurements across all key metrics. The combination of scan-predicted height and VHV manual weight offers comparable overall accuracy (84.59%) and significantly higher sensitivity for "Moderately Wasted" (43.18%) and "Severely Wasted" (50%).Full data: https://cgmiunsheightprediction.z29.web.core.windows.net/
CONCLUSIONS

CGM demonstrated at par or superior performance compared to VHV measurements. Combined with the aspect of portability and faster, more straightforward training for users, it shows the potential of using new technology for performing anthropometric measurements. Health care workers find their jobs easier, leading to positive feedback and high acceptance rates among caregivers. Further research is needed to explore CGM's performance for children <2 years and performing training of algorithms on different ethnicities.

CONFLICTS OF INTERESTS
Dr. Anupama Vadyadagaya and Ankit Gupta are in a paid contractual relationship with Deutsche Welthungerhilfe e.V. as consultants for the Child Growth Monitor Project.

SOAP13_14

EFFECTS OF LUPIN SEEDS CONSUMPTION ON METABOLIC MARKERS IN HEALTHY SUBJECTS

Chiara Bravo-Trippetta[1]; Marina Ramal-Sanchez[1]; Veronica D'Antonio[1]; Elena Corvaglia[1]; Mauro Serafini[1]; Donato Angelino[1]
[1]Department of Bioscience and Technology for Food, Agriculture and Environment, University of Teramo, Teramo, Italy

BACKGROUND AND OBJECTIVES

Cardiovascular diseases (CVDs) are among the leading causes of death worldwide, with dyslipidemia and chronic inflammation as major risk factors [1]. Diet plays a key role in modulating these factors, and legumes, among which lupins, are rich sources of vegetable proteins, fiber and bioactive compounds that may positively affect lipid profiles and inflammation [2]. Despite promising preclinical evidence, mainly on lupin isolates or protein fractions, human studies evaluating the metabolic and anti-inflammatory effects of lupin consumption are limited. With these presumptions, a randomized controlled trial (RCT) has been designed to analyze the effect of chronic lupin consumption on lipid metabolism markers and the potential anti-inflammatory role in healthy volunteers.

METHODS

Healthy adult volunteers (BMI 18–35 kg/m², 25-55 yo), consuming >6 servings of meat/processed meat/cheese, were recruited for a 4-week parallel RCT. In the frame of their habitual diet and lifestyle, participants were randomly assigned to: i) intervention group (INT), 600 g lupins/week and refrain from at least two servings of meat/processed meat/cheese; ii) control group (CTR), 30 g lupins/week. Lupins were provided by the Italian company Madama Oliva SpA. The primary endpoint was the change in triglyceride levels from baseline, secondary ones were anthropometrics and blood pressure, glycaemic, lipidic and inflammatory markers, as well as antioxidant parameters.

RESULTS

Fifty-two healthy participants (24 CTR and 28 INT) concluded the study. Mean age was 33±1 and 37±2 years for CTR and INT respectively, BMI 23.3 and 25.0 kg/m², respectively. All baseline parameters were not significantly different between the two groups. After 4-week trial, a significant improvement in total cholesterol levels (155±9.1 mg/dL vs. 189±7.5 mg/dL, respectively) and LDL-cholesterol levels (84±7.4 mg/dL vs. 119±7.1 mg/dL, respectively) was observed within the INT between females and males. A significant difference in total cholesterol delta values (Δ = -11.79±3.2 mg/dL vs. -2.79±2.4 mg/dL, respectively) and LDL cholesterol (Δ = -6.75±2.4 mg/dL vs. 1.31±1.6 mg/dL, respectively) was also observed between the INT and CTR.

CONCLUSIONS

The abundant consumption of lupin seeds, in the frame of the habitual diet, significantly improved blood cholesterol-related markers in healthy adults. Funding: Italian Ministry of Economical Development, 02/UNITE-MAD.OL 30/11/2021, CUP C47B220001100008.

SOAP13_15

ASSESSING THE STABILITY OF DIETARY DERIVED MICRORNAS AS NOVEL FOOD BIOACTIVES AND BIOMARKERS OF INTAKE

Miguel Cifuentes Acebal[1]; Yvan Devaux[1]; Torsten Bohn[1]
[1]Department of Precision Health, Luxembourg Institute of Health, Strassen, Luxembourg

BACKGROUND AND OBJECTIVES

Dietary derived miRNAs have emerged in recent years as novel food bioactives that can be detected in bodily compartments after ingestion (1), with a potential to act as both biomarkers of intake and biomarkers of effect (2). Nevertheless, the study of miRNA stability during digestion are still unknown. In the same regard, little is known about the role of exosomes in the delivery and uptake of these miRNAs (3). We have studied the stability of dietary derived miRNAs during gastrointestinal digestion, including different digestive conditions and the effect of the food matrix and exosomes on their stability.

METHODS

Using a silica-based column, we have extracted plant-derived miRNAs from gastrointestinal digesta derived from the static INFOGEST model. Later, RT-qPCR was used to study the survival of dietary derived miRNAs (bol-mir-172a; bol-mir-156, bol-mir-1030, bol-mir-164b) before and after digestion, as well as during incubation at higher temperatures to simulate cooking (T= 100ºC, t=20 minutes). Furthermore, we have tested the effect of different food matrices (solid food vs puree) and digestive conditions (i.e. pH value in the gastric phase at 3 and 4; different concentrations of pancreatin, bile salts, and pepsin tested simulating mild, normal, or more rigorous digestion conditions).

RESULTS

Our findings indicate that there was a significant degradation of microRNAs during cooking (thermal incubation) ($P>0.01$). Nonetheless, the biggest challenge for miRNA survival was gastrointestinal digestion, with a reduction in the concentration of eight orders of magnitude, from an average concentration (miRNA copies/mg vegetable) of 1E10 to 5E2 ($p>0.01$). In this regard, we also intend to compare the effect of enzymatic concentration and pH during digestion upon miRNA concentration. Furthermore, due to large differences in stability between the cauliflower and the free spiked miRNA, we have observed that the food matrix plays an important role in the stability of miRNAs.

CONCLUSIONS

Our research has shown that dietary derived miRNAs can survive gastrointestinal digestion and reach concentrations of 1*106 copies/ml in the bioaccessible fraction under physiological plausible conditions. These RESULTS indicate that dietary derived miRNAs may reach the gut epithelia at concentrations high enough to exert bioactive effects in humans. In the following, we will continue to evaluate this hypothesis via studying the cellular uptake and transport of miRNAs, as well as potential targets within the human genome.

SOAP13_16

INFLUENCE OF PATERNAL DIET ON OFFSPRING METABOLIC HEALTH USING DIET INDUCE OBESE MICE

Ligeng Xiong[1]; Latha Ramalingam[1]
[1]Nutrition, Syracuse University , Syracuse, United States of America

BACKGROUND AND OBJECTIVES

Paternal obesity is a significant risk factor for obesity and related metabolic disorders in offspring. While n-3 omega polyunsaturated fatty acids (PUFAs) have demonstrated efficacy in mitigating the negative effects of maternal obesity and improving offspring health, the effects of paternal n-3 PUFA intake and the underlying epigenetic mechanisms in improving offspring health remain unclear. Therefore, we investigated the preconceptional influence of paternal n-3 PUFA intake on offspring metabolic health, with a focus on potential sex-based disparities.

METHODS

We employed a mouse model to examine the preconceptional influence of n-3 PUFA intake in male mice on offspring metabolic health. Male mice were allocated to one of three dietary groups: low-fat (LF), high-fat (HF), or HF supplemented with fish oil (FO) for ten weeks before mating with LF-fed females. Offspring were further divided into six groups based on their paternal diet and post-weaning diet (LF or HF). Glucose and insulin tolerance tests were conducted to assess metabolic function and markers of obesity were measured in muscle and liver.

RESULTS

Our findings revealed a sex-dependent response to paternal n-3 PUFA intake. Offspring born to FO sires exhibited lower body weight at early postnatal stages (7 and 21 days) compared to those with HF sires, despite no significant difference in paternal body weight across groups. Notably, FO-HF females demonstrated enhanced glucose clearance and improved insulin sensitivity compared to HF-HF females. These RESULTS suggest that paternal n-3 PUFA consumption may program early metabolic adaptations in female offspring, potentially enhancing their ability to handle glucose and insulin even under obesogenic conditions. Interestingly, no such effect was observed in male offspring. In conclusion, this preliminary data highlights potential sex-specific programming effects of paternal n-3 PUFA intake on offspring metabolism. These findings contribute to our understanding of the intricate interplay between parental diet and offspring health. Further investigations into the underlying genetic mechanisms are underway to elucidate the molecular basis for these sex-dimorphic responses and their potential implications for chronic disease prevention strategies.

CONCLUSIONS

This research paves the way for the development of more comprehensive approaches to combatting chronic diseases that consider the contributions of both parents.

CONFLICTS OF INTERESTS

INTERVENTION PRIORITISATION OF IMPROVING THE SCHOOL FOOD ENVIRONMENT IN SOUTH AFRICA: CO-DEVELOPED INTERVENTIONS

Ashika Naicker[1]; Pal Imana[2]
[1]Food and Nutrition , Durban University of Technology, Durban, South Africa; [2]Food and Nutrition, Durban University of Technology, Durban, South Africa

BACKGROUND AND OBJECTIVES

As part of UNICEF's blueprint to enhance the school food environment (SFE) in South Africa to improve learner health outcomes, this study employed a systematic intervention mapping approach to identify and prioritise sustainable, inclusive interventions based on the qualitative baseline stakeholder findings of the South African SFE. This study aimed to co-develop actionable interventions to foster a healthier SFE in South Africa.

METHODS

Evidence-based interventions that have improved the SFE were identified through systematic reviews and the NOURISHING database, addressing the barriers and facilitators of the South African SFE from the baseline findings. A Delphi process, conducted over three survey rounds, engaged diverse stakeholders, including principals, teachers, school management teams, governing bodies, parents, learners, vendors, and the Department of Education. In Round 1, stakeholders rated interventions on importance and feasibility using a 5-point Likert scale. High-priority interventions (median 4–5; quartile deviation [QD] < 1) advanced to Round 2 for re-evaluation. By Round 3, interventions achieving strong consensus (median 4–5; QD ≤ 0.5) were finalised. A reference group comprising the National School Nutrition Programme (NSNP) implementers, academia and government stakeholders further refined the list based on the feasibility of implementation.

RESULTS

The Delphi process reduced 31 initial interventions to 25 in Round 2 and 18 in Round 3. The reference group prioritised seven key interventions to improve the SFE in South Africa according to feasibility and costs: 1. Regulation and monitoring of food and beverage sales at school tuckshops. 2. Campaign to promote healthy eating and physical activity among learners. 3. Enhancements to the NSNP to diversify menus and improve meal quality, service, and facilities. 4. Alignment of donations and sponsorships with healthy SFE objectives. 5. Regulations to prohibit unhealthy food marketing and advertising in and around schools. 6. Stakeholder training to improve the SFE. 7. Partnerships with informal vendors to include healthy food and beverage options while maintaining profitability.

CONCLUSIONS

A multi-stakeholder approach identified feasible interventions to improve the SFE in South Africa, for the purposes of piloting the interventions at six public schools in South Africa.

SYNERGISTIC EFFECTS OF PREBIOTIC FRUCTOOLIGOSACCHARIDES AND VIGABATRIN ON EPILEPSY THERAPY USING A PTZ-KINDLED MOUSE MODEL

Binquan Yang[1]; Jason D. Braga[1, 2]; Noriyuki Yanaka[1]; Thanutchaporn Kumrungsee[1, 3]
[1]Food and AgriLife Science, Graduate School of Integrated Sciences for Life, Hiroshima University, Higashihiroshima, Japan; [2]Institute of Food Science and Technology, College of Agriculture, Food, Environment and Natural, Cavite State University, Indang, Philippines; [3]Smart Agriculture, Graduate School of Innovation and Practice for Smart Society, Hiroshima University, Higashihiroshima, Japan

BACKGROUND AND OBJECTIVES

Epilepsy is a neurological disorder characterized by unprovoked seizures due to an imbalance between neuronal excitation and inhibition. To rectify this imbalance, enhancing levels or inhibitory signals of gamma-aminobutyric acid (GABA), the principal inhibitory neurotransmitter, is crucial. For instance, vigabatrin, a well-known antiseizure drug (AED), suppresses seizures by inhibiting GABA degradation, raising brain GABA levels. In addition to AEDs, prebiotics have been shown to alleviate epilepsy. However, research on combining prebiotics with AEDs is limited. Thus, this study explored the synergistic effects of the prebiotic fructo-oligosaccharides (FOS) and the AED vigabatrin on seizure suppression.

METHODS

Male 8-week-old ICR mice were kindled through chronic administration of pentylenetetrazol (PTZ; 35 mg/kg) over 7 weeks. Three weeks before full kindling, mice were assigned to a control or 10% FOS diet. At week 7, the fully kindled mice in each diet group were divided into subgroups (n = 6-7) receiving daily PBS (control) or vigabatrin (250 mg/kg) injections. During vigabatrin treatment, PTZ (35 mg/kg) was administered every 3 days to assess the effects of FOS and vigabatrin on seizure severity. On day 15, when seizures significantly decreased in the FOS-vigabatrin group, PTZ administration was stopped, followed by the T-maze test. After 24 h, mice were euthanized, and blood and tissues were collected.

RESULTS

By day 9 of vigabatrin treatment, mice receiving the FOS-vigabatrin combination showed a significant decrease in seizure scores, whereas those given FOS or vigabatrin alone did not. This suppressive effect persisted through day 15. In the T-maze test, the FOS-vigabatrin group showed a significantly higher alternation percentage (p = 0.0099 vs. PTZ mice), similar to healthy naïve mice, while FOS or vigabatrin alone resulted in slight, non-significant improvement. Both FOS alone and the FOS-vigabatrin combination increased cecal weight and gut GABA levels. In the hippocampus, vigabatrin and the FOS-vigabatrin combination significantly reduced the glutamic acid/GABA ratio and increased homocarnosine levels. The FOS-vigabatrin combination had a stronger effect on increasing this brain-specific, GABA-containing dipeptide homocarnosine compared to vigabatrin alone.

CONCLUSIONS

This study suggests that FOS and vigabatrin synergistically suppress seizures and improve spatial memory, possibly by decreasing the glutamic acid/GABA ratio and increasing homocarnosine levels.

SOAP40_06

INITIAL INFANT FEEDING, SALIVA 1,5 ANHYDROGLUCITROL, AND 6-MONTH WEIGHT GAIN

Douglas Taren[1]; Kinzie Matzeller[1]; Mikayla Hernandez[1]; Jennifer Kemp[1]; Michael Armstrong[2]; Katrina Doenges[2]; Nancy Krebs[1]; Minghua Tang[1, 3]
[1]Department of Pediatrics, Section of Nutrition, University of Colorado Anschutz Medical Campus, Aurora, United States of America; [2]Skaggs School of Pharmacy and Pharmaceutical Sciences, University of Colorado Anschutz Medical Campus, Aurora, United States of America; [3]Department of Food Science and Human Nutrition, Colorado State University, Fort Collins, United States of America

BACKGROUND AND OBJECTIVES

Early infant feeding and infant weight gain can impact the development of chronic diseases. 1,5 anhydroglucitrol (1,5-AG), is a measure of hyperglycemic excursions (HEs) in the preceding 10-14 days but research is limited in infants. Saliva 1,5-AG levels decrease during HEs due to increased urinary excretion. We examined associations between saliva 1,5-AG levels with primary feeding mode and early weight gain in U.S. infants.

METHODS

A subgroup of participants in an ongoing randomized controlled feeding trial (the MINT study) was selected. Saliva was collected from 128 infants at 5 months of age before they were randomized to introduce different complementary foods (CFs), and from 100 infants at 6 months of age to determine early changes in 1,5-AG after starting CFs. Demographics, anthropometrics, and feeding mode (exclusive breastfed (EBF), exclusive formula fed (EFF), mixed (MF)) were recorded at each time point. 1,5-AG analysis was conducted using LC/MS. Weight-for-age z-scores (WAZ) were calculated for birth and each time point. Rapid weight gain (RWG) was classified as $\geq$ 0.67 increase for WAZ from birth to 5 and 6 months.

RESULTS

Saliva 1,5-AG concentrations were negatively correlated with an increase WAZ at Months 5 and 6 ($r = -0.19$ and $r = -0.20$, $p < 0.05$), but Month 6 levels were not significantly correlated with an increase WAZ at Month 6 ($r = -0.13$, $p = 0.19$). 1,5-AG was significantly ($p < 0.001$) greater for EBF infants (1.28±1.08ug/ml) compared with EFF infants (0.23±0.18ug/ml) at 5 months. 1,5-AG levels were also significantly greater at 6 months for EBF infants (1.13±0.73ug/ml) compared with EFF infants (0.22±0.21ug/ml, $p < 0.001$) but not with MF infants at either time period. However, the coefficients for 1,5 AG levels with increase WAZ and RWG using multiple regression and logistic regression, respectively, were not significant when adjusting for WAZ at birth, sex, age, experimental group and feeding modality at 5 and 6 months of age. Additionally, the 1,5 AG concentrations were not significantly different between experimental groups at 6 months.

CONCLUSIONS

Saliva 1,5-AG suggests EBF infants have fewer HEs compared with other infants. Lower saliva 1,5 AG levels were associated with an increase in WAZ and RWG but not when adjusted for birthweight and other factors. Initiating CFs did not affect 1,5 AG levels. Additional analyses are needed to evaluate the impact HEs has on infant growth and health.

HONEY AUTHENTICITY AND ADULTERATION IN THAILAND: A STABLE ISOTOPE ANALYSIS

Kunchit Judprasong[1]; Sang-Arun Meepho[1]; Kanokporn Boonsirichai[2]; Kiattipong Kamdee[2]; Sasiwimon Naksuriyawong[2]; Chakrit Saengkorakot[2]; Nichtima Uapoonphol[2]; Terd Disayathanoowat[3]; Patcharin Phokasem[4]; Chainarong Sinpoo[4]

BACKGROUND AND OBJECTIVES

Honey, a valuable agricultural product, is widely produced in Thailand. Despite stringent quality control standards, concerns persist regarding honey adulteration with added sugars. This study aims to develop a robust method for detecting honey authenticity and adulteration using stable carbon isotope ratio analysis.

METHODS

Honey samples from various regions in Thailand were analyzed using Elemental Analyzer-Isotope Ratio Mass Spectrometry (EA-IRMS) and Cavity Ring-down Spectrometry (CRDS). Stable carbon isotope ratios ($\delta^{13}C$) of both honey and honey protein were determined, along with the analysis of various adulterated sugars.

RESULTS

Natural honey in Thailand typically exhibits $\delta^{13}C$ values below -23.5‰ VPDB, with a small difference between honey and honey protein. Adulteration with sugars, such as high fructose corn syrup, glucose syrup, and maltose syrup, significantly alters the $\delta^{13}C$ values and sugar profiles of honey. Adulteration detection is still limited if the adulteration concentration is lower than 5%, except for the samples mixed with high fructose syrup (55%).

CONCLUSIONS

By comparing the $\delta^{13}C$ values and sugar profiles of honey samples to established standards, this study demonstrates the potential of stable isotope analysis as a reliable tool for safeguarding honey authenticity and detecting adulteration. This study underscores the potential of stable isotope analysis as a robust tool for safeguarding honey authenticity and detecting adulteration, thereby protecting consumers and ensuring fair trade practices.

SOAP40_08

NEUROPROTECTIVE EFFECTS AND MECHANISMS OF DIETARY BIOTIN IN MITIGATING DEMENTIA RISK

Celi Yang[1]; Ai Zhao[1]
[1]Vanke School of Public Health, Tsinghua University, Beijing, China

BACKGROUND AND OBJECTIVES

Association between biotin and dementia were rarely discussed. This study endeavored to investigate the association and potential mechanisms in a population-based and animal-experimental study.

METHODS

For epidemiology, it was derived from UK Biobank, including 210864 participants. Time-dependent Cox model was used to estimate the hazard ratios (HRs) and 95% confidence intervals (CIs) for the association of dietary biotin with dementia risk. Linear regression models were employed to estimate the β coefficients and 95% CIs for associations of dietary biotin with volumetric alteration of brain structure. For animal experiment, it established a biotin deficiency mouse model by using a biotin completely deprived diet. After 9-week dietary intervention, biological experiments dot blot, immunofluorescence, real-time quantitative PCR (RT-qPCR), and molecular docking based on the structures were conducted.

RESULTS

For population study, moderate and high biotin intake were associated with decreased all-caused dementia risk (HR moderate = 0.76 [0.67-0.85]; HR high = 0.73 [0.63-0.83]). Dose-response association was observed, indicating that about 50μg intake of dietary biotin per day may bring lowest all-cause dementia risk. Meanwhile, dietary biotin significantly associated with altered volume of brain structure which highly correlated to the onset and progression of dementia. There exists positive relationship between dietary biotin and concentration of biotin in mice serum and specific locations of brain, such as the hippocampus and prefrontal cortex except the amygdala. Further detection of the transcription levels of dementia-related genes, amyloid precursor protein (APP), presenilin-1 (PSEN1), and apolipoprotein E (APOE) in subregions revealed that in the hippocampus and prefrontal cortex of biotin-deficient mice, the genes APP, PSEN1, and APOE were significantly upregulated, while there was no significant difference in the amygdala, which was consistent with the RESULTS of immunofluorescence. Subsequently, structure model suggested that biotin fell right in the position within the active pocket that was supposed to recognize and cleave β-amyloid (Aβ), thereby reducing the production of pathogenic deposits of Aβ. At the same time, biotin may affect the competitive binding of Aβ/APOE to Low density lipoprotein receptor-related protein 1 (LRP1), then altering the progression of dementia.

CONCLUSIONS

Dietary biotin serves as a defender against dementia, which may originate from the neuroprotection on reduction of accumulation of Aβ in specific regions in brain.

SOAP40_10

EFFECTS OF EXOGENOUS NUCLEOTIDES ON INSULIN RESISTANCE IN THE ELDERLY: A SECONDARY ANALYSIS OF A RANDOMIZED CONTROLLED TRIAL

Shuyue Wang[1]; Lixia Song[1]; Rui Fan[1]; Qianqian Chen[1]; Ruisheng Fu[1]; Yuxiao Wu[1]; Li Yong[1]; Meihong Xu[1]
[1]Department of Nutrition and Food Hygiene, School of Public Health, Peking University, Beijing, China

BACKGROUND AND OBJECTIVES

Aging impairs metabolic homeostasis, exacerbating insulin resistance and reducing quality of life in the elderly. This secondary analysis of a randomized controlled trial (RCT) examined the potential of exogenous nucleotides (NTs) to improve insulin resistance through metabolic and epigenetic mechanisms, offering insights for healthy aging.

METHODS

This was a 19-week, double-blind, randomized, placebo-controlled trial conducted in Chengdu, China, involving 121 elderly participants aged 60–70 years. Participants were randomly assigned in a 1:1 ratio to receive either NTs (1.2 g/day) or placebo, using a computer-generated randomization sequence. The trial is registered with ClinicalTrials.gov (NCT05243108). Data analyzed included: (1) glycolipid metabolic profiles (fasting glucose, glycated hemoglobin, fasting insulin, HOMA-IR, triglycerides, total cholesterol, LDL-C, HDL-C); (2) RNA sequencing (RNA-Seq) of fasting whole blood; and (3) whole-genome bisulfite sequencing (WGBS) of fasting venous blood clot.

RESULTS

NTs significantly improved insulin sensitivity in the elderly. Compared with the placebo group, HOMA-IR was reduced in the NTs group (β = -0.45, 95% CI: -0.86 to -0.04, $P = 0.033$), and fasting insulin levels also decreased significantly (β = -1.28, 95% CI: -2.30 to -0.26, $P = 0.014$). However, no significant differences were observed in fasting glucose, glycated hemoglobin, total cholesterol, triglycerides, HDL-C, or LDL-C ($P > 0.05$). Transcriptomic analysis revealed significant downregulation of nucleotide metabolism-related enzymatic processes (e.g., CTP, AMP, GMP synthesis) in the placebo group but not in the NTs group, suggesting NTs supplementation maintained metabolic function. WGBS analysis identified differentially methylated regions (DMRs) between the NTs and placebo groups post-intervention in the insulin signaling-related gene PRKAR1B (e.g., NC_000007.14_74827801_74828000), with the NTs group showing lower methylation levels and the placebo group exhibiting higher methylation. KEGG analysis suggested that reduced methylation of PRKAR1B might influence PKA activity, potentially optimizing the insulin signaling pathway.

CONCLUSIONS

This secondary analysis provides evidence that nucleotide supplementation improves insulin resistance in the elderly, potentially by maintaining nucleotide metabolism and modulating epigenetic mechanisms associated with the insulin signaling pathway.

SOAP40_11

SPECIFIC PEPTIDES PRESENT IN HUMAN JEJUNUM AFTER MILK CONSUMPTION INDUCE GASTROINTESTINAL HORMONES IN ENTEROENDOCRINE CELLS

Santiaga Vivanco-Maroto[1]; Cristina Gómez-Marín,[1]; Isidra Recio[1]; Beatriz Miralles[1]
[1]CIAL, Institute of Food Science Research, CSIC, Madrid, Spain

BACKGROUND AND OBJECTIVES

Food proteins are recognized as one of the macronutrients with a higher impact on intestinal signalling for hormone secretion. We have previously shown that milk proteins after digestion notably induce the secretion of glucagon-like peptide-1 (GLP-1) and cholecystokinin (CCK) in enteroendocrine cell cultures and some protein domains are especially resistant to the action of gastrointestinal enzymes and can reach distal regions of the gastrointestinal tract. The objective of this work was to screen the *in vivo* resistant peptides after milk proteins consumption as hormone inducers and examine the role of the aminopeptidase dipeptidyl peptidase-IV (DPP-IV) inhibition on their inducing activity.

METHODS

A selection of sequences previously identified in the human jejunum aspirates after ingestion of whey or casein were synthesized and assayed for their GLP-1 and CCK inducing potency in the mouse enteroendocrine cell line STC-1. The inhibition of the DPP-IV of the peptides was determined in Caco-2 cells.

RESULTS

The assayed sequences elicited the release of CCK and GLP-1 to different extents, the most prominent inducers for CCK being from two β-casein domains, and one from β-lactoglobulin. For GLP-1, particularly potent induction was found for selected fragments from β-lactoglobulin. The effect of the amino acids was evidenced. Thus, the successive removal of the N-terminal amino acids of peptide LNVPGEIVE decreased stepwise the CCK secretion, but kept the GLP-1 release. In other sequences, such as VYPFPGPIPN, the sequence shortening increased the hormonal secretion up to different fragments, i. e. YPFPGPI for maximum CCK or YPFPG for GLP-1 release. Some small-size fragments from very active sequences loosed the activity. From these peptides, four casein-derived fragments and five whey-protein sequences were able to inhibit the DPP-IV activity over 80%. Proline at second N-terminal position, an already reported feature, occurred in most of these sequences but three whey derived sequences showed potent activity with other amino acid arrangement.

CONCLUSIONS

Casein and whey-derived peptides were able to significantly induce the secretion of CCK and GLP-1 in enteroendocrine cells. The potent DPP-IV inhibitory effect of some sequences can support the protective effect on GLP-1. The mobilization of the gastrointestinal hormone stores by tailored foods represents a promising strategy to control postprandial glucose levels and intake modulation.

COMPARISON OF TISSUE-SPECIFIC EFFECTS OF A C8/C10 MEDIUM-CHAIN FATTY ACID SUPPLEMENTED KETOGENIC DIET WITH INTERMITTENT AND SUSTAINED CALORIC RESTRICTION IN MICE

Felix Sternberg[1]; Miriam Wimmer[2]; Julia Arapovic[1]; Theresa Hommel[3]; Valeriya Panteva[3]; András Gregor[1]; Kalina Duszka[4]; Barbara Kofler[5]; Veronika Somoza[6, 1, 7, 8]; Elena Pohl[3]; Andreas Dunkel[7]; Jürgen König[1]
[1]Nutritional Sciences, University of Vienna, Wien, Austria; [2]TUM School of Life Sciences, Technical University of Munich, Munich, Germany; [3]Institute of Physiology, Pathophysiology and Biophysics, University of Veterinary Medicine, Vienna, Austria; [4]Center for Animal Nutrition and Welfare, Veterinary, Vienna, Austria; [5]Department of Pediatrics, Paracelsus Medical University, Salzburg, Austria, Austria; [6]Chair for Nutritional Systems Biology, Technical University Munich, Munich, Germany, Germany; [7]Leibniz Institute for Food Systems Biology, Technical University of Munich, Munich, Germany, Germany; [8]Department of Physiological Chemistry, University of Vienna, Vienna, Austria, Austria

BACKGROUND AND OBJECTIVES

The growing interest in medium-chain triglyceride (MCT) supplementation for health promotion and disease prevention highlights the need for a comprehensive examination of its physiological effects. Medium-chain fatty acids (MCFAs, C6-C12) are well-known for their capacity to induce ketogenesis and beneficially influence metabolism and mitochondrial function. Building on our previous findings, which demonstrated cardiac cellular adaptations when MCTs were incorporated into a long-chain triglyceride (LCT)-based ketogenic diet (KD), we hypothesized that elevating tissue levels of C8 and C10 fatty acids (FA) in mice would lead to tissue-specific transcriptional changes in nutrient-sensing and metabolic pathways.

METHODS

Male C57BL/6NRJ mice were fed one of several diets for eight weeks: a standard diet (SD), an LCT-only KD, or a KD composed of both LCTs and MCTs (LCT/MCT at a 70/30 ratio). Additionally, two nutrient-limited SD controls were included for the final two weeks of the feeding period: an intermittent fasting (IF) group (24 h feeding/24h) and a caloric restriction (CR) group (20% reduction in total caloric intake). Tissue samples were analyzed using untargeted metabolomics and lipidomics by LC-MS, gene expression by quantitative PCR.

RESULTS

MCT supplementation did not significantly increase C8 FA in brown adipose tissue, heart, cortex, or striatum, but notable elevations were observed in the liver and skeletal muscle. Conversely, C10 FA levels were consistently higher in LCT/MCT-fed mice than in LCT-fed controls across all tissues except the cortex, as confirmed by targeted LC-MS/MS (e.g., heart: 0.112 ± 0.011 vs. 0.075 ± 0.022 μg/mg; cortex: 0.073 ± 0.021 vs. 0.092 ± 0.015 μg/mg). The LCT/MCT and IF groups showed similar metabolism-related gene expression shifts, suggesting comparable metabolic adaptations independent of body weight or adipose tissue mass. In contrast, the CR group showed the most pronounced weight and adipose tissue loss, with no overlap in gene expression patterns with the LCT/MCT or IF groups.

CONCLUSIONS

The similarities in gene expression patterns between IF and LCT/MCT feeding, and their contrast to CR-induced patterns, suggest that the effects are not solely due to reduced nutrient availability. The observed differences in transcriptional responses indicate that MCFAs uniquely regulate tissue metabolism. Ongoing research aims to further distinguish the metabolic and transcriptional changes specifically attributable to C8/C10 FA from those resulting from altered nutrient states more broadly.

DEVELOPMENT AND ASSESSMENT OF AN INTESTINAL TRI-CELLULAR MODEL TO INVESTIGATE THE PRO/ANTI-INFLAMMATORY POTENTIAL OF DIGESTED FOODS

Marina Ramal-Sanchez[1]; Chiara Bravo-Trippetta[1]; Veronica D'Antonio[1]; Elena Corvaglia[1]; Donato Angelino[1]; Mauro Serafini[1]
[1]Department of Biosciences and Technology for Food, Agriculture and Environment, University of Teramo, Teramo, Italy

BACKGROUND AND OBJECTIVES

Immunonutrition, defined as the potential of foods, nutrients and dietary patterns to modulate the immune system activity, has been proposed as a strategy to enhance the immune response in both metabolic and immune-mediated diseases (1). However, the anti-/pro-inflammatory role of foods and diets is far to be fully ascertained, and thus there is a continued needed for appropriate in vitro cell-culture models to investigate the role of foods in modulating cell-mediated inflammatory processes. This study aims to develop and test an in vitro tri-culture model, simulating the complexity of the intestinal tract and its multiple cell interactions (2,3).

METHODS

The intestinal epithelial barrier was established by co-culturing human CaCo-2 enterocyte-like and HT29-MTX-E12 mucus-producing goblet-like cells, then adding human monocyte THP-1 cells to the basolateral compartment. The integrity and stability of the barrier were monitored and the inflammatory response of the model was assessed using various stressors at different concentrations, both individually and in combination (phorbol-12- myristate-13-acetate or PMA, and lipopolysaccharide or LPS), in terms of cytokines production. To test the model, different concentrations of in vitro digested broccoli (BD) were added to the apical section of the inflamed model during 4 h. Supernatants from the basolateral compartment were collected and analyzed for cytokines production (IL-6, TNF-α, IL-12p70, IL-18 and IL-8) using ELLA Simple Plex. ZO-1 protein from the tight junctions of epithelial cells was analyzed by flow cytometry.

RESULTS

RESULTS indicated that 100 nM PMA added to the whole model for 20 h was the best stressor to simulate a mild-inflammatory status of the gut, as evidenced by TNF-α and IL-6 production. Following treatment with BD at different concentrations, IL-6, TNF-α, IL-8 and IL-18 were significantly reduced compared to the control group. Regarding tight junctions, ZO-1 expression increased at the lowest BD concentration, compared to the control.

CONCLUSIONS

The findings confirm the feasibility of the model for assessing the effects of food digesta representing a valuable strategy for investigating the role of foods in modulating the inflammatory response. RESULTS may support dietary strategies aimed at promoting wellbeing and preventing inflammatory-related metabolic diseases. This research was funded by the EU–NextGenerationEU.ProjectCode:ECS00000041;ProjectCUP:C43C22000380007;Title:Innovation, digitalization and sustainability for the diffused economy in Central Italy–VITALITY.

PREDICTORS OF RECOVERY AMONG 6 – 59 MONTHS CHILDREN HAVING UNCOMPLICATED SEVERE ACUTE MALNUTRITION ATTENDING THE OUTPATIENT THERAPEUTIC FEEDING PROGRAM OF HEALTH CENTRES IN KANDAHAR CITY, AFGHANISTAN: A MULTICENTRE PROSPECTIVE COHORT STUDY

Ahmad Haroon Baray[1]; Giulia Scarpa[2]; Anita Mesic,[3]
[1]Public Health, Kandahar university, قندهار, Afghanistan; [2]Public Health, Institute of Tropical Medicine Antwerp, Antwerpen, Belgium; [3]Clinical Science, Institute of Tropical Medicine Antwerp, Antwerpen, Belgium

BACKGROUND AND OBJECTIVES

Severe Acute Malnutrition (SAM) is a significant contributor to child mortality and morbidity, accounting for millions of deaths annually in low-resource settings such as Afghanistan. Kandahar, one of the most affected provinces, faces a critical situation with over 100,000 under-five children suffering from SAM. This study aims to identify the predictors of recovery among children (6–59 months) having uncomplicated SAM, attending the outpatient therapeutic feeding programs of health centers in Kandahar, Afghanistan.

METHODS

A multicenter prospective cohort study enrolled 713 children from September 2023 to March 2024, with a follow-up period of one to three months. Participants were selected using a consecutive sampling technique. Baseline, follow-up, and exit data were collected through structured questionnaires and anthropometric measurements, guided by the national Integrated Management of Acute Malnutrition (IMAM) protocol. Key variables include socio-demographic factors, parental characteristics, clinical conditions, and adherence to treatment. Recovery was defined as achieving a mid-upper arm circumference (MUAC) ≥125 mm, weight-for-height Z-score ≥−2SD, or absence of edema for two consecutive visits. The chi-square test was used to identify predictors of recovery from uncomplicated SAM; statistical significance was indicated at 95% CI and a p-value of <0.05.

RESULTS

The recovery rate from SAM in this study was 79.5% (567/713), above the nationally accepted standard. Significant predictors of recovery included maternal literacy (OR 12.79, 95% CI 4.00–40.86, $p < 0.001$), full adherence to routine antibiotics (OR 4.28, 95% CI 2.77–6.67, $p < 0.001$), and access to improved water sources (OR 3.82, 95% CI 2.66–5.48, $p < 0.001$). Conversely, predictors of non-recovery included comorbidities (OR 1.76, 95% CI 1.24–2.51, $p = 0.001$), missing RUTF doses (OR 2.12, 95% CI 1.25–3.60, $p = 0.004$), and large family size (>7 members; OR 3.95, 95% CI 2.78–5.63, $p < 0.001$).

CONCLUSIONS

Maternal literacy, antibiotic adherence, and access to improved water were key predictors of recovery, while comorbidities, poor RUTF adherence, and large family size predicted non-recovery. Addressing these factors through policy-level interventions; such as promoting girls' education (future mothers), scaling adherence counselling, treating comorbidities, and increasing access to safe water can significantly improve outcomes. The Ministry of Public Health and healthcare providers should prioritize these predictors in program designs to reduce SAM related morbidity and mortality.

SOAP47_01

SUBSTANTIAL AGREEMENT BETWEEN RATERS WHEN CATEGORIZING ULTRA-PROCESSED FOODS IN A LARGE DIETARY SURVEY – A PILOT STUDY

Torsten Sällström; Linnea Bärebring,[1]
[1]Department of internal medicine and clinical nutrition, Institute of medicine, Gothenburg, Sweden

BACKGROUND AND OBJECTIVES

High consumption of ultra-processed food (UPF) has been associated with negative health outcomes in numerous observational studies. The Nova-system is designed to classify foods based on their degree of processing. Applying the Nova-system on dietary surveys may not be straightforward and substantial differences between raters have been reported. The objective of the present pilot study was to assess the inter-rater reliability (IRR) for categorizing the food items in a large Swedish national dietary survey as UPF or non-UPF.

METHODS

In the latest edition of the Swedish national dietary survey "Riksmaten", 1 797 adults reported their intake through a web-based, self-administered 4-day food record. The dietary database included 1900 food items. A random sample of 100 items was drawn for the purpose of this pilot-study. A detailed protocol was developed based on published definitions, and two researchers (both Swedish residents educated in dietetics) independently classified the items into three categories; 1) UPF, 2) non-UPF, and 3) homemade composite dishes assumed to contain >10 E% UPF. Ambiguous items were flagged for sensitivity analysis by classifying them into alternative groups. IRR was assessed by unweighted Cohen's Kappa (κ).

RESULTS

The overall IRR was considered "substantial" with κ 0.67 (95% CI 0.53, 0.80), and "fair" (κ 0.54 [0.37, 0.71]) for assigning items to sensitivity analysis (Table 1). The level of agreement varied substantially between food categories: fruits & vegetables were classified with 100% agreement, while agreement was considerably lower for beverages and for grains & cereal products. Major sources of inconsistency included determining if food items should be treated as mainly homemade or industrially prepared, as well as assessing the functional properties of food additives.

Table 1. IRR for the classification of foods as UPF

	n	Cohen's κ	95% CI	% Agree
All items, main analysis	100	0.67	0.53 – 0.80	82
Flagged for sensitivity analysis	100	0.54	0.37 – 0.71	79

CONCLUSIONS

This pilot-study shows that the food-items reported in a large national dietary survey could be identified as UPF or non-UPF with substantial level of agreement between two researchers with knowledge about the local food environment. Simultaneously, it highlights the need for a detailed and locally adapted protocol, in addition to previously published definitions.

SOAP47_04

PTEROSTILBENE MODULATES NUCLEAR METABOLITES LINKED TO EPIGENETIC REGULATION IN LIVER CANCER

Cayla Boycott[1]; David Hidalgo Delgado[2]; Tao Huan,[2]; Barbara Stefanska,[3]
[1]Food Nutrition and Health , The University of British Columbia, Vancouver, Canada; [2]Department of Chemistry, The University of British Columbia, Vancouver, Canada; [3]Food Nutrition and Health, The University of British Columbia, Vancouver, Canada

BACKGROUND AND OBJECTIVES

The liver is central to metabolic regulation but is highly susceptible to damage from environmental and dietary factors. Metabolic dysregulation contributes to liver diseases such as hepatic steatosis, steatohepatitis, and hepatocellular carcinoma (HCC). Epigenetic mechanisms, including DNA methylation and histone modifications, regulate gene expression in response to metabolic cues. Polyphenols like pterostilbene (PTS) have demonstrated protective effects in liver disease, particularly in reactivating tumor suppressor genes and silencing oncogenes through epigenetic mechanisms. However, the precise role of PTS in modulating nuclear metabolite availability and epigenetic activity remains unclear. This study investigates the impact of PTS on nuclear metabolites linked to epigenetic regulation in a rat model of HCC.

METHODS

Rats were fed a choline-deficient L-amino acid-defined (CDAA) diet, a model known to induce HCC, with or without PTS supplementation. A custom array of epigenetically relavant metabolites was designed. Nuclear and cytoplasmic metabolites were fractionated using a custom protocol and analyzed by LC-TQMS. RNA sequencing determined differential gene expression between groups.

RESULTS

PTS strongly attenuated HCC development. Liver samples from CDAA+PTS-treated rats showed significant changes in nuclear metabolites from the one-carbon metabolism (OCM) pathway, as compared to CDAA group. Nuclear betaine levels increased, while sarcosine, S-adenosylhomocysteine (SAH), and cystathionine decreased, suggesting a metabolic shift. The nuclear SAM:SAH ratio was significantly higher in the CDAA+PTS group, indicating restoration of homeostasis in methylation reactions. RNA sequencing revealed upregulation of OCM-related genes, supporting PTS-mediated modulation of OCM pathways. Although non-significant, α-ketoglutarate, a co-factor for histone and DNA demethylases, exhibited an increased trend in nuclear fractions, suggesting a potential role in epigenetic remodeling.

CONCLUSIONS

PTS alters nuclear metabolite availability associated to epigenetic mechanisms, largely restoring levels that are present in healthy rats. By shifting nuclear metabolite pools, PTS promotes regaining the equilibrium in methylation reactions, which may translate into changes in the epigenetic landscape and gene expression. Further studies will elucidate polyphenol interactions with epigenetic machinery to optimize dietary strategies for liver disease prevention and treatment.

ASSESSING VITAMIN A STABILITY IN EDIBLE OILS IN ZAMBIA

Grace K Munthali,[1]; Doreen L Daka,[1]; Alick Muvundika,[1]; Dora Panagides[2]; Musonda Mofu[3]; Becky Tsang,[4]; Jenea Lyles[5]; Brent Wibberley[6]; Phillip Makhumula Nkhoma[7]
[1]Food Science Research Centre, National Institute for Scientific and Industrial Research (NISIR), Lusaka, Zambia; [2]USAID AFFORD, TechnoServe, Nicosia, Cyprus; [3]USAID AFFORD, TechnoServe, Lusaka, Zambia; [4]USAID Advancing Food Fortification Opportunities to Reinforce Diets (USAID AFFORD), Food Fortification Initiative (FFI), Atlanta, Georgia, United States of America; [5]USAID AFFORD, TechnoServe, Washington, United States of America; [6]USAID AFFORD, TechnoServe, New York, United States of America; [7]USAID AFFORD, TechnoServe, Nairobi, Kenya

BACKGROUND AND OBJECTIVES

The 2023 Zambia Food Consumption and Micronutrient Status Survey highlights vitamin A deficiency as a critical public health problem. While mandatory fortification of sugar with vitamin A exists, fortifying edible oils could further enhance nutritional status. This study by USAID, Advancing Food Fortification Opportunities to Reinforce Diets in collaboration with the National Institute for Scientific and Industrial Research studied how oil quality, specifically, peroxide value (PV) and free fatty acid (FFA) levels affect vitamin A stability.

METHODS

Four oil types, sunflower, soybean, soy-palm blend, and palm oil were fortified with vitamin A at a concentration of 25 mg/kg and stored in clear virgin polyethylene terephthalate bottles. Oils were stored under light and dark conditions for 12 weeks, with measurements of vitamin A, FFA, and PV taken weekly for the first four weeks and bi-weekly thereafter.

RESULTS

After four weeks, the acid values of unfortified and fortified oils were below the Zambia Standard threshold of 0.6 mg potassium hydroxide (KOH)/g for three oil types, while fortified palm oil stored in light conditions reached 0.68 mg KOH/g. Fortified palm and soy-palm blend oils exceeded the 10-milliequivalents/kg peroxide value threshold, whereas others remained below 50% of the maximum acceptable limit. Vitamin A stability differed with storage conditions, exhibiting losses of 0% to 15%, with palm oil presenting the highest loss.

CONCLUSIONS

The findings underscore the relevance of oil quality and storage conditions in maintaining vitamin A stability, offering valuable insights for enhancing national food fortification strategies.

THE PUTRA COMMUNITY NUTRITION AMBASSADOR PROGRAMME (PUTRACNAP): A CLUSTER-RANDOMIZED CONTROLLED TRIAL TO IMPROVE DIETARY QUALITY AND PHYSICAL ACTIVITY IN LOW-INCOME FAMILIES

Nur Amalin Juhari[1]; Yit Siew Chin[2]; Norhasmah Sulaiman[1]; Juju Nakasha Jaafar[3]; Sukanya Sereenonchai[4]; Poh Ying Lim[5]; Yoke Mun Chan[6]; Nurzalinda Zalbahar@zabaha[1]
[1]Department of Nutrition, Universiti Putra Malaysia, Serdang, Malaysia; [2]Department of Nutrition, Faculty of Medicine and Health Sciences, Universiti Putra Malaysia, Serdang, Malaysia; [3]Department of Crop Science, Universiti Putra Malaysia, Serdang, Malaysia; [4]Faculty of Environment and Resource Studies, Mahidol University, Bangkok, Thailand; [5]Department of Community Health, Faculty of Medicine and Health Sciences, Universiti Putra Malaysia, Serd, Malaysia; [6]Department of Dietetics, Faculty of Medicine and Health Sciences, Universiti Putra Malaysia, Serdang, Malaysia

BACKGROUND AND OBJECTIVES

This study aimed to evaluate the effectiveness of the PUTRACNAP intervention in improving lifestyle practices, specifically dietary quality and physical activity, among low-income mother-child pairs in Kuala Lumpur.

METHODS

A cluster-randomized controlled trial was conducted across 10 low-cost flats in Kuala Lumpur, involving 37 mother-child pairs (children aged 7-12 years). Participants were randomly assigned to either the intervention group (19 pairs), which participated in a 12-week program featuring interactive nutrition education and farming activities aimed at promoting healthy eating and active lifestyle practices, or the control group (18 pairs), which received basic nutrition advice. Dietary quality and physical activity were assessed at baseline, post-intervention, and at a six-month follow-up using standardized questionnaires. Generalized Estimating Equations (GEE) were used to analyze the data, with statistical significance set at $p<0.05$.

RESULTS

For mothers, no significant differences were observed in physical activity levels between the two groups at any time point. However, the intervention group showed a significant increase in vegetable servings (B = 3.34, SE = 1.07, p = 0.002), along with a reduction in total calorie intake (B = -619.80, SE = 278.30, p = 0.026), protein intake (B = -36.75, SE = 14.70, p = 0.012), and fat intake (B = -25.21, SE = 11.89, p = 0.034) compared to the control group at post-intervention, after adjusting for covariates. Additionally, a significant increase in sodium servings was observed in the intervention group at both time points ($p < 0.05$), after adjusting for covariates.

For children, no significant differences were found in physical activity or diet quality. However, the intervention group showed positive trends, including higher physical activity, servings of vegetable, meat, poultry, eggs, legumes, and nuts, alongside reductions in servings of fat, sodium, and added sugar, at both time points.

CONCLUSIONS

The intervention led to significant improvements in dietary habits among mothers, including increased vegetable servings and reduced calorie, protein, and fat intake, while children exhibited positive trends in physical activity and dietary quality despite no significant differences in these areas. Overall, these findings suggest the intervention was particularly effective for mothers and point to the need for further exploration into optimizing interventions for children.

FACTORS ASSOCIATED WITH MODERATE TO SEVERE FOOD INSECURITY IN ULTRA POOR SLUM SETTLEMENTS OF BANGLADESH

Sakib Rahman[1]; Fahmida Akter[1]; Md. Mokbul Hossain[1]; M Shafiqur Rahman[1]; Bachera Aktar[1]; Mehedi Hasan[1]; Abu Abdullah Mohammad Hanif[1]; Abdul Awal[1]; Malay Kanti Mridha[1]
[1]James p Grant School of Public Health, BRAC University, Dhaka, Bangladesh

BACKGROUND AND OBJECTIVES

An understanding of the prevalence and socio-demographic factors associated with food insecurity among the ultra-poor slum dwellers is crucial for achieving nutritional and developmental targets. We assessed the level of household food insecurity and determinants of moderate to severe food insecurity among slum-dwellers in Dhaka and Saidpur.

METHODS

We conducted a cross-sectional study and interviewed 682 mothers with 0-23-month-old children in the slums. Cluster sampling approach was utilized to select the participants. The interview questionnaire comprised socio-demographic, household, food security, clinical and water, sanitation and hygiene related variables. We utilized descriptive analysis to report the status of household food security. Poisson regression with robust variance was used to determine crude and adjusted prevalence ratios (APR) with a 95% confidence interval (CI) to find the factors associated with household food insecurity.

RESULTS

We found that 60.1 % of the households were food insecure (16.2% mild, 17.5% moderate and 26.9% severe food insecure). Female headed households (APR: 1.4; 95% CI:1.2,1.7), lower household monthly income i.e.< 10,000 Taka (APR: 1.5; 95% CI:1.2,1.7), households with 5 or more members living in a single room (APR: 1.4; 95% CI:1.0, 1.8), households not having improved sanitation facility (APR: 1.2; 95% CI:1.0, 1.5) and households using unclean cooking fuel (APR: 1.3; 95% CI:1.1, 1.6) were significant factors associated with moderate to high food insecurity.

CONCLUSIONS

Food insecurity remains high among the slum dwellers. These factors should be considered for designing programs to improve food insecurity among the ultra-poor slum dwellers. Targeted social safety net programs and improvement of housing and sanitation can be undertaken to help reduce food insecurity in the ultra-poor slum settlements.

SOAP47_14

ULTRA-PROCESSED PLANT-RICH DIETS AND RISK OF MORTALITY: FINDINGS FROM A LARGE-SCALE PROSPECTIVE STUDY

Alysha S. Thompson[1]; Amy Jennings[1]; Nicola P. Bondonno[1, 2]; Aedín Cassidy[1]; Tilman Kühn[3, 1, 4]
[1]Co-Centre for Sustainable Food Systems, Institute for Global Food Security, Queen's University Belfast, Northern Ireland, UK, Belfast, United Kingdom; [2]The Danish Cancer Institute, The Danish Cancer Society Research Institute, Copenhagen, Denmark, Denmark; [3]Department of Nutritional Sciences, University of Vienna, Vienna, Austria; [4]Center for Public Health, Medical University of Vienna, Vienna, Austria

BACKGROUND AND OBJECTIVES

The health impacts of plant-rich diets containing high vs. low levels of ultra-processed foods (UPFs) remain to be explored. Here, we investigated whether healthful vs. unhealthful plant-based diet indices (hPDI vs. uPDI) show differential associations with mortality risk based on UPF consumption.

METHODS

Data from 124,791 UK Biobank participants who completed at least two 24-h dietary assessments were analysed. Four modified PDIs were created, retaining the original PDI structure but differing in the inclusion and exclusion of plant-sourced UPFs within plant-food groups. UPF-based scores included only plant-sourced UPFs, while non-UPF-based scores included only plant-sourced non-UPFs. Cox proportional hazards models adjusted for potential confounders were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) across quartiles (Q1-Q4) of the PDIs.

RESULTS

Over a median 10.6 years of follow-up, 5,780 deaths were recorded. Higher UPF-hPDI and non-UPF-hPDI scores were associated with 16% and 12% lower mortality risks, respectively [HR (95% CI) Q4vsQ1: 0.84 (95% CI: 0.78-0.90), p-trend = <0.001; HR (95% CI) Q4vsQ1: 0.88 (95% CI: 0.82-0.95), p-trend = <0.001]. Conversely, higher UPF-uPDI and non-UPF-uPDI scores were associated with 17% and 15% higher mortality risks, respectively [HR (95% CI) Q4vsQ1: 1.17 (95% CI: 1.09-1.26), p-trend = <0.001; HR (95% CI) Q4vsQ1: 1.15 (95% CI: 1.06-1.24), p-trend = 0.002].

CONCLUSIONS

These findings suggest that consuming plant-rich diets influences mortality risk, while the amount of UPFs consumed does not play a major role. Comparable associations across UPF and non-UPF PDIs suggest that dietary quality may outweigh processing in these contexts.

SOAP47_16

ESTIMATION OF TOTAL FLAVONOID AND FLAVONOID CLASS INTAKE OF OLDER AUSTRALIANS FOLLOWING A MEDITERRANEAN DIET AND WALKING INTERVENTION FOR 6-MONTHS

Karen Murphy[1]; Lisa Gavin[2]; Rachel Shanahan[2]; Jessie Clark[1]; Courtney Davis[3]; Greg Kennedy[4]; Andrew Pipingas[4]
[1]Alliance for Research in Exercise, Nutrition & Activity and Clinical Health Sciences, University of South Australia, Adelaide, Australia; [2]School of Biological Health and Sports Science and School of Medicine, Technological University Dublin and The University of Dublin, Trinity College, Dublin, Ireland; [3]Alliance for Research in Exercise, Nutrition & Activity and Justice and Society, University of South Australia, Adelaide, Australia; [4]School of Health Sciences, Swinburne University, Melbourne, Australia

BACKGROUND AND OBJECTIVES

The purported anti-inflammatory and anti-oxidative properties of the MedDiet is likely due to the plant-based nature of the dietary pattern which contains key provides vitamins, carotenoids and flavonoids. We have previously estimated the flavonoid consumption of an older Australian population but not following a MedDiet intervention. The aim of this project was to assess total flavonoid and flavonoid class intake and major food contributors among n=134 older Australians aged 74.2±5.7 years following a MedDiet or habitual diet for 6-months.

METHODS

The MedWalk trial was a multi-site 12-month RCT exploring the effect of a MedDiet and a walking intervention on dementia risk in older Australians. Each participant completed a 4-day weighed food record which was analysed using Foodworks 10. Data was exported to Microsoft Excel and the weight (grams) of each flavonoid containing food was calculated milligram flavonoid per gram of food consumed per person was then estimated using the USDA Database for the Flavonoid Content of Selected Foods (Release 3.3) and Phenol Explorer. Total flavonoids, and six subclasses (anthocyanidins, flavanols, flavanones, flavones, flavonols, and isoflavones were estimated. Linear mixed effects models with a group x time interaction were performed to assess differences in intakes of total flavonoids and subclasses between the MedDiet and HabDiet groups.

RESULTS

Total flavonoid intake was significantly higher in the MedDiet group at 6-months, compared with the HabDiet group (420.2±331.2mg/d vs. 308.1±342.7mg/d, P= .02). Similarly, flavones and flavonols were higher in the MedDiet group at 6-months compared with the habitual group (P<.01). The primary subclass contributing to total flavonoid intake was flavanols, from tea, for both groups. Other major sources of flavonoids in the MedDiet group included berries, citrus fruits, red wine, and juice and white wine, onion, citrus and apples/pears in the HabDiet group.

CONCLUSIONS

These data are similar to other calculated flavonoid intakes from Europe (428mg/d), Korea (318mg/d) and the US (200mg/d), however differed from our previous study in n=1183 middle aged Australians (626mg/d) and another Australian study in older Australians (683mg/d). Nevertheless, the MedDiet appears to be a suitable dietary pattern to increase total flavonoid intake after 6-months.

MACRONUTRIENT, CAFFEINE AND WATER INTAKE ACCORDING TO SEX AND MENTAL MORBIDITY STATUS: A FOCUS ON ANXIETY, INSOMNIA, AND EATING DISORDERS

Valentina Andreeva[1]; Nathalie Arnault[1]; Cécilia Samieri[2]; Stéphanie Chambaron[3]; Marie-Claude Brindisi[3]; Pauline Duquenne[1]; Serge Hercberg[1]; Pilar Galan[1]; Jean-Michel Oppert[1]; Mathilde Touvier[1]; Léopold Fezeu[1]
[1]Équipe de Recherche en Épidémiologie Nutritionnelle (EREN), Paris University 13 - Bobigny Campus, Bobigny, France; [2]UMR1219, Bordeaux Population Health, Bordeaux, France; [3]CNRS, INRAE, Institut Agro, Université de Bourgogne, CSGA, Dijon, France

BACKGROUND AND OBJECTIVES
Mental health has historically received less attention than physical health despite its contribution to disease burden, worsened by the COVID-19 pandemic. Moreover, mental multimorbidity is not uncommon. There is accumulating research evidence from nutritional epidemiology and from nutritional psychiatry, of the prominent role of diet and nutrition in the etiology, treatment and prevention of mental illness. This descriptive, cross-sectional study explored macronutrient, caffeine and water intake according to mental health status, focusing on pure and comorbid anxiety, insomnia, and eating disorders (ED).

METHODS
We used data collected during 2013-2017 in the French NutriNet-Santé general-population cohort. Outcomes included general anxiety, chronic insomnia and ED, assessed with validated tools. Eight mental morbidity groups were studied: no mental morbidity, anxiety alone, insomnia alone, any ED alone, comorbid anxiety and insomnia, comorbid anxiety and ED, comorbid insomnia and ED, and multimorbid anxiety, insomnia, and ED. All data were weighted according to sex-, age- and socioeconomic status in the 2016 French Census, and analyzed with ANOVA.

RESULTS
Among N= 23965 adults, 505 had anxiety-insomnia-ED multimorbidity; a weighted total of 38.9% presented ≥1 mental disorder. For all comorbid and multimorbid conditions, women were at higher risk than were men. Macronutrient intake was more linearly associated with degree of mental morbidity among men than among women. Men with multimorbidity had the highest proportion of carbohydrates in the diet and the lowest intakes of proteins and various lipids. The multimorbidity group had the highest caffeine intake across sex whereas water intake had no dose-response association with degree of mental morbidity.

https://doi.org/10.1017/jns.2026.10126 Published online by Cambridge University Press

CONCLUSIONS

This weighted analysis provided descriptive information about dietary intake according to mental morbidity status. Sex-specific intake profiles emerged which could help inform nutrition prevention programmes and dietary guidelines for at-risk populations. The findings could serve as an impetus for future multimorbidity research and for the generation of novel hypotheses regarding dietary exposures that might play a role in mental multimorbidity risk.

EPO1_003

NUTRITIONAL QUALITY, PERCEPTIONS, AND SENSORY EVALUATION OF PLANT-BASED MEAT ALTERNATIVES

Herrick Zi Min Kong,[1]; Hui Ting Stephanie Tan,[1]; Ives Yubin Lim,[2]; V.M.H. Tan[1]
[1]Health and Social Sciences / Dietetics and Nutrition, Singapore Institute of Technology (SIT), Singapore, Singapore; [2]Biomedical Datahub Division, Bioinformatics Institute, A*STAR Singapore, Singapore, Singapore

BACKGROUND AND OBJECTIVES
Plant-based diets are associated with reduced risk of cancer, cardiovascular disease, diabetes, and overall mortality. Plant-based meat alternatives (PBMAs) are food products that mimic the sensory traits of animal-based products, to encourage meat replacement. With burgeoning popularity in PBMA innovation, little is known about the nutritional quality and acceptability of PBMAs. This study aims to compare the nutritional quality and perceived acceptability of PBMAs with their meat counterparts.

METHODS
Nutritional quality assessment of PBMAs sold in major supermarkets and online grocery retailers were compiled and evaluated against local Recommended Dietary Allowances (RDAs). Subjects (n=52) were recruited to complete a self-administered online survey to assess perceived acceptability (health attitudes, perceptions, knowledge, consumption patterns) of PBMAs. A sub-set of subjects (n=21) were recruited for the sensory evaluation trial, consisting of six different food samples to determine acceptance and sensorial differences between PBMAs, conventional meat products and homemade meat equivalents.

RESULTS
Forty-one food products were evaluated. PBMAs contained the highest fibre content but have lower protein than homemade meats, with plant-based sausages containing the highest saturated fat. Overall, homemade meat products offer better nutritional quality and at a lower cost than PBMAs. About half (51.9%) of the participants are 21–30-year-olds, with equal numbers of each gender (26 males and 26 females), and their mean BMI is 23.3±4.7kg/m2. Males (OR=4.25, *P=0.015*) and being of obese BMI (OR=6.67, *P=0.034*) is associated with higher likelihood of PBMA purchase. Males (OR=3.60, *P=0.029*) and being within the age group 31-40 (OR= 14.00, *P=0.021*) were associated with increased likelihood of replacing meat with PBMAs. Interestingly, the perception of having to eat healthily and that PBMAs are healthier than meat products are associated with purchase and replacement intent ($P<0.05$). Sensory evaluation trial suggested that nuggets and fish fingers were the most susceptible to differential taste preferences (taste, texture, colour, saltiness and fattiness) ($P<0.05$), and meat and patties are just differentiated by salt perception ($P<0.05$).

CONCLUSIONS
Understanding the nutritional differences and perceived acceptability of PBMAs can aid in nutrition education of plant-based diets and help develop evidence-based guidelines, enabling informed food choices when purchasing PBMAs in an evolving food landscape.

MOBILE DIETARY DIARY APP PROMOTING HEALTHY EATING HABITS AND FOLLOWING DIETARY RECOMMENDATIONS

Lidia Wadolowska[1]
[1]Department of Human Nutrition, University of Warmia and Mazury in Olsztyn, Olsztyn, Poland

BACKGROUND AND OBJECTIVES

Many people have difficulty following dietary recommendations [1]. The increasing expectation to achieve goals as easily as possible is growing and includes the use of mobile devices to improve health and prevent diet-related diseases. Aim: To present a new mobile application (Dietary Diary App, DDA) dedicated to the general population, which will make it easier for users to follow dietary recommendations by helping them choose food items and the adequate frequency of food consumption [available on: 2].

METHODS

The app is a mobile version of dietary diary ('Self-monitorYourDiet®') which was previously developed as a printed version. Scientific databases and websites were searched to summarise the evidence regarding dietary guidelines for the general population. In developing dietary recommendations, scientific evidence on diet and health, as well as the environmental implications of the recommended diet (e.g. planetary approach), were taken into consideration. Dietary recommendations and single food items were chosen based on food-based dietary guidelines developed for the Polish general population and other European countries. While developing the diary, a qualitative approach was applied. The dietary recommendations were expressed as recommended frequency consumption of single food items.

RESULTS

The DDA contains 11 foods, including six foods recommended for consumption: vegetables, fruit, dairy foods, whole grains, fish/seafood, legumes/nuts/seeds, and five foods with limited consumption: meat products, sweets/sugar, sweetened beverages/energy drinks, fast foods, alcohols, along with the indicated consumption frequency per day/week. Fats were not included in the DDA because it is difficult for consumers to accurately determine intake of invisible fats. While using the DDA users should record each eating episode of single food items in a qualitative manner (as frequencies). The DDA was tested in 20 adults (female/male). Most of the users reported that they were not burdened with the use of this app, they reported, for example: "it was easy".

CONCLUSIONS

Mobile Dietary Diary App presents a new picture of well-known dietary recommendations for the general population. The first testing of the DDA showed that this app was easy to use for users.

ASSESSING INFORMATION PREFERENCES FOR HEALTH-PROMOTING FOODS IN LATIN AMERICA

Maria Fernanda Elias[1]; Silvia Vanetti[2]
[1]Science, DSM-Firmenich | Escritório JK, São Paulo, Brazil; [2]Insights, DSM-Firmenich | Escritório JK, São Paulo, Brazil

BACKGROUND AND OBJECTIVES
Food and nutrition illiteracy is a growing global concern, exacerbated by the increasing prevalence of misinformation that negatively impacts public health. Conversely, the implementation of effective, evidence-based communication is essential for empowering individuals to make informed dietary choices. This research aimed to map the current ways in which the population in Latin America seeks information about foods and beverages that promote health and well-being. Additionally, it seeks to identify preferences for improving the effectiveness of evidence-based communication in this context.

METHODS
A quantitative study was conducted using online surveys, engaging 6,150 men and women across 11 Latin American countries during January and February 2023. Participants were included based on the criteria that they expressed concern for health and nutrition and were responsible for purchasing food for their households.

RESULTS
Six out of ten Latin Americans primarily seek information about health-promoting foods through online channels. Social networks emerged as the most effective platforms for respondents, with 62% expressing a preference for these channels. Among them, YouTube was the top choice at 31%, followed by Instagram at 28%, Facebook at 27%, and WhatsApp at 17%. In-person assistance from healthcare professionals is also a preferred source of information for 51% of respondents, with Colombia (60%) and Argentina (57%) showing the highest preference. Conversely, radio shows and books are the least favored sources, with only 9% and 14% preference, respectively.

CONCLUSIONS
This study highlights the significant role that online channels, particularly social networks, play in shaping how individuals in Latin America access information about health-promoting foods. The findings underscore the need for healthcare professionals to leverage these platforms for effective communication and education. While in-person consultations remain important, the lower preference for traditional sources like radio shows and books indicates a shift towards digital information. By understanding and utilizing these channels, healthcare professionals can enhance their impact on public health and empower individuals to make informed dietary choices.

BACKGROUND AND OBJECTIVES

Intermittent fasting has gained recognition as a promising approach to improve cardiometabolic health, though findings remain inconsistent. This study evaluated the effects of three dietary interventions—Mediterranean diet (MedDiet), caloric restriction (CR), and time-restricted eating (TRE)—on glycemic regulation applying mixed linear models.

METHODS

A total of 84 participants aged 50-70 years with a BMI of 25-40 kg/m² and incipient fatty liver disease were randomized into three groups: MedDiet (control), CR, or TRE. Continuous glucose monitoring (CGM) data were collected using Abbott FreeStyle Libre 3 devices over seven days, at baseline and after six months. A custom algorithm computed key glycemic metrics, including mean glucose, maximum glucose, AUC, MAGE, MODD, CONGA, J-index, kurtosis, and skewness. Mixed linear models considered time, age, and sex as fixed effects, with participant ID as a random effect.

RESULTS

The TRE group showed significant improvements in glycemic stability, with reduced intra- and inter-day variability (CONGA, MODD). They also experienced lower glucose rises after breakfast. In the MedDiet group, post-dinner mean glucose levels remained elevated. In the CR group, higher kurtosis between 4 p.m. and 8 p.m. indicated more pronounced post-meal glycemic peaks. Additionally, maximum glucose and AUC during sleeping hours increased significantly, suggesting greater nocturnal glucose elevations in this group.

CONCLUSIONS

TRE emerged as the most effective intervention for enhancing glycemic stability, while CR was associated with increased nocturnal glucose levels and MedDiet showed persistent post-dinner glucose elevations. These findings highlight the potential of personalized dietary interventions to individual glycemic patterns for improved cardiometabolic health.

ASSESSMENT OF THE TRADITIONAL FOOD-SHARING BEHAVIOR OF URBAN HOUSEHOLDS IN SENEGAL AND IMPLICATIONS OF THEIR NUTRITIONAL STATUS IN URBAN FOOD SECURITY

Yachiyo Tobita[1]; Sakiko Shiratori[2]; Mandiaye Diagne[3]; Joseph Bassama[4]; Mor Gueye[5]; Kiyokazu Ujiie[6]
[1]Graduate school of Sciences and Technology, University of Tsukuba, Tsukuba, Japan; [2]Information and Public Relations Office, Japan International Research Center for Agricultural Sciences, Tsukuba, Japan; [3]UFR of Economic Sciences and Management, Université Gaston Berger, Saint-Louis, Senegal; [4]Laboratory LABAAM, Université Gaston Berger, Saint-Louis, Senegal; [5]Department of Science Agronomy, Fisheries and Food Technology, Université Gaston Berger, Saint-Louis, Senegal; [6]Faculty of Life and Environmental Sciences, University of Tsukuba, Tsukuba, Japan

BACKGROUND AND OBJECTIVES

This study aimed to quantify the extent of food-sharing behavior and its implications for food security in rapidly urbanizing Senegal. A significant proportion of the population (49.8 %) was affected by moderate or severe food insecurity, which is a considerable concern(FAO Stat,2024). Urban households engage in traditional food-sharing behaviors that involve the consumption of meals prepared by one household and shared with individuals outside the family. Despite the prevalence of food-sharing among urban residents, the nutritional implications of this practice are poorly understood.

METHODS

In 2022, a two-stage sampling approach was employed to select 200 households from 33 districts in Saint-Louis, Senegal(Magnani,1997). For five days, data regarding the weight and ingredients prepared for breakfast, lunch, and dinner and number of individuals consuming these meals were recorded. The number of individuals who shared meals and their relationships were interviewed. A 24-h recall and weighing method was used to calculate the individual mean dietary intake.

RESULTS

The findings indicated that 5%, 15%, and 11% of the total meal weight was provided to non-household members during breakfast, lunch, and dinner, respectively. On average, approximately 2600 kcal per capita was prepared daily in the household, and approximately 360 kcal was shared with others. This amounts to an average of approximately 2500 kcal per household daily being provided to non-household members. These shared meals were often provided to friends, neighbors, and children engaged in religious alms-seeking, reflecting the culture and context of the region. This practice may help improve food access in urban areas.

CONCLUSIONS

African countries, including Senegal, exhibit low food self-sufficiency and rely heavily on imported staples, such as rice and wheat(FAO Statistical Yearbook,2023). This dependence increases vulnerability to food security challenges, including fluctuating international food prices. Traditional food-sharing practices are important in mitigating food insecurity. However, African countries are vulnerable to food crises resulting from unpredictable risks, such as global population growth and climate change. This study emphasizes the urgent need for sustainable food systems and innovative strategies to integrate food culture into regional contexts to ensure long-term food security.

INFLUENCE OF PROBIOTICS ON AMINO ACID ABSORPTION AND METABOLIC RESPONSES TO PLANT-PROTEIN CONSUMPTION

V.M.H. Tan[1]; Ye Won Lee[2]; Wean Sin Cheow[3]; Shiang Chet Tan[4]; Chun Wie Chong[4]; Kai Yee Toh[4]; Jeremy Lim[4]
[1]Health and Social Sciences / Dietetics and Nutrition , Singapore Institute of Technology (SIT), Singapore, Singapore; [2]Health and Social Sciences, Singapore Institute of Technology (SIT) - Dover, Singapore, Singapore; [3]Food, Chemical and Biotechnology, Singapore Institute of Technology (SIT) - Dover, Singapore, Singapore; [4]AMILI, Amili Pte. Ltd., Singapore, Singapore

BACKGROUND AND OBJECTIVES
Emerging evidence suggests that probiotics may augment the absorption of plant proteins. The objective of this study is to examine the impact of probiotics supplementation on postprandial changes in amino acid, glucose and insulin levels in healthy volunteers after the consumption of a plant-protein beverage.

METHODS
A plant-based beverage (20g protein per serve) consisting of a combination of plant-protein blends (brown rice and pea) with an optimal amino acid composition was formulated. In a randomized, single-blind, placebo-controlled, crossover trial, twenty healthy subjects completed two separate 14-day supplementation protocols of either probiotic (L. plantarum, B. logum, B. animalis ssp. lactis.) or placebo, separated by a 4-week washout period. Body composition and demographics were measured upon arrival to the laboratory on day 15, following a 10-12 hour overnight fast. Subjects was given the same plant protein beverage with probiotic or placebo supplement at each study visit. Blood samples were taken at 0 (baseline) and 15, 30, 60, 90, 120, 180 mins post consumption for analysis of plasma amino acid, glucose and insulin concentrations. The area under the curve (AUC180) over 180 mins was calculated using the linear trapezoidal rule for each of the 20 amino acids, insulin and glucose concentrations. Mean differences between treatment were assessed using generalized estimating equations (GEE) and paired observations were compared using the Wilcoxon signed-rank test. A p-value of <0.05 will be considered as statistically significant.

RESULTS
The mean age and BMI of the subjects are 29.0 ± 5.4 years and 20.9 ± 1.2 kg/m2 respectively. Phenylalanine ($P<0.001$), tryptophan ($P<0.001$), tyrosine ($P=0.012$), asparagine ($P=0.034$), and histidine ($P<0.001$) all showed significantly greater AUC with probiotics supplementation than placebo, following the consumption of the plant-based beverage, suggesting increased amino acid absorption to support muscle protein synthesis,. No statistical differences were observed for glucose and insulin responses between treatments ($P>0.05$).

CONCLUSIONS
Probiotics supplementation may be beneficial in improving the bioavailability of certain amino acids from plant-based proteins, making plant-based diets more nutritionally complete and appealing. Further research is needed into the mechanisms by which probiotics can optimize plant-based nutrition and overall health.

BACKGROUND AND OBJECTIVES
The prevalence of eating disorders (ED) and diabetes mellitus (DM), encompassing both type 1 diabetes mellitus (T1DM) and type 2 diabetes mellitus (T2DM), has been observed to exhibit a bidirectional relationship. The complex relationship can adversely impact an individual's quality of life. However, there is a paucity of studies investigating the prevalence of such health complications in Africa. Against this background, this study evaluated the prevalence of eating disorders among diabetes mellitus patients and assessed associations between eating disorders and a range of potential risk factors using the SCOFF questionnaire.

METHODS
Patients (n=101) living with diabetes and being managed at University College Hospital were recruited to fill out a questionnaire on eating disorders using the Scoff Scale, and socio-demographic data were collected.

RESULTS
The vast majority (81.2%) of the study participants had an eating disorder, among which about 59.8% of the females had the condition, and 41.6% of the participants were overweight. Multivariable analysis indicated that the odds of eating disorders in the female participants were 2.17 times higher (OR = 2.17, 95% CI = 1.31 - 3.58%) compared to male participants. Participants aged above 60 years had nearly 2 times higher odds of eating disorders compared to those younger than 20 years; overweight and obese participants had 1.64 and 1.49 times higher odds of eating disorders, respectively, compared to underweight participants. Those who had tertiary education had 0.66 times lower odds of eating disorders when compared to those with no educational levels, and those with professional jobs were 0.62 less likely to have an eating disorder when compared with students. The RESULTS also revealed that retired participants had 0.81 times lower odds of eating disorders when compared with students.

CONCLUSIONS
The findings show that eating disorders are highly prevalent in diabetic patients, which can expose them to complications of diabetes, such as depression and anxiety. It is expedient to diagnose an eating disorder early in diabetic patients because wrong dietary advice may expose them to eating disorders, which would increase the health and economic burden on the nation.

DOSE-DEPENDENT EFFECTS OF OAT AND BARLEY BETA-GLUCAN ON GLYCAEMIC RESPONSE: A REVIEW OF BENEFITS BELOW 4G PER 30G AVAILABLE CARBOHYDRATES

Inga Kutepova[1]; Victoria Holyland[2]; YiFang Chu[3]
[1]Life Sciences, Health and Nutrition Sciences, PepsiCo, Berkshire, United Kingdom; [2]Life Sciences, Health and Nutrition Sciences, PepsiCo, Leicester, United Kingdom; [3]Life Sciences, Health and Nutrition Sciences, PepsiCo Chicago Headquarters, Chicago, United States of America

BACKGROUND AND OBJECTIVES

Postprandial blood glucose levels rise after carbohydrate intake, influenced by food composition and individual factors. Impaired glucose tolerance elevates the risk for cardiovascular disease and metabolic disorders [1-2]. Foods that reduce glycaemic responses without excessive insulin release are beneficial [3]. Beta-glucans from oats and barley lower postprandial glycaemic responses by forming gels in the digestive tract, slowing carbohydrate absorption [4]. In 2011, EFSA confirmed that 4 g of beta-glucans per 30 g of available carbohydrates (avCHO) reduces postprandial glycaemic responses (i.e. incremental area under the curve, iAUC) without disproportionate insulin increases. Later studies suggest this effect may occur with lower beta-glucan intake. The primary aim of this review was to evaluate human studies on the effects of oat and barley beta-glucan intake on glucose iAUC.

METHODS

A PubMed/Medline search was conducted using defined key terms— oat AND barley AND (beta-glucan OR b-glucan) AND (post-prandial OR postprandial) AND (glucose OR glycemi* OR glycaemi*), including only English-language trials. Recent meta-analyses and systematic reviews were also examined to identify additional studies. Studies with chronic feeding, non-oat/barley beta-glucan, or diabetic participants on medication were excluded. Inclusion criteria included only randomized, controlled human studies assessing acute effects of beta-glucan on glucose iAUC and peak glucose rise compared to a control or reference food with similar avCHO. Studies were categorized into dose ranges so the average beta-glucan dose / 30 g avCHO within each of the categories included 1, 2, 3 or 4 g / 30 g avCHO.

RESULTS

We included 26 pertinent studies (51 study arms) [5-30]. Across all studies, iAUC was reduced by 22.74% (95% CI:-26.81, -18.66). The majority of beta-glucan dosages from 1.5 to 3.9g/30 g avCHO significantly reduced glycaemic response measured by glucose iAUC or peak glucose rise. Among all statistically significant interventions, iAUC was reduced by 33.05% (95% CI: -37.89, -28.21). In the 2g dose group (1.5–2.4g), 56% of interventions were significant, with iAUC reduced by 23.23% (95%CI: -29.51, -16.94) among all interventions and by 33.27% (95%CI: -37.68, -28.87) among significant interventions.

CONCLUSIONS

At least 2 g oat beta-glucan / 30 g avCHO taken together with a meal are required for glycaemic benefits. This amount is lower than the amount required for the already approved EFSA claim in 2011 [31]. This dose allows more beta-glucan foods to provide postprandial glycaemic effects, potentially benefiting more individuals.

LUNASIN ACTS AS AN IMMUNOMODULATOR AND ALLEVIATES METABOLIC DISORDERS IN DIET-INDUCED OBESE MICE

Pei-Ying Huang[1]; Chia-Chien Hsieh[1]
[1]Department of Biochemical Science & Technology, National Taiwan University, Taipei, Taiwan

BACKGROUND AND OBJECTIVES
In adiposity, excessive energy accumulates in adipocytes accompanied by chronic low-grade inflammation and immune dysregulation, triggering metabolic disorders. Lunasin, a seed peptide, has been shown to execute various bioactive properties such as anti-carcinogenic, anti-inflammatory, and anti-oxidative effects. This study aimed to investigate the immunomodulatory properties of lunasin in diet-induced obese (DIO) mice.

METHODS
Six-weeks-old male C57BL/6J mice were divided into three groups: normal diet (ND), high fat and high fructose diet (HF), and HF with an intraperitoneal injection of synthetic lunasin at 25 mg/kg body weight/4 days /week (HFL). After 27 weeks of dietary intervention, mice were sacrificed, and body composition, plasma, liver, epididymal white adipose tissue (eWAT), and splenocytes were collected for analysis.

RESULTS
The body weight, fat mass, body mass index (BMI), intraperitoneal glucose tolerance test (IPGTT), and insulin level were higher in mice of the HF group, and the lunasin intervention significantly reduced these parameters. Moreover, lunasin alleviated alanine aminotransferase (ALT) level, liver steatosis, and normalized adipocyte size in the DIO mice. In immunomodulation, lunasin increased T cells proliferation, CD4+ T cells proportion, and interleukin (IL)-6 secretion but decreased IL-10 production in Concanavalin A (ConA)-stimulated splenocytes. In addition, lunasin reduced the proportion of CD19+ and CD19+MHCII+ B cells, and lipopolysaccharide (LPS)-stimulated IL-6 secretion in splenocytes.

CONCLUSIONS
The study has demonstrated that lunasin improved body composition, glucose homeostasis, liver steatosis, adipocyte size, and regulated proportions and responses of T and B cells in the DIO mice. It indicated that lunasin exhibits potential immunomodulatory effects and may be related to alleviating metabolic disorders.

LUNASIN ENHANCES OXIDATIVE STRESS AND CYTOTOXIC ACTIVITY OF SHORT-TERM STARVATION IN BREAST CANCER CELLS

Chen-Jou Cheng[1]; Chia-Chien Hsieh[1]
[1]Department of Biochemical Science & Technology, National Taiwan University, Taipei, Taiwan

BACKGROUND AND OBJECTIVES
Breast cancer is the most common cancer among women worldwide and a leading cause of cancer-related deaths. Accumulating evidence has demonstrated that energy starvation or deprivation can retard or suppress cancer progression. Lunasin is a seed peptide with potential chemopreventive properties in breast cancer. Therefore, we hypothesize that combining lunasin with short-term starvation (STS) may enhance cancer preventive or therapeutic effects.

METHODS
The STS program was set as culturing the breast cancer cell lines MDA-MB-231 and MCF-7 in a medium containing 1% FBS/1 g/L glucose for 16 hours and then changed to a complete medium (10% FBS/ 4.5 g/L glucose) with 50 μM lunasin for 8 hours. The program was repeated for two days, and then cells and supernatants were collected for analysis.

RESULTS
The RESULTS showed that lunasin and STS alone reduced the viability of MDA-MB-231 and MCF-7 breast cancer cells, while the combination exhibited a synergistic inhibitory effect. In wound healing and colony formation assays, the combination treatment tended to suppress cell migration and colony formation in both cancer cell lines compared to individual treatments, but these suppressive effects were revered in normal mammary epithelial MCF-10A cells. Regarding oxidative stress, the combination treatment significantly increased reactive oxygen species (ROS) levels in cancer cells compared to individual treatments, while it reduced STS-induced ROS elevation in MCF-10A cells. These findings suggest that the selective modulation of ROS levels might enhance cytotoxic properties in cancer cells while protecting normal cells. Other experiments are carried out to explore cell cytotoxicity pathways, such as apoptosis and autophagy.

CONCLUSIONS
The study demonstrated that the combination of lunasin and STS synergistically suppressed breast cancer cell proliferation, migration, and colony formation compared to individual treatments. Moreover, the combination increased oxidative stress in breast cancer cells, which might contribute to cell cytotoxicity. These findings highlight that lunasin combined with STS is a potential chemopreventive strategy against breast cancer.

AN EXPLORATION OF THE FRAMING OF ULTRA-PROCESSED FOODS IN THE UK PRINT NEWS MEDIA, 2022-2023: A THEMATIC CONTENT ANALYSIS

Jennie Parnham[1]; Kiara Chang[1]; Michael Essman[2]; Milica Vasiljevic[3]; Mark Petticrew; Martin White[4]; Anthony A Laverty[1]; Emma Boyland[5]; Steven Cummins[6]; Christopher Millett,[7]; Jean Adams[2]; Eszter P Vamos[1]
[1]Primary Care & Public Health, Imperial College London, London, United Kingdom; [2]MRC Epidemiology Unit, University of Cambridge, Cambridge, United Kingdom; [3]Department of Psychology, Durham University, Durham, United Kingdom; [4]Medical Research Council Epidemiology Unit, University of Cambridge, Cambridge, United Kingdom; [5]Department of Psychology, Liverpool university, liverpool, United Kingdom; [6]Department of Public Health, London School of Hygiene & Tropical Medicine, London, United Kingdom; [7]School of Public Health - Faculty of Medicine, Imperial College London, London, United Kingdom

BACKGROUND AND OBJECTIVES
There has been increasing research and policy attention on the concept of 'ultra-processed foods' (UPFs), with ongoing debate over whether they should be incorporated into nutrition guidelines and policy. The media is known to influence the public's perceptions and policy agenda-setting, yet, how UPFs are being presented in the media is not well understood. There has been an intense focus on UPFs in the UK media recently, making the UK an interesting case study on how framing of UPFs in the media may be shaping public and policy discourse. Therefore, this study aimed to analyse the framing of UPFs in UK newspaper and trade press (2022-2023).

METHODS
We systematically searched UK newspaper and trade press publications for articles which substantively discussed UPFs in 2022-23. After screening, 184 articles were identified and analysed using thematic content analysis. The analysis examined article text for overall position towards the UPF concept (accepted /contested /mixed), and framing theory was used to define distinct frames across the articles by identifying the problem, causes of the problem and potential policy solutions proposed in each article.

RESULTS
The majority of articles accepted the UPF concept (52%), 19% contested the concept and 29% presented a mix of arguments. Five distinct frames were found across the articles. The frames ranged from presenting UPFs as a systemic issue which requires governmental policy action (frame 1), presenting UPFs as an issue for individuals to resolve (frame 2), to questioning the UPF concept (frame 4) and highlighting the benefits of UPFs (frame 5).

CONCLUSIONS
There was a wide variation in the framing of UPFs in the UK media, with proposed solutions ranging from regulatory approaches to address the food system drivers of UPF consumption to industry-centred solutions. As there is ongoing attention on the policy approach to UPFs in the UK and worldwide, these frames and their proposed solutions have the potential to influence the direction of future nutrition policy.

STRATEGIES FOR INCORPORATING BITTER FOODS AND BEVERAGES INTO DIETS

ZINAT MOHAMMADPOUR[1]; Page Brooker,[2]; Astrid Poelman,[3]; Amanda Page,[1]; Leonie Heilbronn[1]; Gilly Hendrie,[2]
[1]School of Biomedicine, The University of Adelaide, Adelaide, Australia; [2]Health and Biosecurity, Commonwealth Scientific and Industrial Research Organisation (CSIRO), Adelaide, Australia; [3]Applied Public Health, Commonwealth Scientific and Industrial Research Organisation (CSIRO), Sydney, Australia

BACKGROUND AND OBJECTIVES
Higher-quality diets are reported to taste bitter (1), have healthier nutritional profiles, and align more closely with the recommendations of the dietary guidelines (2). Greater consumption of bitter foods and beverages (F&Bs) may benefit health, but most research has focused on green leafy vegetables (3). However, other F&Bs taste bitter and could increase the bitterness of diets if consumed more (2). Yet, strategies to increase bitter F&B consumption and enhance the bitterness of diets remain largely underexplored.

METHODS
An online-based cross-sectional survey of Australian adults was conducted (in July and August 2023) to explore barriers, facilitators, and strategies associated with willingness to try or increase consumption of bitter F&Bs. Eight non-discretionary bitter F&Bs available in the Australian market (including coffee, tea, soda water, Brussels sprouts, rocket, grapefruit, walnuts, and eggplant) were selected. Conceptual models of food choice guided the design of survey questions. Respondents were asked about their familiarity with and consumption habits of bitter F&Bs and their willingness to incorporate more bitter F&Bs into their diets. Respondents were grouped into those who had never tried bitter F&Bs and non-, low-, moderate- or high-consumers.

RESULTS
This study enrolled 879 respondents across Australia. Most respondents (85.4%) were willing to increase their consumption of bitter F&Bs. While the bitter taste was consistently reported as the main barrier to greater consumption, the reported facilitators and strategies varied between consumer groups and the different F&Bs. More than half of the respondents (61.1%) had never tried bitter vegetables. For this group, 'nutrition education' (selected by 34%) and 'appealing presentation' (selected by 25.9%) were the most selected facilitators and preferred strategies, respectively. Non-consumers of other bitter foods in the survey reported 'price' (selected by 43.8%) and 'convenience' (selected by 16.5%) as the most important facilitator and strategy, respectively. While 'food availability' (selected by 39.3%) was the common facilitator among low-consumers of bitter beverages, 'easier preparation' and 'altering the taste' (selected by 19.9% and 17.3%) were the most preferred strategies.

CONCLUSIONS
These findings could help tailor dietary recommendations to groups of individuals based on their consumption habits of bitter F&Bs to support increased consumption. Further research is needed to understand whether improving bitter F&B consumption increases the bitterness of diets overall and whether this is associated with improved health outcomes.

SUSTAINABLE NUTRITION FOR ATHLETES: EVALUATING GREENHOUSE GAS EMISSIONS AND WATER FOOTPRINT

Nesli Ersoy[1]; Selva Acar[1]
[1]Nutrition and dietetics, Hacettepe Üniversitesi Sıhhıye Kampüsü, Ankara, Türkiye

BACKGROUND AND OBJECTIVES
Given the increasing concern about climate change and the environmental impact of nutrition, ensuring sustainability in athletes' diets has become imperative. This study aims to evaluate athletes' knowledge, attitudes, and behaviors regarding sustainable nutrition, particularly in relation to high-protein diets, and assess the sustainability of their food consumption habits in terms of greenhouse gas emissions (GGE) and water footprint (WF).

METHODS
The study utilized a five-section questionnaire that collected data on athletes' socio-demographic characteristics, knowledge, attitudes, and behaviors regarding sustainable nutrition, as well as food consumption frequency. The data from the food consumption frequency form were used to calculate the amount of red meat consumed, as well as the intake of plant-based and animal-based proteins. Additionally, the greenhouse gas emissions (GGE) and water footprint (WF) associated with their food consumption were calculated.

RESULTS
The study was conducted with 100 professional athletes (mean age: 21.0±3.3 years) from various sports disciplines. The average GGE of the athletes' food consumption was 3017.1±1877.4 g CO2 equivalent/g/day, while the average WF was 5.4±3.2 mL/g/day. Athletes who paid more attention to environmental impact labels when purchasing food had higher dietary GGE and WF values ($p<0.05$). Athletes who prioritized ethical production labels when buying food showed significantly higher GGE values in their diet ($p<0.05$). Differences in GGE and WF values were observed based on sports discipline ($p<0.05$). Team sport athletes had lower GGE and WF values compared to other groups, while strength/power athletes had higher values ($p<0.05$). Additionally, differences in GGE and WF were found based on the number of weekly training sessions ($p<0.05$). Athletes who trained 5 times or fewer per week had lower GGE and WF values than those who trained more frequently ($p<0.05$). The average daily red meat consumption per participant was 95.2±11.6 g, with plant-based protein intake at 58.0±32.0 g and animal-based protein intake at 85.9±54.9 g.

CONCLUSIONS
There is a significant relationship between the amount of red meat consumed, the intake of animal and plant-based proteins, and the GGE and WF values of the athletes' food consumption ($p<0.001$). The GGE and WF values of athletes' food consumption are higher compared to the general population. It is essential to promote the consumption of foods with lower GGE and WF values among athletes to encourage more sustainable nutrition practices.

DIFFERENTIATED SERVICE DELIVERY IN NUTRITION INTERVENTIONS: ENHANCING DEMAND AND ACCESS TO INTERGRATED NUTRITION SERVICES IN RESOURCE-CONSTRAINED SETTINGS

Rayman Mwangosi[1]; Joanita Aigi Muruve[1]; Brenda Mshiu[1]; Dauson Nyanana[1]; Jonathan Sayi[1]; Emmanuel Ndewele[2]; Gaston Runyeto[3]
[1]Health and Nutrition, Save the Children International Tanzania Programme, Dar es Salaam, Tanzania, United Republic of; [2]MEL, Chemonics, Dar es salaam Tanzania, United Republic of; [3]Program, Tanzania Communication and Development Center (TCDC), Dar es Salaam, Tanzania, United Republic of

BACKGROUND AND OBJECTIVES

Remote areas in most of the developing countries like Tanzania face significant challenges related to health supply chain inequalities and limited access to health and nutrition services. These issues exacerbate the problem of malnutrition and hinder efforts to achieve towards universal health coverage. Addressing these challenges requires decentralizing service and tailoring approach to meet specific needs of different community groups. This may involve varying the types of services offered, the delivery methods, or the frequency of interventions based on factors like age, nutritional status, or risk level to ensures that each group gets the most appropriate and effective care for their situation.

METHODS

The USAID Lishe (Nutrition) project is implementing community based nutrition and behavior change intervention by making use of the available community platforms such as Community Health Workers and Village health and Nutrition days. The project Provided training to CHWs on Maternal Infant Young Children and Adolescent Nutrition and supported the formation of Nutrition support groups as measure to increase coverage of clients reached through the routine door to door visits by the CHWs. The project also provided technical support to the CHMTs, VEOs and CHWs on how to coordinate and integrate Health, Nutrition, WASH and Agriculture service. During the VHND the project enhance delivery of health and nutrition services such as Vaccination, Deworming, Nutrition counseling and ssessment.

RESULTS

Through the activities conducted above, in Just four month the project managed to trained 178 CHWs in two districts and supported to formulate 3000 Nutrition support groups through which a total number of 7801 (132 male and 7669 male) group members women and 8471 (4043M and 4428F) under five were reached with nutrition education and counseling. On the other hand through VHND the project have reached 49 villages where total number 10855 people attended the event and receive one or more service, 4183 children were assessed for nutrition. As a result of Nutrition assessment 31 under five children with severe acute malnutrition were identified and linked to service for rehabilitation.

CONCLUSIONS

Differentiated Service delivery in Nutrition intervention in resource constrained settings is essential to decentralize service by applying different person centered approached to bring service close to the community as this will help to increase uptake of service and improve behavior change for the target communities. Additionally this approach serves as means for early detection of malnourished children in the community.

DIETARY CARBOHYDRATE INTAKE AND HEALTH-RELATED OUTCOMES: A PROTOCOL FOR THE EVIDENCE EVALUATION METHODOLOGY FOR THE GUIDELINE OF THE GERMAN NUTRITION SOCIETY

Julia Haardt[1]; Sabrina Schlesinger[2, 3]; Johanna Conrad[1]; Anette Buyken[4]; Sarah Egert[5]; Anna Maria Amini[1]; Nicole Kalotai[1]; Anja Kroke[6, 7]; Lukas Schwingshackl[8]
[1]Department of Science, German Nutrition Society, Bonn, Germany; [2]Institute for Biometrics and Epidemiology, German Diabetes Center (DDZ), Düsseldorf, Germany; [3]German Center for Diabetes Research (DZD), Munich-Neuherberg, Düsseldorf, Germany; [4]Institute of Nutrition, Consumption and Health, Faculty of Natural Sciences, Paderborn University, Paderborn, Germany; [5]Institute of Nutritional and Food Science, Nutritional Physiology, University of Bonn, Bonn, Germany; [6]Department of Nutritional, Food and Consumer Sciences, Fulda University of Applied Sciences, Fulda, Germany; [7]Scientific Committee, German Nutrition Society, Bonn, Germany; [8]Institute for Evidence in Medicine, Medical Center and Faculty of Medicine, University of Freiburg, Freiburg, Germany

BACKGROUND AND OBJECTIVES

A large body of studies indicates an association between the quantity and quality of dietary carbohydrate intake and various health-related outcomes. The German Nutrition Society (DGE) published its last guideline on dietary carbohydrate intake and selected health-related outcomes in 2011. An update to this guideline is now planned. The following protocol outlines the novel methodical procedure for the updating process.

METHODS

A guideline panel was constituted and research questions were defined a-priori. The methodological approach follows established recommendations for guideline updates.

RESULTS

Umbrella reviews will be conducted to examine the quantity and quality of dietary carbohydrates intake in relation to health-related outcomes in the healthy general population. The relevant interventions/exposures encompass total carbohydrates, sugars (including sugar-sweetened beverages), whole grains, fibre, starch, and the glycemic index and glycemic load of foods as well as dietary insulin index and load. The outcomes of interest are obesity-related outcomes, type 2 diabetes, dyslipidaemia, elevated blood pressure, cardiovascular diseases, cancer and dental caries. A literature search will be conducted in MEDLINE and Epistemonikos from 2015 onwards. Systematic reviews (SR) with meta-analyses of randomised controlled trials and prospective observational studies will be selected based on defined inclusion and exclusion criteria, and data will be extracted from the relevant SR. All steps will be conducted by two independent reviewers. The methodological quality of the SR will be assessed using a modified version of AMSTAR 2, and the certainty of evidence will be assessed using the GRADE approach. The guideline recommendations are derived based on the certainty of the evidence and other criteria of the evidence-to-decision framework.

CONCLUSIONS

The protocol provides a state-of-the-art transparent framework for updating the DGE guideline on dietary carbohydrate intake and health-related outcomes according to international standards.

REVISED DIETARY REFERENCE VALUE OF VITAMIN E INTAKE FOR GERMANY AND AUSTRIA – A NEW PROCESS OF DERIVATION

Christina Breidenassel[1]; Volker Böhm;[2]; Ibrahim Elmadfa,[3]; Stefan Lorkowski[2]; Maren Podszun[4]; Karl-Heinz Wagner[5]

[1]Department of Science, German Nutrition Society, Bonn, Germany; [2]Institute of Nutritional Sciences, Friedrich-Schiller-Universität Jena, Dornburger Straße, Jena, Germany; [3]Department of Nutritional Sciences, University of Vienna, Vienna, Austria; [4]Department of Food Biofunctionality, Universität Hohenheim, , Institute of Nutritional Sciences, Stuttgart, Germany; [5]Department of Nutritional Sciences, University Vienna, Vienna, Austria

BACKGROUND AND OBJECTIVES

The last update of the reference values for vitamin E (VitE) given by the German and Austrian nutrition societies dates back to a 2000 report. Since then, a number of new scientific data has been published especially for α-tocopherol concerning metabolism, biomarkers and relationship between VitE intake and chronic diseases. Therefore, there was a need to review and update of the reference value for VitE intake was required. This paper provides a summary of the work undertaken in this regard.

METHODS

A comprehensive literature search was conducted for human studies on vitamin E, α-tocopherol and γ-tocopherol published since year 2000, focusing on data used to derive a reference value, such as bioavailability, functions, deficiency symptoms and prevention of diet-related diseases.

RESULTS

Stable isotope studies and compartmental models have provided a better understanding of the bioavailability and metabolism of VitE, especially α-tocopherol. The other VitE congeners and an excess of α-tocopherol appear to be increasingly catabolized. In addition, there is no evidence of dietary deficiency or insufficient data on the relationship between PUFA intake or the protection of unsaturated fatty acids and VitE status. Intake data appear to overestimate requirements. We therefore suggest a new approach considering daily losses of approx. 5 mg/d and an average absorption rate of α-tocopherol with a balanced diet of about 75 %, appear to be a solid base for deriving a reference value for VitE intake. Based on this data an intake of about 6.5 mg/d α-tocopherol seems to be sufficient to compensate for daily losses. Due to inter-individual variations, a coefficient of variation of 10 % (which corresponds to an addition of 20 %) should be considered. This RESULTS in an estimated value of 8 mg/d VitE for adults 19 years and older for both sexes. In addition, for this amount of VitE potential beneficial effects have already been reported at dietary intake levels ranging from approximately 2-15 mg/day.

CONCLUSIONS

Adequate VitE intake without supplements is possible with a balanced and plant-based diet because foods with high amounts of PUFA usually also contain VitE in appreciable amounts. The recommendation of a regular/daily consumption of foods rich in VitE appears to be sufficient for an adequate supply of VitE as the preventive effect of higher doses remain to be conclusively proven.

LUNASIN ALLEVIATES MUSCLE ATROPHY AND IMPROVES MUSCLE STRENGTH IN DIET-INDUCED OBESE MICE

Chih-Chen Wang[1]; Pei-Ying Huang[1]; Chia-Chien Hsieh[1]
[1]Department of Biochemical Science & Technology, National Taiwan University, Taipei, Taiwan

BACKGROUND AND OBJECTIVES

The global prevalence of obesity is continually increasing in recent years, leading to a rise in related health issues. Sarcopenic obesity is characterized by a decrease in lean body mass accompanied by excessive accumulation of adipose tissue, resulting in the loss of muscle mass, strength, and function. It is related to increased risk of insulin resistance, diabetes, and cardiovascular diseases. Lunasin is a soybean-derived seed peptide with multiple bioactivities including anti-inflammatory, antioxidant, and the prevention of immune-related diseases. This study aimed to investigate the effects of lunasin on mitigating sarcopenic obesity in skeletal muscle.

METHODS

C57BL/6 mice were divided into three groups, including normal diet (ND) with 16% calories of fat, high fat and fructose (HF) diet contained 45% calories of fat and 27% of fructose, and the HF diet received 25 mg/kg body weight of intraperitoneally injected synthetic lunasin (HFL) four times a week. The mice were fed the experimental diets from 7-week-old until 14 or 33 weeks-old and were sacrificed for skeletal muscle mass, grip strength, cross-sectional area, and muscle size analyses.

RESULTS

The mice of the HF group increased 25% of body weight and declined fast-twitch muscle weight, including tibialis anterior, extensor digitorum longus, and gastrocnemius, compared to the ND group since 14-week-old. Interestingly, lunasin intervention decreased more than 10% body weight, increased fast-twitch muscle weight, increased skeletal muscle cross-section area, and the proportion of larger myofibers in 33-week-old mice. In muscle strength, the mice of the HF group have lower grip strength at 14- and 33-week-old, and lunasin improved the grip strength in 33-week-old mice.

CONCLUSIONS

This study first highlighted that lunasin intervention alleviated muscle atrophy and improved muscle strength caused by obesity. Additionally, proteins related to muscle generation and degradation, such as MuRF1, atrogin, and myogenin, are currently analyzed to confirm possible molecular mechanisms of lunasin in mitigating obesity-related sarcopenia.

PERCEPTIONS OF BODY SHAPE AND NUTRITIONAL INTAKE OF FEMALE UNIVERSITY STUDENTS IN TOKYO

Hatsuho Zeniya[1]; Saiko Shirakawa[2]
[1]Department of Physical Education, International Budo University, Katsuura, Japan; [2]Department of Food health science, Showa Women's University, Setagaya City, Japan

BACKGROUND AND OBJECTIVES
Previous studies have pointed out that the proportion of underweight women in Japan is 16%, which is higher than in other countries (Phelps et al., 2024). According to previous studies, one of the factors explaining this tendency among Japanese women is that "their weight perception is heavier than their actual weight or 'desirable weight'". In addition, the National Health and Nutrition Survey of Japan reported that young Japanese women have low energy intake, which may contribute to thinness. The purpose of this study is to investigate the actual proportion of underweight women among female university students, their perception of their body image, and their current nutritional intake, and to collect data to consider ways to reduce the proportion of underweight women.

METHODS
A survey was conducted on 93 female university students at a women's university in Tokyo (mean age: 19.2 ± 3.0 years, mean height: 158.1 ± 5.2 cm, mean weight: 50.6 ± 5.6 kg). Participants completed a body image questionnaire and a dietary survey. Data from 93 participants were analyzed for the body image questionnaire, and data from 48 participants were analyzed for the dietary survey. The dietary survey was conducted using a food frequency questionnaire (FFQ) and compared with the Japanese dietary reference intake values.

RESULTS
In the body image survey, 18 of 93 participants (19.4%) had a BMI of less than 18.5 kg/m². Regarding their own body shape, 25 participants answered that they were “overweight”. The average ideal body weight was 47.5 ± 4.6 kg, and 34 participants (36.6%) answered that their ideal body weight corresponded to a BMI of less than 18.5 kg/m². In the dietary survey, the estimated average energy requirement is 2000 kcal, but only 1666 ± 28 kcal was took.

CONCLUSIONS
A survey conducted on female university students in Tokyo revealed that 19% of the participants were underweight. As with previous studies, it was shown that there is a high possibility that they do not have an appropriate awareness of their current body shape and ideal body shape. Furthermore, this study confirmed that insufficient energy intake contributes to the increase in underweight.In the future, we would like to investigate the causes of the acquisition of incorrect perceptions about body shape, as well as consider ways to establish correct perceptions and improve dietary content.

IODINE DEFICIENCY: THE RENAISSANCE OF A PUBLIC HEALTH ISSUE IN SUSTAINABLE NUTRITION?

Christina Breidenassel[1]; Maria Andersson[2]; Anna Patricia Kipp[3]; Michael Thamm[4]; Johanna Conrad[1]
[1]Department of Science, German Nutrition Society, Bonn, Germany; [2]Nutrition Research Unit, Children's Hospital Zurich - Eleonore Foundation, Zürich, Switzerland; [3]Institute of Nutritional Sciences; Department of Nutritional Physiology, Friedrich-Schiller-Universität, Dornburger Straße, Jena; Germany, Jena, Germany; [4]Epidemiologisches Zentrallabor; Abt. Epidemiologie und Gesundheitsmonitoring, Robert-Koch-I, Berlin, Germany

BACKGROUND AND OBJECTIVES
The implementation of cost-effective public health strategies to enhance iodine status, such as the utilisation of iodised salt and fortification of animal feed, has resulted in a notable improvement in iodine status in previously iodine deficient populations, including Germany, Austria and Switzerland. However, in line with the principles of a healthy and ecologically sustainable diet, it is now recommended to decrease the consumption of animal-based foods, particularly fish and dairy products which are important dietary sources of iodine. In addition, a reduction in salt intake for the prevention of hypertension is advised, which may RESULTS in a decline in iodine intake. The objective of this paper was to evaluate the iodine supply by sustainable and salt-reduced diets and to derive recommendations for improving the iodine supply of the population.

METHODS
A literature search on the dietary iodine supply of different population groups in the context of a sustainable diet was performedand the effect c the exclusion of dairy products or a vegan diet was evaluated.

RESULTS
The adherence to a sustainable diet which is characterized by a reduced consumption of animal-based foods may result in an inadequate iodine supply for vulnerable groups, including children, adolescents, pregnant and breastfeeding women. This is due to the exclusion of dairy products, lack of iodine fortification of plant-based dairy alternatives, and insufficient use of iodised salt in processed foods. This may lead to an increasing prevalence of individuals with inadequate iodine intake and in the long term to adverse health outcomes and rising healthcare costs for society.

CONCLUSIONS
Public health policies that promote sustainable diets and reduce salt intake must be combined with (salt) iodization efforts. In the case of iodine, there is an elevated risk for insufficient supply by a sustainable and salt-reduced diet. For Germany, the following actions are proposed to improve the iodine supply of the population: the enhanced use of iodised salt in processed foods including organic foods, increasing the iodine content of table salt, using iodised salt in communal catering, a mandatory iodine fortification of plant-based milk alternatives and a regular iodine monitoring to determine the iodine status in the population.

ILEAL PROTEIN DIGESTIBILITY OF FAVA BEANS EXTRUDATE IN HEALTHY HUMANS

Corentin Lannuzel[1]; Juliane Calvez[1]; Gheorghe Airinei[1]; Martin Chapelais[1]; Nadezda Khodorova[1]; Pinja Pöri[2]; Iina Jokinen[2]; Nesli Sözer[2]; André Brodkorb[3]; Fabien Wuestenberghs[1]; Robert Benamouzig[1]; Claire Gaudichon[1]
[1]UMR914 PNCA, AgroParisTech - INRAE - Campus Agro Paris-Saclay, place de l'Agronomie, Palaiseau, France, Palaiseau, France, France; [2]Industrial Biotechnology and Food, VTT Technical Research Centre of Finland, Espoo, Finland; [3]Food Reserch Center, Teagasc, Fermoy, Ireland

BACKGROUND AND OBJECTIVES
Favouring the consumption of plant proteins has been identified as a key leverage to reduce the environmental impact of food production. High moisture extrusion is a processing technology commonly applied to mimic the structure and texture of meat. However, knowledge about the nutritional quality of such products is limited. Hence, we evaluated the true protein digestibility of a fava bean meat analogue obtained by high moisture extrusion in healthy adults.

METHODS
After overnight fasting, seven volunteers (five males and two females, mean age: 35 ± 13 years, mean body mass index: 25 ± 2.5 kg/m2) equipped with a naso-ileal tube received a test meal containing 81 g of 15N-labelled fava bean extrudate (equivalent to 290 mmol of nitrogen), panfried with 15 g sunflower oil to which agave syrup was added. Following ingestion, ileal, plasma, and urine samples were collected for eight hours, in which nitrogen, amino acids, and urea were quantified. In these fractions, 15N enrichment was quantified in bulk and in individual amino acids using isotopic ratio mass spectrometer. Concomitantly, polyethylene glycol was perfused as a non-absorbable marker in the ileum via the naso-ileal tube to determine the ileal flow rate.

RESULTS
The total amount of undigested dietary nitrogen recovered after eight hours at the ileum reached 53.7 ± 9.7 mmol, resulting in a true ileal digestibility of nitrogen of 81.5 ± 3.2 %. Over eight hours following ingestion, 17.9 ± 6.6 mmol of dietary nitrogen were recovered in urinary urea, while 31.8 ± 10.2 mmol were still present in body urea after eight hours post-ingestion. Summing these deamination losses with digestive losses allowed the net postprandial protein utilization (NPPU) calculation, which was 64.4 ± 5.5 %.

CONCLUSIONS
The ileal nitrogen digestibility from fava bean extruded meat analogue was moderate. Both ileal nitrogen digestibility and NPPU were comparable to the values previously reported for cooked and dehulled fava beans (Itkonen et al., 2024). The present RESULTS need to be complemented with individual amino acid digestibility to assess further the nutritional quality of proteins from fava bean extruded meat analogues.

CONFLICTS OF INTERESTS
The authors have no conflict of interest.

ABILITY OF THE UPDATED NUTRI-SCORE TO DISCRIMINATE THE NUTRITIONAL QUALITY OF PRE-PACKAGED FOOD IN CHINA AND CONSISTENCY WITH NUTRITIONAL RECOMMENDATIONS OF CHINESE DIETARY GUIDELINES

Lv Wanting[1]; Liu Yang[2]; Ma Aiguo[3]; Han Junhua[4]; Yuexin Yang[5]; Wang Zhu[6]; Chao Gao[6]
[1]Research Assistant, Chinese Nutrition Society, Beijing, China; [2]Department of Food Nutrition Assessment, Chinese Cenier for Disease Contol and Prevenion, beijing, China; [3]Institute of Nutrition and Health, School of Public Health, Qingdao University, Qingdao, China; [4]Secretariat, Chinese Nutrition Society, Beijing, China; [5]President, Chinese Nutrition Society, Beijing, China; [6]Department of Food Nutrition Assessment, Chinese Center for Disease Control and Prevention, beijing, China

BACKGROUND AND OBJECTIVES
The front-of-pack labelling (FOPL) Nutri-Score is a complementary nutritional information system that can inform the consumers of the nutritional value of food, prompt healthier food choices, thus promoting reformulation in the food industry. In contrast, on the Asian side, scientific research on this topic is lacking. This study aims to evaluate the nutritional quality of Chinese prepackaged food using the matrix of Nutri-Score, and to provide practical reference for the establishment of relevant FOPL in China.

METHODS
Contents of energy, fat, sodium, sugar, protein and data of ingredients were extracted from 8656 prepackaged food and their labels of 20 categories, calculated according to the FSAm-NPS nutrient profiling system, before graded A-E, to profile the nutritional quality of prepackaged food in China.

RESULTS
In terms of FSAm-NPS score, foods in this study fell into the range of 17.8±10.1. Among them, 59.1% scattered across Grade A-E, and 86.7% across 3 different grades. The RESULTS showed that the Nutri-Score system is able to profile prepackaged food in China. In particular, the nutritional quality of nut seeds, milk and ready-to-eat cereals is better than that of processed meat products, puffed foods and pastries.

CONCLUSIONS
Nutri-Score can be used to profile the nutritional quality of most prepackaged foods in China, with some categories as exceptions. It is necessary to adapt the selection of indexes and calculation method to the relevant nutrition recommendations, reference intake and other local conditions in China, thus better guiding Chinese residents in making healthier and science-based consumption choices.

ALIGNING ACTION WITH POLICY: EVALUATING COMPLIANCE OF MINISTRIES, DEPARTMENTS AND AGENCIES (MDAS) AND LOCAL GOVERNMENTS (LGS) TO PLANNING, BUDGETING AND IMPLEMENTATION PER THE UGANDA NUTRITION ACTION PLAN II (UNAP II)

Elisha Nangosha[1]; Shirley Kansabe[1]; Tracy Lukiya Birungi[1]; Edward Linton Onekalit[1]; Peterson Kikomeko Kato[1]; Joweria Nambooze[1]
[1]Nutritional Sciences and Dietetics, Kyambogo University, Kampala, Uganda

BACKGROUND AND OBJECTIVES
The Certificate of Compliance (CoC) for the FY 2022/23 Annual Budgets assessed the alignment of Uganda's national budgets with the Uganda Nutrition Action Plan II (UNAP II) and the Third National Development Plan (NDPIII). The assessment sought to evaluate compliance of Ministries, Departments, and Agencies (MDAs) and Local Governments (LGs) with UNAP II; identify gaps in planning, budgeting, and implementation for nutrition-sensitive interventions and; to provide actionable recommendations to enhance alignment with national and international nutrition targets.

METHODS
This study employed a cross-sectional design and focused on four levels: national, sectoral/Ministries, Departments, and Agencies (MDAs), and Local Government (LG). Compliance was evaluated on strategic planning/budget framework papers/ ministerial policy statements, and Annual performance which also served as data sources.

RESULTS
Preliminary RESULTS revealed low alignment, with MDAs averaging 22.6% in strategic planning and 22.7% in performance. The Ministry of Health scored highest with 36.4% in planning and 60.0% in performance, while the Ministry of Trade, Industry, and Cooperatives had 0.0% in planning and 11.5% in performance. Moderate performers included the Ministry of Agriculture, Animal Industry, and Fisheries (32.4%/29.4%) and Kampala City Council Authority (12.1%/18.0%). Several MDAs lacked assessment, highlighting gaps in nutrition planning, resource allocation, and execution. These findings underscore the need for improved coordination and capacity to achieve UNAP II targets.
The FY2022/23 Certificate of Compliance on UNAP II revealed unsatisfactory performance among local governments, with an overall average compliance score of 14.2% for strategic planning and 6.6% for performance. Napak District scored highest (58.8%/16.7%), while several districts, including Nwoya, Kamuli, and Lira, recorded 0% performance. Regional disparities were evident, with Karamoja leading at 16.8%/10.8% and Busoga scoring the lowest at 14.0%/0.0%, underscoring the need for improved planning and execution of nutrition-sensitive interventions.

CONCLUSIONS
The CoC assessment underscores critical gaps in Uganda's approach to integrating nutrition into national and local development frameworks. Once addressed, Uganda can accelerate progress toward its national nutrition and development targets, thereby contributing to the achievement of the NDP IV, Vision 2040 and the Sustainable Development Goals (SDGs).

VITAMIN D NUTRITIONAL STATUS IN MIDDLE EAST REGION : A META ANALYSIS

François Machuron[1]; Robin Dessalles[2]; Léa Ribet[1]; Nele Brusselaers[3]; Mickael Durand-Dubief[1]
[1]Lesaffre Institute of Science & Technology, Lesaffre, Marcq-en-Barœul, France; [2]Nutrition & Health, Robin Dessalles EI, Lyon, France; [3]Women's and Children's health, Karolinska institutet, Solna, Sweden

BACKGROUND AND OBJECTIVES
Adequate vitamin D status is crucial for health, especially for skeletal health. The prevention of vitamin D deficiency disorders represents a major public health concern. Several studies conducted in the Middle East region have reported surprisingly high vitamin D deficiency prevalences, despite high sunlight availability and considered adapting dietary and lifestyle recommendations, as well as fortification policies.
The present study aimed at getting a clearer picture of the vitamin D nutritional status in the Middle East region using a meta-analysis approach.

METHODS
This meta-analysis included 44 studies evaluating serum vitamin D levels in healthy Middle Eastern adult populations, using pooled analyses and meta-regressions to assess the overall levels, the differences between men and women, and the impact of covariates such as age and BMI.
Both raw and imputed data were analyzed to allow the inclusion of the maximum number of studies in the different analyses.

RESULTS
The RESULTS presented show significant disparities in vitamin D status between different countries in the Middle East region.
The meta-analysis found an overall mean serum vitamin D concentration of 45.65 nmol/L (below the recommended cut-off of 50 nmol/L), with a 3.92 nmol/L higher level in men compared to women, and no significant impact of age or BMI on these parameters.

CONCLUSIONS
This meta-analysis provides a comprehensive assessment of vitamin D status in Middle Eastern populations, highlighting the widespread vitamin D deficiency in the region, with potential gender differences, but no clear impact of age or BMI - findings that can inform targeted public health strategies to improve vitamin D nutrition in this part of the world.

DUTCH APPROACH FOR HOUSEHOLD FOOD WASTE PREVENTION: 5 STEPS TO CREATE SCIENCE BASED AND EFFECTIVE STRATEGIES

Lilou van Lieshout[1]; Marjolijn Schrijnen[2]; Kristel Zaal[3]
[1]Sustainable Food, Netherlands Nutrition Centre, The Hague, Netherlands; [2]Food Waste, Netherlands Nutrition Center, The Hague, Netherlands; [3]Behaviour, Netherlands Nutrition Centre, The Hague, Netherlands

BACKGROUND AND OBJECTIVES

Reducing food waste is one of the key strategies to fight climate change and feed the growing world's population. For this reason, the European Union and the Dutch government have committed to Sustainable Development Goal (SDG) 12.3, which sets a target of halving per-capita food waste at the retail and consumer levels by 2030 compared to 2015. The problem of household food waste has proven difficult to eradicate. There is no silver bullit to solve the problem. We need science based and effective strategies to prevent food waste at household level.

METHODS

There are 5 crucial steps to generate science based and effective strategies in the Dutch approach to tackle household food waste: 1. Create a scientific framework, 2. Focus on high-impact strategies, 3. Design an intervention respecting a diversity of factors, 4. Encourage joint implementation and 5. Evaluate to optimise.

RESULTS

There are several best practices on food waste prevention via the 5 step approach. Examples include, but are not limited to:

- Dutch National Food Waste Free week: it is a collaboration between over 150 partners nation-wide to show the positive movement against food waste and provide action perspective. Research in 2023 showed that 5 million (35% of the Dutch population) did something extra to prevent food waste during this week.
- A wide range of kitchen tools: The aim was to create a kitchen environment that makes it easier for people to waste less. Use it up tape (28% less food waste) and a tool-box (23-39% less food waste) including a measuring cup and fridge sticker were developed and implemented widely.
- Campaign and coalition on date labels: Studies show that extra communication on packaging can improve consumers' understanding of the difference between the 'best before' and 'use by date'. Together with retailers and manufacturers we clarify date marking with icons, additional text on packaging and campaigns.

CONCLUSIONS

We have to create a society in which wasting less is the easy and obvious choice.
The responsibility for waste reduction should not entirely lie on consumers shoulders, but there are opportunities in the food chain as a whole. We can all help consumers to make 'food-waste free' the new norm. We believe this can be achieved when we focus on science based effective strategies.

CONFLICTS OF INTERESTS

DESIGNING INCLUSIVE NUTRITION TRIALS: ADDRESSING BARRIERS TO ANTENATAL CARE AND DIETARY PATTERNS IN RURAL RWANDA

Gabriela Sepulveda[1]; Chhavi Tiwari[2]; Riley Ward[1]; Apolline Kampire[3]; Rebecca Henderson,[4]; Eric Matsiko[3]; Aloys Nsabimana[5]; Kathryn Reider[6]; Miles Kirby[7]; Etienne Nsereko[3]; Sarah Mckune[8]
[1]Public Health and Health Professions, University of Florida, Gainesville, United States of America; [2]College of Public Health and Health Professions Department of Environmental & Global Health, University of Florida, Gainesville, United States of America; [3]College of Medicine and Health Sciences, University of Rwanda, Kigali, Rwanda; [4]School of Medicine, University of Alabama, Birmingham, United States of America; [5]Health and Nutrition, World Vision Rwanda, Kigali, Rwanda; [6]International Programs Group, World Vision Inc, Washington, United States of America; [7]Research, Learning, and Analytics Unit | Evidence and Learning Team, World Vision International, Maine, United States of America; [8]Department of Environmental and Global Health, University of Florida, Gainesville, United States of America

BACKGROUND AND OBJECTIVES
Current nutrition recommendations often lack sufficient evidence from all populations, particularly pregnant women in low- and middle-income countries and marginalized groups, whose dietary needs are critical for maternal and child health outcomes. However, persistent barriers to participation in nutrition trials during pregnancy, including delayed engagement in antenatal care and complex dietary behaviors, limit the generalizability of findings. To address this gap, formative research was conducted prior to launching a randomized controlled trial to understand barriers and provide actionable insights for designing nutrition intervention trials tailored to the needs of pregnant women.

METHODS
We explored barriers to antenatal care and women's dietary habits through semi-structured interviews and focus group discussions with mothers, pregnant women, community health workers (CHWs), men and fathers, as well as other healthcare professionals. Qualitative data were collected in rural Nyagatare District, Rwanda from July through August 2023, and included 59 interviews and 30 focus group discussions. The data was analyzed using MAXQDA software.

RESULTS
Inductive content analysis identified six key themes influencing delayed pregnancy detection and reduced attendance at antenatal visits: financial constraints, time constraints, uncertainty surrounding pregnancy status, superstitions about pregnancy, lack of family support, and challenges in motivation and decision-making for care. Further analyses are underway to identify dietary patterns and explore potential overlaps with these barriers.

CONCLUSIONS
By understanding these barriers and habitual dietary patterns, this work offers a framework to enhance diverse participant engagement and retention in trials. This study exemplifies translational science by transforming formative research findings into practical strategies for trial design. By using qualitative methods to explore the interconnected challenges of accessing antenatal care and maintaining dietary habits, this research highlights overlapping factors that can inform inclusive trial strategies. These findings have the potential to increase intervention adherence and generalizability of trial findings, ultimately shaping the next generation of nutrition recommendations during pregnancy.

ON WHAT BASIS THE REQUIREMENTS AND RECOMMENDATIONS OF VITAMINS IS TO BE DETERMINED?

Kiyoshi Tanaka[1]; Akiko Kuwabara[2]; Misora Ao[3]; Akihito Ishigami[4]; Hiroaki Kanouchi[2]
[1]Research Support Center, Shizuoka General Hospital, Shizuoka, Japan; [2]Graduate School of Human Life and Ecology, Osaka Metropolitan University, Habikino, Japan; [3]Department of Health and Nutrition, Osaka Shoin Women's University, Higashi-osaka, Japan; [4]Molecular Regulation of Aging, Tokyo Metropolitan Institute for Geriatrics and Gerontology, Tokyo, Japan

BACKGROUND AND OBJECTIVES
For determining the nutrients requirement, clinical or epidemiological evidences for the individual vitamins are essential, but unsatisfactory by itself. On what basis to determine it is a fundamental issue, but has been little studied for vitamins. Then in this study, we propose the research questions to be answered for such purpose.

METHODS
References regarding the vitamins' requirements were reviewed; Dietary Reference Intakes (DRIs) from various countries including USA (National Academies Press; NAP), European Food Safety Authority (EFSA), series of publications from NAP such as "Guiding Principles for the Inclusion of Chronic Disease Endpoints in Future". Publications other than DRIs such as Biomarkers of Nutrition for Development (BOND) were also reviewed.

RESULTS
We have noticed the following problems. First, the theoretical basis for defining DRIs considering the chronic diseases from NAP has been applied to sodium and potassium, but not to vitamins yet.
Second, requirement has been individually studied for each vitamin, but the common theoretical basis applicable to all vitamins has not been established. We consider that the following question must be answered with high priority. 1. Although the determination of vitamins' requirement must be evidence based, evidence alone is unsatisfactory, and the basis or the position based on which the determination is made. Vitamin insufficiency, milder than deficiency, is a risk of various diseases. Vitamins' requirement greatly varies depending on whether aiming the prevention of deficiency or decreasing the disease risk by correcting the insufficiency. 2. Recently, nutritional biomarkers are classified into exposure, status, and function according to their roles. Although biomarkers are quite suitable surrogate indicators of vitamin status, their appropriate evaluation employing such classification has not been done for vitamins. 3. The theoretical basis for determining the cut-off value of biomarkers has little been argued. 4. Regarding the association between the vitamins status and disease risk, quite often there exist marked discrepancies; robust association in the observational studies and null RESULTS in the intervention studies. "What is the appropriate evidence in evidence-based nutrition?" is an urgent question.

CONCLUSIONS
For the scientific determination of vitamins' requirements and recommendations, arguing the theoretical basis and the efforts to establish the consensus is mandatory in addition to the studies on individual vitamins.

THE RELEVANCE OF MATHEMATICAL OPTIMIZATION AS A TOOL FOR DIET MODELING IN THE DEVELOPMENT OF FOOD-BASED DIETARY RECOMMENDATIONS IN SUB-SAHARAN AFRICA: A SCOPING REVIEW

Sakiko Shiratori[1]; Mudduwa Gamaethige Dilini Abeysekara[2]
[1]Information and Public Relations Office, Japan International Research Center for Agricultural Sciences, Tsukuba, Japan; [2]Graduate School of Agricultural and Life Sciences, The University of Tokyo, Tokyo, Japan

BACKGROUND AND OBJECTIVES
Sub-Saharan African countries (SSA) experience malnutrition linked to unhealthy diets and certain unfavorable trends in food consumption patterns. Although mathematical optimization has proven to be a valuable tool in informing food-based recommendations (FBRs) to promote healthier diets, its application in resource-limited settings such as SSA remains underexplored despite an emerging body of evidence. This scoping review aims to address this gap by synthesizing recent evidence on the role of mathematical programming in developing FBRs in SSA, identifying current limitations, and highlighting opportunities for advancing evidence-based dietary interventions.

METHODS
Following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses- Extension for Scoping Reviews (PRISMA-ScR), a systematic search of PubMed and Web of Science databases (2000–2024), complemented by citation tracking, identified 97 relevant studies. Of these, 30 studies spanning 12 SSA countries met the inclusion criteria. Kenya accounted for the highest representation (n=9), followed by Ghana and Ethiopia (n=4 each), Uganda (n=3), Malawi and Tanzania (n=2 each), and one study each from Benin, Burkina Faso, Mozambique, Niger, South Africa, and Zambia.

RESULTS
The reviewed studies were leveraged on linear programming (LP) or extensions of LP (i.e., linear goal programming) to formulate FBRs by optimizing the current dietary patterns to meet nutritional needs and gaps (n=24), to develop nutritionally and culturally optimized and cost-minimized food baskets (n=4), and to describe the use of LP as a method for designing population-specific food-based dietary guidelines (n=2). The formulated FBRs and optimized diets are often limited to specific demographic groups, with a limited geographic scope reflecting a regional priority. Diets can be optimized both nutritionally and economically by prioritizing locally available food groups and items; however, in some cases, additional supplementation may be necessary.

CONCLUSIONS
The reviewed studies emphasize the potential of LP to support evidence-based, context-specific FBRs and interventions in SSA, facilitated by the availability of user-friendly software. However, LP alone may not fully account for behavioral and practical aspects of food consumption. High-quality input data and incorporating sociocultural contexts will be critical for leveraging mathematical optimization to inform inclusive and effective dietary recommendations in SSA.

THE BIOAVAILABILITY OF IRON IN AUSTRALIAN VEGETARIAN AND OMNIVOROUS DIETS

Jayden Ordner[1]; Linda Atkins,[1]; Ewa Szymlek-Gay[1]
[1]Institute for Physical Activity and Nutrition (IPAN), School of Exercise and Nutrition Sciences, Deakin University, Melbourne, Australia

BACKGROUND AND OBJECTIVES
Maintaining iron balance is crucial for preventing deficiency and its related symptoms. While vegetarian diets (VegDiets) can provide comparable dietary iron to omnivorous diets (OmniDiets) when well-planned, VegDiets lack animal flesh and contain more iron absorption inhibitors (e.g., polyphenols, phytates). This reduces bioavailability and absorbable iron, often resulting in lower iron status. This study evaluated dietary iron adequacy and bioavailability in Australian adults following VegDiets or OmniDiets.

METHODS
Data were analyzed from 12,153 participants in the 2011-12 National Nutrition and Physical Activity Survey. Adults (n = 7,612; 53% female; 18-85 years) were included after excluding those aged under-18, pregnant/lactating individuals, and under-reporters (n = 4,541). Usual iron intakes were estimated using the multiple source method, and the prevalence of inadequacy was assessed via the full probability method. The Monsen & Balintfy algorithm estimated bioavailability and absorbable iron from VegDiets and OmniDiets across various eating occasions. Analyses were conducted using Stata survey commands.

RESULTS
308 Adults followed VegDiets and 7,304 followed OmniDiets. VegDiets provided 8.8 and 8.5 mg/d [95% CI: 8.4 - 8.6 mg/d] by OmniDiets. Inadequacy of dietary iron intakes was 71% [95% CI: 65.5% - 75.7%] for VegDiets and 17% [95% CI: 16.1 - 17.9%] OmniDiets (p-value for difference <0.001). In a subgroup analysis of Female OmniDiets (Age 19-49), 47% [95% CI: 44.8 - 49.2%] had inadequate iron intake. Iron bioavailability in male VegDiets and OmniDiets was 4.6% [95%CI: 4.4 - 4.8%] and 7.2% [95% CI: 7.1 - 7.2%], respectively. Mean bioavailability for female VegDiets and OmniDiets was 4.5% [95%CI: 4.4 - 4.7%] and 6.5% [95%CI: 6.4 - 6.5%], respectively (p-values for difference: <0.001). Mean absorbable iron for male VegDiets and OmniDiets was 0.8 mg/d [95%CI: 0.6 - 0.8 mg/d] and 1.1 mg/d [95% CI: 1.1 - 1.1 mg/d], respectively. Mean absorbable iron for female VegDiets was 0.5 mg/d [95% CI: 0.5 - 0.6 mg/d] and 0.8 mg [95% CI: 0.8 - 0.8 mg/d], respectively (p-values for the difference between diets: <0.001).

CONCLUSIONS
More than two-thirds of those who follow VegDiets, and almost half of females consuming OmniDiets have inadequate iron intake. Iron bioavailability and absorbable iron are lower in VegDiets compared to OmniDiets for both sexes. These findings have implications for Australians consuming VegDiets and females following OmniDiets to improve and optimize iron intake and its absorption.

SALT REDUCTION 2030 TARGETS, STRATEGIES AND MEASURES IN CHINESE FOOD INDUSTRY

Gao Chao[1]; Ge Zeng[2]; Wang Zhu[1]; Yang Yuexin[1]; Li Hanning[1]; Lv Wanting[1]
[1]Department of Food Nutrition Assessment, Chinese Center for Disease Control and Prevention, Beijing, China; [2]Director of Nutrition Program/ Chief Technical Officer, Sodium Reduction., Vital Strategies, Inc. (USA) Jinan Representative Office, Jinan, China

BACKGROUND AND OBJECTIVES

Excessive salt intake is a significant risk factor for diseases such as hypertension, stroke, and stomach cancer. Salt reduction is the most cost-effective public health strategy for preventing hypertension. Salt reduction 2030 targets will provide guidance on healthy lower sodium/salt foods, support the government and relevant administrative departments in managing food manufacturers, provide advice to consumers on purchasing and consuming lower sodium/salt foods.

METHODS

This study is based on the pre-packaged food nutrition label survey conducted by the Chinese Center for Disease Control and Prevention. It analyzes the distribution range of sodium content in various types of foods, combines the RESULTS obtained from consumer questionnaires, sets salt reduction targets, conducts research on food salt reduction technology,in order to formulate the salt reduction targets, strategies and measures in Chinese food industry.

RESULTS

The Guidelines propose four fundamental principles, seven pathways and steps, five specific methods and measures, and recommendations for fostering a supportive social environment to guide the gradual reduction of sodium/salt content in China's processed foods and promote low-salt foods. Using the sodium content distribution data from various food categories collected in 2022 as a baseline, the Guidelines set forth two phased salt-reduction targets based on a step-by-step approach:By 2027, strive to achieve an overall reduction of 5%-10% in the sodium content of various processed foods.By 2030, continue to reduce the sodium content of processed foods by another 5%-10%.Efforts to reduce sodium in the food industry should consider the unique characteristics, types, and varieties of food products. This involves advancing technical research support, enhancing innovation in sodium-reduction technologies, and gradually establishing and improving national or industry policies, regulations, and standards related to low-sodium salts and salt substitutes. Additionally, fostering a supportive social environment for sodium reduction across all sectors is crucial.

CONCLUSIONS

The updating and publication of this Guideline in 2024 will provide scientific and feasible technical guidance on salt reduction for food production enterprises and related staff, set nutrition-oriented food processing standards and objectives, create a healthy diet culture and policy environment, and also provide safeguard support for promoting consumer health.

OPTIMAL DIETARY QUALITY AMONG PREGNANT WOMEN IN A FOOD-RICH LOCALE; CALLS FOR EFFORTS TO ADDRESS ITS DETERMINANTS

Medina Wandella[1]; Germana H. Leyna[2, 3]; Ingunn M. S. Engebretsen[4]; Thorkild Tylleskär[4]; Bruno Sunguya[1]
[1]School of Public Health and Social Sciences, Muhimbili University of Health and Allied Sciences, Dar es Salaam, Tanzania, United Republic of; [2]Department of Community Health and Nutrition, Tanzania Food and Nutrition Centre, Dar es Salaam Tanzania, United Republic of; [3]Department of Epidemiology and Biostatistics, Muhimbili University of Health and Allied Sciences, Dar es Salaam, Tanzania, United Republic of; [4]Department of Global Public Health and Primary Care, Centre for International Health, Bergen Norway

BACKGROUND AND OBJECTIVES
Optimal diet quality during pregnancy has long-lasting effects on child health and development. Despite various interventions, children and women of reproductive age continue to suffer from a high burden of chronic undernutrition including micronutrient deficiencies even in food-rich regions. Evaluating diet quality during pregnancy offers a golden opportunity to address maternal nutrient adequacy and can help to design tailored and population-wide interventions. This study investigated optimal dietary intake and assessed determinants for diet quality among pregnant women.

METHODS
A cross-sectional study was conducted between July and August 2024 among 399 pregnant women (≥ 20 gestational week) attending antenatal care in one of the food-rich regions. The dietary intake was assessed using a food frequency questionnaire. FAO's Minimum Dietary Diversity for Women (MDD-W) index was used to assess dietary diversity, with 5/10 food groups used as a cut-off for the minimum recommended diet. The consumption of 21 healthy and unhealthy food groups was assessed using Prime Diet Qulity Score (PDQS) ranging from 0-42.

RESULTS
The mean age of the study participants was 25.7±6.2 years, and their mean gestational age was 27.3±5.6 weeks. The multigravida accounted for 69.1% of the study participants while 30.9% were primigravida. Among the pregnant women, 38.3% had completed secondary or higher education. Only one in three attained a minimum dietary diversity score and the median PDQS among pregnant women was 17(IQR 15 - 20). While cereal-based foods were universally consumed, only 16% of pregnant women consumed eggs, and 10.3% other vitamin A-rich fruits and vegetables. Women with secondary or more formal education (AOR=1.7:95%CI:0.6-4.4) and multigravida (AOR=2.9:95%CI:1.4-6.1) were more likely to meet the MDD recommendation compared to those with little or no formal education and primigravida respectively.

CONCLUSIONS
Achieving dietary quality and diversification among pregnant women is still a challenge. This study highlights the importance of educating women or ensuring they attend school as a necessary approach that should be strengthened to address nutrition and health challenges. Efforts are needed to address this unprecedented burden with focus among primigravida and women with low levels of education in this region and others with similar contexts.

EPO1_042

A PERSPECTIVE ON THE VALIDITY OF USING JONES FACTORS TO CALCULATE PROTEIN CONTENT

Beulah Pretorius[1]; Hettie Schönfeldt[1]
[1]Department of Animal Science, University of Pretoria, Pretoria, South Africa

BACKGROUND AND OBJECTIVES
Protein-rich foods from animal origin are the most expensive part of consumers' food baskets today. Not only does protein contribute energy to the diet as an essential macronutrient, but it also contributes essential and non-essential amino acids to the diet. Protein content in food is calculated from the nitrogen concentration (determined by Kjedahl or Dumas method) of the food using a nitrogen-to-protein conversion factor - the Jones factor, specific for certain foods. The most commonly used Jones factor is 6.25, which assumes that protein contains 16% nitrogen.

METHODS
In this study, the amino acid content of high-protein foodstuffs (meat, dairy and protein supplements) was analysed (using high-performance liquid chromatography) and the protein content was calculated in two ways. First, using the respective Jones factors and secondly by using the sum of the amino acid residues.

RESULTS
The protein content was over-reported when using the Jones factor. For meat and the supplements, the difference was statistically significant ($p \leq 0.05$). Genetic variability and seasonality in foodstuffs and the effects of how protein sources are produced and processed may to a certain extent explain the discrepancies between values determined for the same type of foodstuff. The more accurate method to determine protein content is to hydrolyse protein to their component amino acids which can then be quantified. The sum of the amino acid residues will represent the protein content of the food. This should be the preferred approach to quantify proteins in foods.

CONCLUSIONS
However, the indirect analysis using the total nitrogen content of the food multiplied by a conversion factor will still be used as it is more cost-effective and requires less sophisticated analytical instrumentation and skill. Therefore, more discussion is recommended on the updating and application of Jones factors.

PHYTASE ADDITION TO IMPROVE NUTRIENT BIOACCESSIBILITY IN CEREAL-LEGUME BASED FOOD PRODUCTS

Priyanka Kumari[1]; Daniel Amanquah[2]
[1]Food and Agribusiness, Sight and Life Foundation, Basel, Switzerland; [2]Food Technology, Sight and Life Foundation, Basel, Switzerland

BACKGROUND AND OBJECTIVES
Over 3 billion people suffer from micronutrient deficiencies, with one-third experiencing anemia and zinc deficiency, particularly in low- and middle-income countries. High levels of phytic acid in plants, which contribute significantly to daily caloric intake, prevent the absorption of essential minerals, leading to mineral deficiency and ultmately, malnutrition. Phytase, an evidence-based solution, breaks down phytic acid, enhancing the absorption of calcium, zinc, iron, and other minerals. The objective of the study is to enhance the nutritional bioaccessibility of cereal-legume based food products by adding phytase, while ensuring safety and cost effectiveness.

METHODS
We studied the impact of adding phytase to cereal-legume-based foods in two steps. In the first step of formulation development and evaluation, Phase 1 focused on formulating phytase-enriched products through dosage optimization and blending validation strategies. Phase 2 evaluated the efficacy of phytase enrichment, and Phase 3 assessed the sensory attributes of the enriched foods. In the second step of performance assessment, we used an in-vitro gastrointestinal digestion assay to determine nutrient bioaccessibility. The analysis included studying the impact on phytic acid content, residual phytase activity, nutrient content, and nutrient absorption.

RESULTS
The study demonstrated that the addition of phytase reduced phytic acid levels by at least 60% in products, while maintaining nutrient content and ensuring residual phytase levels remained below limits defined by good manufacturing practices, all in a cost-effective manner. Key learnings from the study revealed that iron starts becoming bioaccessible when phytic acid is reduced by more than 60%, although the RESULTS vary depending on the product format, the initial phytic acid level, and the iron content. Additionally, the intervention achieved at least a two-fold improvement in mineral absorption by attaining the ideal phytate-to-mineral molar ratio

CONCLUSIONS
Improving nutrient bioavailability with the same food quantities or nutrient levels provides a sustainable and cost-effective approach to combating global micronutrient deficiencies. Sensory evaluations demonstrated high consumer acceptance, highlighting the potential for seamlessly integrating this solution into existing food systems.

CONFLICTS OF INTERESTS

MEDIUM-CHAIN TRIGLYCERIDE SUPPRESS THE RISE IN BLOOD GLUCOSE LEVELS AFTER MEALS

Jun Kayashita[1]; Kodama Kousuke[1]
[1]Regional Development, Prefectural University of Hiroshima, Hiroshima Campus, Hiroshima, Japan

BACKGROUND AND OBJECTIVES
Postprandial hyperglycemia is known as a risk factor for diabetes1). Additionally, the number of diabetes patients aged 65 and older is increasing2). In Asia, rice is a staple food, but it is known to have a high glycemic index (GI)3). Therefore, we observed postprandial blood glucose fluctuations after rice consumption and explored methods to suppress postprandial blood glucose levels that could be feasible even for frail elderly individuals. This study was conducted with the approval of the Prefectural University Hiroshima Ethics Committee.

METHODS
The trial involved 32 university students who consumed either 150g of plain rice (232 kcal, 0.1g fat) or 150g of rice with 8% medium-chain triglycerides (MCT) added 12g (340 kcal, 12.1g fat) as breakfast within 10 minutes. Blood glucose levels were subsequently measured.
Each participant consumed plain rice first, followed by the MCT rice two days later. Blood glucose levels were measured using the FreeStyle Libre device, starting at 0 minutes from the beginning of consumption and continuing every 15 minutes up to 120 minutes to observe fluctuations.

RESULTS
RESULTS showed that both groups reached a peak in blood glucose levels at 45 minutes post-meal. However, the MCT rice resulted in significantly lower blood glucose levels at 45 and 60 minutes post-meal compared to plain rice. The incremental area under the curve (iAUC) for 0–30 minutes and 0–60 minutes was significantly smaller with the MCT rice.

CONCLUSIONS
These findings suggest that while providing energy, the rise in blood glucose levels can be suppressed, indicating potential applications for patients with frailty or sarcopenia among the elderly.

DIET AND LIFESTYLE MEDICINE IN ORTHOPEDICS

Stavroula Pagkrati[1]; Cesare Faldini[2]
[1]freelance, Stavroula Pagkrati, Bologna, Italy; [2]First Orthopedic and Traumatologic Clinic, Istituto Ortopedico Rizzoli, Bologna, Italy

BACKGROUND AND OBJECTIVES

Lifestyle Medicine is an evidence-based medical specialty that uses therapeutic lifestyle interventions and behaviors as a prevention of various chronic conditions, such as obesity, type-2 diabetes, cardiovascular and neurodegenerative diseases and some types of tumors. Besides, there is evidence that Lifestyle Medicine pillars individually can improve age-related pathological musculoskeletal conditions. The most common ones are: sarcopenia (progressive loss of skeletal muscle mass and strength), osteoporosis (gradual bone mass decrease), osteoarthritis (the most prevalent joint degenerative disease), inflammatory episodes (tendinitis, bursitis) and chronic pain on a substrate of silent chronic inflammation. However, there are very few studies that suggest diet and lifestyle strategies for improving musculoskeletal health of orthopedic patients.

METHODS

We present the FACILE (=easy) diet, whose initials are the explanatory evolution of the Mediterranean diet: Flexitarian, Accessible, Conscious, Individualized, Lifelong, Eco-sustainable. It is not only a healthy eating pattern that contributes to the reduction of silent chronic inflammation and oxidative stress. Instead, it should be considered as nourishment and as part of a wider healthy way of living, which includes increased physical activity, improvement of sleep, development of stress-management, cultivation of positive relationships, avoidance of risky substances.

RESULTS

Healthy eating and lifestyle patterns can contribute to a better musculoskeletal health, improving patients' independency and quality of life, and preventing frailty, falls, fractures, hospitalization and death. These strategies can prevent sarcopenia, osteoporosis, osteoarthritis; they can support patients under conservative treatment; they can improve musculoskeletal health of patients who undergo elective orthopedic surgeries, playing an important role in the pre-rehabilitation; they can amplify the effects of postoperative rehabilitation, further improving surgical outcomes.

CONCLUSIONS

A new type of collaboration between orthopedists (who mostly use the expert approach) and nutritionists (who prefer the coach approach) is essential in order to promote healthy nutritional and lifestyle education. When orthopedic patients are supported, informed and empowered, they are intrinsecly motivated to change. This is the engine that can accompany them throughout their lives, mantaining a musculoskeletal health overtime, contributing to healthspan.

BACKGROUND AND OBJECTIVES

Pregnant women are daily exposed to food chemical contaminants that can affect the fetoplacental development with long-term effects on offspring health. Using the RESULTS of the SEPAGES mother-child cohort urine dosages, a mixture of eight compounds from phenol, phthalate, and paraben families (PPPs) were defined for their association with health effects on offspring. Based on these data, the present study aimed to mimic maternal exposure to this mixture of three phenols, one paraben and four phthalates to assess the impact on fetoplacental development in a rabbit model.

METHODS

Female rabbits were orally exposed daily to a mixture of PPPs (PPP group) or to the vehicle (C group) from two months preconception to the end of gestation, i.e. 90 days of exposure. Maternal blood biochemistry was performed before conception and at the end of gestation. Ultrasound and Doppler measurements were performed to explore fetoplacental development and placental vascularization. At 28 dpc, maternal and fetoplacental tissues were collected for biometry. Placental and liver functions were explored by RNAseq.

RESULTS

PPP exposure did not affect maternal biometry but disturbed maternal biochemistry (decreased glucose). Maternal exposure to PPPs did not significantly affect ultrasound data. However, multiple factor analysis (MFA) of ultrasound and Doppler measurements showed separation of the groups. A similar result was observed for MFA combining fetal biometric datasets, on which placental efficiency separated the groups. A sex-specific effect was further observed in the group separation, affecting mostly placental efficiency and relative heart weight. However, no significant differences were found using a linear mixed-effects model for individual biometric data. In addition, transcriptomic analysis identified numerous differentially expressed genes (DEGs) in the placenta and liver between groups.

CONCLUSIONS

Maternal exposure to PPPs at realistic doses had small effects on fetoplacental development, consistent with human data. According to MFAs, fetoplacental biometry as a whole was affected by PPP exposure, although individually no parameter showed a statistically significant difference., Identified DEGs at 28 dpc reflected disruption of placental and hepatic function by exposure to PPPs. Work is ongoing to determine whether this exposure affects fetal biochemistry, hepatic structure and placental morphometry. Our RESULTS already tend to show that we need to become aware of the quality of our food, which appears essential for our health and that of our children.

CO-CREATION AND DISSEMINATION OF HEALTHY EATING AND WELLBEING GUIDELINES WITH MĀORI YOUTH

Boyd Swinburn[1, 2]; Renee Railton,[2]; Rachael Glassey.[2]; Eloise Goddard,[1]; Raun Makirere-Haerewa,[2]; Layla Christison,[2]; David Tipene-Leach,[2]
[1]School of Population Health, University of Auckland, Auckland, New Zealand; [2]Te Kura i Awarua Rangahau Māori Research Centre, Eastern Institute Of Technology, Hawke's Bay Campus, Napier, New Zealand

BACKGROUND AND OBJECTIVES
The conversion of evidence into culturally relevant, meaningful guidelines requires co-creation of messages with the target audience. The objective of this study was to co-create with rangatahi (young people) a set of evidence-based eating and wellbeing guidelines for young people in Aotearoa New Zealand, informed by mātauranga Māori (Māori knowledge).

METHODS
Rangatahi Māori collaborated with Māori and non-Māori experts to review multiple existing health guidelines covering healthy, sustainable eating, physical activity, screen time, sleep and mental wellbeing and developed their own set of guidelines. Four wānanga (workshops) were held at a local marae (meeting house) to 1) develop the guidelines, 2) revise them post-feedback from school peers, 3) develop dissemination materials, and 4) debrief after the 12-week social media dissemination campaign. The process integrated scientific evidence with mātauranga Māori, following tikanga Māori (Māori protocols) to ensure a culturally centred process.

RESULTS
Seventeen rangatahi Māori from four schools with high Māori student enrolment participated in the study, creating ten eating and ten wellbeing guideline messages (here). These messages were invitational (beginning 'Let's try to…') acknowledging the challenging journey for many rangatahi from current to recommended behaviours. Only one quantification (8-10 hours of sleep) was included. Three eating and three physical activity guidelines incorporated the concepts of 'mauri' (life force). The guidelines addressed contemporary issues including sustainable eating, ultra-processed foods, social dimensions of eating and physical activity, screen-time and cyberbullying. They also emphasised respect, rights and responsibilities, and concluded with a motivational whakatauki (proverb) about aspirations. 94 students provided peer-feedback through structured surveys ahead of wānanga 2. Dissemination through a social media campaign created a good audience reach of over 1.4 million accounts, and >19,000 engagement actions.

CONCLUSIONS
Innovative, relevant and contemporary eating and wellbeing guidelines have been successfully co-created by Hawke's Bay rangatahi Māori for all young people in Aotearoa New Zealand. The incorporation of mātauranga Māori was essential for creating culturally centred messages for this priority audience. The use of social media should be central to further dissemination plans.

CLINICAL SIMULATION IN THE TRAINING OF FUTURE NUTRITION PROFESSIONALS: AN UNDERGRADUATE EXPERIENCE AT AN ARGENTINEAN UNIVERSITY

Betiana Leticia Peralta[1]; María Del Carmen Morasso[1]; Carolina Ross[1]; Soledad ÁLvarez De Campos[1]; Marcela Stambullian[1]
[1]Carrera Nutrición, Universidad Austral, Pilar, Argentina

BACKGROUND AND OBJECTIVES

Evidence suggests that teaching with a high theoretical content RESULTS in retention´s rate less than 20%. A student-centered teaching-learning model, such as clinical simulation (CS) can facilitate more meaningful learning and contribute to patient safety. This communication shares the experience of implementing CS throughout a Human Nutrition & Dietetics degree curriculum at a private university in Pilar, Buenos Aires, considering students' perceptions of this teaching approach.

METHODS

A descriptive analysis of the curriculum, the syllabus of the subjects that apply CS and the post-scenarios surveys of 256 students between 2022-2024 was carried out.

RESULTS

The curriculum spans 5 years, with CS progressively integrated from the first year, advancing through zones (Z) of increasing complexity, Z0 to Z2, over the first 4 years. In the 1st year, CS classes were introduced in ´Human Physiology´. Between the 2nd and 4th years, simulation-based instruction (Z1) was used to teach skills for nutritional assessment in children, adults, and athletes, employing peer-to-peer and simulated patient interactions. Technical skills in nutritional support were also developed. In the 4th year, students participate in clinical scenarios (Z2) to assess the nutritional status of simulated patients in both: hospitalized and outpatient care. Although real clinical observations occur throughout the programme, CS develops technical and soft skills to prepare students for their final-year professional internships. Student feedback on CS included: ‘Excellent experience; without this opportunity, it would be more challenging to apply these skills in real-life situations.’ ‘Very good anthropometry practice guided by the professors.’ ‘The activity provided a safe environment for professional practice, free from judgment, with constructive feedback that helped me learn.’ ‘I really enjoyed it as a way to practice and apply my knowledge while developing my interaction skills with patients.’

CONCLUSIONS

Clinical simulation is a well-established teaching-learning method in nursing and medicine but remains novel in nutrition. Acquiring skills in a CS centre enhances students' training and confidence while positively impacting patient safety in their future professional careers. Sharing experiences in CS allows for better implementation of methodology and resources allocation in our discipline.

Association of the updated 2023 version of the front-of-pack nutrition label Nutri-Score with all-cause and cause-specific mortality: prospective RESULTS from the Moli-sani Study

Marialaura Bonaccio[1]; Emilia Ruggiero[1]; Augusto Di Castelnuovo[1]; Simona Costanzo[1]; Simona Esposito[1]; Chiara Cerletti[1]; Maria Benedetta Donati[1]; Giovanni De Gaetano[1]; Licia Iacoviello,[1]
[1]Epidemiology and Prevention, IRCCS Neuromed Mediterranean Neurological Institute, Pozzilli, Italy

BACKGROUND AND OBJECTIVES
The Nutri-Score is a front-of-pack (FOP) nutrition label to inform consumers on the overall nutritional quality of foods, and is being adopted in many European countries on a voluntary basis. In 2023, the algorithm underlying the Nutri-Score was updated to better align with food-based dietary guidelines across joining countries. We tested whether the updated version of the Nutri-Score is associated with mortality in an Italian adult population.

METHODS
Longitudinal analyses were run on 22,893 participants to the Moli-sani Study (2005-2010). Food intake was assessed by a 188-item FFQ. The Food Standards Agency Nutrient Profiling System (FSAm-NPS) score, used to derive the original Nutri-Score, was calculated for each food based on its amount of energy, saturated fat, sugar, salt, fibre, protein, fruits, vegetables, legumes and nuts, according to criteria established in 2023. The FSAm-NPS dietary index (DI) was calculated for each participant as an energy-weighted mean of the FSAm-NPS score, with higher values indicating lower nutritional quality.

RESULTS
Over a median follow up of 13.1 y, 2,565 all-cause deaths occurred, of which 909 were from cardiovascular diseases (CVD) and 939 from cancer. The average value of the updated FSAm-NPS DI was 7.87 (±1.69), and highly correlated with its prior version (spearman correlation coefficient = 0.90). In multivariable-adjusted Cox regression models including known risk factors, a higher adherence to the FSAm-NPS DI was not associated with either all-cause mortality (HR= 1.06; 95%CI 0.94-1.20 for Q4 vs. Q1), nor CVD (HR=1.06; 0.86-1.32) or cancer deaths (HR=1.15; 0.94-1.4). However, the magnitude of these associations was stronger in women (all-cause mortality: HR=1.19; 0.98-1.45 and HR=0.99; 0.84-1.17 for women and men, respectively, p for interaction=0.039; cancer death: HR =1.33; 0.97-1.83 and HR=1.06; 0.81-1.39, for women and men, respectively, p for interaction=0.015).

CONCLUSIONS
The dietary index underlying the updated version of the Nutri-Score FOP nutrition label is not associated with mortality in this large population-based cohort of Italians. Although FOPs are intended to help consumers making healthier food choices, their actual impact on long-term health outcomes remains controversial.

BACKGROUND AND OBJECTIVES

In 2022, it was established a dietitians' study network which includes professionals from 13 countries in order to study the roles and working environment of Clinical Dietitians, giving origin to a series of studies in this sphere. Nutritional care practices in intensive care units (ICUs) have been poorly documented in the literature, particularly in the Latin American context. This research aims to identify nutrition-related clinical practices in ICUs in Latin American countries and to examine environmental conditions that influence nutritional care provided by Dietitians in this region.

METHODS

A cross-sectional survey was administered to 223 clinical dietitians who work in ICUs from 18 Latin American countries to identify their professional activities in public and private health care facilities. The survey consisted of 30 questions related to clinical nutrition tasks. Prior to the application of the survey, a content validity process was conducted by means of the Content Validity Index (CVI). Once the experts of the participating countries had evaluated the questionnaire, the final 23-question version was available, consisting of the questions that obtained high enough scores to be considered. The average score of the questionnaire was 0.87 points. A score was calculated based on 18 activities

RESULTS

The median professional experience among dietitians was 10 years (Interquartile Range [IQR] 6-16), with a predominance of women (87%); participants primarily worked in public, high-complexity hospitals (63.2%). A majority of 61.4% reported a 40-hour work week. Regarding work areas, 70.7% worked in Adult Intensive Care Units (ICUs), 8.4% in Pediatric ICUs, and 20.9% in both Adult and Pediatric ICUs. About 3.7% did not specify the type of ICU where they provided nutritional care. Most surveyed professionals (61.4%) held a postgraduate degree in Clinical Nutrition, with Diplomas being the most common (39.5%), followed by Master's degrees (19.7%), while a smaller percentage held Doctorates (1.3%) or Specializations (0.9%).Associations were investigated with linear regression adjusted by country, sex, type of institution, complexity of the hospital, years of expertise (B: 0431IC95% 0.264-0.598), years being a dietitian and number of postgraduates (B: 0.288 IC95% 0.158-0.417). Factors positively associated with higher scores included greater years of experience and years being a dietitian. No other activities were associated

CONCLUSIONS

There is a lack of standards to regulate and examine the dietitians' workforce gap in order to improve working environment and quality of care.

DIETARY SULFORAPHANE MAY MODULATE S100A8/A9 EXPRESSION AND IMMUNE HOMEOSTASIS IN ANKYLOSING SPONDYLITIS: IMPLICATIONS FOR NUTRITIONAL INTERVENTION

Bruno Campos Casado Lima[1]; Fryda Solis Roldan,[1]; Helena Reyes-Gopar,[1]; Nicholas Dopkins,[1]; Nicholas Liotta,[1]; Matthew L. Bendall[1]; Enrique Hernández-Lemus,[2]; Douglas Fraser Nixon,[1]; Robert L. Furler O'Brien[1]
[1]Translational Research, The Feinstein Institutes for Medical Research, Manhasset, United States of America; [2]Departamento de Genómica Computacional, National Institute of Genomic Medicine, Ciudad de México, Mexico

BACKGROUND AND OBJECTIVES
Axial spondyloarthritis (axSpA) is a chronic inflammatory rheumatic disease primarily affecting the spine and sacroiliac joints1. It typically develops in young adulthood and is characterized by complex immune dysregulation. Nonsteroidal anti-inflammatory drugs (NSAIDs) are commonly used as first-line treatments for pain and inflammation relief in axSpA. If NSAIDs are proven insufficient, biologic disease-modifying antirheumatic drugs (DMARDs) are often employed to control disease activity2, however they can result in serious adverse effects. There is no official universally accepted clinical nutritional recommendation protocol specifically for axSpA, however there is increasing evidence pointing towards a critical role of nutritional factors in this disease modulation. S100A8 and S100A9 are key pro-inflammatory proteins4 implicated in axSpA pathogenesis that form the calprotectin complex6. These proteins are elevated in leukocytes5 in axSpA patients and contribute to inflammation and joint damage. Previous single-cell analyses have revealed complex cell-specific alterations in S100A8/A9 expression across different immune cell subsets in axSpA, highlighting the need for targeted interventions. Sulforaphane (SFN), a compound present in broccoli sprouts with anti-inflammatory and antioxidant properties, has demonstrated efficacy in preclinical models of inflammatory diseases by modulating the Nrf2 pathway and suppressing pro-inflammatory cytokine production7,8. This study investigates the potential of dietary SFN supplementation to modulate S100A8/A9 expression and reduce inflammation in axSpA.

METHODS
Gene expression patterns were analyzed from sequenced single cells (PBMCs and CD4+ T cells) from axSpA patients and healthy controls9. Differential gene expression (DEG) analysis was performed to identify upregulated genes in axSpA. Ongoing *in vitro* studies are evaluating the effects of sulforaphane supplementation on S100A8/A9 expression.

RESULTS
DEG analysis revealed upregulation of S100A8/A9 in axSpA patients compared to controls.

CONCLUSIONS
The upregulation of S100A8/A9 suggests their role in axSpA pathogenesis. RESULTS from the ongoing *in vitro* studies will determine whether SFN can modulate S100A8/A9 expression and potentially serve as a nutritional immune intervention for axSpA. This research could contribute to developing evidence-based dietary recommendations for managing axSpA.

CURRENT STATUS OF NUTRITION DEGREE TRAINING AT UNIVERSITIES IN VIETNAM

Thi Hong Nhung Hoang[1]; Haruna Ubukata[2]; Quoc Hung Lam[1]; Thi Hanh Nguyen[2]; Hiromi Ishida[3]; Yoshiyuki Takato[2]; Do Huy Nguyen[4]
[1]Department of Health, National Institute of Nutrition, Hanoi, Vietnam; [2]SHIDAX RESEARCH INSTITUTE, SHIDAX CORPORATION, Shibuya, Japan; [3]Laboratory of Administrative Dietetics, Kagawa Nutrition University, Sakado, Japan; [4]The Department of Clinical Nutrition and Family Medicine, VNU University of Medicine and Pharmacy, Hanoi, Vietnam

BACKGROUND AND OBJECTIVES

The Ministry of Education and Training of the Socialist Republic of Vietnam approved the bachelor's degree program in Nutrition at Hanoi Medical University in 2013. As of now, 12 universities across the country offer training programs for nutritionists. Over the past decade, the enrollment capacity for these programs have grown significantly. However, details regarding the curriculum, its implementation across universities, and the employment outcomes of trained nutritionists remain unclear. This study aims to examine the current state of nutritionist training in Vietnam.

METHODS

Between January and December 2023, surveys were conducted across 12 nutritionist training institutions to assess curriculum content. Employment and job type surveys were also administered to 564 graduates and 323 final-year students from the class of 2023. Additionally, a survey targeting 63 provincial and city health departments under government oversight and 34 central-level hospitals under the Ministry of Health was carried out to evaluate the employment status of nutritionists and forecast demand through 2030. This study received ethical approval from the Ethics Committee of the Vietnam Nutrition Institute.

RESULTS

Graduation in nutrition at these universities requires completing 138 to 165 credits, exceeding the 120-credit standard set by the Ministry of Education and Training. Among 197 nutritionists (34.9%) and 230 final-year students (71.2%), 139 graduates (70.6%) were employed in medical facilities. Additionally, 148 final-year students (64.3%) expressed a desire to work in medical facilities. Furthermore, responses from 25 health departments (39.7%) and 18 central-level hospitals (52.9%) revealed that 94 nutritionists are currently employed in health departments and 24 in hospitals. Projections indicate a hiring demand by 2030 of 726 nutritionists for health departments and 70 for hospitals, averaging 3.8 positions per hospital.

CONCLUSIONS

This study revealed that universities in Vietnam offering nutritionist training require credit loads exceeding the standards set by the Ministry of Education. The findings also highlighted that medical facilities are the primary employment setting for nutritionists. Furthermore, the research identified a growing demand for nutritionists in health departments and public medical facilities. As the first report of its kind in Vietnam, this study is expected to contribute significantly to the advancement and standardization of nutritionist training and qualifications in the future.

VALIDATING AND EVALUATING DIETARY QUALITY: ALTERNATIVE HEALTHY EATING INDEX FOR MALAYSIAN ADOLESCENTS

Nurul Ain Azizan[1]; Ai Kah Ng[2]; Rahim, Tik Maimunah Abdul[2]; Hazreen Abdul Majid[3]
[1]School of Biosciences, University of Nottingham Malaysia, Semenyih, Malaysia; [2]Social and Preventive Medicine, University of Malaya, Kuala Lumpur, Malaysia; [3]School of Health and Rehabilitation Sciences, Health Sciences University, Bournemouth, United Kingdom

BACKGROUND AND OBJECTIVES
The diet quality of adolescent is a growing concern worldwide, with significant implications for their current and future health. Assessment tools like the Alternative Healthy Eating Index (AHEI) can assesses diet quality. Evaluating diet quality with AHEI is crucial as it helps identify nutritional gaps, promotes healthier eating habits, and addresses diet-related health issues prevalent among the youth. This study aim to validate and evaluate the dietary quality of Malaysian adolescents using newly developed Alternative Healthy Eating Index for Malaysian Adolecent (AHEI-MA). This AHEI-MA was developed based on foods that can prevent chronic diseases and based from the Malaysian Dietary Guidelines for Children and Adolescents 2013.

METHODS
AHEI-MA that was developed and tailored to Malaysian adolescents' specific food and nutrient concerns was used in this study to asses adolescents dietary quality. Data from the Malaysian Health and Adolescents Longitudinal Research Study (MyHeART study) was used to validate this eating index. 424 adolescents aged 15 years old from urban and rural schools in Malaysia provided information on sociodemography data, anthropometry data and dietary intake. Their dietary intake were collected using 7 days dietary history. Their diet quality then were calculated based from the 7 days dietary history using the AHEI-MA.

RESULTS
The AHEI-MA scores were categorized as good diet quality (>80%), diet requiring improvement (51–80%), and poor diet quality (>51%). The findings indicated that urban adolescents exhibited a mean diet quality score of 52.35%, categorized as "needs improvement," whereas rural adolescents demonstrated a poorer mean score of 48.55%. Additionally, female adolescents achieved significantly higher diet quality scores compared to their male counterparts with score of 62.79% compared to 27.03%. Meanwhile, range of score of sugar component intake shows that urban score slightly better than rural (6 vs 4), while both urban and rural adolescents score 0 for sodium component.

CONCLUSIONS
The use of the AHEI-MA for adolescents is crucial in promoting healthier dietary habits and addressing nutritional deficiencies. This study highlights the importance of evaluating diet quality among Malaysian adolescents. However, larger validation studies are needed to further confirm the reliability and applicability of the AHEI-MA in diverse adolescent populations.

HOW ALIGNED ARE THE CHILEAN FOOD-BASED DIETARY GUIDELINES WITH CANCER PREVENTION? A CONTENT ANALYSIS

Sandra López-Arana[1, 2]; Alejandra Ortega-Guzmán[3]; Solange Parra-Soto[4, 2]; María Jesús Vega-Salas[2, 5]; Lorena Rodríguez-Osiac[6, 2]

[1]Faculty of Medicine, Nutrition and Dietetics School, Universidad Finis Terrae, Providencia, Chile; [2]Center for Cancer Prevention and Control, (CECAN), Santiago, Chile; [3]Centro para la Transversalización de Género en I+D+i+e, Unidad de Igualdad de Género en I+D+i, Universidad Autónoma de Chile, Santiago, Chile; [4]Departament Nutrition and Public Health, Biobio University Campus Fernando May, Chillán, Chile; [5]Departamento de Nutrición y Dietética, Escuela de Ciencias de la Salud, Facultad de Medicina, Campus San Joaquín, Pontificia Universidad Catolica de Chile, Santiago, Chile; [6]Escuela de Salud Pública Dr. Salvador Allende, University of Chile - North Campus, Santiago, Chile

BACKGROUND AND OBJECTIVES

Cancer is a multifactorial disease involving a range of genetic, medical, environmental, and health-related behaviors. In 2022, Chile experienced an estimated 59,876 new cancer cases and 31,440 cancer-related deaths. Evidence suggests that 30% to 50% of cancer incidence is linked to unhealthy behaviors. It is therefore important that dietary recommendations, including population-based dietary guidelines, and public policies be designed to support and facilitate healthier choices. We evaluated the alignment between the updated Chilean Food-Based Dietary Guidelines (FBDG) and cancer prevention recommendations from the World Cancer Research Fund (WCRF/AICR) and the Latin America and the Caribbean Code Against Cancer (LAC-Code).

METHODS

A content analysis was performed based on the disclosure and technical documents from the updated Chilean FBDG (2023). A matrix of eight categories were developed to evaluate the relevance of the messages with cancer prevention recommendations: i) scientific evidence-based; ii) local context; iii) population focused; iv) public policy endorsement; v) clear communication; vi) dietary pattern approach; vii) realistic and achievable, & viii) prevention of other diseases. Furthermore, we compared the 10 Chilean FBDG messages with the WCRF/AICR and the LAC Code recommendations.

RESULTS

The updated Chilean FBDG messages met most of the categories included. Four out of ten of the Chilean FBDG messages were directly aligned with LAC Code and the WCRF/AICR recommendations, five had an indirect relationship, and one was not related to any cancer recommendation.

CONCLUSIONS

This study suggests that the updated Chilean FBDG messages are most often indirectly aligned with the worldwide and the Latin American region cancer prevention recommendations over the role of diet, nutrition and physical activity in cancer risk among the general population. Our RESULTS may guide future updates to incorporate direct cancer prevention rationales and messages, considering the high incidence and prevalence of cancer in Chile.

DEVELOPING A NATIONAL ALLIANCE FOR A 'TRUSTED' VOICE TO ENSURE NUTRITION SCIENCE IN GOVERNMENT POLICY MAKING FOR FOOD AND NUTRITION

Margaret Allman-Farinelli[1]; Stuart Barrow,[2]; Penny Brew,[3]; Vicki Flood,[4]; Magriet Raxworthy,[5]; Eleanor Beck,[6]
[1]Faculty of Medicine and Health, University of Sydney, Sydney, Australia; [2]Science Policy, Australian Academy of Science, Canberra, Australia; [3]Program Delivery, Australian Academy of Science, Canberra, Australia; [4]Chair, Nutrition Society of Australia, Sydney, Australia; [5]Chief Executive Officer, Dietitians Australia, Canberra, Australia; [6]School of Health Sciences, University of NSW, Sydney, Australia

BACKGROUND AND OBJECTIVES
A national decadal plan for nutrition science was developed in 2019. This plan identified key research pillars to advance nutrition and highlighted critical enabling infrastructures to support delivery of the plan. Among these was the need for a 'trusted' voice in nutrition science to diminish the cacophony advocating non-evidence-based advice to politicians and community. The objective here is to describe the development of this 'trusted voice'.

METHODS
The conceptualisation of the 'trusted' voice collective as a valued partner by government for food and nutrition policy, involved two phases. Firstly, the model was explored at a one-day symposium. An experienced researcher led discussion with early career researchers to develop a logic model to establish the 'trusted' voice. Secondly, a small steering committee of six Academy of Science National Nutrition Committee researchers, policy experts, and exofficio members was formed to lead the implementation.

RESULTS
The one-day symposium members suggested four key objectives for the 'trusted' voice now known as a national Alliance for Nutrition Science. These included development of a vision, mission and terms of governance, bringing together diverse interested organisations, prioritising and developing the policy recommendations, and advocacy for evidence-based policy. Of critical importance was the ability of an Alliance to amplify voices and this would require both financial commitment, and intellectual input. The steering committee established the proposed vision, mission, scope, and governance via terms of reference. Additionally, it became important to define principles about what constituted highest quality scientific nutrition evidence. Potential member organisations were identified, provided with a brief document outlining the rationale and principles for the Alliance, and invited to a briefing presentation and discussion. Twenty-three organisations attended and expressed willingness to join the Alliance.

CONCLUSIONS
It is possible to bring together diverse professional societies and non-government organisations to amplify messages to government and ensure that the highest level of evidence available in nutrition science underpins the development of food and nutrition policy. This case study shows the importance of a decadal plan with an implementation model to enable the uptake of nutrition science evidence for the public good.

EXAMINING NUTRITION POVERTY AND ITS ASSOCIATION WITH DIETARY DIVERSITY AMONG INDIAN CHILDREN: POLICY RECOMMENDATIONS FROM A LARGE-SCALE HOUSEHOLD SURVEY

Jyothimol Joseph[1]; R Sendhil[1]
[1]Economics, Pondicherry University, Kalapet, India

BACKGROUND AND OBJECTIVES
Chronic malnutrition remains a significant barrier to improving child health outcomes. Addressing this issue requires a multidimensional approach that considers factors beyond income, such as dietary diversity, access to healthcare, and living conditions. In this lieu, this paper aims to (1) develop a Multidimensional Nutrition Poverty Index (MNPI) for under-five children, (2) identify the extent of child nutrition poverty, and (3) examine the linkage between nutrition poverty and diet diversity.

METHODS
The MNPI was developed using the Alkire-Foster dual cut-off approach for household data from the fifth round of the NFHS (2019-20). For the present study, eight indicators were selected under four dimensions, viz., (1) stress: malnutrition and under-five mortality, (2) access: education and living standards, (3) availability: diet diversity and antenatal care, and (4) adequacy: immunization and nutrition knowledge. These indicators were assigned different weights and tested for robustness using Spearman's rank correlation and Kendall's tests. In addition, a regression tree and biplot were used to depict the linkage between nutrition poverty and diet diversity.

RESULTS
MNPI estimation indicated that the headcount ratio (H) and intensity (A), respectively, was 0.605 and 0.48, leading to 29.2% of the children experiencing nutrition poverty. Of the eight indicators chosen for their relevance to child health, it was found that diet diversity (21.68%) was the most contributing factor, followed by living standards (21.17%) and child malnutrition (19.64%). Among the regions, the MNPI was higher in the case of eastern India, like Nagaland (0.5058), Bihar (0.4772), Jharkhand (0.4065), and Assam (0.4017). A comparison between rural and urban India showed that the MNPI was higher in rural regions (31.74%). The regression tree analysis done to identify the correlates of MNPI affirmed that diet diversity largely influenced nutrition poverty, i.e., MNPI. Regional prioritization using biplot analysis indicated a strong linkage between nutrition poverty and regional diet diversity.

CONCLUSIONS
This study offers valuable insights into critical factors that could facilitate efforts to reduce nutrition poverty and identify high-priority areas for policy intervention to record improved health outcomes in the long run.

ADHERENCE TO THE MEDITERRANEAN DIET IS ASSOCIATED WITH REDUCED ABDOMINAL OBESITY IN TAIWANESE RENAL TRANSPLANT RECIPIENTS

I-Hsin Lin[1]; Shih-Wei Nien[1]; I-Hsin Tseng[1]; Yi-Ming Wu[1]; Hsu-Han Wang[2]; Yi-Han Hsieh[3]; Nien-Chieh Yang[3]; Te-Chih Wong[3]
[1]Department of Medical Nutrition Therapy, Linkou Chang Gung Memorial Hospital, Taipei, Taiwan; [2]Department of Urology, Linkou Chang Gung Memorial Hospital, Taipei, Taiwan; [3]Department of Nutrition and Health Sciences, Chinese Culture University, Taipei, Taiwan

BACKGROUND AND OBJECTIVES
This study investigated the association between adherence to the Mediterranean diet (MD) and abdominal obesity among renal transplant recipients (RTRs) in a single-center hospital. It was hypothesized that MD positively impacts waist circumference (WC) in RTRs.

METHODS
This cross-sectional study included 252 RTRs. Demographic and laboratory data were retrieved from medical records. WC was measured at the midpoint between the lowest rib and the iliac crest using a horizontally positioned tape measure. Abdominal obesity was defined as WC ≥ 90 and ≥ 80 cm in men and women, respectively based on Taiwan Ministry of Health and Welfare. Three-day dietary records were collected by trained dietitian. Adherence to MD was evaluated using Literature-Based Adherence Score (LBAS) with scores ranging from 0 to 18 (minimum to maximum adherence).

RESULTS
A total of 252 patients (54.76% men; mean age 49.40 ± 12.57 years) participated. Mean WC and LBAS were 83.92 ± 11.09 cm and 8.48 ± 2.35, respectively. The prevalence of abdominal obesity was 46.43% (n = 117). After adjusting for covariates such as age, sex, energy intake, comorbidities, body mass index, transplant date, donor source, immunosuppressant use, and insulin resistance, a 1-point increase in LBAS was associated with a 21.2% reduction in the likelihood of abdominal obesity (odds ratio: 0.798, 95% CI: 0.635–1.004, p = 0.054).

CONCLUSIONS
High adherence to MD pattern is associated with a lower prevalence of abdominal obesity in RTRs. Mediterranean-style diet may be an effective strategy in Taiwanese RTRs.

EPO1_063

CO-DESIGN OF ANTENATAL MULTIPLE MICRONUTRIENT SUPPLEMENT (MMS) PACKAGING TO SUPPORT OPTIMAL ADHERENCE AND ACCEPTANCE IN CAMBODIA

Sokchea Meng[1]; Cassandra Sauer[2]; Sambo Sreang[1]; Kroeun Hou[3]; Mai-Anh Hoang[4]; Kim Rattana[5]
[1]Nutrition, Helen Keller Intl Cambodia, Phnom Penh, Cambodia; [2]Food, Nutrition and Health, The University of British Columbia, Vancouver, Canada; [3]Nutrition, Helen Keller Intl Cambodia,, Phnom Penh, Cambodia; [4]Nutrition, Helen Keller Intl, New York, United States of America; [5]National Maternal and Child Health Center, Ministry of Health, Cambodia, Phnom Penh, Cambodia

BACKGROUND AND OBJECTIVES
Recognizing the mounting evidence for the effectiveness of multiple micronutrient supplements (MMS) on preventing adverse birth outcomes, the Ministry of Health in Cambodia supports the transition from iron-folic acid to MMS. Previous research has shown that women deem specific colors, logos, and slogans attractive and appropriate for pregnancy. Evidence indicates adequate packaging and brand trust significantly influence adherence to supplementation. This study aims to implement a co-design process to gather insights from Cambodian pregnant women and their partners regarding MMS packaging, focusing on design elements such as color, product name, slogans, logos, and messaging.

METHODS
A convenience sample of 15 pregnant women and their partners were selected to attend a 2-hour participatory workshop in four different provinces in Cambodia. Three preliminary MMS packaging designs were developed based on prior qualitative findings. During the workshops, participants provided quantitative ratings using a Likert scale and qualitative feedback on the different packaging options: color, product name, slogan, logo, and key messages. Qualitative data was analyzed using thematic content analysis, while quantitative data was summarized using descriptive statistics

RESULTS
A total of 4 workshops were held with 84 participants in Kampong Chhnang (n=25), Ratanakiri (n=25), Takeo (n=15), Kampot (n=19). Pink emerged as a favorite color with participants (n=40/84) associating it with beauty and happiness. The product name "Multivitamin" resonated strongly with participants (n=64/84), who valued the idea of receiving multiple nutrients in a single supplement. The slogan "Good friend for pregnant women" was popular among participants (n=44/84), as it conveyed a sense of support for an optimal pregnancy experience. Visual preferences were clear, with Image A receiving high ratings (n=54/84). This image depicted a beautiful woman enveloped by multiple vitamin "bubbles". Participants found the message “supports baby to be strong and smart” to be the easiest to understand (n=26/84) and the most motivational (n=24/84). The simplicity of the message and significance of supporting their baby made it participants top choice

CONCLUSIONS
This co-design process ensures that MMS packaging is visually engaging, culturally relevant, and easily comprehensible. Findings from these workshops will be disseminated with the MoH in Cambodia to ensure pregnant woman and their family members preferences are considered for the final design of the MMS packaging in Cambodia.

CONFLICTS OF INTERESTS

REVAMPED EFSA DRV FINDER: AN INTERACTIVE WEB TOOL FOR DIETARY REFERENCE VALUES

Ionut Craciun[1]; Lucia Fabiani[1]; Nena Karavasiloglou[1]; Leonard Matijević[1]; Ariane Titz[1]; Martínez, Silvia Valtueña[1]; Agnès De Sesmaisons Lecarré[1]
[1]Nutrition and Food Innovation Unit, European Food Safety Authority, Parma, Italy

BACKGROUND AND OBJECTIVES

Dietary reference values (DRVs) is an umbrella term for a set of nutrient reference values that define the nutrient requirements in the general population and inform about the potential risks of excess intakes. DRVs underpin nutrition recommendations, aiding health professionals in dietary assessment and planning, policymakers in setting dietary guidelines, and food manufacturers in product formulation. The European Food Safety Authority (EFSA) is responsible for establishing DRVs for the European population. EFSA has set DRVs for fats, carbohydrates and dietary fibre, protein, energy, water, vitamins, and essential minerals.

METHODS

The DRV Finder is a freely available interactive web tool that provides quick access to EFSA's DRVs and allows users to explore the different values by population group or nutrient. The tool, available in 11 European languages, was first launched in 2018 and has recently been updated to include the most recently established values.

RESULTS

Several DRVs for nutrients are established to address the requirement for a nutrient which varies across individuals. When sufficient data is available, Average Requirement (AR) and Population Reference Intake (PRI) values are set, covering the needs of half and most (97.5%) of the population, respectively. When AR and PRI cannot be determined, adequate intake (AI) and reference intake ranges for macronutrients (RI) are used. AI is the intake level assumed to be sufficient based on observations from groups of apparently healthy people, while RIs are set for energy sources like fats and carbohydrates. DRVs are tailored by age and sex, and when necessary, by other characteristics, to reflect population diversity.
The Tolerable Upper Intake Level (UL) is the highest level of daily intake of a nutrient which is not expected to pose a risk of adverse health effects to humans when consumed chronically. When data are insufficient to characterise the relationship between the nutrient intake and the adverse effect and derive a UL, a safe level of intake is established. Although both values aim to protect against the risks of excessive nutrient intake, the applications of a safe level of intake for risk management purposes are more limited.

CONCLUSIONS

The updated DRV Finder now includes all DRVs established by EFSA, including the latest UL values for selected vitamins and essential minerals, as well as for added and free sugars. The tool also gives access to the respective EFSA opinions, which provide the scientific basis for each value. It is designed to be continuously updated as new DRV opinions are published.

CONFLICTS OF INTERESTS

The authors have no conflict of interest.

EPO1_065

QUANTITY AND FREQUENCY OF AVOCADO CONSUMPTION FOR HEALTH BENEFITS IN FREE LIVING ADULTS: A SCOPING REVIEW

Anthony Villani[1]; Elodie Casey[1]; Fiona Pelly[1]
[1]School of Health, UniSC University of the Sunshine Coast, Sippy Downs, Australia

BACKGROUND AND OBJECTIVES
Avocados are a nutrient dense food and have a unique nutritional profile where regular consumption may favour a number of health benefits. In particular, regular avocado consumption appears to offer protection against cardiovascular disease (CVD) risk, mainly through reductions in blood lipids. Moreover, regular avocado consumption may also improve body composition by promoting reductions in central adiposity. However, there is a lack of evidence-based recommendations on the amount (and frequency) of avocado needed to elicit the proposed health benefits. Therefore, we systematically scoped the existing literature to identify the optimal quantity and frequency of avocado needed to elicit health benefits without adverse health effects in free living adults.

METHODS
A systematic search of the literature was conducted across multiple databases, including MEDLINE (PubMed), SCOPUS, CINAHL Ultimate (EBSCO), ProQuest, Web of Science, and Clinical Trial Registries in July 2024. All types of study designs were included if they reported on the quantity and / or frequency of avocado consumption against any health-related outcome. The protocol for this scoping review was prospectively designed and registered with Open Science Framework with the RESULTS reported according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews (PRISMA-ScR) checklist.

RESULTS
A total of 54 articles were included. Cardiovascular health (n = 25) was the most commonly reported health outcome followed by metabolic health (n = 8) and weight management (n = 8). In clinical trials, lipid lowering benefits were demonstrated with an intake of one avocado per day (ranging from 136-168 grams). Consumption of 0.5-1 avocado per day (70-140 grams per day) was not associated with weight gain. When combined with an energy restricted diet, one avocado per day (136-175g) may help facilitate reductions in central adiposity.

CONCLUSIONS
Current evidence suggests that one avocado per day (ranging from 136-168 grams) has favourable effects on lowering blood lipids in individuals with and without CVD risk factors. However, there is a lack of primary studies to articulate evidence-based recommendations for avocado consumption on benefits related to secondary CVD risk factors, glycaemic control, vascular functioning, cognition, digestive health, cancer risk, reproductive, skin and musculoskeletal health.

CONFLICTS OF INTERESTS
This scoping review was funded by Hort Innovation Australia Limited and the Australian Avocado Growers

MANAGING CHILDREN 6-59 MONTHS WITH MODERATE ACUTE MALNUTRITION USING A LOCALLY-PRODUCED SUPPLEMENTARY FOOD THROUGH THE TOM BROWN PROGRAM IN NORTHEAST NIGERIA

Patricia Welch[1]; Suleiman Bata,[2]; Ayan Seal,[3]; Charles Okoro,[4]; Michael Drenkat,[2]
[1]Centre for Humanitarian Public Health Team, Save the Children Schweiz - Organisation für die Rechte der Kinder, Zürich, Switzerland; [2]Nutrition, Save the children international, Maiduguri, Nigeria, Federal Republic of; [3]Program Development & Quality, Save the Children, Abuja, Nigeria, Federal Republic of; [4]MEAL, Save the, Maiduguri, Nigeria, Federal Republic of

BACKGROUND AND OBJECTIVES
Northeast (NE) Nigeria has been negatively affected by a protracted conflict, which has led to food insecurity and contributed to a high prevalence of global acute malnutrition. In part due to ongoing supply chain issues and resulting stock-outs of commercially-manufactured nutrition supplements, NE Nigeria has experienced critical gaps in treatment coverage for acute malnutrition. In response, Save the Children began implementing the Tom Brown targeted supplementary feeding program (TSFP) in Borno and Yobe states to treat children 6-59 months with moderate acute malnutrition (MAM). The Tom Brown TSFP uses locally-sourced ingredients to create a porridge known as Tom Brown, in combination with community-based support groups. This study aims to add to the evidence base around Tom Brown, including around nutrition outcomes, cost-efficiency, and community-based perceptions and experiences.

METHODS
Multiple methods were used: 1) a quantitative analysis of nutrition outcomes; 2) a cost-efficiency analysis using an ingredients-based costing approach to compare in-kind delivery of Tom Brown commodities vs use of cash and voucher assistance (CVA) for group facilitators to procure commodities; 3) an analysis of post-distribution monitoring survey data (n=204 enrolled mothers); 4) key informant interviews of group facilitators (n=10) and 5) focus group discussions with enrolled mothers (n=20) and male heads of household (n=20).

RESULTS
A 10-week enrolment cycle in the Tom Brown TSFP was found to have notably improved nutrition outcomes compared to an 8-week enrolment, including: a 13% higher recovery rate (94% vs 83%) and 52% lower deterioration from MAM to SAM (2.4% vs 5%). The CVA modality was found to be half as costly as the in-kind delivery modality, with a cost-transfer-ratio of $0.87 (CVA) vs $1.75 (in-kind). Group facilitators reported appreciating the increased autonomy with the CVA modality, though expressed that it required an increase in time commitment. Enrolled mothers and male heads of household reported high levels of satisfaction and acceptance with the Tom Brown TSFP with no unintended consequences.

CONCLUSIONS
This study shows high recovery and low deterioration rates among children with MAM enrolled in the Tom Brown TSFP, and the program has high community acceptance. A 10-week enrolment and a CVA modality are recommended for future Tom Brown programming. The Tom Brown model offers a sustainable approach to treating MAM, particularly in contexts where stock-outs of commercially-manufactured nutrition supplements are common.

THE TRADITIONAL SUBSISTENCE AGRICULTURE OF THE AO NAGA TRIBE: A SOURCE OF FOOD SECURITY AND SOVEREIGNTY

Tajungrenla Longkumer[1]; Rajender Ananthan[2]; Thingnganing Longvah[2]
[1]Food Chemistry and Nutrient Analysis, ICMR - National Institute of Nutrition, Hyderabad, India; [2]Food Chemistry and Nutrient Analysis, ICMR-National Institute of Nutrition, Hyderabad, India

BACKGROUND AND OBJECTIVES
The Ao Naga, an indigenous tribe in Nagaland, has long relied on swidden cultivation, or jhum farming, as the mainstay of their subsistence agriculture. Mokokchung district, with its lush hilly terrain, is an ideal environment for this traditional practice. Here, jhum farming is part of a rich tapestry of diverse, rotational, and primarily indigenous forms of agriculture. Farmers undertake this "shifting cultivation" sustainably and ecologically. Jhum fields are incredibly biodiverse, typically hosting upwards of 30 crops in staggered maturation. These practices ensure a steady supply of food security that is beautifully diverse in both kind and quantity. Moreover, for the Ao Naga, this ecological agriculture underscores food sovereignty unfettered by market dependency. Much of this knowledge is passed down orally from one generation to the next, making it "vulnerable" in the modern world.

METHODS
The study used stratified simple random sampling to choose 21 Ao villages from the Mokokchung district. With the help of the Nagaland government, which facilitated logistics and ensured participation, the researchers held focus group discussions (FGDs) in these 21 villages. Each FGD lasted 60–75 minutes. The researcher secured consent from all participants, who were free to decline, to ensure the conversation was legitimate. The researcher of this study inscribed the findings both by hand and electronically.

RESULTS
During the research, many previously undocumented techniques used in jhum also came to light. These techniques help ensure food and nutritional security for the Ao Nagas. However, the study also found evidence of a worrisome trend: Jhum cultivation is in decline. Communities all over the Ao Naga area are gradually giving up jhum and switching to monocropping practices for economic gains. Those practices result from national food and nutrition policies prioritising energy production over dietary diversity and nutrition.

CONCLUSIONS
This research reveals how important jhum farming is in maintaining Ao Naga food security and sovereignty. It is more than a tool of agriculture; it is also a significant cultural component of the tribe. They should be saved immediately for the good of Ao Naga and serve as a template for sustainable agriculture worldwide. This Indigenous wisdom needs to be retained if we are to support resilient food systems

BACKGROUND AND OBJECTIVES

Around 800 million people around the world were affected by hunger in 2021. The prevalence of undernourishment continues to affect the world, and particularly Sub-Saharan Africa (1). Exacerbated inequalities across and within countries are undermining the nutritional adequacy and affordability of diets and threatening vulnerable groups including children under five years of age and women of childbearing age. This research within the InnofFoodAfrica (2) presents a diet optimization approach where the objective is to identify the nutritional gaps with observed diets and propose food recommendations to reach the nutritional adequacy and affordability of diets across four African countries, namely Ethiopia, Kenya, South Africa and Uganda.

METHODS

We developed diet optimization models to assess nutritional and economic to assess nutritional and economic dimensions of sustainability for children and mothers in two cities per African country leading to 16 theoretical solutions of optimal diets. The data used to calibrate the model and assess the nutritional quality of observed diet came from surveys of food consumption by women of childbearing age and their children aged 6 to 24 months. To assess budget constraints, a food price dataset was built from data provided by the World Bank International Comparison Program.

RESULTS

For all the geographical cases, our RESULTS suggest the need to diversify diets and adjust portion sizes of the main food groups. For women and children, nutritional adequacies of vitamins A and C can be achieved by increasing vegetable and fruit consumption. A reduction in cereals and an increase in pulses are suggested as part of a balanced diet. For children, increasing meat and poultry consumption provides better adequacies of iron and zinc. In terms of affordability, the solutions propose diets for which total expenditures do not exceed our estimates of the current observed budget. Our RESULTS indicate that Uganda is the country that allocates the least resources to food, while South Africa has the least affordable diet. In all cases, affordability does not necessarily imply an unattainable situation for improving the nutritional adequacy of diets.

CONCLUSIONS

Achieving healthier diets in African urban areas requires a multifaceted approach that addresses both demand and supply. By implementing targeted policies to promote healthier consumption choices, there is a need to stimulate the production, accessibility and affordability of nutritionally-sensitive food environment.

THE COPLANT STUDY - FUTURE RESEARCH ON PLANT-BASED NUTRITION

Cornelia Weikert[1]; Ina Danquah,[2]; Christine Dawczynski,[3]; Benedikt Merz,[4]; Beate Fischer,[5]; Michael Leitzmann,[5]; Tilman Kühn[6]; Maria Wakolbinger,[7]; Stefan Dietrich,[1]; Sven Knueppel,[1]; Katharina Penczynski,[1]; Ute Nöthlings,[8]
[1]Food Safety, German Federal Institute for Risk Assessment, Berlin, Germany; [2]Climate Change, Nutrition and Health, Heidelberg University, Heidelberg, Germany; [3]Nutritional concepts, Friedrich-Schiller-Universität Jena, Jena, Germany; [4]Department of Physiology and Biochemistry of Nutrition, Max Rubner-Institute, Karlsruhe, Germany; [5]Epidemiology and Preventive Medicine, University Hospital Regensburg, Regensburg, Germany; [6]Center for Public Health, Medical University of Vienna, Vienna, Austria; [7]Center for Public Health, Medical University Vienna, Vienna, Austria; [8]Nutritional Epidemiology, Rheinische Friedrich Wilhelms University Bonn, Bonn, Germany

BACKGROUND AND OBJECTIVES
Despite the growing interest in plant-based diets and the increasing debate about their risks and benefits, recent studies investigating the associated health status or long-term health effects are scarce. The few available cohort studies were often published years ago, have a limited scope, and are not representative of today's plant-based diets, particularly regarding the consumption of vegan foods, meat substitutes, or dairy alternatives.

METHODS
The planned prospective cohort COPLANT "COhort on PLANT-based diets" began baseline recruitment between April and June 2024 in 6 study centers in Germany. In January 2025, an additional study center in Vienna, Austria, will begin recruitment. A total of about 6,000 participants aged 18-69 years, who have been consistently following a vegan, vegetarian, pescatarian, or omnivorous diet for at least one year based on self-reported adherence, are expected to take part over 3 years. Recruitment aims to balance participants across sex, age, and diet strata.
The NutriDiary app and a detailed food frequency questionnaire encompassing plant-based food items will be used to assess usual dietary intake. Furthermore, body composition, bone health, and nutritional behavior (e.g., meal preparation habits) are assessed. Biological samples (blood, urine, and faeces) will be analyzed to evaluate nutritional status, metabolic markers, relevant contaminants and residues, and gut microbiota composition.

RESULTS
By the end of November 2024, more than 700 participants (12% of the planned sample size) had been recruited. Recruitment data indicate that women are generally easier to recruit than men, and it has been particularly challenging to recruit pescatarians. To address this, target recruitment strategies are being explored, such as outreach via specialized communities. Preliminary data checks indicate good data quality.

CONCLUSIONS
The COPLANT study aims to compare the health benefits and potential short-term and long-term risks of different diets, such as nutrient deficiencies, metabolic imbalances, or sustainability trade-offs. Future RESULTS are expected to improve our understanding of diet-related risk factors and provide a robust evidence base for public health guidelines. These findings should serve as a critical decision-making aid for individuals, healthcare professionals, policymakers, and sustainability advocates.

A STUDY ON ANALYZING AND ADDRESSING GAPS IN ANEMIA CONTROL PROGRAM: AN ATTEMPT TO COMPLEMENT COMMUNITY HEALTH WORKERS PARTICIPATION

Samraggi Roy[1]; Ebbie Thomas[2]; Anita Makhijani,[3]; Sirimavo Nair[4]
[1]Foods and Nutrition, The Maharaja Sayajirao University of Baroda, Vadodara, India; [2]Department of Community Sciences, GMERS Medical College Gotri, Vadodara, India; [3]Nutrition, NIPCCD, New Delhi, India; [4]Nutrition and Fortification, Food Safety and Standards Authority of India, New Delhi, India

BACKGROUND AND OBJECTIVES
Despite advancements in health and technology, anemia remains a critical public health issue in India, especially among women. Government efforts, including the Anemia Mukt Bharat (AMB) program, face challenges such as inadequate IFA tablet supply, poor service coverage, and weak coordination from policy to field level. Accountability and transparency through information-sharing systems (G2G: Government to Government and G2B: Government to Business) remain underexplored. This study evaluates implementation gaps in the AMB program's 6x6x6 strategy and explores opportunities for increased government participation.

METHODS
The study used quantitative methods, including Knowledge, Attitudes, and Practices (KAP) surveys of 100 school-going adolescents (15–18 years) and 30 frontline workers (FLWs: 18 ASHAs, 12 AWWs). Qualitative approaches involved focus group discussions (FGDs) with pregnant women, lactating mothers, and their mothers-in-law. A Village Health and Nutrition Day (VHND) checklist and a structured questionnaire were administered to ten Ministry of Health and Family Welfare officers using Google Forms.

RESULTS
89% of adolescent girls showed poor knowledge about anemia. Although attitudes towards consuming green leafy vegetables were positive, adherence to IFA tablets was low (61%), and WASH practices were inadequate. FLWs performed better in the knowledge component, with 94.4% of ASHAs scoring in the average category, compared to the adolescent girls. Focus group discussions highlighted poor adherence to IFA tablets among women, driven by dislike of the taste and forgetfulness due to household work. Additionally, many lactating mothers and women of reproductive age reported an insufficient supply of IFA tablets. The VHND checklist confirmed a lack of tablets and educational materials for anemia awareness. Anemia prevalence among pregnant women in the block was 42.5% (FY 2022–2023). Officers acknowledged the potential of G2G and G2B systems for better accountability but noted persistent grassroots challenges, including weak multi-sectoral coordination.

CONCLUSIONS
The study highlights gaps in community and healthcare workers' focus on anemia with persistent grassroots challenges and suggests strengthening G2G and G2B data-sharing systems to enhance leadership, accountability, and collaboration in addressing health disparities.

EATING WINDOW AND BODY COMPOSITION IN SCHOOL-CHILDREN: PRELIMINARY ANALYSIS FROM THE EDDY STUDY

Paula Moliterno[1]; Stefanie Franceschini,[1]; Victoria Donhauser,[1]; Kurt Widhalm,[1, 2]
[1]Österreichisches Akademisches Institut für Ernährungsmedizin (ÖAIE), Österreichisches Akademisches Institut für Ernährungsmedizin (ÖAIE), Wien, Austria; [2]Department of Pediatrics, Division of Clinical Nutrition and Prevention, Medical University of Vienna, Vienna, Austria

BACKGROUND AND OBJECTIVES
Apart from the amount and content of food, meal timing intake has been linked to metabolic health. Eating window, among other meal timing variables (number of meals/day, pre-bed fasting time, first and last meal hours, frequency of breakfast), has been extensively studied in adults. However, information on children is still understudied (1,2), We aimed to describe characteristics of meal timing and body composition according to eating duration in a sample of schoolchildren from the EDDY study in Vienna.

METHODS
The EDDY (Effects of sports and diet training to prevent obesity and secondary diseases and to influence young children's lifestyle) was implemented in one intervention school (n=48). Another school acted as control (n=38). Questionnaires assessed meal timing data. The eating window was calculated based on the hours between each child's first and last meal and divided into terciles according to the variable distribution by study group. The number of meals corresponded to an average reported daily intake of meals and snacks. Baseline BMI z-score and body composition variables were compared between children who showed the longest (3rd tertile) vs the shorter (1st tertile) eating window by study group. Changes in anthropometric variables after a 2-year intervention were compared according to terciles of eating window in each study group. The analyses were adjusted for sex and age.

RESULTS
The median age was 8.1 (7.3-9.3) years. Frequency of children with overweight/obesity was 9/48 and 15/38 in the intervention and control group (p=0.003). No baseline differences by group were observed between meal timing variables (p≥0.14). Median eating window in the intervention group was 11:35 (95%CI: 9:30-13:00) hours and 12:00 (95 % CI: 9:00-14:30) hours in the control group (p=0.14). Compared to the control group, where no differences were observed, in the intervention group, children with a longer eating duration [(3rd tercile; ≥12 hours); median 12:33 hours)] had lower BMI z-score, waist-to-height ratio and body fat index (p<0.014) than those with a shorter eating duration [(1st tercile; <11 hours); median 10:21 hours)]. Moreover, the median breakfast frequency was higher (7 vs 3 days, p=0.001). After the intervention, no differences in body fat, BMI z-score, or waist-to-height ratio changes between terciles of eating window were observed.

CONCLUSIONS
Our RESULTS showed a large variation in eating window times in a sample of elementary schoolchildren, ranging from 9:00 to 14:30 hours.

IMPROVING MONITORING OF VITAMIN A SUPPLEMENTATION: A COMPARISON OF ADMINISTRATIVE AND SURVEY DATA ACROSS SUB-SAHARAN AFRICA

Abiodou Moise Owoloye,[1]; Romance Disseka,[2]; Mohamed Lamine Fofana[3]; Melissa Baker[4]; Ndiaye Fatou[5]; Doledec David[4]

[1]Vitamin A Supplementation, Helen Keller INTL, Abidjan, Ivory Coast; [2]Regional Team Vitamin A Supplementation, Helen Keller INTL, Abidjan, Ivory Coast; [3]Vitamin A Supplementation, Helen Keller INTL, Conakry, Guinea; [4]Helen Keller Intl, Helen Keller Intl Kenya, Nairobi, Kenya; [5]Helen Keller Intl, Helen Keller INTL - Regional & Senegal, Dakar, Senegal

BACKGROUND AND OBJECTIVES

Administrative records and household surveys are commonly used to monitor and guide Vitamin A supplementation (VAS) campaigns in Sub-Saharan Africa, providing insights into coverage levels and areas requiring intervention.

METHODS

This study compared Vitamin A supplementation (VAS) coverage data from 2023, using administrative sources and post-event coverage surveys conducted in the first half of 2023 in Burkina Faso, Côte d'Ivoire, the Democratic Republic of Congo (DRC), and Kenya, and in the second half of the year in Mali and Nigeria. This quantitative study employs a two-stage cluster sampling method, stratified by urban and rural areas, with probability proportional to size for household selection. The aim is to assess the coverage of Vitamin A supplementation for children aged 6 to 59 months across different countries.

RESULTS

In all six countries, administrative data reported higher VAS coverage than PECS estimates. In Mali, administrative data indicated 144% coverage, compared to 88.9% from PECS. Similarly, Burkina Faso reported 102.41% administrative coverage versus 82.1% in PECS, while Côte d'Ivoire reported 99.9% administrative coverage compared to 77.5% in PECS. In the DRC, coverage gaps ranged from 7.3% to 26.1%. In Nigeria, PECS survey data showed lower VAS coverage than administrative records, with 46.6% in Bauchi, 72.7% in Kebbi, and 76.6% in Sokoto, compared to 76%, 95%, and 94% respectively. In Kenya, PECS survey data also showed lower VAS coverage compared to administrative records, with variances of 18.4% in Meru, 10.8% in Tharaka Nithi, 8.4% in Nyandarua, and 12.4% in Kirinyaga.

CONCLUSIONS

The study reveals significant discrepancies in VAS coverage between administrative and PECS data. Further research should focus on refining monitoring systems to bridge these gaps and ensure accurate, actionable data.

CONFLICTS OF INTERESTS

OPTIMIZING VITAMIN A SUPPLEMENTATION: TAILORING COMMUNICATION STRATEGIES TO URBAN-RURAL AND SOCIO-ECONOMIC CONTEXTS

Abiodou Moise Owoloye,[1]; Romance Disseka,[2]; Mohamed Lamine Fofana[3]; Melissa Baker[4]; Ndiaye Fatou[5]; Doledec David[4]

[1]Vitamin A Supplementation, Helen Keller INTL, Abidjan, Ivory Coast; [2]Regional Team Vitamin A Supplementation, Helen Keller INTL, Abidjan, Ivory Coast; [3]Vitamin A Supplementation, Helen Keller INTL, Conakry, Guinea; [4]Helen Keller Intl, Helen Keller Intl Kenya, Nairobi, Kenya; [5]Helen Keller Intl, Helen Keller INTL - Regional & Senegal, Dakar, Senegal

BACKGROUND AND OBJECTIVES

Vitamin A supplementation (VAS) campaigns are vital for combating vitamin A deficiency in developing countries. While communication strategies are just one aspect of campaign preparation, they are pivotal in mobilizing and sensitizing populations about VAS. Urban populations generally have greater access to media and healthcare access where they become aware of the campaign schedule and the benefits of VAS. In contrast, rural populations often rely on informal communication channels, with cultural beliefs influencing the dissemination and reception of health information

METHODS

Data were collected from cross-sectional Vitamin A supplementation coverage surveys conducted in Mali and Guinea among caregivers of children aged 6-59 months, as part of post-event coverage surveys for Vitamin A supplementation during the second semester of 2023 and the first semester of 2024. Descriptive analyses and logistic regression were used to examine coverage for each intervention as well as coverage for the full package of interventions. The sample included 14,765 children aged 6-59 months and 8,951 caregivers. The analysis focused on exploring the correlation between information sources, caregivers' understanding of the benefits of Vitamin A supplementation, their attitudes towards supplementation, and the resulting VAS coverage among children.

RESULTS

The RESULTS reveal several significant associations with Vitamin A supplementation in both Mali and Guinea. Key information sources, including public announcers (OR = 2.973, CI: 2.5–3.5), health workers (OR = 3.055, CI: 2.6–3.5), health facility workers (OR = 3.797, CI: 3.2–4.4), and opinion leaders (OR = 3.813, CI: 3.2–4.4), are strongly associated with increased odds of receiving supplementation, with odds ratios well above 1 and confidence intervals consistently indicating positive values. Additionally, other sources such as radio (OR = 2.684, CI: 2.1–3.2) and television (OR = 1.531, CI: 1.2–2.0) also play important roles in improving supplementation coverage. Wealth has a slight but significant negative effect on supplementation, with wealthier individuals being less likely to receive supplementation (OR = 0.941, CI: 0.9–1.0)

CONCLUSIONS

Context-specific communication strategies leveraging community-based actors are crucial for optimizing Vitamin A supplementation (VAS) campaigns, as shown by higher uptake associated with local information sources and significant contextual differences between Mali and Guinea, but no disparity between rural and urban areas.

CONFLICTS OF INTERESTS

The authors have no conflict of interest.

1. Adebayo et al. (2018) highlight the importance of Vitamin A supplementation in reducing child mortality rates in Sub-Saharan Africa. They emphasize the role of supplementation in preventing Vitamin A deficiency, which can lead to a higher risk of infections and poor child development. Kaboré et al. (2020)

BUILDING INVESTMENT CASE(S) IN MICRONUTRIENT DATA AND EVIDENCE

Shruthi Cyriac; Steve Vosti,[1]; Michael Jarvis,[2]
[1]Dept. of Agricultural and Resource Economics, University of California, Davis, Davis, United States of America; [2]Institute for Global Nutrition, University of California, Davis, Davis, United States of America

BACKGROUND AND OBJECTIVES
Policymakers and other stakeholders require evidence to identify micronutrient deficiencies and their root causes, and to design and manage impactful, cost-effective, and sustainable intervention programs. Different types of evidence can be generated with some more expensive than others, and stakeholders may have preferences on the types of evidence. Guidance on developing context-specific investment case(s) for generating and delivering evidence is needed in low- and middle-income countries (LMICs).

METHODS
Based on the nutrition data value chain conceptual framework, six research activities were undertaken. First, we developed an analytical framework for evidence investment cases. Second, we conducted interviews with selected in-country stakeholders and experts to capture the nuances of micronutrient evidence needs. Third, we designed and implemented empirical costing exercises for an example country, focusing on three key data sources: nutritional biomarker surveys, 24-hour dietary recall surveys, and household consumption and expenditure surveys. Fourth, we used the existing literature to identify the benefits and programmatic costs of alternative large-scale food fortification programs, as seen through the lenses of different types of evidence. Fifth, we set the 'marginal benefits' of different types of evidence alongside the costs of generating and delivering them. Finally, these inputs were used to create a general framework for investment cases for micronutrient evidence.

RESULTS
We found that investment cases for micronutrient evidence must encompass data collection, evidence generation, and evidence delivery, each carrying different associated costs. Evidence generation and delivery must align with policy processes for maximum impact as the enabling environment *conditions* the benefits of evidence. Micronutrient policy discussions can begin with incomplete evidence and from experiences of other countries, but country-specific evidence is needed to sustain the enabling environment and to manage intervention programs.

CONCLUSIONS
Policymakers must prioritize diverse evidence needs; partnerships are vital for LMICs to effectively navigate the challenges of evidence generation. By fostering an enabling environment, leveraging existing data, and investing in new data, we can advocate for improved micronutrient intervention programs, leading to improved nutritional outcomes.

CONFLICTS OF INTERESTS

CHALLENGES AND ADAPTIVE SOLUTIONS FOR MAINTAINING NUTRITION SERVICES DURING COVID-19: A QUALITATIVE STUDY

Marc Bosonkie[1]; Benito Kazenza[1]; Eric Mafuta[2]; Paul-Samson Lusamba[3]; Mala Ali Mapatano[1]
[1]Nutrition, Kinshasa School of Public Health, Kinshasa, Congo, Democratic Republic of the; [2]Health Management and policy, Kinshasa School of Public Health, Kinshasa, Congo, Democratic Republic of the; [3]Biostatistics and Epidemiology, Kinshasa School Of Public Health, Kinshasa, Congo, Democratic Republic of the

BACKGROUND AND OBJECTIVES
The rapid spread of COVID-19 forced governments to urgently implement non pharmaceutical measures to stop the surge. These restrictions disrupted provision of services. This study identified challenges and adaptive solutions.

METHODS
A multiple cases qualitative study was carried out. Purposive sampling was used for recruitment of participants (57). The interview guide incorporated nutrition leadership, financing, workforce, infrastructure and commodities, service delivery and information system. For each topic, subtopics were on challenges and adaptations. All transcripts were exported to Atlas Ti V22 and thematic analysis was conducted.

RESULTS
Challenges included the exclusion of nutrition services as a core pillar in the COVID-19 response, the reduction in the number of nutrition service providers, and insufficient funding to sustain activities promoting services continuity. Global supply chain disruptions resulted in shortages of Ready-to-Use Therapeutic Food, while poor data monitoring hindered effective decision-making. Advocacy efforts were made to include nutrition services as a key pillar. Timetables with staff rotation systems were introduced. Community Health Workers were trained to conduct activities independently. In addition, expanding the number of sites for vaccination to minimize patient contact. Facilities develop and utilize locally produced therapeutic foods.

CONCLUSIONS
COVID-19 had a negative impact on nutrition services by affecting the 6 components of the health system. Described adaptation strategies are needed to be drawn upon during periods of calm and be included in a plan for maintaining continuity of nutrition services in times of crisis.

CONFLICTS OF INTERESTS

MULTILEVEL FACTORS ON THE CONSUMPTION BEHAVIOR OF SUGAR-SWEETENED BEVERAGES AMONG PRIMARY AND SECONDARY SCHOOL STUDENTS: A QUALITATIVE STUDY BASED ON TEACHERS' PERSPECTIVES

Yiran Li; Siyu Liang[1]; Wenjia Li[1]; Jiali Duan[2]; Lulu Meng[3]; Ruoxiang Cao[3]; Xiaofeng Liu[2]; Liyu Huang[2]; Jie Li[4]
[1]Nutritional Epidemiology, Hebei Medical University, shijiazhuang, China; [2]Institute for Nutrition and Food Hygiene, Beijing Center for Disease Prevention and Control, Beijing, China; [3]Office of Research and Teaching Administration, Beijing Center for Disease Prevention and Control, Beijing, China; [4]Food Science, Fengtai District Center for Disease Control and Prevention, Beijing, China

BACKGROUND AND OBJECTIVES

The consumption of sugary beverages and the prevalence of obesity among primary and secondary school students in China have increased significantly. This study investigates the factors influencing sugary beverage consumption among primary and secondary school students from the perspective of teachers, aiming to provide actionable insights for public health systems to design effective school-based health education interventions.

METHODS

This qualitative study was conducted from September to November 2024 in eight primary and secondary schools in Beijing. A total of 56 teachers participated in face-to-face interviews, including both individual interviews and focus group discussions. Data were analyzed using the grounded theory approach with three levels of coding.

RESULTS

The analysis yielded 39 subcategories, 15 categories, and five main categories: individual, interpersonal, environmental, societal, and policy levels. The six most frequently mentioned categories were teachers' knowledge and attitudes (128 references), school health education (96 references), drivers of sugary beverage consumption (56 references), students' individual awareness (53 references), the school food environment (40 references), and home-school collaboration (39 references). A core theme was identified: the multilevel factors of students' sugary beverage consumption based on teachers' perspectives.

CONCLUSIONS

This study identifies a range of multilevel factors spanning individual, interpersonal, environmental, societal, and policy dimensions, which influence sugary beverage consumption among students. Teachers' knowledge and attitudes, school health education, the school food environment, students' individual cognition, consumption drivers, and home-school collaboration were the most commonly mentioned factors. School-based health education interventions and efforts to enhance home-school collaboration are crucial for reducing sugary beverage consumption among primary and secondary school students.

EFFECTS OF HIGH-PROTEIN DIET INTAKE ON APPENDICULAR SKELETAL MUSCLE MASS IN COMMUNITY-DWELLING OLDER ADULTS: A PRE-POST COMPARISON STUDY

Keiko Motokawa[1]; Takuya Shibasaki[2]; Tatsunosuke Gomi[1]; Maki Shirobe[1]; Misato Hayakawa[1]; Lena Kalantar[1]; Kana Eguchi[1]; Hirohiko Hirano[1]
[1]Research Team for Promoting Independence and Mental Health, Tokyo Metropolitan Institute for Geriatrics and Gerontology, Tokyo, Japan; [2]Health Care & Nutritional Science Institute, MORINAGA MILK INDUSTRY CO.,LTD., Kanagawa, Japan

BACKGROUND AND OBJECTIVES
Background: Sarcopenia in older adults significantly impacts quality of life and health span. High-protein diets may help maintain and increase skeletal muscle mass. This study examined the effects of incorporating high-protein powder food into daily meals on appendicular skeletal muscle mass index (ASMI) in community-dwelling older adults.
Objective: To investigate the effects of 3 months of high-protein food intake on appendicular ASMI.

METHODS
Methods: This single-arm pre-post study included 56 community-dwelling adults aged ≥65 years. Participants consumed 18 g/day of protein from a high-protein food (4.5 g protein/5 g; Enjoy Protein, Morinaga Milk Industry Co., Ltd.) in 1–4 servings, with intake timing at their discretion. Assessments were at baseline, 1.5 months, and 3 months. Variables included ASMI (InBody S10), height, weight, and dietary intake (brief self-administered questionnaire at baseline and 3 months). Repeated-measures ANOVA and Bonferroni tests were used. This study was approved by the Ethics Committee of the Tokyo Metropolitan Institute for Geriatrics and Gerontology（R23-100）.

RESULTS
RESULTS: Excluding 4 dropouts and 5 with adherence <80%, 47 participants were analyzed (mean age: 71.6 ± 4.2 years; 70.2% female). ASMI increased significantly (baseline: 6.4 ± 1.0 kg/m2; 1.5 months: 6.5 ± 1.0 kg/m2; 3 months: 6.5 ± 1.0 kg/m2 ; $p < 0.05$). Values at 1.5 and 3 months were significantly higher than baseline, with no difference between 1.5 and 3 months. No significant changes were observed in protein intake from diet (excluding test food) or in body weight.

CONCLUSIONS
Conclusion: Three months of high-protein food intake effectively maintained and increased ASMI in community-dwelling older adults. Simple dietary interventions may aid muscle preservation in this population. Future studies with control groups are warranted.

IMPROVING MEASUREMENT OF MATERNAL MICRONUTRIENT SUPPLEMENT COVERAGE

Shelley Walton[1]; Ellina Wood[1]; Melinda Munos[2]; Hanna Berhane[3]; Firehiwot Workneh[4]; Sharif Lotus[5]; Sk Billah[5]; Zubayer Zaman[5]; Nishat Salsabil[5]; Rebecca Heidkamp[6]
[1]Department of International Health, Johns Hopkins University, Baltimore, United States of America; [2]International Health, Johns, Baltimore, United States of America; [3]Department of Nutrition and Behavioural Sciences, Addis Continental Institute of Public Health, Campus, Addis Ababa, Ethiopia; [4]Department of Epidemiology and Biostatistics, Addis Continental Institute of Public Health, Campus, Addis Ababa, Ethiopia; [5]Maternal and Child Health Division, Icddr,b, Dhaka Bangladesh; [6]International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, United States of America

BACKGROUND AND OBJECTIVES
To improve birth outcomes and maternal/child health, micronutrient interventions are recommended, including iron and folic acid (IFA), multiple micronutrient supplements (MMS), and calcium. Accurate sub-national data on supplementation coverage during pregnancy is critical, but national survey questions may lack validity. We conducted formative research and cognitive testing to inform the design of new survey questions and visual aids for better comprehension by women.

METHODS
In Bangladesh and Ethiopia, we mapped available supplements across facilities and markets (n=47). We used qualitative methods to gather data from pregnant and recently pregnant women using free listing (n=26), pile sorting (n=14), and key informant interviews (KIIs) (n=40). Findings informed the design of survey questions and visual aids, which were refined through cognitive testing (n=32). Free listing salience was calculated using FLARES, and pile sorting data were analyzed using multidimensional scaling.

RESULTS
We identified three themes: 1) Distinguishing between different types of supplements, 2) Consumption and adherence, and 3) Tailoring questions for currently pregnant women. Over 40 types of micronutrient supplements are available in Ethiopia and more than 60 in Bangladesh. There are distinctions between government-distributed supplements and those from non-governmental clinics, pharmacies, and other retailers. Visual aids helped women differentiate between supplements. Packaging (e.g., blister packs vs. bottles) plays a role in distinguishing products and estimating adherence. Women found it easier to respond to questions about supplement consumption in terms of a 'typical week' or 'typical month.' The third theme highlighted the need to adapt questions for pregnant women to ensure clarity and relevance.

CONCLUSIONS
The revised questions aim to reduce respondents' cognitive burden and improve the accuracy of maternal micronutrient coverage measurements in national surveys, supporting evidence-based decision-making. These improved methods will be shared with global survey programs and with over 20 countries exploring or introducing multiple micronutrient supplements (MMS). The questions will help countries track progress, including who is receiving iron-containing supplements (IFA or MMS), where they access them, and whether supplementation begins in the first trimester, as recommended by WHO.

DEFINING THE DAIRY MATRIX AND ITS HEALTH EFFECTS

Stephan Peters[1]; Anabel Mulet Cabero[2]; Ivana Gandolfi[3]; Moises Torres-Gonzalez[4]
[1]Sustainability, Nederlandse Zuivel Organisatie, Den Haag, Netherlands, Netherlands; [2]Nutrition, International Dairy Federation, Brussels, Belgium; [3]Dairy and Nutrition, Parmalat, Collecchio, Italy; [4]Nutrition Research, National Dairy Council, Rosemont, IL, USA, United States of America

BACKGROUND AND OBJECTIVES
The health effects of foods extend beyond individual nutrients. For instance, while regular fat dairy contains saturated fats that raise LDL-cholesterol, epidemiological studies often show no link—or even a protective one—between dairy intake and CVD risk. This discrepancy may be explained by the dairy matrix, a concept lacking a precise, globally recognized definition. Establishing a harmonized definition would enhance clarity, consistency, and communication in nutrition science.

METHODS
Seventeen scientists in the area of nutrition and health from thirteen countries participated in discussions, coordinated by the International Dairy Federation, for the establishment of definitions of dairy matrix and dairy matrix health effects. The discussions were based on literature reviews on dairy matrix and food matrix where relevant definitions and snippets of the terms where reviewed.

RESULTS
The harmonised definitions set by the expert panel are: *Dairy matrix* describes the unique structure of a dairy food, its components (e.g., nutrients and non-nutrients) and how they interact; *dairy matrix health effects* refer to the impact of a dairy food on health that extend beyond its individual components. The definitions aimed to balance the complexity of the concepts and their practical application. Similar definitions could be applied for the food matrix and food matrix health effects.

CONCLUSIONS
The harmonised international definitions could help nutrition science by uncovering mechanisms that explain health effects of foods beyond their individual nutrients. They would also highlight the practical implications of the food and dairy matrix on nutrition and health outcomes, supporting the development of evidence-based policies to improve public health. Integrating food and dairy matrix concepts into dietary guidelines, policies, and labelling practices promises a new era of evidence-based, holistic nutrition.

THE IMPACT OF POST-HARVEST HANDLING ON THE BIOCHEMICAL COMPOSITION OF SELECTED INDIGENOUS GHANAIAN FOOD CROPS

Sheila Mensah[1]; Herman Erick Lutterodt,[1]; Gloria Ankar-Brewoo,[1]
[1]Department of Food Science and Technology, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana

BACKGROUND AND OBJECTIVES
In developing countries, inadequate postharvest handling practices contribute significantly to food insecurity and economic losses.While extensive research has focused on quantifying postharvest losses, limited attention has been given to the impact of these practices on the biochemical composition of food crops. Understanding these impacts is critical for devising interventions to preserve nutritional quality and crop value. This study investigates the influence of postharvest handling practices on the biochemical composition of three indigenous Ghanaian crops in the Techiman and Kintampo municipalities.

METHODS
A combination of surveys and supply chain tracing was employed to map handling practices from farms to distribution points and markets. Crop samples were systematically collected at key stages of the supply chain, including harvesting, transportation, and sale.The collected samples are being analyzed for variations in mineral content, fatty acid profiles, proximate composition, and metabolite levels.

RESULTS
Preliminary RESULTS indicate significant changes in nutrient composition due to poor handling practices, underscoring the need for targeted interventions to reduce quality deterioration.

CONCLUSIONS
This research highlights the critical link between postharvest handling and food quality, providing actionable insights for policymakers and stakeholders to enhance food security and economic sustainability in Ghana and similar contexts.

CONFLICTS OF INTERESTS

EPO1_096

A HIGHLY SIGNIFICANT PUBLICATION BIAS BETWEEN AUTHORS THAT ARE OR ARE NOT AFFILIATED WITH THE FRONT-OF-PACK LOGO NUTRI-SCORE

Hans Verhagen[1]; Stephan Peters,[2]
[1]-, Food Safety & Nutrition Consultancy, Zeist, Netherlands; [2]-, Nederlandse Zuivel Organisatie (NZO)/Dutch Dairy Association, The Hague, Netherlands

BACKGROUND AND OBJECTIVES
Nutri-Score has gained significant attention as a front-of-pack labeling (FOPL) system. However, concerns remain about the adequacy of scientific evidence supporting it. Peters and Verhagen (2022) critically evaluated the Nutri-Score system using the European Food Safety Authority (EFSA) framework for health claim substantiation. They emphasized the need for real-life validation studies and independent scientific evaluations. The current evaluation highlights the broader issue of publication bias, particularly in studies affiliated with the developers of Nutri-Score, warranting further investigation into the relationship between author affiliation and study outcomes.

METHODS
We have evaluated the association between author affiliations and reported outcomes related to Nutri-Score (Peters and Verhagen, 2024). The study reviewed published literature to classify outcomes as favorable or not favorable, with authors categorized as affiliated or not affiliated with the developers of Nutri-Score. Following this, a critical reaction by Touvier et al. (2024) was published as a rebuttal to the findings of Peters and Verhagen. The rebuttal, while not a separate study, provided an alternative perspective on the same dataset and further reinforced the observed patterns of potential publication bias. The original study and the rebuttal were analyzed collectively to assess consistency and significance in the reported findings. A Chi-Square test was used to statistically evaluate differences in outcome distributions between the two groups.

RESULTS
It was found that 93% of studies authored by affiliated researchers were favourable, compared to only 39% of those authored by non-affiliated researchers ($X2 = 32$, $p < 0.001$). Similarly, Touvier et al. found that affiliated authors exclusively reported favorable outcomes (100%), whereas non-affiliated authors showed a more balanced distribution, with 45% favorable and 55% unfavorable outcomes ($X2 = 33$, $p < 0.001$). Both analyses consistently demonstrate a strong association between author affiliation and reported study outcomes.

CONCLUSIONS
The findings highlight significant publication bias in Nutri-Score-related research, with affiliated authors overwhelmingly favouring the system, while non-affiliated authors present more varied RESULTS. This bias underscores the need for rigorous, independent studies to objectively evaluate Nutri-Score's public health impact. Ensuring unbiased scientific evaluation is essential for accurately determining the system's validity and guiding policy decisions on front-of-pack labeling.

LEVERAGING ARTIFICIAL INTELLIGENCE FOR QUALITATIVE NUTRITIONAL ANALYSIS: A SCIENTIFIC PERSPECTIVE

Carolina Pimentel[1]; Alexandre Tarifa,[2]; Fernanda Pagotto,[2]; Carlos Antunes,[2]; Leticia Ramires,[2]; Livia Tanizaki[2]; Pamella Torres[2]; Patricia Caldeira,[2]
[1]Health , Vitat, São Paulo, Brazil; [2]Health, Vitat, São Paulo, Brazil

BACKGROUND AND OBJECTIVES
Advances in artificial intelligence (AI) have opened new possibilities for personalized nutritional guidance, addressing challenges like scalability and accessibility in dietary counseling. This study investigates the application of GPT-4-based AI for qualitative nutritional analysis of food images, aligning with the Brazilian Dietary Guidelines. The system integrates computer vision to identify foods and portions and natural language processing (NLP) via GPT-4 to generate tailored nutritional feedback, promoting healthier dietary habits. Objective: To assess the effectiveness of an AI-driven system for qualitative nutritional analysis compared to manual assessments by nutritionists, focusing on accuracy, scalability, and response time.

METHODS
Data from 427 users of the automated system were analyzed, involving 3,404 interactions across 1,833 sessions. The system's performance was evaluated in terms of response time, quality of recommendations, and user engagement. To benchmark, 1,189 manual analyses conducted by nutritionists on a digital platform were assessed. The comparison included analysis precision, feedback quality, and user satisfaction. Feedback was further analyzed to identify patterns of errors and areas for system improvement.

RESULTS
Between February and September 2024, the AI system completed 1,833 nutritional analyses, compared to 430 manual assessments by nutritionists. The AI provided instantaneous responses, while the average response time for nutritionists was 11 minutes and 46 seconds. User satisfaction with the AI was 60%, although 24% reported inaccuracies in the analyses. On the digital platform, manual assessments achieved an average rating of 4.81/5, with no significant correlation between response time and user ratings

CONCLUSIONS
The AI system demonstrated remarkable scalability and significantly faster response times than manual consultations, with the ability to provide personalized feedback. However, it showed limitations in accuracy and food classification. These findings suggest that a hybrid approach, integrating the speed of AI with the expertise of human nutritionists, could achieve superior RESULTS in qualitative nutritional analysis, offering a promising pathway for scalable and precise dietary counseling.

EFFECTS OF BETA-GLUCAN ON WEIGHT IMPROVEMENT AND DYSLIPIDEMIA IN HIGH-FAT DIET-INDUCED OBESITY

Kawthar Belkaaloul[1]; Kaoutar Bouaziz[1]; Samia Addou[1]
[1]Department of Biology, Physiology of Nutrition and Food Safety, Faculty of Nature and Life Sciences, University Oran 1, Oran, Algeria

BACKGROUND AND OBJECTIVES
Obesity is a growing public health problem. Dietary fiber consumption is widely recognized for its role in preventing obesity and overweight. The objective of this study is to evaluate the effect of introducing β-glucan (BG) on body weight management, blood lipid parameters, and histological architecture of the liver and adipose tissue in Wistar rats fed a high-fat diet (HFD).

METHODS
Twenty-four male rats weighing approximately (142 ± 5) g, were included in this study and submitted to different experimental diets for 12 weeks. An extraction and dosage of β-glucan were performed beforehand. The rats were then divided into four groups: a control group receiving a standard diet (C), a group receiving a standard diet supplemented with 5% β-glucan (CBG), a group submitted to a (HFD), and a group submitted to (HFD) enriched with 5% β-glucan (HFDBG). Monitoring of anthropometric parameters was carried out throughout the experiment. The dosage of lipid parameters and the study of the tissue architecture of the liver as well as of the adipose tissue were carried out after the sacrifice of the animals.

RESULTS
The (HFD) induced an increase in food intake, reflected by a significant gain in weight and BMI. On the other hand, the consumption of (BG) limited weight gain. We also noted that the (HFD) induced dyslipidemia reflected by a significant increase in total cholesterol, triglycerides, and LDL-C and a significant decrease in HDL-C. The introduction of (BG) significantly reduced the levels of dyslipidemia. Histological sections of epididymal adipose tissue from groups of rats show a very significant increase in adipocyte diameter in the group subjected to the (HFD). However, the comparison between the group (HFD) and that treated with beta-glucan (HFDBG) reveals a notable decrease in adipocyte diameter. Furthermore, histological sections of the liver of rats subjected to the (HFD) revealed histopathological alterations, characterized by a disorganization of the typical hepatic structure. On the other hand, the administration of (BG) allowed to restore the hepatocellular architecture.

CONCLUSIONS
This study demonstrated that the introduction of (BG) into the diet significantly attenuated the deleterious effects of obesity. These RESULTS highlight the interest of dietary fiber supplementation, particularly β-glucan, in prevention and treatment strategies for obesity related to a high-fat diet.

B-CASEIN MILK A2/A2, REDUCED ABDOMINAL PAIN IN MILK INTOLERANT INDIVIDUALS ABSTRACT

Dolores Ronquillo[1]; Gabriel J. Medel-Rodríguez[1]; María Del Carmen Caamaño-Pèrez[1]; Olga P. García[1]; Jorge L Rosado[1]
[1]Faculty of Natural Sciences / Nutrition, Universidad Autónoma de Querétaro, Santiago de Querétaro, Mexico

BACKGROUND AND OBJECTIVES
Historically, cow's milk has been a staple food in the human diet; however, its consumption may impact lactose digestion and contribute to bacterial overgrowth in the small intestine among individuals with low gastrointestinal tolerance (GIT). The objective of this study is to determine gastrointestinal tolerance, stool consistency, and lactose digestion associated with the consumption of two types of milk: A2 β-casein milk and commercial milk containing both A1 and A2 β-casein, in subjects who self-report milk intolerance.

METHODS
This randomized, double-blind, crossover study investigated the effects of inyake of 100% β-casein A2 milk (A2/A2) versus a commercially available milk containing both A1 and A2 β-caseins (A1/A2) on gastrointestinal tolerance (GIT), stool consistency, lactose digestion, and hydrogen breath excretion in 44 self-identified milk intolerant adults. Participants consumed in a crossover design 300ml of each milk type with a 7-day of a washout period. GIT was evaluated during 4-h postprandial using a symptoms questionnaire, stool consistency with the Bristol Stool Scale, and lactose digestion via hydrogen breath test.

RESULTS
A significant reduction in the mean score of abdominal pain milk was observed at four hours post-consumption of A2/A2 ($p=0.017$) and overall measuring times ($p= 0.013$). A significant association was found between GIT and hydrogen breath values ($p<0.0001$), and between dairy product consumption and GIT ($p<0.0001$). No significant differences in stool consistency were observed between treatments. Nor there were significant differences in hydrogen breath test RESULTS between treatments.

CONCLUSIONS
TA2/A2 milk demonstrated superior tolerance specifically regarding abdominal pain reductioncompared with A1/A2 milk in self-reported milk-intolerant individuals. No differences were found in stool consistency or lactose digestion as assessed by hydrogen breath tests. The study suggests that the type of β-casein may influence GIT in milk-intolerant individuals, but the impact on lactose digestion remains inconclusive.

STRENGTHENING LOCAL ECOSYSTEM VIA RESILIENT COMMUNITY HUBS FOR COMPREHENSIVE DEVELOPMENT OF CHILDREN AND WOMEN

Rohini Saran[1]; Dhrubanarayan Mukherjee,[1]; Priyanka Sharma,[1]; Rhea Reji,[1]; Akshat Singh,[1]; Sonal Sharma,[1]; Mansi Yadav[1]; Shashi Arora,[1]
[1]Anil Agarwal Foundation - Nand Ghar, Vedanta Limited, New Delhi, India

BACKGROUND AND OBJECTIVES

Community-based interventions are critical for addressing multi-dimensional challenges of malnutrition,education and healthcare.Indian Government through its Integrated Child Development Services program has played a crucial role in ensuring that beneficiaries receive comprehensive care and education[1].With a focus on transforming angawanwadi centres into smart learning centres having high-quality infrastructure, there is still a need for concerted efforts to achieve the target for holistic development[2]. Nand Ghar (NG) initiative focuses on transforming these community hubs with the overall objective of establishing sustainable ecosystem that leverages a multi-sectoral approach, community engagement, private sector engagement, integrating nutrition, education, and healthcare services.

METHODS

Piloted in underserved areas with targeted interventions, we used mixed-methods approach to assess impact across 16 states.Quantitative and quantitative methodologies namely structured key-informant interviews, human centered design, secondary data and case studies were conducted with key stakeholders.Digital tools were deployed for real-time monitoring for data-driven decision-making. [3]

RESULTS

7000 structures built using Building as Learning Aid (BALA),provision of water purifiers, child-friendly furniture increased community engagement with 80% increase in attendance.Distribution of millet bars improved median weight impacting 48,000 children in three blocks in Varanasi and access to supplementary nutrition improved benefitting 2.8 lakh children.Imunization camps, provision of Iron Folic Acid supplements to pregnant and lactating women ensured access to primary healthcare,clean water,100% vaccination for children. e-learning through smart TVs,trained frontline workers in Early Childhood Care and Education (ECCE),caregiver awareness achieved 100% school readiness. Women empowerment initiatives increased household incomes by USD 115,market linkages created with government schemes,0.1m trained,0.19m women impacted.Sustainability efforts ensured 100% electricity access through solar panels or grid connections,established over 5000 kitchen gardens, promoted tree plantations, and facilitated the handover of 5000 NG to community [4].

CONCLUSIONS

Scaling Nand Ghars nationwide through multi-sectoral coordination and partnerships will ensure improved health, nutrition, education outcomes, empower women and foster community ownership and contribute to achieving the Sustaniable Development Goals.

A PANORAMA OF MAGNESIUM: EXPLORING DIETARY REFERENCE INTAKE STANDARDS, A NARRATIVE REVIEW

Lusliany Rondon[1]
[1]Centro de Biofísica y Bioquímica, Instituto Venezolano de Investigaciones Científicas (IVIC), Parroquia Macarao, Venezuela

BACKGROUND AND OBJECTIVES

Magnesium is the second most common ion at the intracellular level (IC). Its abundance reflects its important role in the organism (1-6). Various factors may influence Magnesium bioavailability and ingestion. Western dietary habits result in insufficient Magnesium intake and a link between low Magnesium levels and chronic diseases is now well established. Dietary Reference Intake (DRI) are of vital importance in determining the optimal nutrient intake in healthy population. Magnesium DRIs are determined by old balance studies, and outdated anthropometric data. In an intend to update Magnesium DRIs many theoretical and mathematical models have been developed, but discrepancies persist (7-10).

METHODS

To identify the latest recommendations for Magnesium, an internet search was conducted using PubMed and Science Direct, with the Scielo database consulted for data specific to Latin America. No date restrictions were applied, and the following search terms were employed: “Dietary Magnesium,” “Magnesium Recommendations,” “Magnesium Requirements,” “Magnesium Intake,” and “Dietary Reference Intake of Magnesium.”

RESULTS

This narrative review evaluates Magnesium as an essential cation and examines the factors that contribute to its bioavailability, the recent methods used for the determination of Magnesium, and its DRI from a global perspective, aiming for an updated understanding.

CONCLUSIONS

There is a critical need to revise and update Magnesium requirements across populations, as Magnesium plays an essential role in modulating chronic diseases.

ENHANCING DIETETIC EDUCATION THROUGH AI VIRTUAL PATIENT TRAINING

Min-Chun Tsai[1]; Cheng-Tzu Tsao[2]; Ting-Chia Chang[3]; Chia-Ling Tung[3]; Chung-Ting Chou[3]; Chin-yu Liu[3]
[1]Department of Nutrition, Taipei Veterans General Hospital, Taipei, Taiwan; [2]Information Management, Fu Jen Catholic University, Taipei, Taiwan; [3]Nutritional Science, Fu Jen Catholic University, Taipei, Taiwan

BACKGROUND AND OBJECTIVES
In recent years, the application of Artificial Intelligence (AI) in the medical field has grown rapidly, establishing itself as a valuable tool for healthcare training. Research indicates that AI-based communication education modules can significantly enhance medical students' communication abilities. However, despite the importance of communication skills in dietitian training, there remains a notable lack of AI-driven educational resources tailored to nutrition training. This study aimed to assess the impact of AI virtual patient interactions on clinical consultation training among dietetic students.

METHODS
A randomized controlled trial was conducted with 27 dietetic students, who were randomly assigned to one of two groups: the self-learning group (n = 14), serving as the control group and using traditional self-practice methods, and the AI group (n = 13), which practiced with AI-powered virtual patients. Participants in both groups were evaluated on their clinical consultation and communication skills using the Objective Structured Clinical Examination (OSCE). Additionally, their nutritional assessment knowledge was assessed through a written test before and after the intervention.

RESULTS
A total of 27 dietetic students from both groups completed the OSCE and the nutritional assessment knowledge test. Compared to baseline scores, neither the self-learning group nor the AI group showed significant improvements in nutritional assessment knowledge. However, the AI group (mean = 19.1 ± 5.2) achieved significantly higher OSCE communication skill scores ($p = 0.002$) compared to the self-learning group (mean = 13.1 ± 5.2).

CONCLUSIONS
Our study indicates that AI virtual patient training has a positive impact on the nutritional counseling performance of nutrition students who have not yet begun hospital internships. However, it does not demonstrate a significant effect on professional knowledge acquisition. Further research is needed to explore the potential application of AI in dietetic education.

SALT REMOVAL EFFECTS AND BEHAVIORAL CHANGES IN LOCAL INDIGENOUS FOOD TO PREVENT HYPERTENSION: A RANDOMIZED TRIAL ～AGRICULTURE FOR HEALTH AND WELL-BEING～

Yuka Kobayashi[1]; Minami Takayama[1]; Mio Yamasawa[1]; Miyu Tozuka[1]; Hikari Masuda[1]; Yuho Ozasawara[1]; Ayaka Kusano[1]; Airi Endo[1]; Kosuke Hosaka[1]; Sayuri Goryoda[1, 2, 3]
[1]Integrated Food and Agricultural Science, Yamagata University, Tsuruoka, Japan; [2]YAAS, Yamagata University Advanced Agri-Food System Research Center, Yamagata, Japan; [3]Well-being Institute, Yamagata University, Yamagata, Japan

BACKGROUND AND OBJECTIVES
Hypertension affects more than 1.28 billion people worldwide. Approximately one-third of the Japanese population has hypertension. Recently, the consumption of vegetables rich in potassium, which promotes sodium excretion, has attracted attention as an effective preventive measure against hypertension.
This study aimed to cultivate, process, and analyze local foods with potential sodium excretion benefits and to evaluate their impact on salt excretion and dietary behavior through a dietary intervention study.

METHODS
A randomized crossover-controlled trial was conducted with 60 adults. Participants were assessed for lifestyle and urinary sodium-to-potassium (Na/K) ratios and allocated to groups with equivalent ratios. A four-week dietary intervention (Jerusalem Artichoke Tea 133mL) and eight-week washout period followed. The effects were analyzed using paired t-tests and mixed-effects models, with stratification by the Na/K ratio.
An RCT was also conducted using edamame, dadachamame as a food source, stratified by Na/K ratio greater than or equal to 4.0 and less than 4.0. Local indigenous food (dadachamame), containing 1700 mg/100 g potassium, was cultivated in collaboration with local farmers. This potassium level is approximately three times higher than that found in common edamame. The study was approved by the Ethical Review Committee of Yamagata University School of Medicine.

RESULTS
The overall effect of salt removal was not significantly different. However, in the high-risk hypertensive group with an Na/K ratio of 5.0 or higher, the effect of salt removal was 5.59 in the intervention group and 6.64 in the control group (p=0.02), showing a significantly higher salt removal effect. Similar RESULTS were also confirmed in the stratified RCT. Participants in the indifferent phase improved significantly from 50.0% to 33.3% after the intervention and 23.8% after the Na/K ratio measurement.

CONCLUSIONS
Dietary intervention significantly affected salt excretion in the high-risk hypertensive group and induced desirable dietary behavioral changes. This practice is expected to revitalize agriculture and improve the health of residents.

DEVELOPMENT AND VALIDATION OF A PHOTOGRAPHIC FOOD ATLAS FOR PORTION SIZE ESTIMATION AMONG SRI LANKAN ADOLESCENTS

Thushanthi Perera[1]; Nilmini Karunarathna[2]; Renuka Silva[2]; Aulo Gelli[3]
[1]Department of Nutrition and Dietetics, Faculty of Livestock, Fisheries & Nutrition, Wayamba University of Sri Lanka, Makandura, Sri Lanka; [2]Department of Nutrition and Dietetics, Faculty of Livestock, Fisheries & Nutrition, Wayamba University of Sri Lanka, Makandura, Gonawila, 60170, Sri Lanka; [3]Poverty, Gender and Inclusion Unit, International Food Policy Research Institute, Washington DC, United States of America

BACKGROUND AND OBJECTIVES
There is limited dietary intake data of adolescents in low and middle-income countries partly due to the low accuracy in portion size estimation using conventional dietary assessment methods. To address this, a food atlas - a collection of photographs showing various portion sizes of selected food items can serve as a useful tool. This study aimed to develop and validate a photographic food atlas featuring portion sizes of commonly consumed food in Sri Lanka, specifically designed for adolescents.

METHODS
From 15 different food groups, 240 food items that are commonly consumed by Sri Lankan adolescents were prioritized based on data from previous studies. Among these prioritized food items, some were prepared using a standard recipe book, while others were purchased from the local market. These items were photographed using a smartphone with a 13-megapixel camera. Photographs were taken from 90-degree angles to capture the aerial views and 45-degree angles to represent the perspective of a person sitting at a table and looking at a plate in front of him. White crockery with a blue background was used to present the food items. Subsequently, the developed food atlas was used to collect dietary data from selected participants (n-30) for two non-consecutive days employing weighed food records and multi-24-hour dietary recall method, with the food atlas serving as a portion size estimation aid. The validity of the atlas was assessed using percentage error, Cohen's weighted kappa (κw), and Bland-Altman limits of agreement.

RESULTS
A total of 240 food items, each with four portion sizes (small, medium, large, and extra-large), commonly consumed by Sri Lankan adolescents were depicted in the atlas. There were no significant differences reported between weighed food portions and recalled portion size image selection for most food items.

CONCLUSIONS
The Food Atlas will be a valuable tool for accurate dietary assessment and surveys among adolescents in Sri Lanka. The color photographic food atlas developed in this study appears to be a useful and valid tool for estimating portion sizes of the most commonly consumed dishes in Sri Lanka.

THE FIRST EVIDENCE-BASED DIETARY GUIDELINES AND TOOLS DEVELOPED FOR MYANMAR TO IMPROVE DIET AND NUTRITION FOR PREGNANT AND LACTATING WOMEN AND CHILDREN AGED 2 TO 5 YEARS

Hsu Mon Mon Zaw[1, 2]; Warren T K Lee[3]
[1]International Health, Charité – Universitätsmedizin Berlin, Berlin, Germany; [2]Nutrition, Food and Agriculture Organization of the United Nations, Naypyidaw, Myanmar; [3]Nutrition & Food Systems, Food and Agriculture Organization of the United Nations, Bangkok, Thailand

BACKGROUND AND OBJECTIVES
Myanmar's food-based dietary guidelines (FBDGs) have evolved significantly since their inception in 2003 and the subsequent revision in 2007, which provided general dietary guidance without specific recommendations on food quantities, agriculture, food sustainability. The latest guidelines, published in 2023, developed using a globally recognized methodology, represent a transformative step in addressing the unique nutritional needs of pregnant and lactating women (PLW) and children aged 2 to 5 years. These guidelines aim to foster evidence-based dietary practices, facilitate policy implementation, improve nutritional outcomes and prevent all forms of malnutrition in Myanmar.

METHODS
The FBDG development process involved establishing a multi-sectoral working group, conducting an evidence review, and tailoring age-specific guidelines, followed by publication, implementation, and monitoring and evaluation. Analyses of dietary patterns, cultural and socioeconomic factors, and food systems in Myanmar were informed by national surveys, reports, and academic literature. Multi-stakeholder consultation meetings were held to engage policymakers, and sectoral experts. Practical tools, such as diet modeling, food exchange lists, The Myanmar Food Atlas, menu plans, and Information, Education, and Communication (IEC) materials, were developed to ensure nutrient adequacy, dietary diversity, and practicality. Pilot studies were conducted to validate the IEC materials' clarity, feasibility, contextual relevance, and acceptability among communities and stakeholders.

RESULTS
The updated FBDGs provide evidence-based, age-specific recommendations that incorporate considerations for sustainability, accessibility, and affordability of foods in Myanmar. They address persistent nutritional challenges, including inadequate dietary diversity, and significant rates of stunting, anemia, and micronutrient deficiencies in PLW and children. Pilot studies demonstrated improved comprehension of dietary recommendations and highlighted their potential to promote better nutritional practices.

CONCLUSIONS
The development of evidence-based FBDGs marks a significant milestone in public health nutrition, shifting from general recommendations to a comprehensive framework grounded in scientific evidence to promote healthy dietary practices in the country. Sustained commitment through stakeholder collaboration, interdisciplinary efforts, and periodic updates will ensure their long-term impact and adaptability to evolving nutritional needs in Myanmar. EPO1_111

DIETARY CARBOHYDRATE PATTERNS DERIVED BY CLUSTER ANALYSIS ARE ASSOCIATED WITH ADHERENCE TO THE EATWELL GUIDE RECOMMENDATIONS AMONG UK ADULTS

Apple Espino[1, 2]; June Po,[2]; Kate Wellard,[2]; Stephan Haefele,[3]; Andrew Mead,[1]
[1]Intelligent Data Ecosystem, Rothamsted Research , Harpenden, United Kingdom; [2]Natural Resources Institute, University of Greenwich (Medway Campus), Gillingham, United Kingdom; [3]Sustainable Soils and Crops, Rothamsted Research , Harpenden, United Kingdom

BACKGROUND AND OBJECTIVES
The Eatwell Guide (EWG) recommends that a third of the diet should come from starchy carbohydrates. Both quality and quantity of carbohydrates are important in achieving a healthy diet, with studies highlighting a stronger link between carbohydrate type and disease risk than total intake. This study explores dietary carbohydrate patterns among UK adults, adherence to EWG recommendations, and associations with sociodemographic factors.

METHODS
Statistical clustering was used to classify the population according to consumption of starchy-based meals (i.e., potatoes, bread, rice, pasta, and other cereals) using the data from a 4-day food diary of 2,757 adults (19-85 years old) in the National Diet and Nutrition Survey (year 2016-2019). The obtained dietary carbohydrate patterns were assessed for adherence to nine EWG food and nutrient recommendations (fruits and vegetables, oily fish, other fish, red and processed meat, fibre, salt, free sugars, saturated fats, and total fat) by age and sex. Multivariable logistic regression was employed to examine the associations between sociodemographic factors and dietary carbohydrate patterns.

RESULTS
Four distinct dietary carbohydrate patterns were identified: "Balanced Carbohydrate Sources" (48%), "White Bread and Fried Potatoes" (24%), "Pasta, Rice, and Other Cereals" (19%), and "Whole Grains" (9%). The "White Bread and Fried Potatoes" pattern had the highest proportion (37%) of individuals with very low adherence to EWG recommendations (0-2 guidelines met), while the "Balanced Carbohydrate Sources" pattern showed the highest compliance, with 55% meeting 3–4 dietary guidelines. Overall, commonly unmet recommendations included fruits and vegetables (27%), oily fish (20%), and dietary fibre (8%), with mean intakes of 311.2g, 9.1g, and 19.5g, respectively, falling below recommendations. The "White Bread and Fried Potatoes" pattern was also associated with the highest mean intake of less healthy dietary components, such as red and processed meat (71.0g), salt (5.6g), free sugars (54.5g), saturated fat (27.2g), and total fat (74.4g). Significant associations ($p < 0.01$) were observed between dietary carbohydrate patterns and sociodemographic factors, including sex, age, income, and household size.

CONCLUSIONS
Understanding starchy carbohydrate dietary patterns, which are often central to food security for certain demographics, can offer valuable insights for designing interventions that contribute to meeting both food and nutrient recommendations and the cultural preferences of diverse population groups.

BACKGROUND AND OBJECTIVES

Targeted metabolomics is a powerful tool for investigating specific metabolites and metabolic pathways linked to key physiological processes. In the NEPTOX study, we employ targeted metabolomics to examine maternal and infant blood, with the aim of better understanding how early-life exposures, such as nutrition and environmental pollutants, affect metabolic pathways that influence fetal and infant growth, neurodevelopment, and long-term health outcomes. This approach also seeks to identify biomarkers or metabolic pathways that may predict developmental trajectories and health risks, supporting the development of interventions that promote optimal health during critical periods.

METHODS

Targeted metabolic profiling will assess nutritional and functional biomarkers, including B-vitamins, fat-soluble vitamins, and essential amino acids. Central to investigating the effects of nutritional and environmental exposures on growth and development, we will also measure a wide array of complementary biomarkers and metabolites. These include those linked to inflammation and immune activation, energy homeostasis, and cardiometabolic health. The approach will target individual metabolites and biomarkers, whole metabolite classes, and defined metabolic pathways such as C-reactive protein, calprotectin, neopterin, the kynurenines, one-carbon metabolism, and the TCA cycle. Gut-derived metabolites, including short-chain fatty acids, indoles, and choline derivatives, will also be measured to explore microbiome-related metabolic activity and effects. These analyses will employ GC-MS/MS, LC-MS/MS, MALDI-TOF-MS and microbiological methodologies at Bevital, Bergen, Norway.

RESULTS

The targeted metabolic profiling approach enables precise quantification of metabolites associated with nutrient utilization, metabolic shifts, and exposure-related metabolic changes during pregnancy and early life. It will provide insights into molecular mechanisms and enhance understanding of how early exposures effect growth, neurodevelopment, and health outcomes.

CONCLUSIONS

This targeted metabolomics approach supports a deeper understanding of early-life metabolic processes, offering critical insights into the interplay between nutrition, microbiome function, and environmental exposures. These findings will guide interventions and policy recommendations aimed at protecting maternal and infant health, particularly in low-resource settings.

DEVELOPMENT OF THE DUTCH ULTRA-PROCESSED FOOD INDEX: A NEW TOOL TO ESTIMATE DIETARY QUALITY BASED ON INDUSTRIAL PROCESSING LEVELS

Marlou Lasschuijt[1]; Marieke Van Bruinessen[1]; Jeanne Lagerweij,[1]; Ming-Jie Duan[1]; Corine Perenboom,[1]; Jong, Hanne De[1]; Desiree Lucassen,[1]; Edith Feskens[1]; Ciaran Forde[1]
[1]Human Nutrition and Health, Wageningen University and Research, Wageningen, Netherlands

BACKGROUND AND OBJECTIVES
Observational studies have consistently shown that high intake of ultra-processed foods (UPFs) is associated with increased risks of obesity and non-communicable diseases, including type 2 diabetes, cardiovascular disease, and cancer. Most studies apply industrial processing classifications, such as the Nova system to classify foods as UPF. An often overlooked methodological issue is that dietary data used in observational studies is not designed to quantify UPF consumption. Ultra-processed foods form a highly heterogeneous food category and categorizing foods solely based on the degree of processing not taking into consideration nutritional differences. While most of the healthy eating indices are developed based on dietary guidelines focusing on conventional food groups, the contribution of UPFs to diet quality has rarely been considered.

METHODS
We developed a novel Dutch UPF index (DUPFI) that categorizes food intake considering both food processing levels and diet quality. The DUPFI consists of eight categories representing the four Nova classes split into health-beneficial and health-risk. First, all items of the Dutch Food Composition Database (NEVO) were classified according to the Nova Classification system. Composite dishes were disaggregated into ingredients. Each ingredient was assigned the proportionate contribution to the dish based on its weight and all dishes were classified accordingly.

RESULTS
All NEVO items were classified as health-beneficial (a) or health-risk (b) within their Nova class based on available literature and the Dutch Dietary Guidelines. Most dietary assessment methods in the Netherlands rely on the NEVO table, allowing our UPF index to be applied to all dietary assessment methods, to accurately estimate total food and energy intake of healthy and health-risk UPF and non-UPFs across cohort dietary data.

CONCLUSIONS
Future research can apply the index to investigate associations between UPF consumption and health outcomes in Dutch adults, differentiating between health-beneficial and health-risk foods. The Dutch UPF index contributes to providing a clearer understanding of the role food processing plays in public health nutrition.

CONFLICTS OF INTERESTS

DISPUTES OVER THE AGENDA TO PROMOTE ADEQUATE AND HEALTHY EATING - HOW THE BIG SODA INTERFERED IN THE BRAZILIAN TAX REFORM

Vitória Moraes[1]; Bruna Kulik Hassan[1]; Paula Johns[1]
[1]Healthy Food Promotion Program, Associação de Controle do Tabagismo, Promoção da Saúde, São Paulo, Brazil

BACKGROUND AND OBJECTIVES

A large and growing body of evidence demonstrates that sweetened beverages (SB) taxes reduce purchases/consumption of these products. The measure was reinforced as part of a multi-policy package needed to reduce rates of overweight/obesity and other diet-related diseases, and was implemented in several countries, with positive health impacts (WHO, 2023; 2024). Brazil approved an SB tax in December 2024, one of the RESULTS of the Tax Reform (TR) process. Despite this, taxation is one of the most feared measures by the commercial entities (CE), who use strategies to delay and avoid it through corporate political activity (CPA), as in the Brazilian process. Thus, our objective is to map the CPA of the CE throughout TR in 2024.

METHODS

We gathered data on activities of the mapped CE related to SB taxation between March and December 2024 (when National Congress and Ministry of Economy deliberations occurred), mainly from Google Alerts®, but also from social media, official websites and sponsored press media articles. The terms registered were: “ABIR” (Brazilian Association of Sodas and Non-Alcoholic Beverage Industries); “sin tax”; “excise tax”; “Tax Reform beverage”; “Tax Reform soda”. Documents of Executive Level meetings with CE representatives were obtained through the Freedom of Information request Law. Data analysis was based on the Ulucanlar et al. (2023) taxonomy of CPA strategies, by classifying it as action or framing strategy. We examined: (i) action date; (ii) action description; (iii) strategy used; and (iv) CE arguments.

RESULTS

We identified 47 action strategies and 36 framing CPA strategies. The most frequent action strategy was ‘Access and influence policy-making’ (27 times), with the mechanism ‘Attempt to influence policy processes and outcomes’ identified 21 times. The most common framing strategy was “the unacceptable, ‘bad’ solution: whole population, statutory” (19 times), by the mechanism “Policies are unnecessary & unacceptable” identified 7 times.

CONCLUSIONS

The role of CPA in the policy-making process points to the emergence of developing mechanisms to prevent, manage and mitigate industry interference aiming to protect and advance the health and food policy agenda.

HOW EFFECTIVE ARE LAWS AND REGULATIONS IN IMPROVING FOOD SAFETY AND QUALITY? THE CASE OF CÔTE D'IVOIRE AND KENYA

Arlène Alpha[1]; Alexandre Hobeika[1]; Grace Delia[2]; Solange Aka[3]; Florence Mutua[4]; Yolande Aké-Assi[5]
[1]ES/ MoISA, Cirad, Montpellier, France; [2]Natural Resources Institute, University of Greenwich (Medway Campus), Central Avenue, Gillingham, Chatham, UK, Chatham, United Kingdom; [3]Agriculture Durable et Nutrition, CSRS, Abidjan, Ivory Coast; [4]Animal and human health, ILRI, Nairobi, Kenya; [5]Agriculture Durable et Nutrition, Centre suisse, Abidjan, Ivory Coast

BACKGROUND AND OBJECTIVES

Food safety is essential for nutrition, as contaminated food compromises the ability to achieve healthy diets and perpetuates a vicious cycle of foodborne illness and malnutrition. Fresh fruits, vegetables, and animal source foods contribute to nutrition but are often contaminated by microbiological and chemical hazards in Africa. This study evaluates the effectiveness of food safety laws and regulations in Afica, focusing on fresh produce and processed fish in Côte d'Ivoire and milk in Kenya. The targeted foods are central to local diets but they also pose significant food safety challenges.

METHODS

The research applied a multidisciplinary approach: (i) reviewing regulatory frameworks and mapping key stakeholders, (ii) assessing microbiological and chemical contamination in food products through laboratory analyses (540 samples in Côte d'Ivoire) and literature review (milk in Kenya), and (iii) conducting qualitative interviews and workshops. Regulatory frameworks were evaluated for their alignment with public health goals and informal sector capacities.

RESULTS

In Côte d'Ivoire, the targeted foods were contaminated by microbial agents (e.g., *E. coli*, *Staphylococcus aureus*) and chemical agents (e.g., mercury, arsenic, pesticides, and polycyclic aromatic hydrocarbons). Some contaminant levels exceeded international standards but the risk of the hazard occuring is low for consumer. In Kenya, milk was frequently contaminated with biological hazards such as *Salmonella* and toxigenic *E. coli*, and chemical hazards like aflatoxins and antimicrobial residues, largely due to unhygienic handling and inadequate processing. Contaminations across both countries arose from poor production, storage, and distribution practices. Regulatory frameworks lacked enforcement capacity, alignment with the informal sector, and inclusivity in their design.

CONCLUSIONS

Unsafe food undermines nutrition by reducing the availability, safety, and nutrient quality of key food groups essential for health. Contaminated fresh produce and milk can contribute to micronutrient deficiencies and increased disease burden, particularly in vulnerable populations such as children. Strengthening food safety laws and regulations in Africa requires inclusive, risk-based approaches that account for the informal sector's capacities. Policies should prioritize health-focused interventions (e.g. education on safe food handling, low-cost technologies, improved access to clean water). Integrating nutrition-sensitive approaches into food safety policies can better safeguard public health.

CONFLICTS OF INTERESTS

CHALLENGES IN PROVIDING COMPREHENSIVE FISH AND SEAFOOD COMPOSITION DATA

Siân Astley[1]; Angelika Mantur-Vierendeel,[1]; Marion Buso,[1]; Paul Finglas,[1]
[1]Scientific Unit, EuroFIR AISBL Secretariat, EuroFIR, Brussels, Belgium

BACKGROUND AND OBJECTIVES

FISHEUTRUST (Project ID 101060712) is developing tools to maximise trust in fish and seafood quality, safety, and traceability, leveraging a range of smart technologies and genomic and isotopic methods as well as blockchain. These tools will be integrated into the FishEUTrust digital platform, providing a unified approach to traceability. More specifically, FISHEUTRUST wants to enhance understanding of nutritional quality and the role fish and certain seafoods in reducing the global burden of disease. To that end, EuroFIR is updating the SEAFOODTOMORROW dataset and supporting development of the FishEUTrust platform to facilitate data sharing with actors in the value-chain and consumers.

METHODS

The SEAFOODTOMORROW dataset (DOI 10.5281/zenodo.7825958; GA No 773400), initially established in 2018, is being updated using automated searches across 39 food composition databases (FCDBs), incorporating new countries and expanded fatty acid data. Harmonisation was achieved by standardising units, identifying outliers, and addressing duplication. Weighted averages are being calculated for nutrient values, and new datasets for fish and seaweed composition have been created, ensuring compatibility with emerging digital tools and technologies.

RESULTS

Updating the dataset revealed challenges, including inconsistencies in data formats, units, and nutrient definitions across FCDBs, as well as methodological variations in nutrient analysis. Missing data and gaps in coverage for fish– especially in low- and middle-income countries – and macroalgae species further highlight limitations in current datasets. Despite these issues, integration of additional data points and development of weighted averages will improve dataset comprehensiveness. These RESULTS will inform design of the FishEUTrust platform, ensuring delivery of accessible and reliable composition data.

CONCLUSIONS

Providing high-quality, harmonised fish and seafood composition data remains challenging due to methodological inconsistencies and data gaps. However, the updated SEAFOODTOMORROW dataset addresses some of these challenges by leveraging standardised methodologies and advanced digital tools. This work supports greater transparency, promotes consumer trust, and underpins research into the health benefits of fish and seafood consumption in Europe.

SUSTAINABILITY IN FOOD-BASED DIETARY GUIDELINES: A REVIEW OF RECOMMENDATIONS AROUND MEAT AND DAIRY CONSUMPTION

Maddie Sinclair[1]; Esther K Papies,[1]; Emilie Combet[2]; Tess Davis,[3]
[1]MRC/CSO Social and Public Health Sciences Unit, School of Health and Wellbeing, University of Glasgow, Glasgow, United Kingdom; [2]Human Nutrition, School of Medicine Dentistry and Nursing, University of Glasgow, Glasgow, United Kingdom; [3]MRC/CSO Social and Public Health Sciences Unit, University of Glasgow, Glasgow, United Kingdom

BACKGROUND AND OBJECTIVES
Citizens in high-income nations need to urgently change their dietary patterns. They need to move away from animal-based foods, particularly meat and dairy, and shift toward more plant-based diets, to reduce greenhouse gas emissions and land use from the food system. This could also have substantial health co-benefits (e.g., reduced risk of heart disease, stroke, and some cancers). Food-based dietary guidelines are country-specific and communicate nutrition recommendations to the public. However, it is not known how different countries' FBDG communicate reducing meat and dairy intake to citizens in the context of sustainability.

METHODS
We reviewed global consumer-facing dietary guidelines (n=58) to explore information and recommendations for reducing meat and dairy consumption in the context of sustainability, and the pictorial representation of these foods compared to other foods.

RESULTS
A minority of countries used a sustainability argument to recommend reducing meat (6/58) or dairy (2/58) intake. The proportion of meat images within visual food guides was consistently lower than dairy images. Furthermore, guidelines lacked specific actionable advice around sustainability and diet. Only a very small number of countries recommend reducing meat and/or dairy consumption.

CONCLUSIONS
Clearer guidelines backed by current evidence around both health and sustainability are needed. These guidelines should provide justification behind recommendations, actionable advice for meeting the recommendations, and appropriate quantified targets or limits of certain foods. This well-rounded advice is imperative to empower citizens to change their dietary habits, to reduce global meat and dairy consumption and shift towards more sustainable diets for human and planetary health.

PILOT TRIAL COMPARING FEASIBILITY AND EFFECTS OF TWO ALCOHOL CONSUMPTION RECOMMENDATIONS

Rafa Perez-Araluce[1]; Alfredo Gea[1]; Vanessa Bullon-Vela[1]; Carmen Sayon-Orea[1]; Maria Vasij[1]; Victoria Güeto[2]; Guillermo De Ulibarri[3]; Alejandro Fernandez-Montero[4]; Manuel F. Landecho[5]; Miguel A. Martínez-González[1]; Maira Bes-Rastrollo[1]

[1]Dpt. Preventive Medicine and Public Health, University of Navarra, Pamplona, Spain; [2]Centro de Salud de Mendillorri, Servicio Navarro de Salud, Pamplona, Spain; [3]Servicio de Urgencias, Hospital Universitario de Navarra, Pamplona, Spain; [4]Medicina Ocupacional, Clinica Universidad de Navarra, Pamplona, Spain; [5]Medicina Interna, Clinica Universidad de Navarra, Pamplona, Spain

BACKGROUND AND OBJECTIVES

Alcohol consumption remains a significant public health challenge, with debates fueled by conflicting evidence on its health implications. While abstinence aligns with growing global advocacy for zero alcohol consumption, moderate drinking, particularly within the Mediterranean Alcohol Drinking Pattern (MADP), has shown potential health benefits. This study aimed to evaluate the feasibility and short- to medium-term effects of two contrasting public health messages—abstinence versus moderate MADP consumption—on behavioral changes and health outcomes.

METHODS

A pilot randomized controlled trial enrolled 103 participants, who were randomized to either abstention or adherence to the MADP. 76 participants completed the one-year follow-up. Outcomes included changes in alcohol consumption, binge drinking episodes, and health parameters, assessed through biochemical markers, anthropometric measures, and validated questionnaires addressing physical and mental health. Feasibility was also analyzed through recruitment and retention rates

RESULTS

Both interventions significantly reduced alcohol consumption and binge drinking episodes. The abstention group demonstrated greater reductions in total alcohol intake and improvements in blood pressure and liver enzyme markers. The MADP group showed better adherence to the MADP and a reduction in depressive symptoms. However, no statistically significant differences were observed between groups for these outcomes. Cognitive performance in the Mini-mental test was slightly higher in the abstention group (0.69 points [0.09 to 1.30], $p = 0.025$), but this difference was not clinically relevant. Recruitment and retention challenges, largely due to the COVID-19 pandemic, highlighted feasibility concerns, but also informed future trial designs.

CONCLUSIONS

Both abstention and adherence to the MADP effectively reduced harmful drinking behaviors and offered distinct health benefits. These findings underscore the need for larger, long-term trials to provide definitive public health recommendations regarding alcohol consumption.

REFORMULATION OF FOOD PRODUCTS (THE EFFORT STUDY): A SIMULATION OF THE IMPACT ON NUTRIENTS INTAKE AND DIET QUALITY IN THE ITALIAN POPULATION

Daniela Martini[1]; Massimiliano Tucci[1]; Lara Chehade[1]; Donato Angelino[2]; Nicoletta Pellegrini[3]; Cristian Del Bo'[1]; Patrizia Riso[1]
[1]Department of Food, Environmental and Nutritional Sciences (DeFENS), University of Milan, Milano, Italy; [2]Department of Bioscience and Technology for Food, Agriculture and Environment, University of Teramo, Teramo, Italy; [3]Department of Agricultural, Food, Environmental and Animal Sciences, University of Udine, Udine, Italy

BACKGROUND AND OBJECTIVES
Reformulation of food products is a promising strategy to reduce the intake of nutrients of concerns such as sugars, saturates and salt. Indeed, in many countries including Italy, a large proportion of salt, sugar and saturated fats in the diet comes from packaged foods. The EFFORT study, part of the OnFoods project (www.onfoods.it), aims at investigating the impact of different strategies of reformulation of food products in terms of intake of critical nutrients and diet quality.

METHODS
In the first steps, the main food categories contributing to the intake of critical nutrients have been evaluated and their content is being analyzed in food products currently on the Italian market based on the information reported on the food labeling. Then, strategies of reformulation have been hypothesized for different case-studies (e.g. biscuits and bread) to identify the potential impact of reformulated food products on nutrient intake. Finally, the impact of reformulating the food categories that contribute most to nutrient intake on diet quality using different dietary scenarios is assessed.

RESULTS
Up to three different strategies were identified to improve the nutritional quality of the different products under study: i) reformulation aimed at allowing the use of nutrition claims (e.g. decrease of sugars and saturated fat by 30%, and reduction of salt by 25%; ii) reformulation based on minimum levels of critical nutrients in top-selling products commercially available; iii) reformulation aimed at improving front-of-pack labels. When used to simulate the impact of such strategies on the reduction of the intake of specific critical nutrients, the reformulation aimed to allow the use of nutrition claims such as “reduced in salt” led to the major improvements in diet quality. As regards the reduction of salt intake, consuming reformulated bread in line with the Italian dietary guidelines produced a reduction up to 0.5 g/day. Similar impacts have been obtained for sugars by reformulating biscuits largely consumed in the Italian population. In addition, reformulation of plant-based alternatives significantly contributed at reducing the intake of at-risk nutrient such as sodium and sugar.

CONCLUSIONS
Reformulation of packaged foods can be optimized promoting potential win-win strategies for both the food industry and the consumers. Ongoing studies will show the practical benefits of different approaches on diet quality achieved by the consumption of reformulated food products.

CONFLICTS OF INTERESTS
The authors have no conflict of interest.

MOM-CARE: A PHASE III DOUBLE-BLIND, ADAPTIVE RANDOMIZED TRIAL OF ANTENATAL AND POSTNATAL MMSPLUS VERSUS STANDARD MMS AND IFA TO IMPROVE INFANT BIRTH OUTCOMES AND GROWTH

Fyezah Jehan[1]; Zahra Hoodbhoy[2]; Muhammad I Nisar,[2]; Ayesha Khalid[2]; Rakhshanda Ishaque[3]; Amal Fatima[2]; Dania Mushtaq[2]
[1]Department of Paediatrics & Child Health Medical College, Aga Khan University, Karachi, Pakistan; [2]Paediatrics and Child Health, Aga Khan University, Karachi, Pakistan; [3]Research and Program, VITAL PAKISTAN TRUST, Karachi, Pakistan

BACKGROUND AND OBJECTIVES
Malnutrition remains a critical global challenge, disproportionately affecting maternal and child health in low- and middle-income countries. Recent evidence highlights the potential of optimizing multiple micronutrient supplementation (MMS) with key additions, such as NAD precursors, Choline, calcium (Ca), and DHA, to improve maternal and infant health. Findings from the MumtaPW trial demonstrated significant benefits of these vitamins and minerals, particularly on birth weight, stillbirths and neonatal mortality outcomes. The MOM-CARE trial aims to evaluate the impact of antenatal MMSPlus, enriched with NAD, Choline, calcium, and DHA, compared to standard MMS, and postnatal MMSPlus compared to standard MMS and IFA on infant health outcomes at birth and growth metrics at 6 months of age.

METHODS
This double-blind, adaptive randomized controlled trial will recruit 3,000 pregnant women from established surveillance sites within an Integrated Research Platform. Participants will be randomized during the antenatal phase to receive either MMSPlus or standard MMS and re-randomized postnatally into three groups (MMSPlus, standard MMS, or IFA). The primary outcome in the antenatal phase is a composite ordinal measure of infant health at 28 days of life, which includes categories ranging from stillbirth and neonatal death to preterm or term births with small-for-gestational-age (SGA) or appropriate-for-gestational-age (AGA) infants, and infant length velocity (cm/month) at 6 months. Secondary outcomes encompass maternal and neonatal morbidity, gestational weight gain, growth z-scores, and stunting prevalence. Data analysis will employ Bayesian cumulative logistic regression, with interim adaptive analyses conducted at predefined milestones.

RESULTS
This study utilizes an adaptive trial design to enhance efficiency, integrating key learnings from the Mumta PW trial and other research on calcium and DHA, to provide robust evidence for policy and programming in maternal and child nutrition.

CONCLUSIONS
MOM-CARE represents a critical step forward in addressing the global burden of malnutrition, with potential implications for scaling up maternal micronutrient supplementation programs worldwide.

AN ANALYSIS OF THE DIETARY SOURCES OF FIBRE IN THE UK USING THE NATIONAL DIET AND NUTRITION SURVEY DATA ACROSS TIME (2008-2018)

Anam Wajid[1]; Kyle Janet[2]; E Kiltie Anne[3]; P. Scott Karen[1]; Ayesh Aladdin[4]
[1]The Rowett Institute, University of Aberdeen, Aberdeen, United Kingdom; [2]Institute of Applied Health Science, University of Aberdeen, Aberdeen, United Kingdom; [3]School of Medicine, Medical Science and Nutrition, University of Aberdeen, Aberdeen, United Kingdom; [4]School of Natural and Computing Science, University of Aberdeen, Aberdeen, United Kingdom

BACKGROUND AND OBJECTIVES

Dietary fibre provides many health benefits, despite this most people in the UK do not meet the 30 g/day fibre intake recommendation (1). The role of fibre intake in prevention of diseases like metabolic diseases and cancers is well established (2). Studies also show links between different food sources and types of fibre with metabolic pathways and gut microbiota (3). This highlights the importance of better understanding the different food sources and types of fibre consumed in diet to improve and personalise fibre recommendations for target groups. The objective of this study was to investigate the contribution of different dietary sources of fibre and how they differ across time.

METHODS

Secondary data analysis of the UK National Diet and Nutrition Survey (NDNS) data from Year 1 (2008/09) to Year 11 (2018/19) was performed. The contribution of NDNS main Food Groups to daily total fibre intake of the study population was calculated. The food items within each food group where then categorised to form new fibre focused food groups based on common characteristics, including main ingredient or cooking method. The percentage contribution of the new aggregated food groups to total fibre intake was calculated.

RESULTS

Our analysis confirmed that the average fibre intake of the population is below recommended levels and has not changed over time i.e. 18 ± 6.6 to 18.8 ±7.2 g/day. The contribution of food groups to total fibre intake has changed over time, these reflect differences in the number of consumers (either increased or reduced over time). However, three food groups did not follow this trend. Within main NDNS defined food groups, the contribution of foods to fibre intake has changed considerably from 2008, so has the number of consumers. For example, in the group “vegetables not raw” the fibre contribution and consumers of carrots declined by 2.8% and 7.9% respectively. Fibre contribution and consumers of other cooked vegetables like broccoli, beetroot and sweet potato increased whereas baked beans, swede and cauliflower decreased.

CONCLUSIONS

Dietary sources of fibre and their consumption have changed over time. A novel aspect of this study is the exploration of fibre intake of food items within the NDNS main groups across time. An interesting finding of this study is that the amount of fibre contributed by foods and the consumption of foods have both changed. This study will, in the future, focus on exploring yearly variations and the impact of demographic differences on the food sources of fibre.

CONFLICTS OF INTERESTS

The authors have no conflict of interest.

PROOF OF CONCEPT OF INCREASE VIABILITY CACO-2 CELLS EXPOSED TO A PROBIOTIC FERMENTED FRUIT JUICE

Habibullah Moradian[1]; tristan GABRIEL-SEGARD[2]; Stephane Paul[3]
[1]Groupe Immunité des Muqueuses et Agents Pathogenes - GIMAP, Jean Monnet University - North Campus Hospital, Saint-Priest-en-Jarez, France; [2]MICALIS Team FInE, Inrae Ile-De-France, Jouy-en-Josas, France; [3]Group Immunite des Muqueuses et Agent Pathogen - GIMAP, Jean Monnet University - North Campus Hospital, Saint-Priest-en-Jarez, France

BACKGROUND AND OBJECTIVES
Probiotics are live bacteria and when consumed adequately they exert beneficial effects on the host's health including gut mucosa. Is fermentation process a probiotic strains revitalization impacting the protective effect on cell model.

METHODS
Wild type Caco-2 cell line has been used as an in-vitro model of intestinal epithelial barrier. Monolayers of cell culture on 96 multiwell plates were exposed to hydrogen peroxide (H2O2), followed by co-treatment with or without probiotic fermented fruit juice. The protective effects of probiotic fermented juice against H2O2-induced oxidative damages have been assessed by MTT cell viability assay, according to Kit protocol. Also, cell cultures on Transwell inserts were exposed to bacterial lipopolysaccharide (LPS) and the LPS-disruption of cell monolayer integrity and tight junctions have been assessed via the measurement of transepithelial electrical resistance (TEER) and immunofluorescent detection of zonula occludens-1 (ZO-1) tight junction protein, respectively.

RESULTS
Our data showed that co-treatment with probiotic fermented juice significantly (P value <0.0027) prevented the reduction in percentage of cell viability in H2O2-treated Caco-2 cell culture model. In addition, we have shown that after 24 hours of LPS exposure, Caco-2 cell monolayer has shown significant lowering of TEER values, while these lowering of TEER values were attenuated upon probiotic fermented juice co-treatment. Furthermore, our data has also exhibited that LPS exposure led to the disruption of tight junction protein ZO-1, while these disruptions were prevented upon probiotic fermented juice co-treatment. These RESULTS indicate the effectiveness of probiotic fermented fruit juice in the protection of cells lining of gut mucosa.

CONCLUSIONS
To conclude, our RESULTS highlighted that the fermentation process of fruit and vegetables juice with probiotic consortia showed beneficial effects in protecting the damages of H2O2 and LPS-treated Caco-2 intestinal cell model, indicating a probiotic potential for this fermented fruit juice.

MICRONUTRIENT POWDERS AND CONVENTIONAL FORTIFICATION: A BIOEQUIVALENCE TRIAL COMPARING THEIR EFFECTIVENESS IN IMPROVING SERUM ZINC LEVELS AND FUNCTIONAL OUTCOMES

Juliana Kiio[1]; Sophie Ochola[1]; Ruth Nduati[2]
[1]Food, Nutrition and Dietetics, Kenyatta University, Nairobi, Kenya; [2]Paediatrics, University Of Nairobi - Main Campus, Nairobi, Kenya

BACKGROUND AND OBJECTIVES
Zinc is an essential micronutrient playing a key role in human health. However, there is no robust evidence that zinc-fortified foods improve functional outcomes, even if the serum zinc concentration increase. We assessed the bioequivalence of conventional zinc fortification compared to micronutrient powders (MNPs) on serum zinc levels, recovery from wasting, morbidity and appetite among children with moderate acute malnutrition.

METHODS
A cluster randomized trial was designed to establish bioequivalence of MNPs to conventional fortification in improving zinc status, recovery from wasting, appetite and morbidity of children with moderate acute malnutrition aged 6-36 months in informal settlements, Kenya. Twelve villages were randomized to four study groups. Three experimental groups received different formulations of MNPs added to CSB; multiple micronutrients (MMN) containing Zn (CSB-sprinkle-MMNZn), MMN without Zn (CSB-sprinkle-MMN) and Zn singly (CSB-sprinkle-Zn). The control group received conventionally Zn-fortified CSB containing MMN. CSB was prepared centrally in each of the participating villages and enrolled children fed daily on the assigned formulation for a period of six months. Sample size was calculated to show bioequivalence within ±20% limit. A total of 346 children (MUAC ≥11.5 - <12.5cm) were enrolled CSB-sprinkle-MMNZn (N=84), CSB-sprinkle-MMN (N=88), CSB-sprinkle-Zn (N=93) and control group (N=81). Mixed effects linear regression was used to model pre-post change in serum levels, adjusting for age, sex and socio-economic status.

RESULTS
Compared to control group, the change in serum zinc levels was significantly lower for CSB-sprinkle-MMN (β= -20.0μg/dL; 95% CI: -26.5, -13.5) and significantly higher for CSB-sprinkle-MMNZn (β=5.9 μg/dL; 95% CI: 0.5, 11.3). Kaplan Meier disease-free survival and recovery from wasting were not significantly different among study groups (log rank test; p>0.05). Change in appetite scores was not significantly different among study groups (mixed effects linear regression; p>0.05).

CONCLUSIONS
Conventional fortification was not bioequivalent to MNPs in improving serum zinc levels. A significantly higher increase in serum zinc levels was observed among children receiving multiple micronutrient MNPs formulation. Conventional and MNP fortification interventions are effective in improving serum zinc levels with no significant effect on functional outcomes but may offer protection against future diarrhoea episodes and zinc losses.

“WHAT GETS MEASURED GETS MANAGED”: INSIGHTS FROM THE GFDX ON LARGE-SCALE FOOD FORTIFICATION DATA

Karen Codling[1]; Reed Atkin,[2]; Mathilde Maurel,[3]; Marie Krottenthaler[4]; Helena Pachón[5]
[1]Global Fortification Data Exchange, Global Fortification Data Exchange, Atlanta, United States of America; [2]Micronutrient Forum, <span Seattle, United States of America; [3]Iodine Global Network, Iodine Global Network, Ottawa, Canada; [4]Nutrition, GAIN, Utrech, Netherlands; [5]Rollins School of Public Health | Food Fortification Initiative, Emory University, Atlanta, United States of America

BACKGROUND AND OBJECTIVES
The Global Fortification Data Exchange (GFDx) is a collaboration among four organizations working to reduce micronutrient malnutrition through food fortification. GFDx collects, collates, visualises and promotes the use of fortification data in 196 countries for five foods. GFDx indicators assess the fortification **opportunity**, the policy or regulatory **foundation** of fortification, and fortification **performance**. In 2024, after seven years of operation, a baseline assessment was conducted to map data availability in GFDx to guide future investments in fortification data.

METHODS
All data in GFDx was downloaded on 25 July 2024. We evaluated the availability of data for 15 indicators for all countries and foods, using pre-determined denominators and criteria for categorising availability.

RESULTS
Across all foods, GFDx has 95% of the data for food intake/availability and the food standard; 50% for proportion of the food industrially processed, 47% on compliance, 37% on population coverage of the fortified food and 36% on availability of heath impact. GFDx has 58%, 55%, 52%, 49% and 32% of of data on wheat flour, rice, salt, maize flour, and oil respectively.

CONCLUSIONS
Data gaps in GFDx exist because (i) GFDx has not identified an effective way of accessing available data, or (ii) the data do not exist as it has not been monitored or documented, potentially reflecting weaknesses in national fortification systems. By identifying data gaps, national and global fortification stakeholders can develop targeted strategies to improve data access and strengthen monitoring systems for national fortification efforts.

MICRONUTRIENTS ADEQUACY ACCORDING TO SIX DIET QUALITY INDICES IN AN ADULT COHORT

Itziar Zazpe,[1]; Susana Santiago[2]; Maria Barbería-Latasa[3]; Maira Bes-Rastrollo[3, 4, 5]; Carmen De La Fuente-Arrillaga[3]; Miguel A. Martínez-González[3]

[1]Department of Nutrition and Food Sciences and Physiology, University of Navarra, Pamplona, Spain; [2]Nutrition and Food Sciences and Physiology, University of Navarra, Pamplona, Spain; [3]Dpt. Preventive Medicine and Public Health, University of Navarra, Pamplona, Spain; [4]CIBERobn, Carlos III Health Institute, Madrid, Spain; [5]Diet and Lifestyles, Instituto de Investigación Sanitaria de Navarra (IdiSNA), Pamplona, Spain

BACKGROUND AND OBJECTIVES

Diet quality indices (DQI) tend to relate positively to micronutrient intake. Our aim was to investigate the association between six DQIs and inadequate intake for 19 micronutrients in an adult cohort.

METHODS

We assessed 16768 participants (59.3% women, 37.8 years mean age). Diet quality was evaluated using Dietary Approaches to Stop Hypertension (DASH); Mediterranean Diet Adherence Screener (MEDAS); Alternate Healthy Eating Index (AHEI-2010); Food-Based Global Diet Quality Score (GDQS); Alternative Mediterranean Diet Score (aMED) and Mediterranean Diet Score (MDS). Logistic regression analyses were conducted to estimate the probability of failing to meet Estimate Average Requirement (EAR) for either ≥ 3 or ≥ 6 micronutrients.

RESULTS

Overall, the lower and higher prevalence of inadequacy in fifth quintiles was for vitamins A, C, B1, B2, B3, B6, Fe, P and Cr, and for vitamins E and D, respectively. In the multivariable adjusted model, the OR for failing to meet ≥3 DRI for the highest versus the lowest quintiles of DASH, MEDAS, AHEI-2010, GDQS, aMED y MDS were: 0.03 (95 % CI 0.02 – 0.03), 0.06 (95 % CI 0.05 – 0.07), 0.10 (95 % CI 0.09 – 0.12), 0.05 (95 % CI 0.04 – 0.06), 0.03 (95 % CI 0.03 – 0.04), and 0.03 (95 % CI 0.03 – 0.04), respectively.

CONCLUSIONS

Adherence to six DQIs showed inverse associations with micronutrient inadequacy. Food-based DQIs could be a useful prevention tool. GDQS and MEDAS do not require deriving nutrient intake data, particularly MEDAS, which is even easier and quicker to fill out.

EXPERTS' AND STAKEHOLDERS' INSIGHTS ON TARGETING STRATEGIES AND CHANNELS FOR MULTIPLE MICRONUTRIENTS (MMS) AND BALANCED ENERGY AND PROTEIN (BEP) SUPPLEMENTS DELIVERY TO ADOLESCENT GIRLS IN RESOURCE-LIMITED SETTINGS

Moustapha Soungalo Drabo[1, 2]; Firehiwot Workneh[3]; Hanna Berhane[4]; Marjolijn Vos[2]; Hans De Steur[5]; Carl Lachat[2]

[1]Centre Universitaire de Gaoua, Université Nazi Boni, Bobo-Dioulasso, Burkina Faso; [2]Department of Food Technology, Safety and Health, Universiteit Gent - Campus Coupure, Gent, Belgium; [3]Department of Epidemiology and Biostatistics, Addis Continental Institute of Public Health, Campus, Addis Ababa, Ethiopia; [4]Department of Nutrition and Behavioural Sciences, Addis Continental Institute of Public Health, Campus, Addis Ababa, Ethiopia; [5]Department of Agricultural Economics, Universiteit Gent - Campus Coupure, Gent, Belgium

BACKGROUND AND OBJECTIVES

Multiple micronutrients (MMS) and balanced energy and protein (BEP) supplements are promising interventions to improve nutrient adequacy in adolescent girls in resource-limited settings. However, clear strategies for delivering MMS and BEP effectively and sustainably are lacking. We explored the barriers and success factors of delivery channels and mechanisms for MMS and BEP targeting adolescent girls in resource-limited settings and implementation strategies that could facilitate reaching underserved adolescent girls.

METHODS

A total of 40 experts from international technical advisory groups, government bodies from Burkina Faso and Ethiopia, non-governmental organisations, UN agencies, and supplement producers participated in in-depth interviews. Qualitative data analysis software NVIVO version 15 was used to examine transcripts for themes and contents. A coding team of 4 researchers developed a common understanding of the study objective and coding frame.

RESULTS

School systems and health facilities, regularly used channels to distribute supplements to adolescents, were considered unable to reach the most vulnerable ones (*i.e.*, out-of-school adolescent girls in rural areas). Community-based health workers and social marketing through pharmacies or health facilities were identified as the most effective channels and cost-sustainable mechanisms to reach underserved adolescent girls. Besides, the participants in this consultation draw attention to community adherence as a potential barrier and recommended strong awareness-raising. Furthermore, given the length of adolescence (*ca.* 9 years), they highlight the importance of targeting a narrow age range to ensure cost sustainability for both supplements. Unlike MMS, BEP were further recommended to be targeted toward adolescents diagnosed with clear malnutrition, areas with high malnutrition levels, and humanitarian settings to prevent energy overload and obesity. While no single channel was identified enough to reach all adolescent girls, governmental organisations have been recognised as key stakeholders in promoting adherence for supplement programs.

CONCLUSIONS

Multiple delivery channels (*e.g.*, governmental organisations, health facilities, schools, community-based platforms, NGOs, and UN agencies) and mechanisms (*e.g.*, social safety nets, social marketing, awareness raising, target segmentation) are required to effectively and sustainably deliver MMS and BEP to adolescent girls in resource-limited settings.

ADDRESSING NUTRITION INSECURITY AMID GLOBAL WARMING: INSIGHTS FOR EFFECTIVE STRATEGIES

Maria Fernanda Elias[1]; Silvia Vanetti[2]
[1]Science, DSM-Firmenich | Escritório JK, São Paulo, Brazil; [2]Insights, DSM-Firmenich | Escritório JK, São Paulo, Brazil

BACKGROUND AND OBJECTIVES
Global warming and extreme meteorological events have direct impact on people's health and on the achievements of the Sustainable Development Goals (SDGs). The SDGs aim to address a range of social needs, including ending all forms of malnutrition in populations experiencing low-income. It is crucial to understand these populations´ health values and consumption habits, so nutrition interventions can be successful. This study investigated the food consumption profile and health concerns of a populations experiencing low-income in Brazil to suggest insights for sustainable solutions.

METHODS
A multicentric field study was conducted using combined quantitative and qualitative techniques, where trained interviewers applied structured questionnaires to perform a systematic collection of data about behavior, perception, attitudes, consumption habits and health concerns. The study engaged a total of 452 people equally distributed in 3 state capitals of Brazil: São Paulo (33%), Fortaleza (33%) and Salvador (34%). As inclusion criteria, only women and women with kids participated.

RESULTS
Most prevalent items that made up the composition of meals were rice (93%), bread (86%), chicken/beef/fish (89%), beans (82%), fruits (79%), pasta (75%), legumes (75%), milk (73%), butter (68%), juice (62%), cookies (58%), couscous (58%) and yogurt (52%). Common health concerns were tiredness (25%), overweight (24%), headache (23%), vision impairment (21%), hypertension (19%) and diabetes (15%). From a socioeconomic perspective, 76% of the women were 25 years-old or older, only 6% didn´t have children, 69% mentioned that the main source of income depended on their partners contribution.

CONCLUSIONS
The participants declared that rice was the most prevalent item in their meals, indicating a potential risk in case of rising sea level and consequent low rice production and price increase. On the other hand, it can represent an opportunity, as rice could be an excellent vehicle for enrichment with vitamins and minerals to enhance the nutritional density of meals and address some of the women´s main health concerns. Both scenarios need to be evaluated aiming to take strategic actions to secure food and nutritional security, and the achievement of the SDGs in the country.

NUTRITIONAL PROFILES AND SENSORY PROPERTIES OF PLANT-BASED MILK ALTERNATIVES

Aylin Bayındır Gümüş[1]
[1]Vocational School of Health Services, Kırıkkale University, Yahşihan, Türkiye

BACKGROUND AND OBJECTIVES
In recent years, the popularity of plant-based milk alternatives (PBMAs) has been increasing1, with the tendency to adopt PB diets that positively affect human and planet health. However, compared with cow's milk, nutritional profiling and sensory properties are among PBMAs' barriers to uptake2. The study aimed to determine healthy omnivore consumers' sensory assessments of PBMAs available in Türkiye and their nutritional values examination with cow's milk.

METHODS
PBMAs were selected from supermarkets in Ankara/Türkiye, and nine local products (almond/sugar-free, hazelnut/sugar-free, oat, coconut/sugar-free, soy/sugar-free) were reached. PBMAs' nutritional contents were on the label per 100 mL. Chilled (~4°C) PBMAs were coded and presented randomly in mouthful amounts (40-50 mL) in clear and odor-free plastic cups. Participants were recruited from Vocational School of Health Services students satisfying the study's inclusion criteria: willing to taste PBMAs, aged between 20-50 years old, having normal weight, not smoking, not allergic or intolerant to ingredients of PBMAs, and not pregnant or lactating. 17 semi-trained panelists tasted PBMAs in a suitable room with a neutral color, good ventilation, moderate lighting/temperature, and a safe distance from noise. PBMAs were evaluated using a 9-point hedonic scale (1= “dislike/not extremely” to 9= “like/yes extremely”).

RESULTS
Oat milk’s energy, carbohydrate, fat, soymilk’s protein, and coconut milk’s saturated fat were most like cow's milk. Calcium, vitamins B12 and E were the most frequently added micronutrients to PBMAs. PBMAs' main ingredient content was between 2.5-10%. Gender quotas were not implemented, and all panelists (n=17) were female with a mean age of 21.3±0.6 years. Oat milk [color (8.0/9), appearance (7.7/9)], hazelnut milk [flavor/taste (7.3/9), odor/smell (7.8/9)], and almond milk [texture (7.4/9)] were the most liked PBMAs. No sugar soy milk was the most disliked PBMA, and panelists (94.1%) stated never consuming it again.

CONCLUSIONS
Adding plant protein and increasing the main ingredient would be beneficial to improve PBMAs. Moderate sugar addition in soymilk significantly improved the sensory properties of the product. The variety of PBMAs to be produced towards consumers' recommendations should be increased in markets.

CONFLICTS OF INTERESTS

TEACHER TRAINING FOR HEALTHY AND SUSTAINABLE EATING: KITCHENS AND CHILDHOODS PROJECT

Ariela Doctors[1]; Erika Fisher[2]; Juliana Furlaneto,[3]; Andrea Wang,[4]; Roseli Berkovits,[4]; Daniella Brochado[5]; Betzabeth Slater Villar,[6]
[1]Nutrição, Faculdade de Saúde Pública USP, São Paulo, Brazil; [2]Institutional, Instituto Comida e Cultura, São Paulo, Brazil; [3]Communication, Instituto Comida e Cultura, São Paulo, Brazil; [4]Nutrition, Codae, São Paulo, Brazil; [5]Pedagogical, Instituto Comida e Cultura, São Paulo, Brazil; [6]Nutrition, Faculdade de Saúde, São Paulo, Brazil

BACKGROUND AND OBJECTIVES

Introduction: The Human Right to Adequate and Healthy Food is one of the most elementary rights enshrined in the Brazilian Federal Constitution. The topic is regulated directly or indirectly within a legal framework that has mirrored a series of federal public policies, such as the National School Meal Program in Brazil. Sadly ironic, in contrast to “Zero Hunger”(SDG2), a modern face of malnutrition has been emerging in the field of food security: the dizzying growth in the incidence of chronic non-communicable diseases related to overweight. This scenario can be explained by the extreme concentration of the agro-industrial production model corroborates extreme climate events, impressing upon humanity the sad condition of a global syndemic.
Objectives: Develop and evaluate a training program for early childhood education educators, based on the concept of Knowledge about the History of Human Food and the History of the formation of Brazilian culinary culture, Domestic Culinary Skills and Healthy Eating, using the Food Guide as a reference for the Brazilian Population with a systemic education approach, in order to demonstrate its effectiveness in implementing Food and Nutritional Education (FNE) from early childhood in schools, with the aim of strengthening good habits and food choices, such as indicates law Nº 13.666/18.

METHODS

Methodology: The pedagogical intervention strategy,“Kitchens & Childhoods”,was developed through a conceptual theoretical model of the Integral Theory that promote the expansion of knowledge in its pedagogical matrix. A set of synchronous classes and a face-to-face meeting are taught over a semester to educators and nutritionists from the SP municipal early childhood education network, aiming to provide educators with training to develop dynamics related to the topic of food. Two assessment instruments validated by the Faculty of Public Health will be applied at the baseline and in the final stage, the Domestic Culinary Skills Scale and the GAB instruments, based on three different constructs from the Food Guide for the Brazilian Population. Pedagogical practices will be analyzed.

RESULTS

RESULTS: Effectiveness of the pedagogical matrix, effective reduction of teachers without culinary skills, from 14%, to just 4% at the end of the program.

CONCLUSIONS

The need to train public school educators in EAN with a view to planning actions and public policies that promote students' autonomy to make healthy food choices in favor of security, food and nutritional sovereignty and climate security.

OPEN-ACCESS HARMONIZATION OF AGRIBALYSE AND FNDDS: DEMOCRATIZING SUSTAINABLE DIET SERVICES

Thomas Louis[1]; Ingrid Grenet[1]; Andrea Lulovicova[2]; Lionel DANIEL[1]
[1]R&D, JAD, Nice, France; [2]ESPACE (UMR 7300), Université Côte d'Azur, Nice, France

BACKGROUND AND OBJECTIVES

Harmonizing environmental and nutritional databases (DB) is a crucial step toward building a sustainable society by enabling eco-friendly and health-conscious food choices. Despite substantial public funding, some efforts remain closed-access[Muzzioli-Nature2024], or behind paywalls[EuroFIR-Fee]; fortunately, there are free- and open-access DB like France's Agribalyse, focused on Life-Cycle Assessment (LCA), and the USA's FNDDS, focused on food composition. In this context, our work presents both an advanced AI-driven methodology for efficiently merging and maintaining food DBs, and a fusion of Agribalyse/Ciqual with FNDDS to empower applications (over +300,000 health and fitness apps in stores) with LCA insights in nutritional guidance.

METHODS

We designed a original pipeline to map food labels across DBs, focusing on the natural aliments of Agribalyse and FNDDS due to their widespread use. Our pipeline integrates four AI-driven algorithms: (1) text embedding similarity, (2) fuzzy string matching, (3) food nutritional similarity, and (4) semantic label matching using a Large Language Model (LLM). A web-based interface allows experts to correct these mappings, with their aggregated votes determining final decisions. When Agribalyse or FNDDS are updated, about once a year, experts can focus only on the changes and on the previous mappings that they rated as *unsatisfactory*, saving time by not reviewing the *satisfactory* ones.

RESULTS

After correcting the AI mappings, experts rated 87% of the final mappings as *satisfactory*, which is thus the current degree of harmonization of the two DBs. Among these satisfactory mappings, 58% are rated as *excellent*. Experts have corrected 24% of *satisfactory* mappings, but only 17% of *excellent* mappings : thus our AI pipeline accuracy is between 76% and 83%. Our harmonized DB enables us to examine differences in dietary habits and environmental impacts between French and American populations.

CONCLUSIONS

This study demonstrates an operational pipeline for harmonizing heterogeneous nutritional DBs. Our free and open Agribalyse-FNDDS fits a versatile model for future DB harmonization projects, addressing the need for accessible and freely available scientific knowledge among small but numerous stakeholders.

To overcome the hurdle for a successful data standardization, this paper aimed to explore the general structure of food composition and life cycle inventory (LCI) databases and to provide a semi-automatized approach on how to successfully interlink data of two example databases. The structure, the

https://doi.org/10.1017/jns.2026.10126 Published online by Cambridge University Press

data availability and accessibility of food entries (FI) from the LCI database Agribalyse and selected food composition EuroFIR databases were analyzed. Harmonized food names from LanguaL™ codes from food classification systems were gathered and validated manually in order to use as descriptors to tag database entries in an automated way. Both databases, EuroFIR and Agribalyse, provided sufficient amount of meta data to interlink FI with the standardization approach proposed. Information on food name, food specification, food processing and the type of production was used for data interlinkage purposes. Manual validation of data interlinkage showed that two out of a sample of 54 entries were found to have incorrectly assigned descriptors. Agreeing on common principles (e.g., use of a specific classification system, common database formats) and improving meta data availability would facilitate database interlinkage and improve both, accuracy and efficiency. Developing solutions to increase meta data availability and accessibility of FI in food databases should become a key area of research in order to transition into more reliable database connection systems.} }

DIFFERENCES IN THE LEVEL OF INTEREST IN GLOBAL ENVIRONMENT AND FOOD CRISES, AND IN ONE'S OWN DIETARY HABITS INFLUENCE THE ACCEPTANCE OF ENTOMOPHAGY AMONG UNIVERSITY STUDENTS

Makiko Kawaguchi[1]; Naoko Kaneda[2]
[1]Department of Human Sciences, Kobe Shoin University, Kobe, Japan; [2]Department of Nutritional Sciences, Tezukayama Gakuin University , Sakai City, Japan

BACKGROUND AND OBJECTIVES
The FAO report of 2013 identified entomophagy as a promising solution to the food crises. This has led to a worldwide increase in the momentum for research on insect food. In Japan, the number of young people who are interested in environmental impact has increased. In addition, a way of thinking unique to today's young people has emerged regarding dietary control. Not drinking alcohol and practicing protein intake such as chicken breast on a daily basis is recognized as a kind of status. Therefore, we investigated the awareness of eating insects as a substitute for meat, interest in the global environment and the food crises among university students. At the same time, we analyzed the relationship between awareness of health and nutrition issues, dietary habits and acceptance of insect food.

METHODS
We conducted a questionnaire survey of a total of 435 university students majoring in food science and students of nutritionist and national registered dietitians training facility. The survey was performed between May and July 2024. Differences in students' opinion about global environmental issues and food crises, dietary habits, and awareness of insect food were investigated. Descriptive statistics were calculated for the survey responses using SPSS software.

RESULTS
69.9% of the students answered that they were interested in the global environment, and the most common place to learn about the problem was "high school" (74.5%). 81.4% of students answered that they were concerned about the global food crisis, and the most common place to learn about the problem was "high school" (51.7%). They answered entomophagy was "rich in protein" (66.9%), "rich in minerals" (47.8%), and "saving food crises" (55.9%). However, 72.4% of them replied negatively to the question "I want to try it.". Interest in environmental issues and food crises and interest in insect food were both positively correlated. There was also a correlation between dietary scores and interest in insect food.

CONCLUSIONS
It was suggested that learning about the global environment and food crises in junior and high school will continue to interest students in these issues and stimulate their interest in solutions. However, it has become clear that, despite understanding entomophagy is a solution to these problems, their aversion to entomophagy persists.

THE DEMOCRATIC REPUBLIC OF CONGO'S FOOD AND ENVIRONMENT NEXUS

Eric Nobela[1]
[1]Monitoring and Evaluation, Helen Keller intl, Kinshasa, Congo, Democratic Republic of the

BACKGROUND AND OBJECTIVES

The Democratic Republic of Congo (DRC) is a country rich in natural resources, but faces major challenges in terms of nutrition and the environment. Understanding the link between these two aspects is crucial to improving the living conditions of the Congolese people.

METHODS

To analyse the link between nutrition and the environment in the DRC, we examined published data on malnutrition and environmental practices, as well as case studies of local initiatives. Statistics on malnutrition and the main agricultural crops were used to illustrate the impact of environmental mismanagement.

RESULTS

Impact of the Environment on Nutrition: Deforestation reduces sources of animal protein and River pollution affects fishing.
Population dependence on natural resources: Around 70% of the population depends on subsistence farming agriculture; Overexploitation of natural resources exacerbates food insecurity.
Effects of Malnutrition on the Environment: 3,3 million children under 5 suffer from acute malnutrition; Unsustainable agricultural practices degrade soil.
Malnutrition statistics in the DRC: 3.3 million children under the age of 5 suffer from acute malnutrition; 27.3 million people are acutely food insecure.
Main crops affected:

- Cassava: Affected by deforestation and land degradation.
- Maize: Affected by deforestation and unsustainable farming practices.
- Rice: Affected by river pollution.
- Beans and peas: Affected by loss of soil fertility and climate change.

Initiatives to improve nutrition and protect the environment: Projects to combat food and nutritional insecurity; Promotion of good nutrition and hygiene practices.

CONCLUSIONS

The relationship between nutrition and the environment in the DRC is complex and interdependent. Promoting sustainable practices that protect the environment while meeting people's food needs is essential to improving food security and nutrition. Collaboration between local communities, non-governmental organizations, and the government is crucial to achieving these goals.

A Dutch Survey Tool Adapted to Assess Factors Influencing Meat Consumption by U.S. College Students: Validation and Pilot RESULTS

Deanne Moosman[1, 2]; Melani Duffrin[2]; Deepa Handu[2, 3]; Julie A. Patterson[4]
[1]Human Performance & Wellness, Virginia Military Institute, Lexington, United States of America; [2]Interdisciplinary Health Professions, Northern Illinois University, DeKalb, United States of America; [3]Evidence Analysis Center, Academy of Nutrition and Dietetics, Chicago, United States of America; [4]Health Studies, Northern Illinois University, DeKalb, United States of America

BACKGROUND AND OBJECTIVES

Generation Z (those born between 1995 and 2010) is a growing consumer group gaining independence with their dietary decisions. Understanding this generation's dietary habits is critical for addressing human and environmental health concerns. However, few validated surveys exist that examine meat-consumptive behaviors and factors associated with these behaviors among Gen Z college students in the U.S. The objectives of this study were to (1) adapt and validate a Dutch survey tool to ensure suitability for a U.S. college student population, and (2) assess pilot data to explore the dietary patterns of U.S. Gen Z college students, their intentions to reduce meat intake, and factors that influence meat consumption using a behavioral theoretical framework.

METHODS

A Dutch survey tool (61-item; van den Berg et al., 2022) was validated with student and professional reviews, and by piloting the survey at a large midwestern college. An exploratory factor analysis was used for item reduction and Cronbach's alpha measured reliability of six piloted survey categories. Descriptive statistics were utilized to understand dietary patterns, meat consumptive habits, and intentions to reduce meat intake. We assessed which demographic factors (4 items) and behavioral constructs (six categories; 18 items) best explained weekly meat intake using generalized linear models (GLM) and Akaike Information Criterion (AIC) to compare support for different models.

RESULTS

The final instrument included 39 items, and Cronbach's alpha values exceeded 0.7 for six assessed survey categories. Most (84%) participants identified as omnivores and less than half (44%) reported eating meat 6 – 7 days per week (n = 284). Most (64%) were satisfied with their weekly meat intake and over half (53%) were unlikely to reduce their meat intake over the next five years. Demographic factors did not appear to influence meat consumptive habits. However, comparisons of AIC scores suggested weekly meat intake was best explained by a model with automatic motivation, psychological capability, and the interaction of the two.

CONCLUSIONS

The modified Dutch survey tool and its underlying theoretical framework was applicable to a U.S. college student population. Preliminary RESULTS indicate that most participants eat meat and are reluctant to reduce their meat consumption. Students with both high automatic motivation (e.g., impulsive behavior) and low psychological capability (e.g., knowledge and cognitive skills) had the most frequent meat consumption.

CONFLICTS OF INTERESTS

EPO2_013

UNDERSTANDING THE CHALLENGES OF AFFORDABILITY FOR A HEALTHY DIET IN THE SAHEL (BURKINA FASO, NIGER, AND MALI)

Saidou Magagi[1]; Tanimoune Mahamadou[1]; Nikiema Victor[1]
[1]PPG-Nutrition RBD, Bureau Régional du Programme Alimentaire Mondial (PAM) 10 Avenue Pasteur, Rue Galliéni, Dakar, Senegal

BACKGROUND AND OBJECTIVES
Burkina Faso, Niger, and Mali are facing persistent food and nutrition insecurity, exacerbated by climatic shocks, high and volatile food prices, rapid population growth, and civil insecurity. More than half of Sahelian households cannot afford a healthy and nutritious diet, with this proportion rising to four out of five households during the lean season.
To understand the challenges faced by low-income households in accessing healthy foods in the current food environment in the Sahel

METHODS
This study relies on data collected from the CILSS/WFP pilot study (January to July 2024) in Burkina Faso, Mali, and Niger. It examines the cost of dietary regimes and households' economic capacity, accounting for contextual factors and market access. Costs of energy-dense and healthy diets were calculated using market monitoring and food expenditure data. The analysis covers 123 markets in 29 regions across the three countries and includes a linear regression for the impact of food group prices on affordability and a variance analysis for the costs of different dietary regimes.

RESULTS
Limited access to affordable and quality foods, along with seasonal constraints in the context of civil insecurity, are the main barriers to healthy eating. Economic and spatiotemporal factors are significant, but personal factors also play a role. Seasonal variation showed significant increases in the costs of both diets between January and July in Burkina Faso and Mali. In Niger, there was a significant increase in the energy-dense diet cost and a decrease in the healthy diet cost. Certain food groups were significantly associated with diet costs and non-affordability differently across the countries.

CONCLUSIONS
The food environment in the Sahel strongly influences the affordability of a healthy diet, impacting food and nutrition security. Economic conditions, geographic location, seasonality, food availability, and civil insecurity are the key determinants. Future research on longitudinal approaches to track changes in access and affordability over time is recommended

FACILITATING SUSTAINABLE DIETARY SHIFTS BY EXPLORING CONSUMER EATER PROFILES

Sadaf Mollaei[1]; Goretty M Dias[2]
[1]School of Hospitality, Food and Tourism Management , University of Guelph, Guelph, Canada; [2]School of Environment, Enterprise and Development, University of Waterloo, Waterloo, Canada

BACKGROUND AND OBJECTIVES
Food system activities, from farm-to-fork are among the major contributors to climate change. Because livestock-based foods contribute greatly to climate change, meat-heavy dietary patterns are problematic. To shift dietary patterns towards more sustainable food choices, understanding consumer food perceptions and choices is critical for decision-makers. This study provides insight into the characteristics of XXX eater profiles and identifies the underlying food environment factors impacting their food choices. The findings can inform a more targeted intervention design, which increases the chances of successfully promoting sustainable food choices and creating a dietary shift.

METHODS
An online survey was conducted, which targeted the recruitment of a representative sample of the XXX population. The survey included questions related to (1) socio-demographic data, (2) factors influencing food choices (grounded in Social Cognitive Theory), and (3) diet characteristics of the respondents. An Exploratory Factor Analysis (EFA) was performed to reduce the number of variables (factors influencing food choices) and identify the main determinants (latent variables) of eating behaviours among the respondents. K-means cluster analysis was used to create eater profiles, by segmenting the respondents into clusters with similar behavioral patterns, based on the importance placed on the identified factors in their eating behaviours.

RESULTS
Overall, 3,329 respondents were included in the study. Using EFA the determinants of food choices among the target population, were reduced to five factors including Sustainability and Health, Food Influencers, Joy and Pleasure, Convenience and Familiarity. For the eater profiles, six segments were identified which were (1) The concerned consumer (22.5%), (2) The trend and tradition-follower consumer (18.9%), (3) The conventional consumer (17.5%), (4) The “eat what you love” consumer (16.0%), (5) The sustainable healthy consumer (15.6%), and (6) The convenience seeker (9.4%).

CONCLUSIONS
RESULTS from the study, enable decision-makers and stakeholders to pinpoint approaches for dietary shifts that could contribute to a sustainable food system. The findings highlight the importance of developing well-rounded, segment-specific interventions while creating food environments that facilitate/promote sustainable food choices.

CONFLICTS OF INTERESTS
The authors have no conflict of interest.

BEYOND THE DESICCATION——PROBLEMS OF FOOD SOURCES AND THEIR CORRESPONDING NUTRIENT DEFICIENCY-RELATED DISEASES CAUSED BY THE SHRINKING ARAL SEA

Zhouxing Liao[1]
[1]Department of Life Sciences, The Chinese University of Hong Kong, Hong Kong, China

BACKGROUND AND OBJECTIVES
Desiccation of the Aral Sea, as one of the most severe ecological disasters in the world, has always been the focus of investigators. Closely related to the desiccation, the health problems, especially those nutrient deficiency caused by problematic food sources have always been ignored.

The purpose of this study is to comprehensively review the food source problems caused by the shrinking Aral Sea, and how did these problematic food lead to nutrient deficiency-related diseases of the locals. Besides, I will make a comparison between the local patients and those 'normal' people.

METHODS
In this study, I comprehensively reviewed the food source problems caused by the shrinking Aral Sea, and the ways that these problematic foods lead to sicknesses of the locals. Moreover, I conducted detailed assessments of the diseases and proposed their leading factors, population characteristics, and possible remedies.

RESULTS
Food shortage and drinking water contamination were two primary factors that led to nutrient deficiency-related sicknesses in the Aral Sea regions. Evidence showed that both grain and fish productions, especially the production per capita, in Kazakhstan,Turkmenistan, and Uzbekistan, had been drastically declining (>70%) in the 1990s because of the shrinking Aral Sea.

CONCLUSIONS
Investigations found out that three types of problems including malnutrition, chronic diseases (Anemia, Cardiovascular Diseases, and Cancer), and waterborne diseases (Diarrhea, Typhoid, and Hepatitis) were frequently reported from 1988 till now. Moreover, assessments indicated that newborns and school-aged children were more likely to get sick than adults. Besides, the overall conditions of the problems in the North Aral Sea region were more severe than those in the South. Further assessments displayed that the problems were caused not only by diet-led factors but also environmental and social-economic ones. Therefore, the government should put more efforts to raise both health and hygiene awareness of the locals.

CONFLICTS OF INTERESTS

DAIRY CONSUMERS SHOW COGNITIVE DISSONANCE BETWEEN ATTITUDES, KNOWLEDGE AND BEHAVIOURS RELATED TO DAIRY PRODUCTS: FINDINGS FROM A CROSS-SECTIONAL SURVEY OF UK ADULTS

Hattie Bracey[1]; Mike Barnard,[1]; Solveig Mendowski[2]; Jérémie Renaud[3]; Stuart Gray[4]; Emilie Combet[1]
[1]Human Nutrition, School of Medicine, Dentistry and Nursing, University of Glasgow, Glasgow, United Kingdom; [2]Research & Innovation, Valorex, Combourtillé, France; [3]International Development, Bleu-blanc-Coeur, Rennes, France; [4]BHF Glasgow Cardiovascular Research Centre, School of cardiovascular and Metabolic Health, University of Glasgow, Glasgow, United Kingdom

BACKGROUND AND OBJECTIVES
Milk provides energy, high-quality protein and a range of micronutrients. However, its production has ethical and environmental concerns, notably methane emissions from enteric fermentation. Changes to farming practices can improve the nutritional qualities of milk and its sustainability, with opportunities for innovation. This study explored consumer willingness for improved products, and the interrelationships of knowledge and attitudes towards the dairy industry in relation to purchasing and consuming dairy products.

METHODS
We conducted an online survey of UK adults from November 2021 to March 2022, covering knowledge and attitudes towards dairy, dairy consumption, likelihood to purchase improved milk, and socio-demographics. Participants were classified as low or high dairy consumers if intake was below or above two portions of dairy per day. Multiple choice questions assessed knowledge, whilst attitudes were evaluated using 5-point Likert items. Differences between high and low consumers were examined using Mann-Whitney U statistical tests.

RESULTS
The survey received responses from 706 dairy consumers, of whom 42% reported consuming two or more portions of dairy products daily. Participants had a positive attitude towards dairy farmers, particularly their role in ensuring UK food security (91% ‘agree’ or ‘strongly agree’) and maintaining high animal welfare standards (84% ‘agree’ or ‘strongly agree’). There was greater agreement (20% greater, $p<0.001$) for these two aspects in high dairy consumers. Conversely, greater agreement (18% greater, $p<0.001$) for statements relating to the negative environmental implications of dairy production (e.g. methane emissions) was found for low consumers. Supermarket own-brand milk dominated habitual purchasing (75% often or always), with price having the greatest influence on behaviour. However, when presented with descriptions of milk with differing production standards, 50% of participants favoured the product that displayed fair trade standards, improved welfare and sustainability, nutritional enrichment through cows’ diet, production location, and a novel quality assurance brand, regardless that this product had the highest price per litre.

CONCLUSIONS
Despite concerns about animal welfare and intention to purchase products with improved ethical and trade standards, most consumers seldom purchased products carrying information about these traits. Our findings indicate an intention-behaviour gap between consumer values and behaviours, possibly explained by misperceptions about the impacts of dairy production or the limited opportunities to purchase improved milk.

CHICKPEA ANTINUTRITIONAL PROFILE DEPENDS ON AGRONOMIC CONDITIONS AND IMPACTS FAT-SOLUBLE MICRONUTRIENT BIOACESSIBILITY

Angélique Berthomé[1]; Stéphane Georgé[2]; Lambert Quentin[3]; Reboul Emmanuelle[1]
[1]Team 1: Micronutrients and Metabolic Diseases, C2vn, Marseille, France; [2]Unité qualité nutritionnelle des produits végétaux, Ctcpa - Technical Center Food, Avignon, France; [3]Direction de l'action régionale et du transfert, Terres Inovia, Baziège, France

BACKGROUND AND OBJECTIVES

Consuming more legumes as substitutes for meat may enhance the sustainability of our diet [1]. However, legumes contain bioactive compounds that are considered "antinutrients" because they alter micronutrient bioavailability. Optimizing chickpea processing reduces antinutrient levels but is insufficient to improve fat-soluble vitamin bioavailability [2]. Our objectives were thus to determine the impact of agronomic conditions (culture localisation, varietal choice and year) on chickpea antinutrient profile, and to assess the impact of contrasted antinutrient profiles on fat-soluble micronutrient bioacessibility.

METHODS

Chickpea samples of 4 different varieties, cultivated in different French departments, were collected two consecutive years (2023 and 2024). Their raw phytate, saponin and tannin contents were assessed by indirect spectrophotometry. Nine samples of 2023 harvest were selected for their contrasted antinutrient profiles. They were soaked and cooked in water prior to their incorporation in a fat-soluble micronutrient-rich recipe (vitamins E, D and carotenoids). Chickpea antinutrient content was also measured after cooking. Samples of this recipe were submitted to a static *in vitro* digestion. Micronutrient bioaccessibility was estimated as the ratio of amounts in mixed micelles to those in digesta, quantified by HPLC or LC-MS/MS. 3 samples from 2024-harvest, matching the variety and culture localisation as 2023, were submitted to the same cooking, digestion and bioaccessibility assessment.

RESULTS

A crossed varietal and localisation effect was found for saponin, tannin and phytate contents in raw chickpeas in 2023. There was no correlation between raw and cooked saponin and phytate contents for the 9 selected varieties, but negative correlation was observed for tannins ($r=-0.782$, $p=0.013$). Positive correlations between raw and antinutrient loss by cooking were also noticed. The vitamin D bioacessibility from meals containing antinutrient-rich chickpea was significantly lower than that from meals containing antinutrient-poor chickpeas (5.3±5.1% vs. 28.3±6.9%, respectively). This was also observed for carotenoids (lycopene, β-carotene and zeaxanthin) and tocopherols (α- and γ-) naturally present in the recipe. Analysis for 2024-chickpea samples are currently in progress.

CONCLUSIONS

Agronomic conditions appear critical for the modulation of chickpea antinutrient content. In agreement with previous studies, raw antinutrient-rich profiles tend to cause lower fat-soluble micronutrient bioacessibility than poor profiles. This study reinforces the importance of considering the impact of increased legume intakes on micronutrient bioavailability.

INNOVATIVE DEVELOPMENT OF INDIGENOUS CROP-BASED DISHES TO ENHANCE CONSUMPTION AMONG PRIMARY SCHOOL CHILDREN"

Hlekani Vanessa Mbhatsani[1]; Mthokozisi Kwazi Zuma[2]; Betrand Tambe Ayuk[3]; Xikombiso Mbhenyane[4]
[1]Nutrition, University of Venda, Thohoyandou, South Africa; [2]Research, Agricultural Research Council , Pretoria, South Africa; [3]Public health, University of Buea Main Campus Entrance, Buea, Cameroon; [4]Human Nutrition, Faculty of Medicine and Health Sciences, Stellenbosch university,, Cape Town, South Africa, South Africa

BACKGROUND AND OBJECTIVES

Consumption of indigenous crops and dishes is low among the youth and children. Traditional preparation methods seem not to appease the young generation. The study focused on creating innovative vegetable dishes using three indigenous crops, with the goal of encouraging children to consume these nutritious foods.

METHODS

A quantitative approach was used, using traditional preservation, experimental, and laboratory methodologies, to develop recipes and perform nutrient analysis. This involved developing dishes from three leafy vegetables (*Amaranthus, Bidens Pilosa* and Cowpea) to yield the *Amaranthus* cabbage, *Bidens* dumpling, and Fishpea. Nutrient analysis was done at the Aspirata/NOSA testing laboratory in Cape Town, South Africa.

RESULTS

Sensory evaluation RESULTS revealed that all three dishes were acceptable and liked by children for all three attributes of colour, taste, and smell, with *Amaranthus* cabbage being the highly acceptable dish for all three attributes. The RESULTS on the palatability of the three dishes using open-ended questions affirm that more children had positive comments on the dishes, which concurs with the quantitative data. Adherence to consumption of the indigenous dishes was also high and signified less plate waste for *Bidens* dumpling than the other dishes. Nutrient analysis indicated that the three crops yielded acceptable amounts of proximates and selected vitamins and minerals.

CONCLUSIONS

Innovation and culinary services in developing recipes using Indigenous crops can improve the consumption and diversify the diet of primary school children.

SUSTAINABILITY IN HOSPITAL NUTRITION: USE OF ORGANIC FOODS IN THE PRODUCTION OF DIET THERAPY IN A HOSPITAL

Betzabeth Slater Villar,[1]; Weruska Barrios[2]; Aline Rissatto Teixeira[2]
[1]Nutrition, Faculdade de Saúde, São Paulo, Brazil; [2]NUTRITION, University of Sao Paulo, School of Public Health, SÃO PAULO, Brazil

BACKGROUND AND OBJECTIVES

The path to sustainable hospital diets goes through agriculture, planetary health and the production of diet therapy. Because of an unsustainable food system that does not respect biodiversity, there has been an unbridled change in the quality of the diet, classified as the fourth cause of DAYLs (Disability Adjusted Life years). A sustainable diet can reduce water use, minimize CO2 emissions, promote biodiversity, traditional values, locavorism and are equally nutritionally rich. The objective of this study was to stimulate the insertion of sustainable foods in the production of diet in a hospital in Brazil, training the different actors involved in menu planning, purchasing and cooking.

METHODS

Intervention project, single center applied in 3 stages involving: (1) the organization of an agroecological fair; (2) Technical visit for qualification of agroecological suppliers (3) practical training that involved buyers, nutritionists, cooks, assistants and hospital unit cupbearers. The goals were categorized and divided as follows: (1) Articulate spaces of approximation. Tool: Agroecological Fair for the exhibition of local farmers. Indicator: number of editions / number of exhibitors. (2) Stimulate agroecological purchase. Tool: Technical visits in the field – focus on supplier qualification. Indicator: number of hospitals participating /technical visit. (3) Train actors involved in the Hospital Diet production chain. Tool: Theoretical/practical training.

RESULTS

12 editions of the Agroecological Fair were held, promoting articulation with more than 80 local farmers/producers. We carried out 5 technical visits in sustainable agriculture with 144 nutritionists representing 70 Brazilian hospitals, who facilitated the insertion of organic green banana (biomass) and green banana peel (culinary preparation) with a focus on the integral use of food in the production of diets in the Hospital Complex of a Brazilian municipality. Menu planning, purchasing, kitchen, pantry and clinical nutritionists were trained.

CONCLUSIONS

It was possible to stimulate the insertion of agroecological foods by proposing change based on the choice of a food. It contributed to the adhesion of the project, the awareness of the entire team, starting with the planning of the menu, purchase, receipt, cooks and finally the pantry team that delivers the food to the patient.

DEVELOPING SUSTAINABLE FOOD BASED DIETARY GUIDELINES FOR LEBANON: INTEGRATING HEALTH, ECONOMIC RESILIENCE, AND SUSTAINABILITY

Nahla Hwalla[1]; Nour Deeb[1]; Farah Naja[2, 3]; Lara Nasreddine[1]
[1]Department of Nutrition and Food Sciences, American University of Beirut, Beirut, Lebanon; [2]Department of Clinical Nutrition and Dietetics, University of Sharjah, Sharjah, United Arab Emirates; [3]Faculty of Agricultural and Food Sciences, American University of Beirut, Beirut, Lebanon

BACKGROUND AND OBJECTIVES
Background: Developing Sustainable Food-Based Dietary Guidelines (SFBDGs) aligned with sustainable healthy diets (SHDs) is critical for addressing food and nutrition insecurity, mitigating diet related diseases, improving public health, and promoting environmental sustainability. Lebanon, a low-middle-income Eastern Mediterranean country, faces significant challenges including high prevalence of food insecurity, wide-spread noncommunicable diseases, limited land and water resources and ongoing economic and environmental crises.
Objective: To develop culture-specific SFBDGs for Lebanon aligned with recommendations for SHDs, integrating health, nutrition, economic, and environmental factors.

METHODS
Methods: The SFBDGs were formulated using a diet optimization mathematical tool which generates patterns resembling current diets while satisfying nutritional health, cost, and environmental footprint (EFP) constraints. Data from the latest national food consumption survey of Lebanese adults served as the reference for current food consumption pattern. Nutritional constraints were based on EAT-Lancet and World Health Organization (WHO) recommendations and Dietary Reference Intakes (DRIs). Cost constraints were maximized to match the cost of food groups within the current consumption pattern, while EFP constraints were based on the environmental impact of these food groups. The optimized consumption was later translated into SFBDGs.

RESULTS
RESULTS: Compared to current national consumption, the optimized diet recommended increases in whole grains (+287%), dairy products (+61%), legumes (+50%), and fish (+26%) and reductions in refined grains (-66%), red meat (-65%), poultry (-32%), and added sugars and fresh fruit juices (-12%). Diet optimization led to a reduction in calorie intake (-6%) and EFPs, including greenhouse gas emissions (-24%), energy use (-7%), and water use (-6%), while maintaining cost.

CONCLUSIONS
CONCLUSIONS: The developed optimized diet and resulting Lebanese SFBDGs addressed health, nutrition, economic, and environmental sustainability of current food consumption pattern, providing a scientific foundation for policies promoting SHDs that are affordable and culture-specific, which can mitigate food insecurity and malnutrition and alleviate some of the country's challenges.

DIET THERAPY AND SUSTAINABILITY: EVALUATION OF THE ECOLOGICALLY CONSCIOUS BEHAVIOR OF NUTRITIONISTS IN HOSPITAL

Betzabeth Slater Villar,[1]; Weruska Barrios[2]; Hermes Moretti Ribeiro Silva[3]; Eduardo Eugênio Spers[4]
[1]Nutrition, Faculdade de Saúde, São Paulo, Brazil; [2]NUTRITION, University of Sao Paulo, School of Public Health, SÃO PAULO, Brazil; [3]Production Engineering, College of Engineering - FE - Unesp - Bauru, Bauru, Brazil; [4]Economics, Administration and Sociology, Luiz de Queiroz College of Agriculture, University of São Paulo, Piracicaba, Brazil

BACKGROUND AND OBJECTIVES

Professionals working in health-related institutions can influence nutrition policies and implement interventions if they have the knowledge and awareness of sustainable nutrition. This research is part of a doctoral project on the implementation of sustainable diets in hospitals in Brazil. Identifying the level of ecologically conscious behavior of nutrition professionals can guide the methodology of the main survey since people ecologically engaged in their households tend to favor professional projects focused on sustainability. The objective of this study was to verify the level of conscious consumption behavior of professional nutritionists who work with diet therapy in hospitals.

METHODS

Descriptive research with a quantitative approach, using an Ecologically Conscious Consumer Behavior (ECCB) scale adapted to the Brazilian context, with a web survey, applied to Hospital Nutritionists and conducted between the months of May and August 2023. Construct with 3 hypotheses: H1: Concern with health is directly related to the attitude towards recycling. H2: The concern with recycling is directly related to the attitude towards change. H3: Concern with health is directly related to the attitude to change.

RESULTS

535 questionnaires were sent and 226 were answered. The predominant age group was 31 to 40 years, representing 40% of the respondents, and 49% worked in large hospitals. The significant relationships between the constructs proposed in the hypotheses (H2:H3) were positive, which shows knowledge and concern when it comes to food and consequences for one's own health and environment. A low level of concern was observed regarding the material used in the product and packaging and its impossibility of recycling (H1).

CONCLUSIONS

The standard deviation was 1.65, a high standard deviation for a Likert scale of 1 to 7, demonstrating that there are two groups of consumers who are very different from each other, those who are highly aware and those who have much more utilitarian motivations. That is why Food and Nutrition Education should be increasingly promoted with a focus on sustainability in this group of professionals who are responsible for prescribing and disseminating healthy eating. Considering that nutritionists are an educator for healthy and sustainable eating, future research is important to have a representation of the population.

EPO2_025

THE EFFECT OF INSECT ADDITION AND SEASONING ON THE EVALUATION OF CAKES: A STEP TOWARD PROMOTING INSECT CONSUMPTION

Mana Yamashita[1]; Minatsu Kobayashi[1]
[1]Studies in Human Life Sciences, Graduate School of Studies in Human Culture, Otsuma Women's University, Chiyoda City, Japan

BACKGROUND AND OBJECTIVES
In May 2013, the FAO highlighted insects' potential for addressing food crises due to their nutrition, economic, and environmental benefits. However, insect consumption remains limited in Japan. This study aims to conduct a preliminary investigation to promote the acceptance of insect-based foods among Japanese women by utilizing cakes, which are popular among young women.

METHODS
In November 2023, a sensory evaluation was conducted with 11 students from the Faculty of Home Economics at University O. The evaluation consisted of two parts:
(1) Evaluation of Insect Content: Baked cheesecakes containing 10g and 20g of three types of insects—Acheta domesticus (house cricket), larval Vespa analis (small Japanese hornet), and bamboo worms—were prepared. Participants consumed and rated each sample..
(2) Pound cakes combining Acheta domesticus with banana, tea, cocoa powder, matcha, or roasted soybean flour (kinako) were prepared. Participants consumed and evaluated each flavor combination.
Participants rated five attributes—appearance, aroma, taste, texture, and overall impression—using a 5-point scale (5: very favorable to 1: not favorable at all). Scores were totaled, with a possible range of 55–275 points.

RESULTS
(1) Across all insects types, cakes with 10g of insects received higher scores than those with 20g. Notably, the score difference for in score the yellow-vented hornest larvae was smaller (236 points for 10g and 212points for 20g).
(2) Among the flavor combinations, black tea received highest score (227 points), followed by cocoa (218 points), matcha (209 points), no flavor additive (192 points), and kinako (176 points).

CONCLUSIONS
Higher quantities of insects in cakes intensified their distinct flavor, negatively affecting palatability. Arthropods, in particular, tend to evoke aversion due to their appearance, aroma, and texture, making it advisable to use powdered forms in small amounts advisable. Regarding Pairing with other ingredients, those that conceal insects' appearance and aroma with strong colors or fragrances achieved higher evaluations.
Overall, RESULTS indicate a preference for cakes where the presence of insects was less noticeable. This suggests that greater efforts and time will be needed to increase the acceptance of insect-based foods.

TRADE-OFFS BETWEEN INCREASING ORGANIC FOOD CONSUMPTION AND REDUCING LAND OCCUPATION

Julia Baudry[1]; Justine Berlivet[1]; Philippe Pointereau,[2]; Christian Couturier[2]; Benjamin Allès[1]; Denis Lairon[3]; François Mariotti[4]; Mathilde Touvier[1]; Thomas Nesme[5]; Chantal Le Mouël[6]; Hélène Fouillet[4]; Emmanuelle Kesse-Guyot[1]

[1]Nutritional Epidemiology Research Team (EREN), Université Sorbonne Paris Nord and Université Paris Cité, Inserm, INRAE, CNAM, CRESS, Bobigny, France; [2]Solagro, Solagro, Toulouse, France; [3]C2VN, Aix Marseille Université, Inserm, INRAE, Marseille, France; [4]UMR PNCA, Université Paris-Saclay, AgroParisTech, INRAE, Palaiseau, France; [5]ISPA, Bordeaux Sciences Agro, Villenave d'Ornon, France; [6]Institut Agro, INRAE, Rennes, France

BACKGROUND AND OBJECTIVES

Organic agriculture typically requires greater land area than conventional agriculture to produce the same food quantity. This study aimed to identify trade-offs between agricultural land occupation (LO) and the share of organic food in the diet (%Org) using data from a large cohort.

METHODS

A diet modelling was conducted for five dietary patterns (high-, medium-, and low-meat eaters, pesco-vegetarians, and vegetarians) under nutritional and acceptability constraints. After searching for the minimal dietary changes required to ensure nutritional adequacy, a compromise modelling approach was used to assess the potential to minimise LO or maximise %Org while exploring intermediate trade-off scenarios that progressively prioritised LO reduction over %Org increase.

RESULTS

Achieving nutritional adequacy with minimal changes led to increased energy intake and LO across all groups, particularly among vegetarians. Under nutritional adequacy, LO (m2/d) was reducible from 15.1 to 6.5 in high meat-eaters, from 8.2 to 5.2 in medium meat-eaters, and from 5.5 to 4.2 in low meat-eaters, while it had to increase from 4.3 to 4.4 in pesco-vegetarians and from 4.2 to 6.6 in vegetarians. In scenarios giving full prioritisation to LO, consumption patterns were greatly changed; meat (beef, pork and poultry) was thus considerably reduced compared to the observed situation in high and medium meat-eaters: up to 5 and 4, respectively, while meat disappeared in low meat-eaters. In trade-off scenarios, progressively prioritising LO reduction over %Org maximisation under nutritional adequacy, LO could initially decrease without compromising maximal %Org, with LO reductions ranging from ~20% (18% to 25%) in vegetarians to ~50% (41% to 59%) in meat-eaters. Further LO reduction required %Org degradation; this conflicting phase, consistent across all dietary patterns, allowed an additional ~20% (13% to 21%) LO reduction at the cost of %Org minimisation.

CONCLUSIONS

In conclusion, while nutritional adequacy and organic consumption may limit to a certain extent LO reduction, important opportunities remain, especially among meat consumers.

PRACTICING PLANET-FRIENDLY SCHOOL MEALS: A CASE STUDY OF JAPANESE SCHOOL LUNCH PROGRAM

Marika Nomura[1]; Koji Ishizuka[2]; Miho Ujiie[1]; Takuya Shizume[1]; Maki Ozawa[1]
[1]Human Development Department, Japan International Cooperation Agency (JICA), Tokyo, Japan; [2]Delicious School Lunch Division, Fukuroi Municipal Board of Education, Shizuoka, Japan

BACKGROUND AND OBJECTIVES

Investment in nutrition is not only necessary for the first 1000 days of life, but also for the first 8000 days, which include the following 7000 days. In low- and middle-income countries, the provision of regular school meals is effective for children to go to school, receive education, reduce social disparities, and receive social protection. On the other hand, in high-income countries, school meals also function as a foundation for healthy eating habits to prevent NCDs in the future. Furthermore in Japan, recent school meals are playing a role in creating local economies and mitigating climate change, going beyond the health, nutrition and education of children, and this is called the “Planet-friendly school meal”. Here, a question about how can we realize a school meal that achieves a win-win situation for children's health and the planet's health, has rised. However, until now, there has no evaluation of the Planet-friendliness of Japanese school meals.

METHODS

Interviews were conducted with local government, nutrition professionals, cooks, schools, farmers and children, using the Planet-friendly school meals conceptual framework as an example of the school lunch program being implemented in Fukuroi City, Shizuoka Prefecture, Japan.

RESULTS

In Fukuroi City, Shizuoka Prefecture, the local government's leadership in promoting Planet-friendly school meals was a key leverage. The local government's policy was to actively purchase a certain amount of vegetables from local farmers. As a result, from 2017 to 2023, local vegetables were served in school lunches from only 14 days in a year to every day. In addition, the amount of salt was reduced, and the deliciousness was achieved in the menu and cooking process, so the amount of leftover food did not increase. By using the amount of leftover food as an important indicator for monitoring and giving the RESULTS back to community involved, it was possible to encourage to participate to the planet-friendly school meals.

CONCLUSIONS

In order to realize planet-friendly school meals, in addition to the local government leadership, delicious menus and cooking, and participation of local farmers, it is also vital to utilize the data.

CHANGES IN FOOD CONSUMPTION IN POLAND AND THE EU FROM THE PERSPECTIVE OF SUSTAINABLE DIET RECOMMENDATIONS

Marta Plichta[1]; Ewa Halicka[1]
[1]Institute of Human Nutrition Sciences, Warsaw University of Life Sciences, Warsaw, Poland

BACKGROUND AND OBJECTIVES
Unsustainable consumer choices may result in – among others – excessive food and water consumption, increased greenhouse gas emissions, land degradation, and waste. High levels of meat supply have the most adverse effect on the environment, followed by milk products and eggs. Therefore, one of the core principles of healthier and more sustainable diets is to moderate the consumption of animal products and replace them with plant-derived foods. The study aimed to evaluate changes in annual food consumption levels of eight selected food groups, which are markers of sustainable diets: vegetables, fruits, pulses, cereals, starchy roots, meat, eggs, and milk products.

METHODS
The data used for the evaluation originate from the FAO Food Balance Sheet (FBS) database. The consumption changes of aggregated food groups were analyzed for Poland and the European Union (EU-27, excluding the United Kingdom) in the years 2010-2022.

RESULTS
Meat consumption in Poland during the analyzed period oscillated on average at 83.2 kg/capita/year, while in the UE, it decreased from almost 85.0 to 78.8 kg/capita/year. At the same time, the consumption of pulses grew from 1.8 to 3.2 kg/capita/year in Poland, while in the EU only from 2.7 to 2.9 kg/capita/year. An increase was also observed in the case of fruits and milk products. However, consumption levels were considerably higher in the EU than in Poland. Vegetable consumption fell slightly in Poland and increased in the EU. Cereals and starchy roots consumption decreased in both Poland and the UE. However, the decrease in the consumption of these food groups was higher in Poland than in the EU. In the case of eggs, a decrease was observed in Poland by more than half, while an opposite and much slower trend in the EU was noted.

CONCLUSIONS
Based on the analysis of available FBS data, it can be concluded that in 2010-2022, the directions and rates of changes in food consumption in Poland and the EU varied. Despite the much-needed increase in the consumption of pulses and fruits in Poland, their levels are low, while the consumption of animal products remains high. The observed changes, including a decrease in vegetables, cereals, and starchy roots consumption, imply that the most important recommendations of sustainable diets, namely reducing meat consumption and replacing it with other protein sources, are not being followed. Further monitoring of trends and accelerating the shift towards more sustainable consumption choices is needed, as well as the identification of factors that can boost such a transformation.

EXTREME PRECIPITATION INCREASES HOUSEHOLD ESCHERICHIA COLI WATER CONTAMINATION AND DIMINISHES BENEFITS OF IMPROVED WASH PRACTICES IN A COMPLEX ENVIRONMENT IN NORTHERN UGANDA

Ian Moore[1, 2]; Erin Coughlan De Perez[2]; Kenneth Chui[3]; Shibani Ghosh[2, 1]
[1]Feed the Future Food Systems for Nutrition Innovation Lab, Tufts University, Boston, United States of America; [2]Friedman School of Nutrition Science and Policy, Tufts University, Boston, United States of America; [3]Public Health and Community Medicine, Tufts University School Of Medicine, Boston, United States of America

BACKGROUND AND OBJECTIVES
Ingestion of contaminated water is a major contributor to the burden of disease, particularly in SSA, causing diarrhea, EED, and malnutrition, resulting in around 1.4 million deaths globally annually [1-3]. Environmental factors play a key role in the proliferation, fate, transport, and human ingestion of bacterial water contaminants. Previous research indicates increased water contamination and diarrheal disease after extreme precipitation, but there is little evidence from SSA [4-6]. We examined the effect of extreme precipitation on household water contamination and interaction with WASH practices in Uganda.

METHODS
We combined household water *E. coli* and survey data from three timepoints, March-April 2021 (n=358), July-Dec. 2021 (n=334), and Aug.-Dec. 2022 (n=281), of a longitudinal cRCT in northern Uganda with daily precipitation and temperature from the ERA5 Reanalysis (0.25°x0.25°) [7,8]. We computed extremes as daily precipitation above the 80th, 90th, and 95th percentiles from 2018 to 2023 for each household location. We calculated household WASH scores (0-13) with 13 binary WASH variables including defecation and handwashing practices. We used generalized linear mixed models with quasi-Poisson distributions and log link functions to estimate the effect of precipitation extremes on same-day *E. coli* (CFU/100mL) and interaction with WASH score. Models were adjusted for intervention assignment, daily mean temperature, timepoint, and robust SEs were calculated using random intercepts for household and sampling cluster.

RESULTS
Daily precipitation above the 90th and 95th percentile was significantly associated with two times (IRR=2.16; p<0.001) and three times (IRR=3.30; p<0.001) increased concentration of *E. coli* (CFU/100mL) in household drinking water, respectively. Precipitation above the 80th percentile was not significantly associated with increased water contamination (IRR=0.85; p=0.294). Higher WASH score was associated with significantly lower *E. coli* for households with daily precipitation below the 90th percentile but not above.

CONCLUSIONS
We show precipitation extremes may result in increased water contamination in complex environments in SSA with persistent multi-dimensional poverty. Precipitation extremes may also diminish the protection from WASH practices. Future research should focus on how WASH development can change to improve community adaptation to climate extremes.

EPO2_031

AN EXAMINATION OF SUSTAINABILITY MESSAGING WITHIN EUROPEAN FOOD-BASED DIETARY GUIDELINES

Fanny Salesse[1, 2]; Samara Jones[1]; Rebecca Finlay[1]; Eileen Gibney[1, 2]
[1]Institute of Food and Health, University College Dublin, Dublin, Ireland; [2]Insight Centre for Data Analytics, Belfield, University College Dublin, Dublin, Ireland

BACKGROUND AND OBJECTIVES
Transitioning to healthier and more sustainable diets can help reduce the environmental impact of food systems and current dietary patterns alongside promoting population health (1). In this context, food-based dietary guidelines (FBDGs) represent an opportunity to provide sustainable dietary recommendations for populations (2). This research assessed the occurrence of sustainability messaging in European FBDGs based on criteria from the Food and Agriculture Organisation (FAO) and World Health Organisation's "Sustainable Healthy Diets Guiding Principles" and the British Dietetic Association's (BDA) "Sustainable Diet Recommendations".

METHODS
The FAO's online repository was used to access FDBGs. Three types of FBDG documents were reviewed; consumer, health care professionals, and background documents. Sustainability messaging was considered direct when criteria were included with explicit mention of sustainability, and indirect when specific criteria were included but did not mention sustainability.

RESULTS
Consumer FBDGs published after 2014 included more sustainability messaging, with Northern Europe showing the highest rate of inclusion and Southeast Europe the lowest. Consumer FDBG documents had the lowest incorporation of criteria with explicit reference to sustainability while background documents showed the highest. Overall, the inclusion of direct sustainability messaging was low in FBDGs, however, implicit sustainability mentions suggest that adhering to current guidelines may indirectly have environmental benefits alongside health improvement.

CONCLUSIONS
These findings highlight the potential to revise FBDGs to provide both nutritional and environmental messages, to support consumers in healthy and sustainable food choices (3).

MULTI-SECTORAL INTERVENTIONS WITH BENEFITS FOR CLIMATE CHANGE AND NUTRITION: A SYSTEMATIC REVIEW OF THE EVIDENCE

Lais Miachon Silva[1]; Tyler Vaivada[2]; Cecilia Fabrizio[1]; Li Jiang[2]; Prajjwal Dhungana[1]; Kieran Holmes[2]; Thalia Sparling[3]; Ruobin Wu[4]; Saskia Osendarp[1]; Zulfiqar Bhutta[2, 5]
[1]Standing Together for Nutrition, Micronutrient Forum, Washington, United States of America; [2]Center for Global Child Health, The Hospital for Sick Children, Toronto, Canada; [3]Department of Population Health, London School of Hygiene and Tropical Medicine, London, United Kingdom; [4]Food and Nutrition Division, Food and Agriculture Organization of the United Nations, Rome, Italy; [5]Institute for Global Health and Development, Aga Khan University, Karachi, Pakistan

BACKGROUND AND OBJECTIVES
Food insecurity, malnutrition and climate change are intertwined existential threats. There are many options for intervention that can improve food security and nutrition or buffer against climate change (or both) but prioritising these actions across global settings presents a quagmire. Despite growing literature in the food system-nutrition-climate nexus, the strength of empirical evidence from interventions is unclear, even from recent reviews. As such, we summarized the evidence on multi-sectoral interventions with potential benefits for climate change adaptation or mitigation and nutrition.

METHODS
We conducted a systematic literature review of multisectoral interventions across food systems, social protection systems, water, sanitation and hygiene (WASH), health systems, and other systems (e.g.: education, financial) to coalesce their effects on climate change (through climate mitigation or adaptation) and nutrition (including food security, diets, all forms of malnutrition, and diet-related non-communicable diseases). We also considered the various contexts in which these interventions were implemented, and how interventions contribute to or pose potential trade-offs for gender equality and women's empowerment. The review was registered in PROSPERO (ID: CRD42024588770).

RESULTS
Five academic databases and 23 organizational websites were systematically searched, resulting in 14,576 peer-reviewed records and 165 grey literature records published on or after 2000 after duplicates were removed. From these, we preliminarily identified 2,661 potentially eligible full-text records for further screening (currently ongoing). Data extraction will capture study characteristics (including study design, population, study location, intervention type, study outcomes), and quantified estimates on climate- and nutrition-related outcomes, including food security, nutrition outcomes, diets, and mitigation of greenhouse gas emissions. We will conduct a range of descriptive analyses of the included interventions, including summarizing quantified outcomes across key characteristics and a sub-analysis of interventions that contribute to gender equality or women's empowerment.

CONCLUSIONS
Our findings will help program and policy makers weigh the potential efficacy of various multi-sectoral interventions to support nutrition and climate resilience. They will provide clarity on the evidence behind actions towards impact, including mitigating and adaptive potential, potential to improve food security and nutrition, and co-benefits for human nutrition and climate action.

EPO2_033

UNVEILING THE DIFFERENT ENVIRONMENTAL AND CARDIOMETABOLIC IMPACTS OF INDICES OF ADHERENCE TO THE SUSTAINABLE EAT-LANCET REFERENCE DIET: FINDINGS FROM A NATION-WIDE PROSPECTIVE COHORT STUDY

Huicui Meng[1]; Wenjing Liu[1]; Yiqian Lv[1]; Man Wu[1]
[1]School of Public Health (Shenzhen), Sun Yat-sen University, Shenzhen, China

BACKGROUND AND OBJECTIVES
Diet, population health and planetary health are closely interconnected. Transitioning to sustainable diets can provide long-term benefits for both planetary and population health. The potential co-benefits of the EAT-Lancet reference diet for cardiometabolic health and sustainability in Chinese adults are unclear. We aimed to investigate the associations between indices of adherence to the EAT-Lancet reference diet, including EAT-Lancet Reference Diet score (ERD), World Index for Sustainability and Health (WISH) and Planetary Health Diet Index (PHDI), and risk of new-onset cardiometabolic diseases (CMDs), including myocardial infarction (MI), type 2 diabetes mellitus (T2DM) and stroke, and all-cause mortality and greenhouse gas (GHG) emissions, in a nation-wide prospective cohort of Chinese adults.

METHODS
Adults (N=14,652 for CMDs and 15,318 for all-cause mortality) from the China Health and Nutrition Survey (1997-2015) were included in the analysis. Dietary intake data were collected and ERD, WISH and PHDI scores were computed with established methods. Cox proportional hazard regression models were used for statistical analysis.

RESULTS
Over a mean follow-up period of 10 years, greater adherence to the EAT-Lancet reference diet, as reflected by higher WISH or PHDI scores, were inversely associated with risk of MI (Q4 vs Q1:HR=0.68 (0.48-0.96) for WISH and 0.14 (0.07-0.29) for PHDI), T2DM (Q4 vs Q1:HR=0.81 (0.67-0.96) for WISH and 0.68 (0.57-0.82) for PHDI), all-cause mortality (Q4 vs Q1:HR=0.80 (0.68-0.95) for WISH and 0.60 (0.46-0.80) for PHDI) and GHG emissions in fully adjusted models (all *P*-trend<0.05). ERD, WISH and PHDI were not significantly associated with risk of stroke.

CONCLUSIONS
Our findings supported the co-benefits of the EAT-Lancet reference diet for both cardiometabolic health and environmental sustainability, and long-term adherence to this reference diet guided by higher WISH or PHDI scores may be an effective strategy for reducing the risk and burden of CMDs and all-cause death in Chinese adults. These findings contribute new insights to the current literature highlighting the need to consider incorporating WISH or PHDI-assessed EAT-Lancet reference diet into dietary guidelines and utilized as an effective tool intended to help reduce the risk of CMDs and premature death in Chinese adults.

ADOPTION OF REGION-SPECIFIC DIETS IN CHINA CAN HELP ACHIEVE GAINS IN SUSTAINABLE HEALTHY AGING

Bingqi Ye[1]; Yan Liu[1]; Min Xia[1]
[1]Guangdong Provincial Key Laboratory of Food, Nutrition, and Health, and School of Public Health,, SUN YAT-SEN UNIVERSITY, Guangzhou, China

BACKGROUND AND OBJECTIVES
The unparalleled scale and speed of aging in China not only RESULTS in a higher burden of late-life diseases, but also leads to an increasing human demand on ecosystem. Due to an intrinsic link of diet to both aging and environmental sustainability, a health and environment-friendly diet is recognized as an indispensable approach to achieve sustainable healthy aging. In this context, we have recently developed a region-specific reference diet (RRD)[1] that is better aligned with Chinese culinary traditions, affordable, sparing of natural and environmental resources, and contributes to health. However, its potential in achieving sustainable healthy aging and reducing regional and gender disparities remains unknown.

METHODS
The alignment of RRD with nutritional adequacy for the elderly and economic affordability were first assessed. Then, the improvement in sustainable healthy aging, characterized by healthy life expectancy (HLE) and ecological quality index (EQI), was quantified by counterfactual analysis. Moreover, the potential of RRD in narrowing the gaps across regions with various socioeconomic status and between genders were assessed by the increase in the share of life expectancy (LE) free of disease of total LE (HLE/LE) and reduction in unhealthy LE.

RESULTS
The adherence to RRD ranged from 52.20 to 78.02% across China, and was able to fulfil the elderly daily nutrients demand. The average cost of RRD for different food groups varied from 4 to 7% of daily household income per capita, which was well affordable for the vast majority. Moreover, adoption of RRD was projected to extend HLE by 0.16 years and increase EQI by 5.16% by 2030. No matter following the upper, mean, or lower boundary of the recommended intakes of RRD, it was sufficient achieve the targets on greenhouse gas emissions, freshwater use, land occupation, and eutrophying and acidifying emissions across China. Furthermore, the discrepancy attribute to socioeconomic status in HLE, HLE/LE, and unhealthy LE could be reduced by 11.29%, 7.32%, and 4.41%, respectively when RRD was fully adopted. Similarly, the projected gender gap in HLE fell from 5.60 years to 4.65 years, the HLE/LE dropped by 3.32%, and the gap in unhealthy LE narrowed by 2.43%.

CONCLUSIONS
Given the overarching connections between aging and sustainability, RRD offers a viable solution for sustainable healthy aging. We believe that the framework of RRD would also serve as a valuable reference for other developing countries undergoing similar population aging and grappling with environmental challenges.

TRENDS IN SUSTAINABLE DIETARY PATTERNS AMONG US ADULTS, 2007-2018

Sukyoung Jung[1]
[1]Department of Health Care Policy Research, Korea Institute for Health and Social Affairs, Sejong-si, Korea, Republic of

BACKGROUND AND OBJECTIVES
A transition to healthy diets within a sustainable food system is essential to improve both human and planetary health. In this study, we characterized trends in sustainable dietary patterns among US adults, quantified using the Sustainable Diet Index for US adults (SDI-US), and examined changes over time in its sub-index components: diet quality, diet-related environmental impacts, food expenditures, and food practices.

METHODS
This study used data from the National Health and Nutrition Examination Survey 2007–2018 (n = 25,543 aged 20 years and older). The SDI-US (range: 4–20 points) comprised four sub-indices representing nutritional, environmental, economic, and sociocultural dimensions and was calculated using 24-hour dietary recall data and responses from consumer and dietary behavior questionnaires. A higher SDI-US score indicates greater adherence to sustainable diets. Mean SDI-US and six diet-related environmental impacts, food expenditures, and food practices across survey cycle were estimated, and statistical significance of linear and quadratic trends were examined using orthogonal polynomial contrasts in regression models. Interactions between survey cycle and demographic factors were tested. All analyses accounted for the complex survey design.

RESULTS
Overall, there were no significant trends in total SDI-US score between 2007 and 2018 (overall mean SDI-US = 13.1). While nutritional and sociocultural indicators showed little change over time, the economic indicator (food expenditures) worsened (21.4% to 26.4%, $p<.05$ linear trend) between 2007-2008 and 2017-201. Environmental impacts initially worsened between 2007-2008 and 2013-2014 but showed improvement through 2017-2018 (all $p <.05$ quadratic trend). Despite a significant interaction between survey cycle and age, there were no substantial differences in SDI-US trends by age group.

CONCLUSIONS
From 2007 to 2018, total SDI-US largely remained unchanged, whereas there was a decline over time among adults ≥60 years old. Continued monitoring and integrated improvements across all dimensions are needed to achieving sustainable diets, especially for older adults.

SUSTAINABILITY AND NUTRITION IN BRAZIL: INSIGHTS FROM THE REVISED MULTIDIMENSIONAL INDEX FOR SUSTAINABLE FOOD SYSTEMS [MISFS-R]

Isabela Gonçalves Camusso[1]; Marina Maintinguer Norde[1]; Ana Luiza Gomes Domingos[2]; Aline Carvalho[1]
[1]Nutrition, Faculdade de Saúde Pública USP, São Paulo, Brazil; [2]Postdoctoral Researcher, Escola de Artes, Ciências e Humanidades EACH- USP, São Paulo, Brazil

BACKGROUND AND OBJECTIVES
The global syndemic, defined by the interconnected pandemics of obesity, undernutrition, and climate change, underscores the urgent need for a comprehensive evaluation of food systems and their impacts on health. Brazil faces ongoing challenges in food systems sustainability and equity. This study proposed a longitudinal analysis of the Brazilian Multidimensional Index for Sustainable Food Systems Revised [MISFS-R] to assess changes in food systems and their implications. Evaluating the evolution of the MISFS-R indicators across two time points will help identify changes and patterns, providing a robust foundation for developing context-specific strategies to protect planetary health and advancing the transformation of food systems toward sustainability.

METHODS
A longitudinal analysis of the MISFS-R indicators was conducted through paired mean comparisons between the periods 2006–2009 and 2017–2021, using Brazil's 26 states as analytical units, with statistical significance set at $p<0.05$. Data were retrieved from online platforms of government agencies and analyzed using Stata SE® 17.0 software.

RESULTS
The longitudinal analysis of MISFS-R indicators revealed stable agricultural productivity over the last decade ($p=0.36$), with increased profitability ($p=0.04$) and reduced land use ($p=0.01$). Environmental impacts, including deforestation, greenhouse gas emissions, and reduced crop biodiversity, have worsened ($p=0.00$, 0.02 and 0.01, respectively), reflecting the environmental impact related to a commodity-focused export model. Despite the stable agricultural productivity, the food production system was insufficient to ensure food availability, shown by the rise in acute thinness prevalence ($p=0.01$), which highlights social vulnerability and undernutrition, contrasting with progress in reducing nutritional deficiencies ($p<0.001$) and intestinal infections ($p<0.001$) in the Brazilian population, as well as a decline in child stunting ($p<0.001$).

CONCLUSIONS
The global syndemic demands profound transformation of food systems in Brazil. While agricultural productivity has remained stable over the past decade, environmental impacts have increased, and significant challenges to achieving food and nutrition security persist. These findings highlight the critical role of food system measurement tools, such as the MISFS-R, in identifying vulnerabilities and guiding context-specific strategies to address these complex challenges, ensuring long-term food security, environmental sustainability, and population health.

COMPARISON OF EAT-LANCET BASED INDICES FOR ASSESSING DIETARY HEALTH AND SUSTAINABILITY: FINDINGS FROM THE FRENCH NATIONAL INCA3 SURVEY

Agustin Miranda[1]; Florent Vieux[2]; Matthieu Maillot[3]; Eric Verger[1]
[1]MOISA, Research and Development Institute IRD Montpellier, Montpellier, France; [2]MS Nutrition, MS-Nutrition, Marseille, France; [3]MS Nutrition, MS Nutrition, Marseille, France

BACKGROUND AND OBJECTIVES
Measuring adherence to EAT-Lancet recommendations for healthy and sustainable diets is challenging, leading to diverse methods and a lack of consensus on standardized metrics (1,2). Available indices vary mainly in scoring systems, food components, units, energy adjustments, and thresholds (2). The aim was to evaluate and compare the measurement performance of six dietary indices for assessing adherence to EAT-Lancet reference diet.

METHODS
Food consumption data of 1,723 adults were obtained from the Third French Individual and National Food Consumption Survey (INCA3) (3). The six indices studied were: World Index for Sustainability and Health (WISH), Planetary Health Diet Index (PHDI), EAT-Lancet Diet Index (ELDI), EAT-Lancet Index (ELI), Healthy and Sustainable Diet Index (HSDI), and EAT-Lancet Diet Score (ELDS). The validity and reliability of these indices were assessed following standardized statistical procedures (4), using sociodemographic data, nutritional measures (nutrient adequacy and diet quality), and environmental data (14 indicators of environmental pressure), with a statistical significance level of 0.05.

RESULTS
The analysis revealed that the four indices assessing food components with quantitative scoring (WISH, PHDI, ELDI, ELI) captured dietary variability, were less dependent on energy intake and converged to a large extent with nutritional indicators. While the two indices based on binary scoring systems (HSDI, ELDS) showed a stronger correlation with environmental indicators, one quantitative index (ELDI) converged with both domains. Indices had valid unidimensional structures supporting the use of total scores. Also, indices differed between sociodemographic groups, demonstrating concurrent-criterion validity. Higher scores were associated with higher nutritional quality and lower environmental impact, but with unfavorable RESULTS for zinc intake, vitamin B12 and water use. A low concordance rate (from 32% to 43%) indicated that indices categorized individuals differently.

CONCLUSIONS
Researchers should select indices that align with their study objectives, considering the indices' applicability and assumptions. Quantitative indices provide a detailed view of dietary health and sustainability, useful for clinical and epidemiological research, while binary indices offer a simplified approach, ideal for surveys and public health/environmental evaluations. Understanding the strengths and limitations of each type of index is essential for a thorough evaluation of dietary impacts.

ASSESSING SUSTAINABLE AND HEALTHY DIETS IN LARGE-SCALE SURVEYS: DEVELOPMENT OF A DIETARY INDEX BASED ON A BRIEF FOOD GROUP PROPENSITY QUESTIONNAIRE REPRESENTING THE EAT-LANCET PLANETARY HEALTH DIET

Agustin Miranda[1]; Anna Maria Murante[2]; Fabio Consalez[3]; Federica Manca[2]; Fabrice Declerck[4]; Anant Jani[5]; Eric Verger[1]
[1]MOISA, Research and Development Institute IRD Montpellier, Montpellier, France; [2]Management and Health Lab - Institute of Management, Scuola Superiore Sant'Anna, Pisa, Italy; [3]Sustainable Food Systems, ICLEI European Secretariat GmbH (ICLEI Europasekretariat GmbH), Freiburg im Breisgau, Germany; [4]EAT, EAT, Oslo, Norway; [5]Heidelberg Institute of Global Health, Heidelberg University, Heidelberg, Germany

BACKGROUND AND OBJECTIVES
Ensuring healthy diets within planetary boundaries is essential (1). However, current instruments measuring adherence to the EAT-Lancet planetary health diet are unsuitable for large-scale surveys. Simplified tools assessing consumption frequency can improve response rates, lower costs, and facilitate administration (2). Thus, this study aimed to develop a practical brief tool for evaluating EAT-Lancet diet adherence across large-scale multi-country surveys

METHODS
Initially, the EAT-Lancet Consumption Frequency Index (ELFI) was developed using a brief food propensity questionnaire of 14 food groups representing the planetary health diet from the FEAST survey, which encompassed 27 European countries (n = 27,417) (3). Subsequently, ELFI was further validated utilizing data from the INCA3 survey (n = 1,645) (4). The index was then validated against 24-hour dietary recalls by correlating it with the established EAT-Lancet Index (ELI), as well as with measures of nutritional health (nutrient adequacy and diet quality) and environmental impact. The analyses, following standardized procedures (5), included tests for reliability, structural validity, concurrent validity, and nomological validity.

RESULTS
ELFI showed strong reliability (alpha > 0.80) and factor analysis revealed a two-factor solution: “foods to encourage” and “foods to balance and to limit”. All models in confirmatory factor analysis demonstrated adequate fit. ELFI concurrent validity was confirmed as it was associated with sex, age, education, income, household size, physical activity/sedentary behavior and smoking habit (all $p < 0.05$). ELFI correlated with ELI (0.44, $p < 0.0001$) and 24-hour recall data. As for nomological validity, ELFI subscores were associated with better nutritional health ($\beta = 0.62$ and 0.23, $p < 0.0001$) and lower environmental impact ($\beta = -0.16$ and -0.36, $p < 0.0001$).

CONCLUSIONS
Overall, the ELFI approach provides a robust and easy-to-use tool for assessing adherence to planetary health diet in large-scale multi-country studies, offering valuable support for understanding dietary patterns within sustainability and health research.

ASSOCIATIONS BETWEEN KNOWLEDGE, ATTITUDES, BEHAVIOURS AND HEALTHY AND SUSTAINABLE DIET QUALITY IN YOUNG AUSTRALIAN ADULTS: A CROSS-SECTIONAL STUDY

Bill Lam[1]; Ewa Szymlek-Gay[1]; Claire Margerison[1]
[1]Institute for Physical Activity and Nutrition, Deakin University, Melbourne, Australia

BACKGROUND AND OBJECTIVES
The rising prevalence of chronic diseases worldwide and the exacerbation of environmental degradation highlights the urgent need to promote healthy and sustainable diets.[1] Young Australian adults may be a pivotal group for encouraging these diets, as despite having poor diet quality,[2] they are strongly committed to climate action.[3] Before designing targeted nutrition programs to improve diet quality, it is vital to understand the determinants of their diet. Therefore, this study aimed to investigate factors associated with adherence to a healthy and sustainable diet in young Australian adults.

METHODS
This cross-sectional study required young Australian adults (n=107; aged 18-25 years) to complete an online survey and up to four 24-h diet recalls. Survey questions assessed nutrition and planetary health knowledge; attitudes, self-efficacy, food motives; and food behaviours. Diet recalls were collected via the Australian Automated Self-Administered 24-Hour Dietary Assessment tool. The World Index for Sustainability and Health (WISH) was used to assess adherence to healthy and environmentally sustainable diets. Associations between WISH score and nutrition and planetary health knowledge, attitudes, and behaviours were assessed using linear regression.

RESULTS
Individuals who reported following a plant-based diet (n=36, 34%) had higher WISH score (p=0.003). Higher knowledge of healthy and sustainable diets (p=0.01) and favourable attitudes of these diets being beneficial for the environment (p=0.003), ‘tasty’ (p=0.02), ‘affordable’ (p=0.02) and ‘easy to follow’ (p=0.006) were positively associated with WISH score. Confidence in substituting meat (p=0.002) and in achieving protein requirements through plant-based alternatives (p=0.0003) were also positively associated. Participants with higher WISH score thought that understanding the environmental benefits (p=0.048) and animal welfare concerns (p=0.004) would encourage them towards these diets. On the other hand, participants with higher adherence were less likely to consider these diets as having a positive impact to their own health (p=0.04). Participants with stronger health (p=0.004) and ethical (p=0.04) motives to food choice had a higher WISH score. Preference for meat consumption (p<0.0001) and the perception that 'meat and dairy are essential for health' (p=0.004) were associated with lower WISH score.

CONCLUSIONS
RESULTS from the study indicate that planetary health diet knowledge, attitudes and behaviours should be accounted for when designing nutrition programs for young adults.

THE ROLE OF FOOD CONSUMPTION IN THE GLOBAL SYNDEMIC: A CONCEPTUAL MODEL

GIOVANNA GARRIDO[1]; Fernanda Severo[2]; Samantha Bonfim[3]; Ana Luiza Gomes Domingos[4]; Aline Carvalho[5]

[1]Nutrição, Faculdade de Saúde Pública USP, São Paulo, Brazil; [2]Departamento de Nutrição, Faculdade de Saúde Pública USP, São Paulo, Brazil; [3]Nutrition, Universidade de São Paulo, São Paulo, Brazil; [4]Nutrition and Public Health Department, University of São Paulo, São Paulo, Brazil; [5]Nutrition, Faculdade de Saúde Pública USP, São Paulo, Brazil

BACKGROUND AND OBJECTIVES

Food systems are networks involved in food production, processing, distribution, consumption, and disposal, interacting with other subsystems. These systems drive the global syndemic, a major 21st-century challenge, marked by obesity, undernutrition, and climate change. Key factors include agriculture, urbanization, and eating behavior. While progress has been made, the impact of food consumption on the three syndemic pillars remains unclear. The objective is to develop a conceptual model to evaluate these relationships.

METHODS

A literature review was conducted to identify variables and relationships between food consumption and the syndemic. Based on a scoping review, an initial model was developed and then underwent refinement through a collaborative effort involving the research team which included a two-hour online meeting where the preliminary model, outlining the causes and consequences of the global syndemic related to food consumption.

RESULTS

The conceptual model illustrates the complexity of interactions between food consumption and the global syndemic, grouping 23 factors into five dimensions: individual, household, individual/household (I/H), city, and environment. The individual dimension focuses on eating behavior and health issues, while the household dimension emphasizes food security and access, influenced by financial stability. The I/H dimension highlights geographic accessibility and infrastructure, noting the impact of road proximity on food availability. Environmental and city factors address climate change, infrastructure, greenhouse gas emissions, and agricultural practices. The model also emphasizes food groups, offering a holistic view of interconnected factors impacting food consumption, climate change, and health.

CONCLUSIONS

The conceptual model highlights the complex interrelationships between food consumption and key components of the global syndemic, such as obesity, undernutrition, and climate change. It underscores the need for integrated public policies that promote healthy, minimally processed diets with a low carbon footprint, addressing both individual factors and broader contexts like urbanization and agricultural practices to ensure sustainability and equity.

MANDALA PROGRAM: BRINGING NUTRITION BACK TO THE PLATE WITH LOCAL FOODS TO PREVENT MALNUTRITION IN INDONESIA

Siti Helmyati[1, 2]; Delima Citra Dewi Gunawan[3]; Muhammad Ridwan Ansari[4]; Lily Arsanti Lestari[1, 2]; Gifani Rosilia[2]; Cut Alima Syarifa[2]

[1]Department of Nutrition and Health, Faculty of Medicine, Public Health, and Nursing, Universitas Gadjah Mada, Yogyakarta, Indonesia; [2]Center for Health and Human Nutrition, Faculty of Medicine, Public Health, and Nursing, Universitas Gadjah Mada, Yogyakarta, Indonesia; [3]Nutrition Department, Faculty of Health Science, Respati University of Yogyakarta, Yogyakarta, Indonesia; [4]Nutrition Science Study Programme, Faculty of Public Health, Ahmad Dahlan University - Campus 3, Yogyakarta, Indonesia

BACKGROUND AND OBJECTIVES

Approximately 40% of Indonesian children did not consume the minimal amount of food diversity. As a part of Matching Fund Patriot Pangan, MANDALA program aimed to bring nutrition back to the plate with locally grown food to prevent malnutrition in the community. This initiative also seeked to improve food diversification in the community. By increasing food diversity in households and communities, this program was expected to help reduce the risk of stunting and improve the quality of human resources in Indonesia.

METHODS

This initiative was implemented in 2022. This program employed three strategies to achieve its goals: (1) initiating a network of universities as government partners through "a nutrition-sensitive value chain-based program," (2) enlisting the media and business actors through "diversity from field to plate" activities, and (3) empowering the community through "bringing back nutrition into my plate" initiatives. Those strategies were developed into several activities aimed at universities, community, government, business actors, and media.

RESULTS

This program initiated a commitment from five universities as government partners to enhance food security, involving 51 undergraduate nutrition students in developing local food-based menu innovations. The universities, in collaboration with the government and other stakholders, held a virtual food fair to promote local food-based products. Community-focused activities involved training in preparing local infant and young child foods to prevent malnutrition. Additionally, the program empowered women in collective land use for community gardens and liquid natural fertilizer production, with support through seed distribution and fertilizer-making media.The program produced three modules and three videos as educational media to enhance community knowledge. At the program's end, a virtual meeting succeeded in gathering 273 participants, including students, academics, government and non-government institutions, media, business actors, and the general public, to promote local food diversity.

CONCLUSIONS

By engaging various stakeholders, the program supported the use of locally grown foods, enhanced community nutrition knowledge, and empowered households to adopt diverse and nutrient-rich diets. It can help in improving community health and nutritional status, as well as promoting sustainable diet behavior.

EFFECTS OF A “HEALTHY SETTING APPROACH” IN THE REMOTE AREA OF SOLOMON ISLANDS WITH LIMITED MEDICAL RESOURCES AND AFFECTED BY CLIMATE CHANGE

Marika Nomura[1]; Ken Hashimoto[2]; Adrian Leamana[3]; Alby Lovi; Yusuke Kamiya[4]
[1]Human Development Department, Japan International Cooperation Agency (JICA), Tokyo, Japan; [2]Independent Global Health Consultant, None, Hyogo, Japan; [3]National Health Promotion Department, Ministry of Health and Medical Services, Honiara, Solomon Islands; [4]Faculty of Economics, Ryukoku, kyoto, Japan

BACKGROUND AND OBJECTIVES
In remote islands in Solomon Islands with limited healthcare resources, people often only receive treatment after they have become seriously ill, and there are many premature deaths, so there is an urgent need for a locally based strategy that emphasizes prevention. However, villages are located along the coast of the islands, but because of climate change, the frequency of storm surges has increased, and vegetables cannot be grown due to salt damage, so the balance of diet is poor. JICA supported the government on promoting "healthy setting approach (WHO)", and by strengthening the capabilities of village health promoters (VHP), it provided technical support for kitchen gardens, and promoted vegetable cultivation. Thus, the purpose of this study is to investigate whether "healthy setting approach" has impact on the eating habits of community people (adults and children) in regions that are vulnerable to climate change and have limited access to medical services, in Solomon Islands.

METHODS
Questionnaire surveys (health behavior, anthropometry, blood pressure measurement, fasting blood glucose measurement) were conducted before (2017) and after (2020) the project in a total of 15 villages in the provinces of Guadalcanal and Makira Urawa, divided into an intervention group and a non-intervention group, and a before-and-after comparison was made. Data were analyzed by a difference-in-differences test using the statistical software STATA.

RESULTS
We received responses from 383 people in the baseline survey and 422 people in the endline survey. As a result, villagers in the intervention group significantly reduced blood glucose levels (p<0.1), augmented fresh fruit intake (p<0.01), and improved knowledge and attitude related to NCDs (p<0.05), compared to those in the control group. In addition, changes were seen in children's diets, assuming through the health education to adults (parents). In particular, the frequency of intake of yellow and green vegetables both increased significantly.

CONCLUSIONS
The "healthy settings approach" may be utilized as a tool to enhance healthy diet practices of both adults and children, in resource-limited islandy contexts.

FATTY ACID COMPOSITION AND NUTRITIONAL INDICES OF LIPIDS IN FOODS OF ANIMAL AND PLANT ORIGIN

Viktor Koczka[1]; Tamás Marosvölgyi[2]; Timea Dergez[2]; Éva Szabó[3]
[1]Doctoral School of Health Sciences, University of Pécs Faculty of Health Sciences"D", Pécs, Hungary; [2]Institute of Bioanalysis, University of Pécs Medical School, Pécs, Hungary; [3]Department of Biochemistry and Medical Chemistry, University of Pécs Medical School, Pécs, Hungary

BACKGROUND AND OBJECTIVES
Nowadays, diets based on plant-based foods are gaining in popularity. The consumption of whole foods derived from plants has been demonstrated to exert beneficial effects on human health. The food industry has developed a range of alternative products that differ considerably from a whole-food, plant-based diet in terms of their composition and degree of processing. The objective of this study was to conduct a comparative analysis of the fatty acid composition and fatty acid-based nutritional quality indices of ground beef-based foods and their fully plant-based alternatives produced by different manufacturers.

METHODS
A total of twelve different products were investigated, comprising six plant-based and four beef hamburger patties, as well as one plant-based and one beef minced meat product. Each product was tested with three different expiry dates. Following homogenisation, the lipids were extracted and quantified by gravimetry. The fatty acid composition was determined by gas chromatography. Additionally, the essential fatty acid index, n-3/n-6 polyunsaturated fatty acid ratio, unsaturation index (UI), atherogenicity index (AI), thrombogenicity index (TI), and hypocholesterolemic/hypercholesterolemic ratio (HHR) were also calculated.

RESULTS
Based on both label information and gravimetry measurement, significant differences ($p<0.01$) were found in the fat content of plant-based and animal-based products (animal-based: 19.67% [16.16%; 26.68%], plant-based: 10.25% [8.60%; 14.87%], median [Q1; Q3]). Except for one product, the plant-based alternatives had higher UI and HHR (UI: 129.62 [96.84; 146.10]; HHR: 50.13 [45.69; 54.14]) than animal-based hamburger patties (UI: 8.18 [3.13; 11.59]; HHR: 1.35 [1.23; 1.43]). By contrast, plant-based alternatives had lower AI and TI (AI: 0.13 [0.09; 0.58]; TI: 0.26 [0.20; 0.32]) compared to animal-based products (AI: 0.83 [0.77; 0.94]; TI: 1.87 [1.72; 2.17]). Significantly different fatty acid composition profiles were found between the investigated product groups and within a given group for both animal- and plant-based product groups.

CONCLUSIONS
According to our RESULTS, today's popular plant-based meat alternatives have significantly different and variable fat content and fatty acid composition, resulting in differences in nutritional value. To provide a more accurate and comprehensive picture, further analytical and clinical studies are needed to investigate the long-term health effects of the foods included in the study.

CONFLICTS OF INTERESTS

HARMONIZING NIGERIA'S SECTORAL NUTRITION POLICIES: THE STRATEGIC ROLE OF THE NATIONAL COUNCIL ON NUTRITION

Clementina Okoro; Emeka Vitalis Obi[1]; Sanjo O. Faniran[2]; Christiana Yunanah[2]; Tope Omotola[2]; Julius Likuna[2]
[1]Permanent Secretary, Federal Ministry of Budget and Economic Planning, Abuja, Nigeria, Federal Republic of; [2]Social Development Department, Federal Ministry of Budget and Economic Planning, Abuja, Nigeria, Federal Republic of

BACKGROUND AND OBJECTIVES

Effective multisectoral coordination is essential for addressing malnutrition in Nigeria, a country with diverse socio-economic and regional disparities. The National Council on Nutrition (NCN) plays a significant role in harmonizing sectoral nutrition policies to achieve cohesive and impactful national nutrition programs. This study aims to evaluate the NCN's contribution to harmonizing nutrition policies and identify opportunities for enhancing its effectiveness in fostering integrated nutrition strategies.

METHODS

A qualitative analysis was conducted, involving a review of sectoral nutrition policies and strategies, the National Policy on Food and Nutrition, National Multisectoral Plan of Action for Food and Nutrition, and reports from NCN meetings between 2018 and 2023. Key reports from various ministries, departments, and agencies (MDAs) participating in NCN activities were reviewed. Data were analyzed to assess the alignment of sectoral policies and the mechanisms employed by the NCN to ensure coherence and collaboration among stakeholders.

RESULTS

Findings revealed that the NCN successfully established a unified framework for aligning sectoral nutrition objectives, fostering dialogue among MDAs, and integrating nutrition considerations into national development plans. However, challenges such as inconsistent funding, limited inter-agency accountability, and gaps in data sharing hindered the full operationalization of coordinated efforts. Opportunities for improvement include institutionalizing monitoring frameworks, enhancing capacity-building initiatives, and strengthening policy advocacy mechanisms.

CONCLUSIONS

The NCN serves as a critical platform for harmonizing sectoral nutrition policies in Nigeria. Strengthening its operations and addressing identified challenges can accelerate progress toward achieving national and global nutrition targets. This study highlights the importance of sustained commitment to multisectoral coordination for improving nutrition outcomes and advancing sustainable development in Nigeria.

LEGUMES: SUSTAINABLE FOODS THAT CAN MAKE A SIGNIFICANT CONTRIBUTION TO FOOD AND NUTRITIONAL SECURITY - THE CASE OF BENIN

Youna Hemery[1]; Rokhaya Cissé[2]; Elise Dagorret-Bonetto[1]; Sonia Fortin[2]; Morgane Chapron[2]; Guillaume Grondin[2]; Christèle Icard-Vernière[2]; Waliou Amoussa Hounkpatin[3]; Claire Mouquet-Rivier[2]
[1]UMR QualiSud, Institut de Recherche pour le Développement (IRD), Cotonou, Benin; [2]UMR QualiSud, Institut de Recherche pour le Développement (IRD), Montpellier, France; [3]Human nutrition and Food sciences, FSA/UAC, Abomey Calavi, Benin

BACKGROUND AND OBJECTIVES
Legumes are particularly sustainable foods whose agronomic and nutritional benefits are widely recognized, and whose place in food systems should be promoted. However, few data exist on the consumption of legume-based foods in West Africa, and on the possible impact of the food transition on this consumption. The aim of this study was to assess the current consumption of these foods in a West African country (Benin), and their contribution to meeting the nutritional requirements of the population.

METHODS
The legume consumption was measured during a repeated cross-sectional survey, among a sample of adult population using a one-week retrospective food frequency questionnaire to estimate the contribution of legume-based dishes to the recommended nutrient intakes, based on their consumption frequency, portions sizes, and nutritional composition (determined by laboratory analysis). Thus, in 2023 and 2024, 1476 individuals in urban and rural areas of 3 regions of Benin (South, Centre, North) were interviewed, to study the impact of seasonality and agro-ecological conditions on the legume consumption.

RESULTS
Legumes are still widely consumed in Benin: respondents had eaten in average 4 different legume species in the week prior to the survey (among the 10 species listed), and 95% of Beninese people surveyed declared having consumed cowpea in the week preceding the survey, compared with 94% for peanut, 87% for African locust bean, and 84% for soybean. Few significant differences in legume consumption were observed according to gender or age, with the exception of soybean, which was less consumed by the elderly ($p<0.00001$), who are less accustomed to this relatively recently introduced species. However, an effect of the geographical gradient (South/North) and the type of area (urban/rural) on legume consumption was noted. The mean daily contribution of legume-based foods to the recommended protein intakes were 28% for cowpea, 20% for soybean, and 18% for peanut. Legume-based foods also made significant contributions to the recommended intakes of minerals and thiamine.

CONCLUSIONS
This regular and high consumption of legumes by the Beninese population should be encouraged, as it significantly contributes to the nutritional security of the population. In a context of nutritional transition, it is important to maintain this high level of consumption through awareness-raising messages conveying a positive image of these foods, and through the development of cowpea-based products adapted to people's needs.

TOWARDS SUSTAINABLE FOOD SYSTEMS WITHIN THE WILLIAMS TREATIES FIRST NATIONS

Ashleigh Domingo[1]; Kerry-Ann Charles[2]; Teresa Harrigan[1]; Jaden Gray[2]; Tammy Charles[3]
[1]Human Health and Nutritional Sciences, University of Guelph, Guelph, Canada; [2]Indigenous Projects, Cambium Indigenous Professional Services, Curve Lake, Canada; [3]Georgina Island First Nation, Georgina Island First Nation, Georgina Island, Canada

BACKGROUND AND OBJECTIVES

Food security and climate change are deeply connected, as climate change can significantly impact food systems, particularly for Indigenous Communities in Canada. Minwanjigewin is a collaborative project led by four partnering Communities of the Williams Treaties First Nations in Ontario, Canada: the Chippewas of Beausoleil, Rama, and Georgina Island First Nations, and the Mississaugas of Curve Lake First Nation. It is a community-based project that aims to strengthen the capacity for Community-led initiatives on food security and food sovereignty, including considerations for building climate-resilient food systems. The objectives are to describe a process of community-led food system planning to enhance food security and food sovereignty in partnering communities.

METHODS

Grounded in Community-based participation, the project will identify and expand on community-assessed strengths to inform and establish an Indigenous-led Community-based food project. Georgina Island First Nation community members completed a collaboratively developed strengths-based survey with the support of community food liaisons. Completion of the survey is underway in Rama and Curve Lake First Nations.

RESULTS

In Georgina Island, approximately 40 households completed the survey. A range of community strengths was identified and mapped, including key food system actors (e.g., producers, farmers, hunters, fisherme, cooks, champions); existing programs (e.g., food boxes, community garden); and physical resources (e.g., community freezer, infrastructure). Community projects of interest and recommended actions were identified within three areas: (1) improving access to affordable food, (2) strengthening connections to land and traditional food acquisition practices; and (3) supporting locally grown food in the community. As this project is ongoing, a cross-community analysis will unfold next year, with initial RESULTS expected by Spring 2025.

CONCLUSIONS

By integrating traditional Anishinaabe culture, ecological, and more recent Western agri-food techniques, the research will foster awareness and uptake of environmentally sustainable modes of food production to support future actions. By developing community-based approaches to managing food systems that affirm Indigenous autonomy, we can foster greater food security and build more climate-resilient food systems.

WHAT INFLUENCES THE IMPLEMENTATION OF SUSTAINABLE DIETARY BEHAVIORS IN JAPANESE AND GERMAN ADULTS: A COMPREHENSIVE CROSS-CULTURAL COMPARISON

Yui Kawasaki[1]; Emi Yoshii[2]; Kahori Fujisaki[3]; Misa Shimpo[2]; Sayaka Nagao-Sato[4]; Jana Boehnke[5]; Rie Akamatsu[6]; Petra Warschburger[5]
[1]Institute for SDGs Promotion, Ochanomizu University, Bunkyo City, Japan; [2]Faculty of Health and Human Development, The university of Nagano, Nagano, Japan; [3]Faculty of Nutritional Science, Sagami Women's University, Kanagawa, Japan; [4]Depertment of Nutrition, Takasaki University of Health and Welfare, Takasaki, Japan; [5]Department of Psychology, University of Potsdam, Potsdam, Germany; [6]Natural Science Division, Ochanomizu University, Bunkyo City, Japan

BACKGROUND AND OBJECTIVES
The concept of integrated sustainable dietary behavior (SDB) covers a wide range of issues, such as food choices that are healthy and/or environmentally friendly, food choices and cooking behaviors that reduce food waste, reusing plastic waste, and disposal actions that minimize water pollution. This study qualitatively describes factors that influence the implementation of SDBs and quantitatively compares the RESULTS between Japan and Germany.

METHODS
Data were obtained from online focus group interviews with 16 Japanese participants (50.0% female) and online open-ended questions involving 498 Japanese and 197 German respondents (56.6% female), conducted in 2021. Manifest content analysis was employed for qualitative data. Data from each country were initially analyzed separately and then combined after extensive researcher discussions. Qualitative data were converted into a quantitative total score reflecting category frequency. Chi-square and Fisher's exact tests were used to assess cross-cultural differences in code proportions for each main category.

RESULTS
The 2,515 codes, 32 subcategories, and 20 categories that emerged from the content analysis were divided into five categories: 1) intrapersonal, 2) interpersonal, 3) food environment, 4) government, local governments, and research institutions, and 5) other. Japanese and German participants exhibited differences in the distribution of codes related to factors affecting SDB implementation across various categories. Compared to the Germans, the Japanese participants had a higher percentage of references to the "intrapersonal" and "government, local governments, and research institutions" categories ($p < 0.001$). Japanese participants were more likely to cite psychological factors, portion size, and other factors, whereas German participants frequently referenced biology, skills of SDB, local access to sustainable food, and neighborhood characteristics.

CONCLUSIONS
The study identified cultural differences in the perceived factors for implementing SDBs, particularly in categories reflecting varying circumstances like social norms and geographical conditions between the two countries. This research offers insights into these factors and can help develop promotion strategies that account for the cultural backgrounds of target populations.

COMPARING THE COST AND AFFORDABILITY OF NUTRITIOUS AND SUSTAINABLE FOOD BASKETS BY ZONE OF IRAN: 2016-2019

Arezoo Rezazadeh[1]; Aghaalikhani Fatemeh[1]; Eini-Zinab Hassan[1]; Sobhani Reza[2]
[1]Community Nutrition, NAtional Nutrition and food Technology research institute, Tehran, Iran, Islamic Republic of; [2]Nutrition, Medicine, Mashhad, Iran, Islamic Republic of

BACKGROUND AND OBJECTIVES
Sustainable diets are characterized by being culturally acceptable, economically fair, affordable and accessible, nutritionally sufficient, safe, healthy, and efficiently utilize human and natural resources. This study aimed to determine the difference in the cost and affordability of nutritious and sustainable food baskets in different zone of Iran in 2016-2019.

METHODS
In this repeated cross-sectional study, the expenditure and income data of128,716 Iranian households participated in the “Household Income and Expenditure Survey” during the years 2016-2019 were used. The data were categorized to 11 zone. The sustainable and nutritious food baskets were modeled using linear programming and ideal programming. The cost of the baskets was calculated by summing the average price of each food item based on the amount (gram) of each in the food basket. Affordability was estimated based on the total cost of each basket compared to the average monthly disposable income of the household. Data was analyzed using R software (version 4.3.0). One-way analysis of variance and post-hoc statistical tests were used to compare the differences between zones.

RESULTS
In all zones, the cost of a nutritious food baskets was higher than the cost of a current food basket, and the cost of a sustainable food basket was lower than the cost of the current food basket.The highest cost of current and sustainable food basket was in zone1 (93001.89and73290.27Rials,respectively) and the lowest cost of those baskets was in zone10(81484.38 and 63655.62Rials,respectively).About nutritious food basket,the highest costand the lowest cost was belonged to zone1(116277.05Rials)and zone 3(29210.98Rials), respectively.About affordability, in all food baskets, households in zone5 had the highest (74.34%,57.49%and92.12%,respectively) and households in zone8 had the lowest (24.28%,19.20% and30.00%,respectively)percentage of the income spent on food baskets.

CONCLUSIONS
The findings indicate that, overall, in all different zones of Iran, the cost of the nutritious and sustainable food basket was higher and lower than the current food basket, respectively. Regarding affordability, households in zone 5 allocated the largest percentage of their income to preparing food baskets. These findings emphasize the importance of future planning and policy implementation focused on food support, particularly in drought-affected and deprived zones. Additionally, targeted interventions could focus on enhancing the affordability of the nutritious and sustainable food basket for vulnerable populations.

PROMOTING SUSTAINABLE DEVELOPMENT THROUGH PLANT-BASED MEALS

SHU CHI LIN[1]; Jiyuen Tieng Chen[2]; Yu-Hsien Chao[1]
[1]Department of Nutrition, Taiwan Adventist Hospital, Taipei, Taiwan; [2]Department of Nutrition, Taiwan Adventist Hospital, Taipei, Taiwan, Taiwan

BACKGROUND AND OBJECTIVES

Taiwan Adventist Hospital has integrated food sustainability into its practices, supporting the achievement of SDGs. In 2021, the hospital launched the *My Healthy Plate—Enhancing Patient Health Literacy* program, focusing on educating patients about proper food choices and portion control through individual nutritionist consultations. The initiative encourages healthier eating habits by presenting meals in a structured, visual format, aiming to reduce food waste and improve nutritional knowledge.

METHODS

A randomized sample of 150 patients consuming regular hospital diets (non-therapeutic) was assessed. Silicone-covered utensils were used to evaluate carbon emissions and leftover food volume of plant-based meals compared to equivalent pork bento meals.

RESULTS

1. **Carbon Emissions:** Each plant-based meal resulted in 0.82 CO2eq per person, with a total of 2.46 CO2eq per day per person. The total carbon emissions for 150 participants were 369 CO2eq per day.
2. **Food Waste Reduction:** Prior to the program, daily food waste per patient was 72kg (water weight). Post-implementation, the leftover food per meal was reduced to 102g, resulting in a total daily reduction of 41.4kg of food waste for 150 participants.

CONCLUSIONS

Hospitals are ideal platforms for promoting sustainable eating practices. Low-carbon diet education contributes to the development of healthy, sustainable eating habits and aligns with SDG 13 (Climate Action). Taiwan Adventist Hospital will continue to promote green, sustainable food services for staff, patients, and the community.

UTILIZATION OF EDIBLE SLAUGHTERED FISH BYPRODUCTS: A HEPATOPROTECTIVE GROUPER HEAD HYDROLYSATES

Pei-Yu Li[1]; Yi-Ling Lin[1]; Yi-Feng Kao[2]; Hui-Jun Tsai[2]; Yi-Chen Chen[1]
[1]Department of Animal Science and Technology, National Taiwan University, Taipei, Taiwan; [2]Seafood Technology Division, Fisheries Research Institute, Ministry of Agriculture, Keelung, Taiwan

BACKGROUND AND OBJECTIVES
Groupers' byproducts, accounting for approximately 43% of their weight (15% fish head, 6% fins, 12% middle bones, and 10% viscera), are often discarded or processed into bone meal for feed additives due to their strong odor and limited consumer acceptance, leading to ineffective utilization. Grouper head hydrolysates (GHHs), produced via Alcalase hydrolysis, are rich in aromatic amino acids, branched-chain amino acids, and taurine, known for their antioxidant and hepatoprotective properties. This study aimed to evaluate the effects of GHHs on liver fibrosis by investigating their anti-inflammatory and antioxidant activities.

METHODS
Eight-week-old male Wistar rats (n=8 per group) were randomly divided into 5 groups: (1) control (saline + distilled water); (2) model (TAA + distilled water); (3) low-dose GHHs (TAA + 50 mg kg^{-1} GHHs); (4) high-dose GHHs (TAA + 100 mg kg^{-1} GHHs); and (5) positive control (TAA + clam essence, CE). Liver fibrosis was induced by thioacetamide (TAA) injections three times weekly. After 10 weeks, body weights, serum biochemical markers, liver histopathology, antioxidant enzyme activities, and pro-inflammatory cytokine levels were assessed.

RESULTS
Supplementation with GHHs in TAA-treated rats mitigated body weight loss and significantly reduced serum markers of liver injury (AST, ALT, and ALB) ($p < 0.05$). GHHs enhanced the activities of antioxidant enzymes (SOD, CAT, and GPx) and lowered pro-inflammatory cytokine levels (IL-1β, TNF-α, and IL-6) in livers ($p < 0.05$). Histological analysis revealed reduced cell infiltration and collagen deposition in TAA-treated rats receiving GHH supplementation.

CONCLUSIONS
GHH supplementation alleviates liver fibrogenesis through anti-inflammatory and antioxidant mechanisms, with even low doses achieving the expected RESULTS. The development of GHHs not only adds value to grouper byproducts but also presents a promising approach to reducing liver dysfunction and supporting liver health.

ASSESSING DIET QUALITY AND CARBON FOOTPRINT: A CROSS-SECTIONAL STUDY AMONG YOUNG ADULT WOMEN

Merve Ilhan-Esgin[1]; Rana Yanikkaya[1]; Ebru Unsal[1]; Gokce Bilgin[1]
[1]Nutrition and Dietetics, Ankara University Faculty of Health Sciences, Ankara, Türkiye

BACKGROUND AND OBJECTIVES

Sustainable diets aim to have a low environmental impact; however, the carbon footprint of nutrient-rich animal-based foods is higher compared to plant-based foods. This study aimed to evaluate the diet quality and carbon footprint of young adult women's diets.

METHODS

This cross-sectional study included 332 women aged 18-30 years. Individuals with chronic diseases, pregnant and lactating women, as well as those with a daily energy intake of less than 500 kcal or more than 3500 kcal, were excluded from the study. Data were collected through face-to-face interviews using a questionnaire. Participants provided two-day dietary records (weekday and weekend). Carbon footprints (g CO2 emission/1000 kcal) were calculated from dietary records, and the NRF 20.3 index (per 1000 kcal) was computed. Data were analyzed using ANOVA, Tukey HSD post-hoc test, and Pearson correlation ($p<0.05$) in SPSS v.26. This study was supported by the Scientific and Technological Research Council of Turkey (TÜBİTAK) 2209-A Project (1919B012221084).

RESULTS

Of the 332 individuals participating in the study (21.51±2.04 years; 21.80±2.91 kg/m²; 78.3% with normal BMI), 62.3% were students who lived in dormitories. Carbon footprint values did not show a statistically significant difference between weekdays and weekends. Diet quality was lower on weekdays compared to weekends ($p=0.009$). A positive correlation was found between carbon footprint values and NRF 20.3 index scores ($r=0.229$, $p<0.001$). Table 1 presents the NRF 20.3 index score according to carbon footprint tertiles.

Table 1. Nutrient Rich Foods (NRF) 20.3 Index Scores by Carbon Footprint Tertiles

	Carbon footprint (gCO2e/1000 kcal)			
	Q1 (n=111)	Q2 (n=111)	Q3 (n=110)	p
	Mean±SD (95% CI)	Mean±SD (95% CI)	Mean±SD (95% CI)	
NRF 20.3 index score (per 1000 kcal)	734.9±176.55a (701.8-768.1)	771.8±196.23a,b (734.9-808.7)	818.3±192.12b (781.9-854.6)	0.005

CONCLUSIONS

As diet quality increases, the carbon footprint values of individuals also tend to rise. This relationship highlights the challenge of balancing improved nutritional outcomes with sustainability. Therefore, dietary planning should focus on strategies that reduce the environmental impact of food choices while maintaining or even enhancing diet quality.

EPO2_057

DETERMINING THE ECOLOGICAL FOOTPRINT AND NUTRIENT COMPOSITION OF SOME INNOVATED DISHES

Vahide Tas Ozdemir[1, 2]; Funda Pinar Cakiroglu[3]
[1]Department of Nutrition and Dietetics, Ankara University, Graduate School of Health Sciences, Ankara, Türkiye; [2]Nutrition and Dietetics, Hasan Kalyoncu University, Faculty of Health Sciences, Gaziantep, Türkiye; [3]Nutrition and Dietetics, Ankara University, Faculty of Health Sciences, Ankara, Türkiye

BACKGROUND AND OBJECTIVES
Sustainable nutrition has the potential to improve both human and planetary health. Growing population and current dietary trends are not only increasing non-communicable diseases but also deepening environmental risks. The adoption of plant-based diets with low ecological impact, particularly models like the Mediterranean diet, optimizes global resource use by reducing carbon and water footprints. This study is an innovation project aimed at reducing the ecological footprint, improving the nutritional content, and examining the sensory effects of transforming traditional dishes with plant-based alternatives.

METHODS
In the study, five main dishes (mantı, içli köfte, çökertme kebabı, hünkâr beğendi, karnıyarık) and one dessert (ekmek kadayıfı) were selected, and animal-based ingredients were replaced with plant-based alternatives. The carbon and water footprints of the meals were calculated using factors derived from the literature, and their nutritional content was analyzed using the BeBiS 8.2 TAM program. Cost calculations were based on official institution and chain market data, while sensory evaluation was conducted through a panel of volunteer participants. The obtained RESULTS were compared and discussed.

RESULTS
In the innovated dishes, a reduction in carbon footprint ranging from 23.5% to 95.5%, and a reduction in water footprint ranging from 47.4% to 85.7% were observed compared to traditional recipes. The energy content generally decreased, while carbohydrate and fiber content increased in most of the main dishes. In the dessert, the use of alternatives like soy milk led to an increase in the water footprint. When analyzing the costs, the innovated main dishes showed a reduction in cost ranging from 53.5% to 75.8%, while the cost of the dessert increased by 44%. In sensory evaluations, most of the innovative dishes were well-liked by panelists, although some received lower ratings. These findings indicate positive effects on environmental sustainability and nutrition, while also leading to some changes in cost and taste.

CONCLUSIONS
Replacing animal-based foods with plant-based alternatives reduces carbon and water footprints, offering cost benefits. Research shows replacing red meat lowers ecological impacts, while dairy substitutions vary. Nutritional improvements, such as better energy, fiber, fat, and cholesterol levels, enhance health. Sensory evaluations indicate general acceptability, supporting ecological and economic sustainability.

CONFLICTS OF INTERESTS
The authors have no conflict of interest.

CAN LOCAL AGRICULTURE IMPROVE THE NUTRITIONAL QUALITY OF DIET WHILE REDUCING THE ENVIRONMENTAL IMPACT IN GUADELOUPE ? A SYSTEM MODEL APPROACH FROM FORK TO FARM

Sophie Drogué[1]; Joaquin Ameller Pavez[2]; Jean-Marc Blazy[3]; Loic Guindé[3]; Gabin Guillemaud[4]; Eleonore Loiseau[4]; Pascaline Rollet[1]; Maria Somaraki[1]; Uyen Vu[1]; Marlène Perignon[1];
[1]MoISA, Univ Montpellier, CIHEAM-IAMM, CIRAD, INRAE, Institut Agro, IRD, Montpellier, France; [2]UMR MoISA, Cirad, Montferrier-sur-Lez, France; [3]UR ASTRO, Inrae Domaine De Duclos, Petit-Bourg, Guadeloupe; [4]UMR ITAP, INRAE Centre Occitanie-Montpellier, Montpellier, France

BACKGROUND AND OBJECTIVES
In Guadeloupe, agriculture is strongly oriented towards export crops, which limits the capacity of local production to meet domestic demand. In addition, the territory is facing urgent public health issues with increasing rates of nutrition-related chronic diseases along with a profound change in the diet structure. The aim was to assess the extent to which local agricultural production could contribute to improve the nutritional quality of diet in Guadeloupe, while limiting its impact on the environment.

METHODS
Data from a food consumption survey conducted in adults > 15 years were related to food prices, nutritional composition of food and dishes and the share of local origin of each food consumed. The mean observed diet of the general population and its cost were estimated based on these data. Diet optimization models were built using mathematical programming to assess the possibility of maximizing foods from local origin in the diet while fulfilling nutritional requirements and without increasing the observed cost. Then, a bioeconomic model (MOSAICA) was used to simulate the impact of a transition toward the optimized diet on the agricultural sector in Guadeloupe, to assess its feasability at the territory scale. Finally, an environmental assessment at the level of the Guadeloupe territory was performed using Life Cycle Assessment.

RESULTS
RESULTS showed that the share of local products can be increased up to 75% while increasing the nutritional quality of the diet and without increasing the baseline cost of 7 €/day/person. The RESULTS from the bioeconomic model showed that this transition toward a healthier and more local diet would be hampered by the lack of farm labor, lack of available land and sanitary risk due to chlordecone pollution. The main positive environmental impacts induced by such transition toward more local food in the diet would be on water eutrophication and land use due to more quantity of local yam and bovine meat.

CONCLUSIONS
Improving the nutritional quality of the diet while increasing the share of local food without increasing the observed budget in Guadeloupe is feasible. However, two conditions should be met to reach this result: a higher plant-based diet is necessary to lower the environmental impact; then, increasing the agricultural workforce and mobilizing new farmland are necessary to not destabilize existing sectors.

CONFLICTS OF INTERESTS

INTEGRATING CASH ASSISTANCE AND BEHAVIORAL INTERVENTIONS TO PREVENT CHILD AND MATERNAL MALNUTRITION IN SOMALIA: INSIGHTS FROM A CLUSTER RANDOMIZED CONTROLLED TRIAL

Shelley Walton[1]; Kemish Alier[1]; Samantha Grounds[1]; Sydney Garretson[1]; Qundeel Khattak[2]; Tripaldi Marina[2]; Fabrizio Loddo[2]; Said Mohamoud[3]; Mohamud Ali Nur[3]; Sadiq Abdikadir[3]; Emily Mitchell[2]; Nadia Akseer[1]
[1]Department of International Health, Johns Hopkins University, Baltimore, United States of America; [2]Humanitarian Response, Save the Children, London, United Kingdom; [3]Research, Save the Children International, Garowe, Somalia

BACKGROUND AND OBJECTIVES
Wasting is a significant public health challenge, especially in humanitarian contexts like Somalia, where children under 5 (CU5) and pregnant and lactating women (PLW) face elevated risks of morbidity and mortality. CashPlus programs, which combine cash transfers with behavioral education or other assistance, have been used to support communities in humanitarian settings for years, despite evidence gaps on which combinations and durations of assistance are most effective at reducing wasting in CU5 and PLW. Understanding the specific drivers of wasting is critical for shaping effective policies and programs.

METHODS
A cluster randomized controlled trial was conducted within Save the Children's "CashPlus for Nutrition" program in Somalia's Bay and Hiraan regions, comparing three interventions: (1) cash only, (2) cash plus social and behavior change communication (SBCC), and (3) cash plus top-up cash. A total of 33 villages were randomized (11 per study arm), targeting 1,492 households. The study evaluated the effectiveness and cost-effectiveness of each arm in reducing wasting among CU5 and PLW after three and six months. Data was also used to assess the determinants of child and maternal wasting through regression models.

RESULTS
Child wasting prevalence at baseline was 15%, which dropped to 13% (cash-only arm) and 9% (cash + SBCC arm) by midline, with no significant reduction in the cash + top-up arm. Wasting remained the same in the cash + top-up arm at 15% (12.1% - 18.6%). By endline, little change was observed from the midline. Maternal wasting decreased in all groups, but differences were not statistically significant. Dietary diversity, household conditions, and hunger levels improved across all arms, with cash + SBCC being the most effective and cost-effective intervention. Risk factors for wasting included poor waste disposal practices, open defecation, household food insecurity, and low maternal education, while protective factors were consumption of animal-based foods and having more than one CU5 in the household.

CONCLUSIONS
The combination of cash assistance and SBCC was the most effective approach for reducing child and maternal wasting, improving household food security, and reducing moderate and severe hunger. Drivers of wasting in Somalia may vary by seasonality, region, and child age. Policies should focus on empowering mothers, improving health and sanitation practices, and increasing household food security and access to nutrient-dense foods. Findings will enable more efficient and effective use of strained humanitarian assistance budgets, maximizing the reach and impact of assistance packages in Somalia and similar contexts around the world.

CONSUMPTION OF ULTRA-PROCESSED FOODS AND HOME-MADE FRIED FOODS WITH SUSTAINABLE LIFESTYLES IN IBERO-AMERICAN

Duran Aguero Samuel[1]; Solange Parra-Soto[2]; Leslie Landaeta-Díaz[3]; Israel Rios Castillo[4]; Valeria Carpio,[5]; Gladys Morales[6]; Lima Joao[7]; Jacqueline Araneda[8]; Eliana Meza[9]
[1]Faculty of Health Sciences, San Sebastián University, Providencia, Chile; [2]Departament Nutrition and Public Health, Biobio University Campus Fernando May, Chillán, Chile; [3]Núcleo de Investigación en Nutrición y Ciencias Alimentarias, University of the Americas, Providencia, Chile; [4]Salud, FAO, Panama City, Panama; [5]Nutrition and Dietetic Career, ESPOCH, Riobamba, Ecuador; [6]Deparment of Public Health, University of La Frontera, Temuco, Chile; [7]H&TRC - Health & Technology Research Center, Polytechnic University of Coimbra, Coimbra, Portugal; [8]Department Nutrition and Public Health, Biobio University Campus Fernando May, Chillán, Chile; [9]Centro Multidisciplinario de Investigaciones Tecnológicas, Universidad N, San, Paraguay

BACKGROUND AND OBJECTIVES
Worldwide, consumption of ultra-processed foods has increased in recent years, and although there is much evidence that consumption of these foods is associated with increased risk of chronic diseases, there are no studies linking it with sustainable activities of daily living. The aim of this study is to associate the consumption of ultra-processed foods and home-made fried foods with sustainable activities in Ibero-America.

METHODS
An observational, analytical, multicenter study was conducted with 6,067 participants from 14 Ibero-American countries via an online survey. Consumption of ultra-processed foods and home fried foods according to a validated survey. The validated sustainable lifestyle survey is subdivided into 3 items: 15 questions assessing food and shopping; 12 questions assessing transport, recreation and self-care; and 11 questions assessing the environment. This gives a range of 50 to 185 points, the higher the score, the better the adherence to sustainable lifestyles. linear regresion models were applied, adjusted for sex, nutritional status, schooling and age.

RESULTS
The mean age of participants was 35.2 years (SD 12.7). Associations between food consumption and EVS showed that compared to no consumption, occasional consumption, 1 portion/week, 2 portions/week and ≥3 portions/week of these 3 food groups decreased the EVS score proportionally. In the case of fried foods consumption of ≥ 3 servings day (β -13.221; CI95% -15.445*;* -10.997), Fast Food (β -15.976; CI95% -20.489*;* -11.463) and sugary drinks (β -10.874; Ci95% -13.287*;* -8.460).

CONCLUSIONS
The higher consumption of ultra-processed foods and home-made fried foods is negatively associated with sustainable lifestyles

YOUNG ADULTS' STRUGGLES WITH THEIR FOOD ENVIRONMENT – A CASE STUDY USING PARTICIPATORY VIDEO MAKING IN TWO AGRO-PASTORALIST COMMUNITIES

Irmgard Jordan,[1]; Lydiah M Waswa[2]; Céline Termote[1]; Gudrun B. Keding[3]
[1]Food environment and consumer behaviour, Alliance of Bioversity International and CIAT, Nairobi, Kenya; [2]Department of Human Nutrition, Egerton University, Faculty of Health Sciences, Nakuru, Kenya; [3]Institute of Nutritional Sciences, Justus Liebing University Giessen, Senckenbergstr. 3, Giessen, Germany

BACKGROUND AND OBJECTIVES

The food environment (FE) is the context in which people select, acquire, prepare, and consume food and is thus a determinant of diet quality and nutritional outcomes as people mainly consume what is within their physical and economic reach. Limited information is available about the perception of young people living in drylands often affected by food insecurity. This study invited thus young adults living in (agro-) pastoralist communities living in drylands to share their food environment perspectives.

METHODS

Eight groups (n=5) of 18-24-year-old adults ((agro-)pastoralists) were invited by the village leaders to participate voluntarily in the study. The concept of FE was introduced using 7-day dietary recalls and FE mapping. Smart-phones were lended to the adults to produce videos of their FE. The adults received basic training on videomaking and editing. The final videos were transcribed verbatim, translated and subtitled in English. Grounded theory was applied to derive theories on young people's perceptions on their FE.

RESULTS

Skipping meals, searching food in the wild, and asking for external support were strategies to combat hunger following a serious drought. There was interest to taste modern foods like pasta, but cooking methods were limited because of lack of resources to buy diverse ingredients and lack of knowledge to prepare healthy meals. Vegetable and fruit farming were considered as strategy to improve food availability. However, safe water for drinking is already scarce, leaving limited options for farming. Income generating opportunities are limited, partially because of poor schooling opportunities and lack of skills besides livestock keeping. Even if financial resources would allow to purchase food, options to buy foods were limited. Still, participants emphasized on the need for income opportunities to enable food purchases for healthy diets. Fruits, if consumed, were collected from the wild after walking long distances. Existing food aid distribution places were not presented in the young adults' videos, and food aid was seen only as a short-term solution. Participants were more interested in making their own food choices with their own resources.

CONCLUSIONS

Market, road and public transport infrastructure needs to be improved to allow supplying diverse foods to dryland areas and buying them in close proximity. The young adults concluded that vegetable farming and restoration activities to protect wild foods are important activities to sustainably improve accessibility to healthy foods and livelihoods.

INVESTIGATING WEB-BASED NUTRITION EDUCATION INTERVENTIONS FOR PROMOTING SUSTAINABLE AND HEALTHY DIETS IN YOUNG ADULTS: A SYSTEMATIC LITERATURE REVIEW

Nadine Ghammachi[1]; Putu Novi Arfirsta Dharmayani[1]; Seema Mihrshahi[1]; Rimante Ronto[1]
[1]Faculty of Medicine, Health and Human Sciences, Macquarie University, Macquarie Park, Australia

BACKGROUND AND OBJECTIVES
Our current rapidly growing food systems are imposing a heavy burden on both environmental sustainability and human health. Sustainable and healthy diets aim to promote optimal health and have a minimal environmental impact. This study aimed to critically review and synthesise the evidence on the effectiveness of web-based nutrition education interventions aiming to promote sustainable and healthy diets among young adults.

METHODS
A systematic search of four databases (Medline, PsycINFO, Scopus, and Embase) was conducted in March 2021. Studies were included if they used an online platform to deliver the intervention to young adults and measured at least one aspect of sustainable and healthy diets, such as plant-based food intake, food waste, and local and seasonal produce.

RESULTS
Of the 2991 studies, a total of 221 full-text articles were assessed for eligibility of which 22 were included in the final review. A majority of the studies (82%) targeted fruit and vegetable consumption, and close to a quarter of studies (23%) targeted other aspects of a sustainable and healthy diet, such as red meat intake. Only one study included multiple aspects of a sustainable and healthy diet. Program delivery outcomes reported overall positive feedback and engagement.

CONCLUSIONS
This review suggests that web-based interventions may be effective in promoting some sustainable diet-related outcomes in young adults. However, there is a need for developing and evaluating future programs to promote sustainable diets more comprehensively in order to help young adults make healthy and sustainable food choices.

ADHERENCE TO PLANETARY HEALTH DIET, ENVIRONMENTAL IMPACTS, AND HYPERTENSION RISK: A PROSPECTIVE COHORT STUDY FROM THE CHINA HEALTH AND NUTRITION SURVEY

Wenting Wang[1]; Aiping Fang[2]; Dan Li[1]
[1]School of Public Health, Sun Yat-sen University, Guang Zhou Shi, China; [2]School of Public Health and Emergency Management, Southern University of Science and Technology, Shen Zhen Shi, China

BACKGROUND AND OBJECTIVES
It remains unknown whether adherence to the Planetary Health Diet (PHD) protects against hypertension. Thus, we investigated the association of two PHD scores with hypertension risk and diet-related environmental impacts among Chinese adults with predominantly plant-based diets.

METHODS
We included 16,124 adults aged 18-80 years from the China Health and Nutrition Survey (1991-2015) who were free from hypertension, diabetes, cardiovascular diseases, and cancer at baseline. Dietary intake was assessed repeatedly using individual-level 3-day 24-hour dietary recalls supplemented with household-level weighing methods in each survey. The planetary health diet score (PHDS) and planetary health diet index (PHDI) were employed to evaluate adherence to PHD. Hypertension was ascertained via blood pressure measurement, previous medical diagnosis, or current use of anti-hypertensive medication.

RESULTS
During a median follow-up of 11.1 years, 5,367 participants developed hypertension. PHDI was not associated with hypertension risk (HRQuartile4 vs Quartile1=0.98; 95% CI, 0.90-1.07), whereas higher PHDS was associated with a lower risk of hypertension (HRQuartile4 vs Quartile1=0.80; 95% CI, 0.74-0.88; *P*-trend < 0.001). In contrast, higher PHDS was related to higher greenhouse gas emissions (β=0.39kg CO2 equivalent; 95% CI, 0.37 ~ 0.40 kg CO2 equivalent), water use (β=0.41m3; 95% CI, 0.38 ~ 0.43m3), and land use (β=0.42m2; 95% CI, 0.39 ~ 0.46m2), whereas higher PHDI was related to lower water use (β=-0.12m3; 95% CI, -0.15 ~ -0.09m3) and land use (β=-0.27m2; 95% CI, -0.32 ~ -0.23m2).

CONCLUSIONS
The two proportional scoring systems representing PHD exhibited differences in their construction, applicability, and association with both health and environmental outcomes. The PHDI, primarily developed for western populations, showed environmental benefits on water and land use, but was not necessarily associated with hypertension risk. In contrast, the PHDS, developed for a Chinese population residing in Singapore, was associated with a lower risk of hypertension but had higher environmental impacts. Thus, it is crucial to develop scoring systems that can accurately represent PHD within the Chinese population in future studies.

ATTITUDES TOWARDS FOOD WASTE AND WILLINGNESS TO PAY FOR LEFTOVERS IN SELF-SERVICE RESTAURANT

Leo Lepistö[1]; Kati Mokkala[1]; Anu Hopia[1]
[1]Nutrition and Food Research Center, Faculty of Medicine, University of Turku, Turku, Finland

BACKGROUND AND OBJECTIVES
SSRs (self-service restaurants) are restaurants offering lunch buffets; thus, the diner decides the amount of food taken. The freedom of choice may lead to larger portion sizes, consequently resulting in increased food waste. Attitudes, emotions, and values greatly influence food choices and eating habits. Therefore, it is necessary to understand diners' attitudes towards waste. This study aims to assess the attitudes toward food waste, food waste behavior, and motivations in terms of reducing food waste in SSR.

METHODS
The study was conducted in intelligent SSR, at the University campus area. The food waste monitoring is automated in the study's SSR by integrated scales. The study involved 157 participants, with 146 completing it. Of the participants 78% (n=115) were women, 21% (n=31) were men, and 1% (n=2) another gender. The mean age was 40.4 years (SD=12.6). Attitudes and emotions toward food waste were surveyed using questionnaires. The SSR platform enables linkage between participants' questionnaires and the waste amounts.

RESULTS
Of the participants, 67% (n=97) were aware of the impacts of food waste, 29% (n=42) were somewhat aware, and 4% (n=5) were unaware. Of the females, 97% (n=111), and 93% (n=28) of males were at least somewhat aware of food waste and its impacts (p=0.025, Exact Cochran-Armitage trend test). According to the questionnaire, 12% of participants left food (n=8) and 92% did not leave food waste in the study (n=131). Reported food wastage, in general, was linked to the study's food waste: 5% (n=6) of those participants who do not in general leave food, left food in the study, while 29% (n=6) of participants who generally leave food, left food in the study (p<0.003, Fisher's Exact test). Overall, 38% (n=54) of participants were willing to pay for leftovers. Males were more willing to pay for leftovers (67%, n=20) than females (30%, n=34) (p<0.001, Fisher's Exact test). In addition, younger participants (under 50) were more willing to pay for leftovers (44%, n=46) compared to those aged 50 and above (21%, n=8) (p=0.0184, Fisher's Exact test). Interestingly, high food waste awareness did not significantly influence willingness to pay (p=0.35, Exact Cochran-Armitage trend test).

CONCLUSIONS
Overall awareness of food waste and its impact was high in this highly educated study population. Gender impacted both awareness and attitudes toward paying for food leftovers, while age impacted paying for leftovers. The study highlights significant gender and age differences in attitudes toward food waste.

CONFLICTS OF INTERESTS

WILLINGNESS TO TRY NOVEL PROTEIN POWDERS: MUNG BEAN AND MEALWORM PROTEIN

Johanne Vermetten; Miriam Urlings[1]; Emmy Van Den Heuvel[2]; Laura Domínguez[3]; Virginia Fernández-Ruiz[3]; Montaña Cámara[3]; Alie De Boer[1]
[1]Food Claims Research Centre, Campus Venlo, Faculty of Sciences and Engineering, Maastricht University, Venlo, Netherlands; [2]Centre for Healthy Eating and Food Innovation, Campus Venlo, Maastricht University, Venlo, Netherlands; [3]ALIMNOVA research group, Universidad Complutense de Madrid, Madrid, Spain

BACKGROUND AND OBJECTIVES
Protein powders for supplementation (e.g. whey protein) have gained popularity over the last decade. The search for more sustainable alternatives has resulted in the inclusion of mung bean and mealworm protein in the European Union List of Novel Foods (Regulation (EU) 2017/2470). This study investigates willingness to try protein powders from these novel sources and interplaying factors such as food neophobia and food technology neophobia in a young adult population in the EU.

METHODS
An online survey was conducted in October 2024 in Spain and the Netherlands assessing the willingness to try mung bean and mealworm protein powder. A total of 402 participants were recruited, between the age of 18 and 40 years old. All participants reported to have previously consumed whey protein supplementation. Willingness to try is measured on a 7-point Likert scale for all proteins through the combination of through three questions: (1) interest in trying the product, (2) openness to taste the product, and (3) willingness to sample the product in a recipe or shake.

RESULTS
Protein supplementation was reported to be mostly consumed through dairy products like yoghurt and pudding with added protein (75% reported consumption at least once per month), followed by protein shakes (67%) and bars (66%). The participants reported the highest mean willingness to try for whey protein of 5.71 on a 7-point Likert scale, followed by plant (4.98) and insect (2.99). A great majority rated whey protein a 7 out of 7 (39%, 50% and 51.2% for statement 1,2, and 3 respectively). In contrast, a significant number rate insect protein with a score of 1 out of 7 (42.3%, 36.1%, and 37.8% respectively), suggesting a strong aversion or negative perception. Willingness to try mung bean protein more closely resembles a normal distribution, however the majority of consumers rated a 5 or higher out of 7 (58.9%, 68.4%, and 69.9%).

CONCLUSIONS
Mealworm protein was not readily accepted by most participants, and a great majority rated it a 1 out of 7 Likert scale, indicating a strong disinterest or aversion to the product. However, this study reveals an opportunity for mung bean protein as a form of protein supplementation in the diet of young adult protein consumers in the EU.

ADHERENCE TO CHINESE PLANETARY HEALTH DIETS, ALL-CAUSE MORTALITY, AND ENVIRONMENTAL IMPACT IN THE CHINA HEALTH AND NUTRITION SURVEY

Jialin Lu[1]; Dan Li[2]; Aiping Fang[3]
[1]Guangdong Provincial Key Laboratory of Food, Nutrition and Health, Department of Nutrition, School of Public Health, Sun Yat-sen University, Guangzhou, China; [2]Department of Nutrition and Food Hygiene, School of Public Health(Sun Yat-sen University), Guangzhou, China; [3]School of Public Health and Emergency Management, Southern University of Science and Technology, Shen Zhen Shi, China

BACKGROUND AND OBJECTIVES
The EAT-Lancet Commission launched a planet-healthy diet (PHD) to promote human health and environmental sustainability. However, the current PHD scoring systems, developed mainly in Western populations, cannot balance health and environmental benefits in the Chinese population. We aimed to develop a PHD scoring system tailored for the Chinese population and to investigate its association with all-cause mortality and environmental impact.

METHODS
We used data from the China Health and Nutrition Survey (CHNS) 1991-2015. Participants aged 18 years or older without a history of cardiovascular disease or cancer at baseline were included. Dietary intake was repeatedly assessed by individual three consecutive 24-hour dietary recalls and household food inventory weighing methods. We constructed a Chinese PHD score (range 0-140) based on the recommended consumption of 14 food components by the EAT-Lancet Commission. Death was ascertained through household surveys in each wave. Time-dependent Cox proportional hazards regression models were used to calculate multivariable-adjusted hazard ratios (HRs) and 95% confidence intervals (CIs).

RESULTS
We included 19,659 adults in the analysis. The median PHD score was 48.0 (IQR: 42.6-52.9) points. Over a median follow-up of 10.9 years, 1,615 deaths were observed. After adjustment for potential confounders, compared with participants in the lowest tertile(T) of PHD score, those in the highest tertile had a 13% lower risk of all-cause mortality (HR=0.87, 95% CI: 0.76-0.99; P-trend=0.04). The HR for each 10-point increment in PHD score was 0.91 (95% CI: 0.86-0.97). In the term of environmental impact, PHD scores were inversely associated with environmental impact, with significant differences between the lowest and highest tertiles for greenhouse gas emissions (85.0 vs. 58.9 10kgCO2), water use (6.4 vs. 6.0 $10m^3$), and land use (62.9 vs. 59.3 $10m^2$) (all *P*-trend < 0.001).

CONCLUSIONS
Better adherence to the PHD, assessed using a Chinese PHD scoring system, was associated with a reduced risk of all-cause mortality and a lower environmental burden in Chinese adults. These findings support the potential of the PHD as a tool for promoting both human health and environmental sustainability within the Chinese population.

CONFLICTS OF INTERESTS
The authors have no conflict of interest.

CREATING HEALTHY AND SUSTAINABLE DIETS WHILST MINIMISING CHANGE FROM CURRENT DIETS: A LINEAR PROGRAMMING APPROACH

Hannah Griffin[1]; Anne Nugent[1]; Breige Mcnulty[2]; David Wright[3]; Lorraine Brennan[2]; Patricia Eustachio Colombo[4]

[1]School of Biological Sciences, Queen's University Belfast, Belfast, United Kingdom; [2]UCD School of Agriculture and Food Science, University College Dublin, Dublin, Ireland; [3]School of Medicine, Dentistry and Biomedical Sciences, Queen's University Belfast, Belfast, United Kingdom; [4]Department of Medicine, Karolinska Institutet, Stockholm, Sweden

BACKGROUND AND OBJECTIVES

Sustainable diets can be defined as 'those with low environmental impacts, nutritionally adequate, affordable, safe and healthy, culturally acceptable and accessible' (1), but how these translate in terms of food intake is less clear. The objective of this study was to model, using data from the island of Ireland, what nutritionally adequate and sustainable diets could comprise, with modelled diets having minimal deviation from the current baseline diet to ensure acceptability.

METHODS

Linear programming was used to optimise three new population diets for two combined food surveys representing adults on the island of Ireland, providing a total cohort of 1484 adults aged 18-64y. Three scenarios were applied to baseline diets with the primary aim of maintaining acceptability. Constraints were applied in a stepwise manner. First, constraints relating to greenhouse gas emissions (GHGe) and Blue Water Use (BWU) were applied (scenario 1), followed by constraints relating to energy, 20 nutrients, Irish food based dietary guidelines (IFBDG's) and GHGe and BWU (scenario 2). In the final scenario, constraints relating to essential amino acids were added to those of scenario 2 (scenario 3).

RESULTS

In scenario 1, 100% of the cohort met the constraints, this reduced to 45% for scenarios 2 and 3. Three food groups were excluded in scenario 1 which included 'lamb and lamb dishes', 'liver and liver dishes' and 'tea, coffee and water'. In scenario 2, food groups 'lamb and lamb dishes' and 'liver and liver dishes' were excluded and four food groups were excluded in scenario 3, ' lamb and lamb dishes', 'liver and liver dishes', 'tea, coffee and water' and 'butter'. Mean daily intakes of a number of food groups that changed from the baseline diet across scenarios differed, with mean daily intakes of 2 food groups increasing in scenario 1, 16 food groups increased in 2 and in 3. When nutritional and environmental constraints were applied (scenarios 2 and 3) there is a trend whereby intake of plant based food groups increased and animal based food groups decreased in order to fulfil the constraints.

CONCLUSIONS

A nutritionally adequate and sustainable diet is possible, however, with increasing model constraints it is harder to create diets that are likely to be acceptable. This highlights the importance of balancing sustainability and nutritional adequacy with individual acceptability, highlighting a key area for future research: enhancing the acceptability of healthy and sustainable diets.

REMOVAL OF BEST BEFORE END DATES AND PACKAGING REDUCTION POLICIES - UPTAKE AND IMPACT ON FRUIT AND VEGETABLE OFFERINGS: A UK RETAILER AUDIT

Kathryn Hart[1]; Amy Elsom[1]; Nathan Chan[1]; Charo Hodgkins[1]
[1]Faculty of Health and Medical Sciences, University of Surrey, Guildford, United Kingdom

BACKGROUND AND OBJECTIVES
Household food waste (HHFW) remains a global environmental and socioeconomic problem. In 2022, The Waste and Resources Action Programme (WRAP) published a report recommending the removal of best before dates (BBDs) and plastic packaging from fresh produce to reduce HHFW in the UK (1). However, the extent of adoption by UK retailers, the products included and the potential impact, including unintended consequences, on consumer behaviour, remain unclear. To understand whether these policies had the desired impact on retailers, this study aimed to audit whether BBDs and plastic packaging were being removed as stated in the WRAP guidelines, and to what extent this affected product quality.

METHODS
Data were collected prospectively over two audits at four retailers (representing a range of store types) in Guildford, UK. Four produce types (apples, broccoli, peppers, and tomatoes), chosen to reflect popularity, packaging types and availability, were audited at every retailer. Packaging type and date labelling were recorded and a quality scoring system was developed and applied to enable a visual assessment of each item across four characteristics to be conducted, with higher scores representing worse quality.

RESULTS
445 individual items were assessed over 4 stores. 91% produce had BBDs removed but only 29% were sold without plastic packaging; smaller, lower-budget retailers were less likely to sell loose produce. While peppers with BBDs had significantly higher quality than peppers without ($p=0.005$), there was no significant difference between tomatoes with and without BBD. No significant differences were found in overall quality for any produce type when comparing those with and without plastic packaging, however there was an effect of retailer type for all products except tomatoes. Total Quality Score was highest (representing poorer quality) in the smaller, lower-budget retailers.

CONCLUSIONS
Although BBD removal was successfully implemented by most retailers, no retailer met recommendations to offer at least one loose alternative for each produce (2). Smaller, lower-budget retailers appeared the least compliant with plastic removal but also the most likely to stock lower quality produce, suggesting influences on quality beyond packaging. Minor differences in visual quality were seen when loose and packaged produce were compared, suggesting minimal impact of packaging removal however further research is required to chemically investigate any differences in nutrient content.

A "SUSTAINABLE AND HEALTHY FOOD TOOLKIT" FOR EARLY CHILDHOOD EDUCATION SETTINGS

Alison Spence[1]; Audrey Elford[1]; Margaret Rozman[2]; Kylie Hesketh[1]; Penelope Love[1]
[1]Institute for Physical Activity and Nutrition (IPAN), Deakin University, Geelong, Australia; [2]National Nutrition Foundation, (NNF), Melbourne, Australia

BACKGROUND AND OBJECTIVES
Early Childhood Education and Care (ECEC) settings provide food to a large number of young children. This is a complex task involving all centre staff, as centres are required to provide healthy food within budget, time and skill constraints. Practices promoting environmental sustainability are sub-optimal, for example, one study found an average of 27% (up to 64%) of prepared food was wasted. The objectives of this study were to co-design, and assess the acceptability, feasibility and appropriateness, of a "sustainable and healthy food toolkit", to support ECEC centres to make practical changes to promote sustainability and planetary health, while maintaining standards for promoting child nutrition.

METHODS
A "sustainable and healthy food toolkit" was co-designed with the sector based upon the Food and Agriculture Organization and World Health Organization sustainable healthy diets guiding principles. The toolkit promotes plant-based proteins, vegetables, fruits, wholegrains, locally sourced foods, drinking water/milk, and adequacy without exceeding needs, while discouraging highly processed foods, food packaging and food waste through a suite of co-designed tips and resources. A 3-arm intervention randomly assigned participating ECEC centres in Victoria, Australia, to receive either the toolkit, a food waste audit tool, or both. ECEC educators, directors and cooks participated in pre-and post-intervention surveys, including Weiner et al's implementation outcome measures for acceptability, appropriateness and feasibility of interventions, which were analysed descriptively, and open-ended items to describe practice changes, analysed thematically.

RESULTS
Post-intervention data collection concludes in February 2025. Of 44 centres recruited, 28 completed the intervention by December 2024. Sixteen received the toolkit (10 completed), 13 received the audit (11 completed; not included in these analyses), and 15 received both (7 completed). Preliminary analyses of respondents that received the toolkit or both (20 staff from 8 centres) shows that 85% agree that the toolkit is acceptable, 80% agree that it is appropriate, and 75% agree that it is feasible. All educator respondents (n=11) reported practice changes such as involving children in serving food portions proportionate to appetite, and discussing food sourcing and food waste with children.

CONCLUSIONS
Preliminary findings suggest acceptability, appropriateness and feasibility of a co-designed toolkit to support sustainable healthy food practices in ECEC, with positive changes in practice. The toolkit can be adapted with country-specific resources.

PRELIMINARY SCOPING OF THE EVIDENCE-BASE ON CARBON EMISSION FACTORS AND FOOD COMPOSITION DATA IN THE UK

Eimear Howard[1, 2]; Carla Arenhart[1]; Karen O'brien[1]; Frankie Douglas[1]; Damian O'kelly[1]; Alicia Nicklin[3]; Laura Bardon[3]; Maria H Traka[3]; Eileen O'brien[2]; Laura B Kirwan[1]
[1]Scientific and Regulatory Affairs, Nutritics, Main Street, Swords, Dublin, K67 FY88, Ireland., Dublin, Ireland; [2]School of Biological Health and Sport Sciences, Technological University Dublin, Grangegorman Lower, Dublin 7, D07 H6K8, Ireland, Dublin, Ireland; [3]Food and Nutrition National Bioscience Research Infrastructure, Quadram Institute, Rosalind Franklin Rd, Norwich NR4 7UQ, United Kingdom., Norwich, United Kingdom

BACKGROUND AND OBJECTIVES

Climate change is a significant health and environmental challenge. Sustainable dietary changes are estimated to reduce global Greenhouse Gas Emissions (GHGe) by up to 32% (1). Food composition databases provide important reference data for clinical practice, industry, nutrition policy and research (2). Linking environmental factors with composition databases is key to advancing research on sustainable and healthy diets and provide an evidence base for the development of Sustainable Food Based Dietary Guidelines (SFBDG)(3), as already developed by countries such as Denmark, Sweden, and Germany (2). The objective of this study is to conduct a preliminary search to assess the current evidence base on emission factors and food composition data, identify sources of information underpinning emission factors, and highlight gaps and limitations in linking nutrition and sustainability data for the UK.

METHODS

Studies with emission factors and food composition data within the UK were reviewed. The search was completed on PubMed on December 6th 2024. Search criteria were defined as follows; (Emission factors OR carbon OR environmental impact OR environmental metrics) AND (Composition database OR Composition data OR Composition dataset) AND (Food OR Recipe) AND UK AND (Life Cycle Assessment OR LCA), for years 2014 to 2024.

RESULTS

Fourteen scientific papers were identified and manually reviewed. Five were excluded (One as a retracted article, three as no emission factors, one as not food related) (Figure 1). Nine scientific publications with carbon emission factors and food composition data are available in the UK, one being a literature review and eight representing original research. The search RESULTS consisted of five studies quantifying LCA in products, two exploring dietary sustainability, and two focusing on food waste and menu-based interventions.

CONCLUSIONS

This preliminary search provides the first step in a systematic evaluation of the research available on food composition data and carbon emission factors in the UK. This search indicates a fragmented body of work, underscoring the need for standardised search criteria and larger scope to fully evaluate the evidence base. Integrating emission factor databases with food composition data is essential in ensuring environmental impact can be considered in industry, healthcare and research. Future research should evaluate additional sources using extended search terms, include multiple sources such as grey literature and non-open access databases, and incorporate additional environmental factors.

FOOD AND NUTRITION SUSTAINABILITY KNOWLEDGE AND DIET AMONG STUDENTS

Sanrika Sahadeo[1]; Ashika Naicker[2]
[1]Food and Nutrition, Durban University of Technology, Durban, South Africa; [2]Food and Nutrition , Durban University of Technology, Durban, South Africa

BACKGROUND AND OBJECTIVES
The current South African food system and emanating consumer food choices have a direct impact on climate change. This study aimed to investigate food and nutrition sustainability knowledge and practices among university students and appraise the diet quality and the impact of diet on the environment through an event to advance consciousness towards food and nutrition sustainability.

METHODS
In this cross-sectional study, awareness, knowledge, and attitudes of food and nutrition sustainability were investigated among 405 registered university students at a university using a validated questionnaire. Diet was recorded using a 24-hour food recall, and diet quality was assessed through the global diet quality score (GDQS). The environmental impact of the diet was assessed using an online environmental food carbon footprint calculator to determine greenhouse gas emissions. Lastly, an event called the SAFBUC was implemented to advance consciousness towards food and nutrition sustainability. Data was analysed using descriptive statistics, chi-square goodness-of-fit-test, one sample t-test and the Mann-Whitney U test.

RESULTS
A notable 54.8% (n=222) of students were unfamiliar with the Sustainable Development Goals (SDGs), and the remaining 45.2% (n=183) heard of it but lacked knowledge. Male participants showed major micronutrient deficiencies, including calcium (74.3%), magnesium (96.7%), vitamin D (92.8%), vitamin K (89.5%), and folate (94.1%). Female participants had similar nutrient inadequacies, particularly in dietary fibre, calcium (94.0%), magnesium (93.1%), vitamin D (93.1%), vitamin K (83.1%), and folate (92.3%).
The global diet quality score (GDQS) indicated that 99% of students were at high risk for nutrient inadequacy and related non-communicable diseases (NCDs). Males had a significantly higher dietary carbon footprint (308,060 CO_2e) compared to females (23,910 CO_2e). In response, the South African Food Boost University Challenge (SAFBUC) was introduced to encourage greater fruit and vegetable consumption. These findings highlight the need for enhanced awareness and dietary improvement among students.

CONCLUSIONS
This study highlights the lack of knowledge and awareness related to food and nutrition sustainability among young university adults. The study underscores the need for targeted educational interventions to bridge the knowledge gap and empower young adults to make informed and sustainable food choices.

EPO2_075

IDENTIFYING NUTRIENT QUALITY METRICS SUITABLE FOR A COMBINED NUTRITIONAL AND ENVIRONMENTAL ASSESSMENT OF GRAIN PRODUCTS: A CASE FROM SWEDEN

Martina Cassarino[1]; Marta Bianchi[2]
[1]Department of Sustainable Food Process, Catholic University of Sacred Heart, Piacenza, Italy; [2]Food and Agriculture, Rise Research Institutes Of Sweden, Gothenburg, Sweden

BACKGROUND AND OBJECTIVES

Grain-based foods are essential for human nutrition, but their nutritional quality can vary greatly. These products generally have a low carbon footprint and may fulfill consumer's interest in environmentally friendly foods. Therefore, the sustainability assessment of grain-based foods should integrate environmental impact and nutritional quality. The aim of this study is to identify suitable nutrient quality metrics and apply them as complementary functional units (FUs) to carbon footprints in grain-based products consumed in Sweden.

METHODS

To identify nutrient quality metrics, a literature search was conducted between 2014-2024 in three databases (Scopus, PubMed and SciFinder). Selected nutrient quality indicators were applied to 378 grain-based products from the Swedish food composition tables [1]. Sweden-representative carbon footprints [2] were matched, and suitable nutrient metrics used as complementary FUs. Ranking of foods according to different nutrient-based FUs will be assessed for alignment with the Nordic nutrition recommendations [3].

RESULTS

RESULTS are preliminary, as the project is still on-going. The literature searched retrieved 1320 articles, of which 19 were included. Nine different nutrient metrics were identified and screened for suitable application as FU to grain-based products in Sweden. The following front-of-package nutrition labelling and other scoring systems were chosen: Carbohydrate Food Quality Score (CFQS)- 5 [4], Nordic Keyhole [5], Nutrient Rich Foods (NRF) 11.3 [6], Nutrient Rich Food Index carb (NR-FIcarb) [7], Nutri-Score [8], Nutri-Score with whole grains [9]. All indicators, except the Nordic Keyhole, could be applied as FU when ranking foods for their carbon footprint. The percentage of products defined as high nutritional quality according to the indicators was as follows: 41.3% for Nutri-Score; 39.9% for NRF 11.3; 30.4% for Nutri-Score with whole grains; 25.9% for CFQS-5; 17,7% for Keyhole.

CONCLUSIONS

Six different nutrient metrics were identified for their suitability to assess grain-based products in Sweden, of which 5 can be used as FU. Among them, Nutri-Score and NRF11.3 showed the highest percentage of products qualified as high nutritional quality. Once completed, the project will provide an indication of the best suited metric to be applied in integrated nutritional and environmental assessments of grain-based foods.

STRATEGIES FOR REDUCING FOOD WASTE: EDUCATIONAL AND CAMPAIGN INTERVENTIONS IN AN APPLIED UNIVERSITY SETTING

Annelies Verspeek[1]; Antien Zuidberg[2]
[1]Design Methods in Food, HAS green academy, 's Hertogenbosch Netherlands, Netherlands; [2]Design Methods in Food, HAS Green Academy, 's-Hertogenbosch, Netherlands

BACKGROUND AND OBJECTIVES

The HAS green academy aims to reduce food waste by half through a systematic approach that combines measurement, education, and intervention. As a first step the amount of food waste in the building was measured, highlighting the reduction potential (70-90 kg of food waste per week, of which 1/3 in food preparation areas, 1/3 waste bins, and 1/3 catering). A three-year "Zero Food Waste Challenge" was introduced, targeting applied universities in the Netherlands focusing on: awareness building, understanding who is contributing (students, staff, catering personnel and guest) and new product development with waste streams. Based on those activities a campaign was launched to reduce food waste in event catering. This research aims to identify whether the campaign was effective by measuring the food waste.

METHODS

A number of qualitative measurements are carried out to determine the % of leftovers. This is done at different types of events such as lunches with a maximum of 20 people and a number of larger events such as a dinner for employees (n=200) and Christmas breakfast (n=300).

RESULTS

RESULTS of food waste measurements across different event types and outcomes of qualitative interviews

CONCLUSIONS

In the presentation we will present whether awareness around food waste has been increased and whether the campaign has led to food waste reduction and what further actions should be implemented. The presentation will detail the effectiveness of the campaign interventions.

CONFLICTS OF INTERESTS

REAL-TIME NUTRITION INTAKE IN INTELLIGENT SELF-SERVICE RESTAURANT

Leo Lepistö[1]; Kati Mokkala[1]; Anu Hopia[1]
[1]Nutrition and Food Research Center, Faculty of Medicine, University of Turku, Turku, Finland

BACKGROUND AND OBJECTIVES

Objective and accurate measurement of dietary intake is a major challenge when investigating nutrient intake. The objective is to present the usability of an intelligent Self-Service Restaurant (SSR), in measuring nutrient intake during lunch. SSR in this study is a multidisciplinary research platform, located in the University campus, with an estimated 600 diners/day.

METHODS

In this study, we evaluated lunch nutrition intake in SSR using data from 157 participants. Nutrient intake data were available from 132 participants (83% female, 18% male; age (mean 40.2, [12.3]). Detailed data were collected via scales and RFID-tagged trays that track food choices and nutrient content. Participants were divided into age groups (AG): AG 1) 8-29 years; AG 2) 30-39 years; AG 3) 40-49 years; AG 4) 50-59 years; and AG 5) 60-70 years.

RESULTS

Significant differences in nutrient intake between vegetarian (VG, n=67) and meat (MT, n=65) main courses were found in: fiber (Median 6 [IQR 5-8]g VG vs. 5 [4-6]g MT, $p<0.001$, Mann-Whitney U test), carbohydrates (52[43-67]g VG vs. 41 [32-57]g MT, $p<0.001$), protein (17 [15-21]g VG vs. 16 [12-21]g MT, $p=0.047$), NaCl (1.5 [0.9-2.3]g VG vs. 1.8 [1.4-2.3]g MT, $p=0.033$) and energy 340 [328-532]kcal VG vs 337 [269-436]kcal MT, $p=0.006$). Further statistically significant differences were detected between the AGs in intake of fat (15 [12-26]g AG 1 (n=29) vs 11 [8-15]g AG 2 (n=42), $p=0.03$; and 10 [7-16]g AG 4 (n=27), $p=0.01$ (Kruskal Wallis and Mann-Whitney test with Bonferroni corrections), and protein (19 [15-27]g AG 1 vs. 14 [11-17]g AG 4, $p=0.01$), carbohydrates (57 [48-83]g AG 1 vs 40 [28-58]g AG 4, $p=0.040$) and energy (443 [354-643]kcal AG 1 vs 310 [246-460]kcal AG 4, $p=0.020$). Gender differences were observed in intake of fat (11 [8-15]g W vs 14 [11-20]g M, $p=0.009$), protein (16 [13-20]g W vs 20 [15-25] g M, $p=0.019$), carbohydrates (45 [35-59]g W vs 57 [45-76] g M, $p=0.01$), NaCl intakes (1.6 [1.1-2.1]g W vs 2.3 [1.6-3.4]g M, $p<0.001$), and energy (372 [296-439]kcal W vs 451 [352-586]kcal M, $p=0.006$).

CONCLUSIONS

Intakes of fiber, protein, carbohydrates and energy were higher while intake of NaCl was lower in VG as compared to MT. Fat, proteins, carbohydrates and energy intake were higher in younger compared to older participants. Measuring nutrient intake in Intelligent SSR, provides accurate information on nutrient intake in real-time in a large scale, which can be utilized e.g., when studying the impact of background and behavioural on dietary choices.

CONFLICTS OF INTERESTS

EPO2_078

CONSUMER PERCEPTION AND NUTRITIONAL EVALUATION OF PLANT-BASED MEAT ALTERNATIVES IN KOREA

Yun-A Lee[1]; Mi-Kyeong Choi[1]
[1]Food and Nutrition, Kongju National University, Yesan, Korea, Republic of

BACKGROUND AND OBJECTIVES
As demand for alternative meats rises worldwide, driven by concerns about climate change, environmental protection, animal welfare, and ethical consumption, more people are choosing plant-based meat alternative products. The purpose of this study was to assess the consumer perceptions and nutritional value of plant-based meat alternatives.

METHODS
This study was conducted in three stages. In the first stage, a survey was conducted to assess consumers' perception of plant-based meat alternatives. In the second stage, the nutrient content of commercial plant-based meat alternatives was examined. In the final stage, the mineral and dietary fiber contents of plant-based meat alternatives was analyzed. A total of 410 adults were surveyed regarding their awareness, experience, consumption, and purchase behavior of plant-based meat alternatives. Nutritional information was gathered from nutrition labels at online stores for 118 plant-based meat alternatives and 65 plant-based instant foods. Additionally, 22 plant-based meat alternatives and 24 meat products were analyzed for mineral content using ICP-MS and for dietary fiber content using the enzymatic-gravimetric method.

RESULTS
The findings indicate that consumers are relatively aware of plant-based meat alternatives, with an average awareness score of 3.8 out of 5. Awareness was significantly higher among individuals who were older, married, had a higher level of education, were more health-conscious. Additionally, participants had a high level of experience and intention to use plant-based meat alternatives. In terms of nutritional comparison, plant-based meat alternatives were found to be lower in energy, fat, saturated fat, trans fat, and cholesterol compared to meat products. However, they had higher sodium content. Regarding minerals, plant-based meat alternatives contained higher levels of calcium, magnesium, iron, copper, manganese, molybdenum, and chromium, but zinc than meat products. Moreover, plant-based meat alternatives were found to have significantly higher dietary fiber content both per serving and per 100 g compared to meat products.

CONCLUSIONS
Overall, while plant-based meat alternatives are higher in sodium and lower in zinc, their nutritional profile is generally better than that of animal-based meats, making them a healthier option in most respects. These findings suggest that consumer awareness of and intention to use plant-based alternatives are high, highlighting the potential for these products to be a viable part of a healthy diet.

MINIMALLY PROCESSED, NOVEL FOOD PROTOTYPES MADE WITH WATERCRESS TO IMPROVE NUTRIENT DENSITY OF DIETS IN FOOD INSECURE POPULATIONS

Sumanto Haldar[1]; Amy Tucker,[2]; Viveka Santharam[2]; Damilola Tomi James,[1]; Tom Amery,[3]; Jeffrey Bray,[2]
[1]Faculty of Health and Social Sciences, Bournemouth university, Bournemouth, United Kingdom; [2]Bournemouth University Business School, Bournemouth university, Bournemouth, United Kingdom; [3]Managing Director, The Watercress Company, Dochester, UK, Dorchester, UK, United Kingdom

BACKGROUND AND OBJECTIVES
Diet-related chronic diseases such as cardiovascular diseases and type 2 diabetes continue to increase globally, including the UK, arising from poor diet quality, with lower intakes of protective foods such as fruit and vegetables and greater intakes of harmful foods, including those made from highly processed refined carbohydrates and saturated fats (1). These chronic diseases affect disproportionately in food insecure populations, who often suffer from 'hidden hunger', having inadequate nutrient quality to maintain optimal health (2). Drivers for this include the inability to purchase fresh produce and a preference to spend limited food budget on energy-dense, convenience foods. Thus, there is an urgent need to provide tasty, affordable, convenient and minimally processed nutrient-dense fruit/vegetable products, to increase consumption of these foods within food insecure populations.

METHODS
Watercress being one of the most nutrient dense of all vegetables (3), we collaborated with The Watercress Company, Dorset, UK to use surplus watercress, often discarded in farms, to convert them into two accessible and popular food prototypes, namely watercress pesto and watercress soup. Using these prototypes, we undertook a consumer survey and sensory evaluation in 60 participants using a mixed-methods approach. Quantitative data were gathered through surveys and opinion cards, combining fixed criteria with open-ended comments for a comprehensive analysis. Participant sampling was carefully designed to ensure a broad age (18-75 years) and gender profile (65% F) and strong representation from food insecure groups.

RESULTS
The study revealed very good or good ratings for both prototypes as taster options for taste (82% Pesto, 73% Soup), texture (82% Pesto, 72% Soup), appearance (both 83%) and overall likings (77% Pesto, 66% Soup). Pesto was preferred by younger individuals, whereas, soup was preferred in older individuals (age ≥50 years). The food prototypes were also tested as part of main meal options and found similar consumer acceptability.

CONCLUSIONS
This proof-of-concept study demonstrated that surplus nutrient-rich agricultural commodities can be converted into minimally processed food prototypes with a favourable consumer and sensory profile. This in turn will decrease food waste in farms (at source), reduce cost of fresh produce and can increase both accessibility and affordability of these foods and thereby improve nutrition and food security in vulnerable populations, who often do not meet their fruit and vegetable intake recommendations.

CONFLICTS OF INTERESTS

FOOD ENVIRONMENT IMPACT ON FOOD CHOICES, FOOD SECURITY AND NUTRITION TRANSITION IN SOUTH AFRICA

Mthokozisi Kwazi Zuma[1]; Vhushavhelo Nedzingahe[2]; Xikombiso Mbheneyane[3]
[1]Research, Agricultural Research Council , Pretoria, South Africa; [2]Human Nutrition, Stellenbosch University, Stellenbosch, South Africa; [3]Division of Human Nutrition, Faculty of Medicine and Health Sciences, Stellenbosch University, Cape Town, South Africa

BACKGROUND AND OBJECTIVES
Food environments are the interface through which people interact with the broader food systems. To determine the effects of food environments on peoples' food choices and food security, it is crucial to understand what people consume and the type of environment around them. This paper investigated the impact the food environment has on food choices, food security and nutrition transition in South Africa.

METHODS
The study reviews the work done by the research chair in food, environment and health in South Africa. The three studies employed an analytical, cross-sectional study, using quantitative techniques across three provinces (Limpopo, Western Cape and Mpumalanga) in South Africa.

RESULTS
In Western Cape province, almost a quarter of the households were food secure. A majority (96.7%) of spaza shops were present in the communities and a total of 88.8% had staple food available. Households that had a medium score (score of 8 to 11) were 44.1% and those with an excellent score (14-17) were 24.4%. Anxiety and uncertainty over food was experienced by 71% of the household participants as they were worried that their households would run out of food in the past month. In Mpumalanga province, only 21.9% of households were food secure. Over two thirds (74.0%) experienced the domain: anxiety and uncertainty over food and less expensive foods was the common coping strategy in 62.3% of households when experiencing food shortages. Over two thirds of the households had a low score (score of 4 to 7) were 68.8% and surprisingly, there weren't any with adequate and excellent dietary intake. The household food environment lacked diversity and most of the households were food insecure. Affordability was an important factor in households when accessing food. In Limpopo (Nedzingahe et al 2023), almost half of the households (48.4%) had a low dietary diversity Score. The study further revealed that 46.0% of households were food secure. The study revealed that 45.2% of households faced anxiety and uncertainty over food, having had worried about the availability of food in the household, and 46.0% had insufficient food intake in the preceding month.

CONCLUSIONS
The studies highlighted that food environment influences food choices, food security and nutrition transition. The reasons for the persistence of hunger and malnutrition in South Africa are complex and interrelated, spanning environmental, health, economic, socio-political and agro-food issues.

FROM THE MARKET TO THE BIN: INFLUENCE OF EMOTIONS AND GENDER ON FOOD WASTE PRACTICES

Paula Hernandez Hirsch[1]
[1]PhD Student, Freie Universität Berlin, Berlin, Germany

BACKGROUND AND OBJECTIVES
Around one-third of the world's food production is lost or wasted annually (FAO, 2011, UNEP, 2024). This issue has profound environmental implications and is directly related to food insecurity, as resources and nutrients are squandered while millions face hunger and malnutrition. Despite extensive data on the volume of food waste, the cultural and behavioral factors that underlie the transition of food from "edible" to "inedible" remain underexplored. This study investigates the cultural dimensions of food waste in households.

METHODS
Using ethnographic methods, data were collected through in-depth interviews and participant observation with eight middle-class Chilean migrant households in Berlin. The study employed a Grounded Theory approach to explore the meanings and behaviors associated with food management and waste practices.

RESULTS
Women in these households were typically the "food gatekeepers," responsible for food-related tasks and expressing strong emotional responses to waste (Russell et al., 2017). Nutritional discourse created tension between two key imperatives: the desire to avoid waste and the pressure to maintain balanced diets. These conflicts revealed complex, culturally influenced decision-making processes that mediate the transition of food from "edible" to "inedible."

CONCLUSIONS
This research highlights the central role of cultural and emotional factors in shaping food waste behaviors. By understanding how gender roles and cultural norms influence food waste practices, the study provides a framework for further research on sustainable dietary behaviors. These findings underscore the importance of integrating socio-cultural dimensions into nutritional science to address nutrition guidelines and food waste cohesively and effectively.

ASSOCIATION BETWEEN WATER INSECURITY AND FOOD INSECURITY IN PANAMA: IMPLICATIONS FOR PUBLIC POLICY AND VULNERABLE POPULATION

Jael Alfonso,[1]; Karla Santos[2]; Alex Brito,[3]; Iliana Nunez,[2]; Israel Rios Castillo[4]
[1]Food Security, Universidad Espec, Panama City, Panama; [2]Nutrition, FAO, Panama City, Panama; [3]Nutrition, San Seb, Concepción, Chile; [4]Salud, FAO, Panama City, Panama

BACKGROUND AND OBJECTIVES
Food insecurity is a well-documented social phenomenon; however, its relationship with water insecurity in Panama remains understudied. This research aims to determine the association between water insecurity and food insecurity in Panama.

METHODS
An observational, analytical study was conducted using a cross-sectional survey administered from January to March 2024. An online questionnaire was used to collect sociodemographic data (e.g., sex, age, income, employment status), as well as information on food and water security. Food insecurity was assessed using the FAO's Food Insecurity Experience Scale (FIES), estimating probabilities of moderate to severe, and severe food insecurity through the RASH method. Water insecurity was measured using the Household Water Insecurity Experiences (HWISE) scale. Linear regression and multiple logistic regression were applied to determine associations between food insecurity and water insecurity, adjusting for sociodemographic variables.

RESULTS
A total of 222 participants, aged 18 to 78 years, were evaluated; 66% were female, 86% resided in urban areas, 83.3% had a high educational level (higher education), and 53.6% reported monthly incomes of USD 1,000 or more. The mean prevalence and margin of error for moderate to severe food insecurity were 29.7% (±8.1), while severe food insecurity alone was 6.1% (±4.3). Additionally, 27% of households were classified as experiencing water insecurity. Moderate to severe food insecurity was associated with water insecurity (β=19%; 95% CI: 8%–31%) and with economic income (no income vs. USD 1,000+/month: β=25%; 95% CI: 5%–44%; USD 501–1,000: β=11%; 95% CI: 1%–22%). Water insecurity was linked to the probability of moderate to severe food insecurity (OR=5.58; 95% CI: 2.53–13.22), lack of access to potable water (OR=4.58; 95% CI: 1.21–17.38), and the number of household members (OR=0.33; 95% CI: 0.15–0.72).

CONCLUSIONS
High prevalence of food and water insecurity was observed, both strongly associated with sociodemographic variables. Comprehensive public policies addressing structural determinants of food and water insecurity are urgently needed, particularly to support the most vulnerable populations.

INTEGRATING BIODIVERSITY, CLIMATE CHANGE, AND NUTRITION: PATHWAYS TO SUSTAINABLE HEALTHY DIETS AND FOOD SECURITY

Israel Rios Castillo[1]; Alex Brito,[2]; Karla Santos[3]; Leslie Landaeta-Díaz[4]
[1]Salud, FAO, Panama City, Panama; [2]Nutrition, San Seb, Concepción, Chile; [3]Nutrition, FAO, Panama City, Panama; [4]Núcleo de Investigación en Nutrición y Ciencias Alimentarias, University of the Americas, Providencia, Chile

BACKGROUND AND OBJECTIVES
The interrelationship between biodiversity, climate change, and nutrition presents complex challenges for achieving sustainable healthy diets and long-term food security. Current dietary patterns, characterized by high consumption of highly processed foods and beverages derived from a limited number of commodities, negatively impact the environment through greenhouse gas emissions, excessive water and land use, and biodiversity loss. This review aims to explore the nexus between biodiversity, climate, and nutrition, emphasizing strategies for sustainable healthy diets and identifying critical research and policy gaps.

METHODS
This narrative review synthesizes existing literature and reports to examine the interconnectedness of biodiversity, climate change, and nutrition. It highlights the environmental impacts of current dietary patterns and discusses strategies and interventions that support sustainable healthy diets. The review also identifies gaps in research and policy integration needed to address these global challenges.

RESULTS
Sustainable healthy diets, defined by diverse intake of unprocessed or minimally processed foods, balanced across food groups, and restricted consumption of highly processed products, can reduce the environmental footprint of agrifood systems. Promoting biodiversity through neglected and underutilized species, valorizing food by-products, and adopting climate-resilient agricultural practices enhances nutrition and builds climate resilience. Strategies include public education, government policies, economic incentives, technological innovations, and food system-based dietary guidelines. Front-of-pack nutritional warning labels guide consumers toward healthier choices. Working with parliamentarians to strengthen food security legislation is crucial for enabling sustainable diets. Robust data collection and analysis are essential for monitoring progress, evaluating policies, and guiding evidence-based interventions. Nutrition education empowers communities to make informed choices aligned with health and sustainability goals. However, critical gaps remain, including integrating biodiversity data into decision-making, assessing trade impacts on local systems, and fostering multidisciplinary research to address these challenges.

CONCLUSIONS
The nexus between biodiversity, climate change, and nutrition underscores the central role of food systems in supporting ecosystem functions, providing nutritious options, and mitigating climate change.

COMPLEXITIES OF THE AGRICULTURAL VALUE NETWORK COULD LIMIT SYSTEM CHANGES TO REDUCE GREENHOUSE GAS EMISSIONS

Benjamin Mccormick,[1]; Nicholas Roxburgh[2]; Licida Giuliani[3]; Gary Polhill[2]; Jennie Macdairmid[1]
[1]The Rowett Institute, University of Aberdeen, Aberdeen, United Kingdom; [2]Information and Computational Sciences, The James Hutton Institute, Aberdeen, United Kingdom; [3]School of Biological Sciences, University of Aberdeen, Aberdeen, United Kingdom

BACKGROUND AND OBJECTIVES

Food producers are increasingly asked to adapt their behaviours to reduce their environmental impacts, since the food system is a major driver of greenhouse gas emissions and biodiversity loss. However, farms are constrained by the realities of running a business and by their place within the wider food system. The objectives were first to examine the likelihood and magnitude of transitions between farm enterprise types, and then to explore the potential for change given the shared resources between different farm activities.

METHODS

We analysed Scottish agricultural census data (2012-2020) to determine how often farms change, and the type of change between EU economic classes, e.g., changing from sheep to beef, or from dairy to horticulture. We analysed the inputs and outputs of the main farming activities (e.g., machinery and land requirements, fertiliser or feed as inputs and grain or livestock as outputs) as a network to determine how similar different enterprises are in terms of shared resources as a proxy for how difficult it would be to adapt from one to another. Finally, we compare the classification of farms by their current activities, defined by economic stratification into 46 categories, versus their potential to adapt given their current resources.

RESULTS

Farms are unlikely (probability < 0.01) to change their economic classification between years. Farms were most likely to stay the same (mean probability = 0.59), but this varies by farm type. Changes were typically modest, moving between activities that shared most resources, for example sheep and cattle to specialist sheep or specialist indoor vegetables to mixed indoor specialist. The farming system is highly interconnected through resources, with land and labour the most connected resources, but organic excreta the most central, linking arable and livestock activities.

CONCLUSIONS

Together with biophysical constraints in Scotland, these RESULTS demonstrate the practical and financial challenges for farms to make the significant changes needed to lower emission activities. Furthermore, the farming network is highly sensitive to the continued availability of resources and would necessitate alternative sources or substitutes if some (e.g., organic manures) were removed.

SEAFOOD SUPPLY MAPPING REVEALS PRODUCTION AND CONSUMPTION MISMATCHES AND LARGE DIETARY NUTRIENT LOSSES THROUGH EXPORTS IN THE UNITED KINGDOM

Anneli Löfstedt[1]; Bernhard Scheliga,[2]; Magaly Aceves-Martins[1]; Baukje De Roos[1]
[1]The Rowett Institute, University of Aberdeen, Aberdeen, United Kingdom; [2]Digital Research Services, University of Aberdeen, Aberdeen, United Kingdom

BACKGROUND AND OBJECTIVES
Transforming our diets to build a more healthy and sustainable food system is paramount to improving public health and achieving net zero. Arguably, such diets will include more seafood. For the first time, we provide a high-resolution perspective on United Kingdom (UK) seafood supplies and nutrient flows, by species and sector, as a case study for high-income countries worldwide that have a high reliance on trade to keep fisheries and aquaculture profitable, but also to meet consumer demand and preferences.

METHODS
We mapped seafood production (capture and aquaculture data), trade (imports and exports), purchases (within and out-of-home), and seafood consumption (national diet survey), between 2009 and 2020.

RESULTS
Overall, the UK is a net importer of seafood. UK dietary recommendations for finfish consumption were not achieved by domestic production nor national supplies. Mapping dietary nutrient flows revealed that through imports of prawns, cod, and haddock, the UK experiences net gains in selenium and iodine, although the contribution towards the RNI of these nutrients is relatively small. The UK undergoes significant losses of omega-3 fatty acids, vitamins B12 and D, that could potentially contribute 73%, 46%, and 7% towards UK recommended nutrient intakes, respectively, through exports of oily fish such as salmon, herring, and mackerel.

CONCLUSIONS
We highlight the potential opportunities to reshape our seafood supply chains, by proposing increased consumption of locally caught species, such as herring, and mackerel, that optimise nutrient intake, whilst at the same time considering ways to reduce climate emissions and reduce pressures on aquatic stocks from nutritionally vulnerable nations. Understanding how national seafood consumption relates to food supply chains and global trade is essential to help develop both fisheries as well as public health policies that promote the consumption of locally produced species.

CAPABILITY, OPPORTUNITIES AND MOTIVATION TO REDUCE MEAT CONSUMPTION AND PERCEIVED EFFECTIVENESS OF POLICY INTERVENTION TO REDUCE MEAT CONSUMPTION

David Mcbey[1]; Graciela Martinez Sanchez[2]; Graham Horgan[2]; Jennie Macdairmid[1]; Benjamin Mccormick,[1]
[1]The Rowett Institute, University of Aberdeen, Aberdeen, United Kingdom; [2]Human Health and Nutrition, BioSS, Aberdeen, United Kingdom

BACKGROUND AND OBJECTIVES
Transitioning to sustainable diets is crucial if climate targets are to be met, which means reducing consumption of animal-based foods. However, population-level dietary changes are notoriously difficult, and eating less meat is particularly unpopular. The objectives were (i) to explore people's motivation, capability and opportunities to reduce meat and (ii) to determine what are viewed as effective policy interventions.

METHODS
A nationally representative population of adults living in Scotland completed an on-line survey (n=1590) to assess current patterns of current and future meat consumption based on Capability, Opportunities and Motivation (COM-B model of behaviour change). Latent Class Analysis (LCA) was used to identify different subpopulations of participants based on their responses to the COM-B statements. Participants ranked from best to worst their view of the effectiveness of different interventions aimed at reducing meat consumption.

RESULTS
Sixty one percent of participants reported being willing or currently reducing their meat consumption. The LCA revealed four subgroups; Resistant (14%), Ambivalent (25%), Open (45%) and Actively seeking to reduce meat (16%). The Open class were moderately motivated to change and reported some opportunities and capability but felt economically constrained. Interventions to reduce the price and improve tastiness of non-meat alternatives were viewed as most effective, while those aimed at raising awareness (e.g. media and other communication) least effective. Perceived effectiveness of different policies was very similar across all LCA subgroups.

CONCLUSIONS
Policies interventions targeting pricing of plant-based alternatives and tastiness, rather than only on education, are likely to be more effective.

PROGRESS, BUT NOT FAST ENOUGH: A DECADE OF CHANGES IN ATTITUDES OF ADULTS AND YOUNG PEOPLE TOWARD SUSTAINABLE DIETS

David Mcbey[1]; Emily Cleland[2]; Jennie Macdairmid[1]; Benjamin Mccormick,[3]; Lucy Rothenberg[1]; Heather Morgan[2]
[1]The Rowett Institute, University of Aberdeen, Aberdeen, United Kingdom; [2]Applied Health Sciences, University of Aberdeen, Aberdeen, United Kingdom; [3]The Rowett Institute, The Rowett Institute, Aberdeen, United Kingdom

BACKGROUND AND OBJECTIVES
It is important to understand if and how attitudes and willingness to change diets have moved on in the past decade to gauge the action needed today. More information is available to the general population about dietary changes required to achieve targets to reduce greenhouse gas emissions, in particular reducing consumption of meat, however changes in how this information is received are needed. The objective of the study was to revisit populations within the same geographic regions after 10 years to observe any changes in knowledge, attitudes towards the impact of diets on climate change, and willingness to modify diets.

METHODS
Focus groups were used to provide an in-depth understanding of views and knowledge of the contribution of diets to climate change and willingness to take action. The focus groups were conducted in 2013 and then again 2023 with different groups of people but within the same geographic areas and age groups, with a similar range of socio-economic situations. Focus groups were conducted with adults (> 18 years) and young people in secondary school (11-18 years) separately. Thematic analysis was used to identify themes around how the food system was perceived to contribute to climate change, willingness to reduce meat consumption and confidence in the information received.

RESULTS
In general, over the decade, knowledge about the association between meat consumption and climate change increased, with a greater awareness of the association than in 2013. People today were more receptive to the concept of reducing meat, albeit this was not the case for all participants. Scepticism surrounding information about the association between food and climate remained, including that from scientists and media. A theme of agency emerged around the relative merits of an individuals' actions to make a difference and how this impacts willingness to do so. Other persisting beliefs included other actions, such as reducing packaging and food miles by choosing local food, that were deemed more important than dietary changes.

CONCLUSIONS
The study shows that knowledge has increased over the past decade with more media exposure to the science being published, but that this information is not always trusted. While progress is being made in changing attitudes towards reducing meat consumption, the pace of change and resultant action needs to accelerate to make the impact required to limit climate change.

ECONOMIC AND ENVIRONMENTAL IMPACTS OF COMMERCIAL MILK FORMULA IN INDONESIA: ESTIMATES USING THE MOTHERS MILK TOOL AND GREEN FEEDING TOOL

Nabila Nur Septiani[1]; Andini Pramono[2]; Roger Mathisen[3]; Tuan Thanh Nguyen[3]; Julie Smith[4]
[1]IPB, IPB University, Bogor, Indonesia; [2]Department of Applied Epidemiology, The Australian National University, Canberra, Australia; [3]Alive & Thrive East Asia Pacific, Alive & Thrive East Asia Pacific, Hanoi, Vietnam; [4]National Centre for Epidemiology and Population Health, The Australian National University, Canberra, Australia

BACKGROUND AND OBJECTIVES
The health importance of breastfeeding for infants, young children and their mothers is increasingly acknowledged but the economic and environmental impact of suboptimal breastfeeding is less recognised. Breastfeeding has been declining, and sales of commercial milk formula (CMF) are rising rapidly in East Asia Pacific Region, including Indonesia. This study aims to analyse the economic and environmental impacts of CMF marketed for infants 0-6 months in Indonesia

METHODS
We assessed economic and environmental impacts of CMF in Indonesia using the Mothers Milk Tool (MMT) and the Green Feeding Tool (GFT). These tools estimate countries' production of human milk, and carbon and water footprints using UNICEF datasets on births and infant and young child feeding practices, and key assumptions about infants' daily milk intake, and carbon and water footprints of CMF.

RESULTS
The MMT analysis reveals a substantial economic loss from CMF displacing breastmilk in Indonesia: at least 62.42 million liters of breastmilk were lost in 2020 due to introduction of CMF among infants aged 0-6 months. The monetary value of breastmilk is US$45.5 billion annually. Also in 2020, 27,200 tonnes of CMF were sold in Indonesia and loss of economic value was US$6.2 billion. The GFT estimated a carbon footprint of 213.80-272.10 million kg of CO2 and a water footprint of 92,460 million liters

CONCLUSIONS
Current breastfeeding practices in Indonesia are associated with substantial economic production loss, as well as carbon and water footprints. For informed policy-making, we recommend including breastmilk in national food balance sheets to facilitate its inclusion in GDP, and strengthening advocacy for breastfeeding as a measure to improve the environment

DIETARY-RELATED EXPOSURE ASSESSMENTS IN THE EUROPEAN PROSPECTIVE INVESTIGATION INTO CANCER AND NUTRITION (EPIC) COHORT: AN INTEGRATED MULTI-TIERED APPROACH USING THE FOODEX CLASSIFICATION SYSTEM

Inge Huybrechts[1]; Genevieve Nicolas[1]; Inarie Jacobs[1]; Guri Skeie[2]; Marc Gunter[3]; Sofia Ioannidou[4]
[1]Nutrition and metabolism branch, IARC - International Agency for Research on Cancer, Lyon, France; [2]Department of Community Medicine, UiT The Arctic University of Norway, Tromso, Norway; [3]School of Public Health - Faculty of Medicine, Imperial College London, London, United Kingdom; [4]Integrated Data (iDATA) Unit, European Food Safety Authority (EFSA), Parma, Italy

BACKGROUND AND OBJECTIVES
Large-scale cohorts such as the European Prospective Investigation into Cancer and Nutrition (EPIC) (n~500,000) are invaluable for investigating health effects of dietary-related exposures such as food contaminants and additives. Dietary questionnaire intake data can be matched with food occurrence data to estimate individual dietary-related exposures. To provide a common link to the diverse food databases used by different European countries, EFSA has developed the FoodEx food classification system that standardises the identification and characterisation of foods and that is used in the EFSA chemical monitoring and food consumption database. We aimed to develop an integrated approach for calculating new dietary-related indicators such as food contaminants, additives and environmental food production indicators (e.g. greenhouse gas emissions) in EPIC.

METHODS
Stepwise procedures were used to facilitate matching of novel food occurrence data classified via the FoodEx classification system. Initially, the simplified EPIC food list which assembles the dietary questionnaire items (~12000 different foods reported) were categorised according to FoodEx. Thereafter, food occurrence data from the EFSA occurrence databases could efficiently be matched with the EPIC dietary intake data via their FoodEx coding. Finally, individual-level dietary exposures could be computed by multiplying EPIC individual dietary intakes (in g/day) with the food occurrence data (in μg/kg food) matched with the EPIC food list items.

RESULTS
The end-user EPIC dietary exposure databases can be used to investigate associations between dietary exposures (e.g. contaminants, additives) and health risks (e.g. cancer risk, mortality, etc.). To consider uncertainties in food occurrence data, three different scenarios were calculated, namely a lower, middle bound and upper bound approach. RESULTS for cadmium exposures are used as an example to describe the different procedures and computations involved in these exposure calculations.

CONCLUSIONS
This work facilitates the further matching of diet-related indicators such as food contaminants and additives, but also planetary health indicators related to our food consumption data that were coded via the EFSA FoodEx classification. A detailed description of the procedures used in EPIC and the problems encountered can be of interest for future projects aiming to link their food consumption data with the FoodEx classification system.

THE BURDEN OF NON-COMMUNICABLE DISEASES ATTRIBUTABLE TO DIETARY RISKS IN CHINA AND ITS PROVINCES, 1990-2021: AN ANALYSIS OF GLOBAL BURDEN OF DISEASE STUDY 2021

Aidong Liu[1]
[1]Nutrition, National Institute for Nutrition and Health, Chinese Center for Disease Control and Prevention, Beijing, China

BACKGROUND AND OBJECTIVES
Diet-related non-communicable diseases (NCDs) are significant contributors to global morbidity and mortality, including in China. However, the impact of dietary risk factors on the burden of NCDs has not been systematically evaluated in China and its provinces. This study aims to analyze the temporal trends and geographic variations in diet-related NCDs in China from 1990 to 2021.

METHODS
Utilizing a comparative risk assessment methodology, we estimated the proportion of disease-specific burden attributable to each dietary risk factor among adults aged 25 years and above. The primary inputs for this analysis encompassed the intake level of each dietary factor, the magnitude of the effect of the dietary factor on the disease endpoint, and the intake level associated with the lowest mortality risk. Subsequently, by employing disease-specific population attributable fractions, mortality data, and disability-adjusted life-years (DALYs), we computed the number of deaths and DALYs attributable to diet for each disease outcome.

RESULTS
In 2021, NCDs attributable to dietary risks in China led to 1,703,174 (95% UI: 687,641 - 2,683,260) deaths and 38,364,150 (95% UI: 16,198,391 - 58,567,281) DALYs. From 1990 to 2021, the age-standardized mortality and DALY rates decreased by 40.51% and 41.94%, respectively. The burden of cardiovascular diseases was the heaviest, and high sodium intake was the primary dietary risk factor. In some provinces such as Tibet, Heilongjiang, and Qinghai, the age-standardized mortality and DALY rates attributable to dietary risk factors were relatively high. In terms of different dietary factors, the burdens of high sodium and low fruit intakes remained relatively heavy, the burden of low vegetable intake decreased significantly, and the burdens of low polyunsaturated fatty acid and high red meat intakes increased in many provinces. From 1990 to 2021, the burden of diet-attributable chronic diseases in China was higher in men than in women, and the same was true for disease types such as cardiovascular diseases, tumors, diabetes, and chronic kidney diseases. The burden of diet-attributable NCDs was positively correlated with age, and the burden was the heaviest in the group of 70+ years.

CONCLUSIONS
The study underscores the pivotal role of dietary factors in driving NCD burdens in China, despite overall reductions in disease rates. Continued efforts are needed to mitigate dietary risks, particularly in regions where the burden remains high.

CAN INCREASING LOCAL FOODS IMPROVE THE SUSTAINABILITY OF SCHOOL MEALS? A MULTI-OBJECTIVE OPTIMIZATION STUDY IN GUADELOUPE, FRANCE

Marlène Perignon[1]; Pascaline Rollet[1]; Marine Peccatus[2, 3]; Maria Somaraki[1]; Jean-Louis Diman[2, 3]; Caroline Méjean[1]; Sophie Drogué[1]
[1]MoISA, Univ Montpellier, CIHEAM-IAMM, CIRAD, INRAE, Institut Agro, IRD, Montpellier, France; [2]UE PEYI, INRAE Centre Antilles-Guyane, Petit Bourg, France; [3]ARECA, ARECA, Baie-Mahault, France

BACKGROUND AND OBJECTIVES
Guadeloupe, a French overseas region, faces rising rates of obesity and diet-related chronic diseases, with prevalence higher than in mainland France. School meals are a lever to promote healthy and sustainable diets and reduce health inequalities. The supply of foods locally produced in French overseas regions is encouraged by legislation to improve the sustainability of school catering. The objective was to assess whether increasing local products in school meals could be a lever for improving different dimensions of sustainability (nutrition, environment, cost), and to identify which local foods should be favored.

METHODS
Data on 47 series of 20 meals served in primary schools were collected from 27 school catering structures in Guadeloupe: meal components, dish ingredients, food price and source of supply. The nutritional quality and environmental impacts of the series of meals were respectively assessed by the mean adequacy ratio (MAR) expressed as a percentage of the daily recommendations in ‘positive’ nutrients, and greenhouse gas emissions (GHGE), water use, land use and a weighted score of 14 environmental metrics (single score). Optimized series of 20 meals were developed using mathematical optimization and compared to the observed series (baseline). The optimized series maximized the share of local products, complied with the French mandatory nutritional guidelines for school meals, and met two scenarios: i) no increase in cost and environmental impacts compared to observed levels (MAXLOCAL scenario), and ii) 30% reduction in cost and GHGE (MAXLOCAL-RED scenario)).

RESULTS
In MAXLOCAL, the proportion of local products was 77% (vs. 36% at baseline), MAR was improved (91% vs. 85% at baseline), GHGE and the single score were reduced by 14%, and land use by 30%. Cost and water use remained at baseline levels, and menu diversity was maintained (45 different foods in the series vs. 46 at baseline). Locally produced foods with the largest increases were identified across food categories: carrot and zucchini, pineapple and grapefruit, dry beans and yams, chicken. In MAXLOCAL-RED, the share of local products was 66%, MAR was 91%, the single score was reduced by 29%, water use by 20% and land use by 41%, but menu diversity was reduced (39 different foods).

CONCLUSIONS
This study identified school menus with increased amount of local foods, improved nutritional quality, and reduced environmental impacts at no additional cost or loss of menu diversity. Future research should test the implementation of these optimized menus in Guadeloupe schools to assess feasibility by school catering managers and acceptability by children.

REPLACING ANIMAL MEAT WITH PLANT-BASED MEAT ALTERNATIVES: THE IMPACT OF PROTEIN QUALITY ON PROTEIN ADEQUACY IN THE DUTCH DIET

Anne Wanders[1]; Samantha N. Heerschop[2]; Sander Biesbroek[2]; Mariska Dötsch-Klerk[1]
[1]Nutrition and Health, Unilever Foods Innovation Centre - Hive, Wageningen, Netherlands; [2]Division of Human Nutrition and Health, Wageningen University & Research, Wageningen, Netherlands

BACKGROUND AND OBJECTIVES
A shift to more plant-based consumption patterns may lower the protein adequacy of diets. The objective of this study was to model the impact of replacing animal meat with plant-based meat alternatives on protein intake and adequacy while taking into account protein quality, in the context of the average Dutch diet.

METHODS
Habitual total and utilizable protein intakes were calculated from meal-based food consumption data from 1633 participants from 18 to 70 years of the Dutch National Food Consumption Survey 2012-2016. Utilizable protein intake was calculated as the sum of protein intake per meal adjusted for Protein Digestibility-Corrected Amino Acid Score (PDCAAS) and compared to the Estimated Average Requirement for Dutch adults to calculate the percentage of the population with an adequate protein intake. In the modelling scenarios all animal meat was replaced gram-for-gram by meat alternatives from various protein sources currently available on the Dutch market.

RESULTS
Replacing all meat with meat alternatives decreased the intake of animal protein from 59 to 36%, total protein intake from 1.14 to 1.09 g/kg/day, utilizable protein intake from 0.94 to 0.86 g/kg/day, and protein adequacy from 93 to 86%. Additional scenarios indicated that the protein adequacy was mostly impacted by total protein content, lysine content, and protein digestibility of the meat alternatives.

CONCLUSIONS
This modelling study indicated that when all animal meat was replaced by plant-based meats, total and utilizable protein intake remained adequate for the majority (86%) of the Dutch adult population. People who get most of their protein from plant-sources should ensure a sufficient total protein intake from a variety of sources.

CONFLICTS OF INTERESTS
AW and MD are employees of Unilever, a company that produces and markets foods and beverages including plant-based meat alternatives. The other authors report no conflict of interest.

EPO2_097

COMPARING THE NUTRIENT COMPOSITION OF PLANT-BASED MEAT WITH ANIMAL MEAT AND LEGUMES: A REVIEW OF ANALYTICAL DATA ON 45 NUTRIENTS

Tessa De Bie[1]; Ans Eilander[1]; Anne Wanders[1]
[1]Nutrition and Health, Unilever Foods Innovation Centre - Hive, Wageningen, Netherlands

BACKGROUND AND OBJECTIVES
To date, publications on the nutritional quality of plant-based meat mostly focus on a limited range of nutrients derived from on-pack nutrition labels. We aimed to systematically review analytical data on the nutrient composition of plant-based meat and compare it with animal meat and legumes.

METHODS
Data sources were selected based on the availability of original and validated analytical data on plant-based meats. Nutrient levels were compared with animal meat and legumes, benchmarked against nutrient requirements (e.g. 15% of nutrient reference values), and nutrient density calculations were done based on 15 nutrients to encourage and 3 nutrients to limit.

RESULTS
Although plant-based meats can have distinct nutrient levels depending on the protein source, as compared to animal meat unfortified plant-based meat is similarly high in protein, lower in energy and saturated fat and higher in sugar, carbohydrates and fiber. When benchmarked against nutrient requirements, plant-based meat can be a source of alpha-linolenic acid, vitamins B1, B2, B3, folate, E, K, calcium, magnesium, manganese, copper, iron, potassium, phosphorus, selenium and zinc. However, unlike plant-based meat, animal meat can be a source of vitamins B5, B6, B12 and D. Compared to legumes, plant-based meat can contain more protein, energy, fat and sodium and similar or higher amounts of vitamins and minerals. Nutrient density was comparable between plant-based meat, animal meat and legumes.

CONCLUSIONS
Unfortified plant-based meats that are currently available on the market can offer unique types and quantities of essential nutrients, resulting in a similar nutrient density compared with animal meat and legumes. Whether plant-based meat should be fortified with micronutrients that animal meat specifically provides depends on the consumption pattern and needs further investigation. When product reformulation efforts to minimize nutrients to limit continue, plant-based meat fits in a healthy diet.

CONFLICTS OF INTERESTS
All authors are employees of Unilever, a company that produces and markets foods and beverages including plant-based meat alternatives.

ENHANCING ACCESS TO NATIVE FOODS IN FIJI FOR BETTER NUTRITION THROUGH COMMUNITY MAPPING

Rupantri Raju[1]
[1]Biology, The University of the South Pacific, Suva, Fiji

BACKGROUND AND OBJECTIVES

Traditional subsistence farming systems in Fiji have been replaced by intensive farming of root crops, sugarcane, and kava for the export markets. The monoculture of these export commodities has affected the production and supply of native crops that are highly nutritious and resilient to the impacts of climate change. As a result of this limited access to native foods, such as yams, island cabbage (bele), plantains, and tree ferns, there is a high dependence on imported foods, such as rice, tinned meat, and instant noodles. The new diet, which consists of highly processed food, has caused an increase in non-communicable diseases, such as diabetes and obesity, among the Fijian population. Traditional farming systems produce a diverse range of native crops that are resilient and highly nutritious. The objective of this paper is to present the findings from community mapping as a tool for better access to native food around Fiji.

METHODS

A literature review of the nutritional data and the Pacific food composition was conducted using desktop analysis. A seven-day healthy food basket (HFB) consisting of only native foods for three household types (low-income, middle-income, and high-income) was developed through focus groups with local residents in each of the communities in the central and western parts of Fiji. The native foods identified in the food basket were collected from the central and western markets of Fiji using a purposive sampling technique. The food samples were categorized based on the different food groups.

RESULTS

Some varieties of native food were available in the local markets in each of the areas, but it did not complete the food basket consisting of only native foods. There were nutritious varieties of new crops available in the markets, but these were expensive for low-income households. The Ministry of Agriculture distributed the new varieties of crops as resilient crops for farmers. Seasonal variation and extreme weather events were some factors that affected the availability of some of these new crops in some areas. Native foods were limited in supply because of the shift in land use.

CONCLUSIONS

This paper presents the nutritional implications of the shortage of native food. The information gathered in this study can be useful for the Ministry of Agriculture and the National Food and Nutrition Center to understand the gaps and accessibility to nutritious native foods. The purchasing power of different households is also a factor that needs to be considered.

FOOD BIODIVERSITY AND ITS ASSOCIATION WITH DIET QUALITY AND HEALTH OUTCOMES - A SCOPING REVIEW

Jinke Baan Hofman[1]; Celia Bannenberg[2]; Mariska Dötsch-Klerk[1]; Anne Wanders[1]; Corné van Dooren[3, 2]; Baukje De Roos[4]; Edith Feskens[2]; Sander Biesbroek[2]
[1]Nutrition and Health, Unilever Foods Innovation Centre - Hive, Wageningen, Netherlands; [2]Division of Human Nutrition and Health, Wageningen University & Research, Wageningen, Netherlands; [3]WWF-NL, 3708 JB, Zeist, Netherlands; [4]The Rowett Institute, University of Aberdeen, Aberdeen, United Kingdom

BACKGROUND AND OBJECTIVES
Food biodiversity is receiving increased scientific attention, due to the global food system being a major contributor to biodiversity loss. The FAO suggests that food biodiversity, defined as the diversity of plants, animals and other organisms used for food, may benefit both human and planetary health. Despite this potential, there is a lack of comprehensive understanding regarding the association of food biodiversity with healthy diets. This scoping review aims to present an overview of available data relating food biodiversity to diet quality and health outcomes.

METHODS
Three search strategies were performed in Scopus and PubMed to identify articles on food biodiversity related to 1) diet quality, 2) health outcomes and 3) environmental impact indicators.

RESULTS
Six studies were identified describing the association between food biodiversity and diet quality, of which one also evaluated health outcomes. Two additional studies were identified assessing food biodiversity and health outcomes. No studies were identified describing the association between food biodiversity and environmental impact. Four studies on diet quality quantified food biodiversity using Dietary Species Richness (DSR), one study used Nutritional Functional Diversity (NFD), and one study used both. All studies showed significant positive associations between food biodiversity and nutritional adequacy. However, the use of different metrics and methodologies hampers direct comparison of outcomes between studies and inference of implications. Two studies assessing food biodiversity and health outcomes -in a large EU cohort- showed a 10 to 20% reduced risk of total and cause-specific mortality and a 5% reduced risk of gastrointestinal cancers per 10-species DSR increment. Lastly, one study reported an inverse association between DSR and body fat percentage.

CONCLUSIONS
Although a limited number of studies was available, they consistently describe positive associations between food biodiversity and diet quality, and inverse associations with some health risks. Further research is needed to support and unravel the mechanism behind the association between food biodiversity and diet quality and health outcomes, and to explore how food biodiversity is associated with environmental impact.

ESTIMATING THE SUPPLY OF NUTRIENTS FROM AGRICULTURAL COMMODITIES IN CLIMATE CHANGE SCENARIOS

Benjamin Mccormick,[1]; Mike Rivington[2]; Jennie Macdairmid[1]
[1]The Rowett Institute, University of Aberdeen, Aberdeen, United Kingdom; [2]Information and Computational Sciences, The James Hutton Institute, Aberdeen, United Kingdom

BACKGROUND AND OBJECTIVES
Governmental commitments to Net Zero will increase the demand for land from multiple sectors and is already taking land out of food production. Choices about where and what foods are produced is important for nutrition security, but has rippling consequences for land use, rural populations and the food system. The objective was to estimate the realised and potential nutritional value of land though the commodities produced considering future climate changes. We use Scotland as a case-study of a bioclimatically constrained high-income setting.

METHODS
Annual Scottish agricultural census data were used to identify commodities produced for human consumption, which were matched to the minimally processed foods items (e.g. flour from cereals), not necessarily what is eaten. The energy, macro- and micronutrient composition of these food items were taken from the UK Composition of Foods Integrated Dataset and mapped onto land based on the Land Capability for Agriculture classification of agricultural potential. Under climate change scenarios, the yield and area of each commodity was estimated to forecast nutrient supplies.

RESULTS
Cereals in Scotland are mostly used for purposes other than human consumption, such as alcohol and ruminant feed so their contribution to nutrient supply is attenuated despite their yields in Scotland likely increasing given climate change. A small range of vegetables with high yields are an important source of nutrients despite relatively little hectarage. However, ruminant meat production, which uses a significant proportion of agricultural land (including fodder crops, animal feed and grazing) has a disproportionately small contribution to nutrient supply. The supply of energy (71% of population needs), fibre (64.1%), iron (68.5%), selenium (59.7%), niacin (90.5%) and vitamins D (21.1%) and E (55.8%) are all less than that population needs from Scottish land alone.

CONCLUSIONS
Around half of the food consumed in Scotland is domestically produced. Understanding the potential and realised nutrient supply from domestic agricultural production helps to develop greater nutrition security of a country and opportunities to reimagine food production and land use.

CONFLICTS OF INTERESTS
The authors have no conflict of interest.

IMPACT OF THE 'RAISING THE PULSE CAMPAIGN' ON PULSE-RICH DISH SELECTION AND FOOD WASTE IN UNIVERSITY HALLS OF RESIDENCE AND CATERING OUTLETS

Yankho Kaimila[1, 2]; Olotu Oyinkansola[1]; Clegg Miriam[3, 1]; Kim Jackson[1, 4, 5]; Julie Lovegrove[1, 5, 4]
[1]Hugh Sinclair Unit of Human Nutrition, Department of Food and Nutritional Sciences, University of Reading, Reading, United Kingdom; [2]Biological and Biomedical Health Sciences, University of Malawi, Zomba, Malawi; [3]School of Food and Nutritional Sciences, University of College Cork, Cork, Ireland; [4]Institute for Cardiovascular Metabolic Research, Harry Nursten Building, Pepper Lane, University, University of Reading, Reading, United Kingdom; [5]Institute of Food, Nutrition and Health, University of Reading, Reading, United Kingdom

BACKGROUND AND OBJECTIVES
Studies have reported higher intakes of pulses are associated with an optimum diet quality, higher micronutrient status and a more sustainable diet (Willet et al, 2019). However, nutrient dense foods such as vegetables contribute the largest portion of waste annually which could have a negative impact on the environment (Torode et al, 2023). The aim of this study was to assess the impact of the Raising the Pulse intervention (a pulse-enriched menu and educational campaign) on the selection of pulse-based meals and total food waste in University of Reading catering outlets.

METHODS
In collaboration with Menus of Change, a living lab consisting of 3x3 week interventions was designed. Weeks 1-3 acted as the control to assess meals purchased and waste produced. In weeks 4-9, a high pulse-enriched menu was introduced in two catered student halls of residence and a campus restaurant, first without informing the consumers (week 4-6); followed by our 'Raising the Pulse campaign' informing students of the pulse-enriched menu and the health and environmental benefits of consuming pulses using emails, posters, information sessions and table talkers (week 7-9). Food waste was calculated by multiplying remaining portions by grams per portion at the end of each mealtime. Number of meals was estimated using automated meal swipes to enter canteens. Linear regression compared the impact of the intervention across the three phases with amount of food produced included as a covariate in the model.

RESULTS
A total of 44,220 meals were purchased over the 9 weeks. The mean±SD daily meal purchases were 203±26, 297±57 and 364±6 for breakfast, lunch and dinner respectively. The mean quantity (kg) of foods selected per meal was 1287±1160, 4202±3812 and 3128±1847; and wasted was 99±129, 191±370 and 193±178 for breakfast, lunch and dinner respectively. The mean pulse enriched meals selected (kg/person/day) in weeks 4-6 was 2.9±1.0 which increased to 3.9±2.3 in weeks 7-9, $p<0.001$. Subsequently, pulse enriched meal waste reduced from 0.7±0.3 to 0.5±0.4 in weeks 4-6 and 7-9 respectively, $p<0.001$.

CONCLUSIONS
In this study, the Raising the Pulse intervention encouraged higher consumption of pulse enriched food and lowered food waste. Educational programs encouraging higher consumption of healthful and sustainable diets could mitigate food waste in university catering outlets.

FOOD IRRADIATION: FOR FOOD PRESERVATION TOWARDS A REDUCTION OF POST-HARVEST LOSSES IN NIGERIA

Halid Sheriff Adegbusi[1]
[1]Department of Biological Sciences/Teaching, Nigeria Police Academy CBT Center, Wudil, Nigeria, Federal Republic of

BACKGROUND AND OBJECTIVES
Postharvest losses were found to cause a loss of about 13 million metric tons of agricultural crops in Nigeria, especially tomato of which about 0.7 million metric tons were found lost annually. Resulting in annual loss of about 3.7 trillion and 72 billion Nigeria Naira, of agricultural produce and especially of tomato. Food irradiation offers a better method of food preservation compare to the commonly used conventional and primitive techniques, which though does not serve their replacement. This paper is a contributory information dissemination on the commercial usage of food irradiation for food preservation that may help to reduce postharvest losses of agricultural produce in Nigeria.

METHODS
Narrative literature review was carried out using relevant review and original articles, books, and documents obtained from searches in Google Scholar, PubMed, and Bibliographies of articles.

RESULTS
Food irradiation was used to preserved yam, water yam, onions, sesame seeds and other crops without reported toxic effect and changing of nutritional values. The only one irradiation facility available in Nigeria is Gamma Irradiation Facility operated on Co-60 radioactive source, and currently under laboratory use.

CONCLUSIONS
Putting the facility under commercial usage can help reducing postharvest losses of agricultural crops, thus strengthening food security for achieving sustainable development goal 2 (SDG 2) in Nigeria. Following the economic innovation through the technology in such countries as United states of America, Brazil, China, Japan, Malaysia and others, it may also stimulate, when aptly applied, agricultural productivity for gross domestic product (GDP), export and currency growth in Nigeria. It is therefore recommended, for quick commercial operation of food irradiation, that positively adequate education about the technique is disseminated among relevant stakeholders, and that government should establish more irradiation facilities at strategic areas in Nigeria for easy access by both farmers and marketers of perishable food crops, and interested individuals.

OPPORTUNITIES AND NUTRITIONAL POTENTIAL OF SEAWEEDS IN PLANT-BASED MEAT ALTERNATIVES

Heather Kenny[1]; Clare Reynolds[1]; Emma Feeney[1]
[1]Institute of Food and Health, University College Dublin, Dublin, Ireland

BACKGROUND AND OBJECTIVES
With the growing demand for sustainable food systems, seaweeds are emerging as functional food ingredients. Seaweeds are high in protein, polyunsaturated fatty acids, vitamins, iodine, dietary fiber, antioxidants, polysaccharides, minerals, and bioactive compounds. While they have been consumed worldwide, particularly in Asian countries, their potential as novel food ingredients is now being explored. This review examines the nutrient profile of seaweeds, factors affecting bioavailability, applications in alternative meat products, and associated challenges.

METHODS
A comprehensive review of scientific literature was conducted using databases such as PubMed, Scopus, and Google Scholar. Studies were included that evaluated the nutritional composition of seaweeds, their bioavailability, and their use in alternative meat products. Challenges and future prospects for use were also included.

RESULTS
Seaweeds demonstrate significant potential to enhance the technological, organoleptic, and nutritional properties of food products. Protein-rich seaweeds have been successfully incorporated into plant-based burgers, frankfurters, pâtés, sausages, etc showcasing their versatility as novel food ingredients. Seaweeds also function as salt substitutes in meat products, contributing to flavour and reduced sodium content. However, the bioavailability of key nutrients is influenced by factors such as polysaccharide structure and mineral-binding properties, requiring further investigation.

CONCLUSIONS
Seaweeds have great potential as sustainable, nutrient-dense ingredients for plant-based meat alternatives. While their incorporation can address both nutritional and functional goals, future research is essential to overcome challenges related to nutrient bioavailability to optimize their applications. Future research should focus on novel uses of seaweed ingredients to develop safe and environmentally friendly meat alternatives.

CONFLICTS OF INTERESTS

THE EFFECTS OF SPIRULINA DOSAGE ON GLUCOSE METABOLISM, BLOOD PRESSURE, AND LIPID PROFILE: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

Stavroula Chaloulakou[1]; Foteini Lympaki[1]; Kalliopi-Anna Poulia[1]; Emilia Papakonstantinou[1]
[1]Food Science and Human Nutrition, Agricultural University of Athens, Athina, Greece

BACKGROUND AND OBJECTIVES
Spirulina, a microalga with a promising nutritional profile, has attracted significant interest from the scientific community, with numerous studies investigating its functional characteristics and potential impact on human health. Despite this, the effect of different doses of spirulina remains unclear. The objective of this systematic review and meta-analysis was to study the effects of the dosage of spirulina on glycemic control, blood pressure, and lipid profile.

METHODS
Randomized controlled trials (RCTs) were identified using PubMed, SCOPUS, and Google Scholar, and the search took place until September of 2023.

RESULTS
20 RCTs met the inclusion criteria and were included in this systematic review, of which 11 were included in the meta-analysis.

CONCLUSIONS
This meta-analysis uniquely evaluated the impact of spirulina supplementation on various biomarkers, in addition to examining the influence of different dosages. While our meta-analysis found a significant effect of spirulina on these biomarkers, the dosage meta-analysis did not show significant effects for any particular dose. This discrepancy can be attributed to several factors and highlights the need for further studies.

EPIDEMIC PREVENTION NUTRITION: STARTING WITH MY PLATE TO PROMOTE EMPLOYEE HEALTH THROUGH VIDEO LIVE STREAMING

Kai Hsin Chang[1]; SHU CHI LIN[1]; Jiyuen Tieng Chen[2]; Yu-Hsien Chao[1]; Hsiao Jung Tsai[1]
[1]Department of Nutrition, Taiwan Adventist Hospital, Taipei, Taiwan; [2]Department of Nutrition, Taiwan Adventist Hospital, Taipei, Taiwan, Taiwan

BACKGROUND AND OBJECTIVES
In response to the COVID-19 pandemic, nutrition care and meal services were adapted to support epidemic prevention and promote employee health. By leveraging public policy and digital tools, this initiative aimed to create a supportive nutritional environment and enhance remote health promotion. The project focused on adjusting employee meal boxes to be nutritious and health-promoting.

METHODS
1. **Digital Education**: Online videos and live streaming reduced group gathering risks while delivering health education.
2. **Interactive Learning**: A web-based quiz game was used to engage employees in an enjoyable way to acquire health knowledge.
3. **Educational Videos**: "My Healthy Plate" videos were integrated into employee meal boxes, helping staff understand portion control and balanced food choices.
4. **Surveys**: Online surveys via QR codes and Google Forms collected feedback from employees, which was then analyzed.

RESULTS
754 employees participated in the program. Survey RESULTS showed that 92% were satisfied with the course content and teaching methods, 91% had a clear understanding of the material, and 91% felt the course benefited their work. Employees also suggested adjusting the timing for quiz participation to enhance engagement.

CONCLUSIONS
This initiative, by digitizing nutrition education and promoting health via meal boxes, improved employee physical health, emotional well-being, and stress management, ultimately enhancing healthcare service quality and promoting long-term wellness.

THE IMPACT OF AGRICULTURAL PRACTICES ON THE BIOCHEMICAL COMPOSITION OF INDIGENOUS GHANAIAN FOOD CROPS

Herman Erick Lutterodt,[1]; Amos Otopah Anim[1]; Gloria Ankar-Brewoo,[1]
[1]Department of Food Science and Technology, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana

BACKGROUND AND OBJECTIVES

In Ghana, several farming practices – slash and burn, monoculture, traditional subsistence farming and mono-culture with heavy chemical inputs are employed to cultivate food consumed nationwide. However, these practices are drivers of biodiversity loss and have largely unexplored impacts on the biochemical composition of crops. These factors are vital to crop quality, influencing both their nutritional value and potential effects on consumer health. This study explores how these agricultural practices affect the composition of crops.

METHODS

Three indigenous Ghanaian food crops were sampled from multiple farms in the agrarian Techiman and Kintampo municipalities and analysed for their proximate, ionomic, metabolomic, and fatty acid profiles. Metadata on agricultural practices from each farm were also collected to contextualize the compositional data, to correlate farming practices to compositional data.

RESULTS

Full dataset not ready yet, but will be ready and presented at the congress.
Expected outcomes: That the relationship between dominant agricultural practices and crop composition be substantiated. Also, that practices associated with improved composition be identified. Conversely, practices that degrade soil health or compromise crop quality can be mitigated or avoided, ensuring the long-term sustainability and resilience of agricultural systems in Ghana.

ATTITUDES AND SUSTAINABILITY PERCEPTIONS OF DUTCH CONSUMERS TOWARDS MEAT ALTERNATIVES

Linsay Ketelings[1, 2]; Eline Benerink[1]; Remco Havermans,[2]; Stef Kremers[3]; Alie De Boer[1]
[1]Food Claims Research Centre, Campus Venlo, Faculty of Sciences and Engineering, Maastricht University, Venlo, Netherlands; [2]Laboratory of Behavioural Gastronomy, Maastricht University Campus Venlo, Venlo, Netherlands; [3]NUTRIM - Department of Health Promotion, Maastricht University, Faculty of Health Medicine and Life Sciences, Maastricht, Netherlands

BACKGROUND AND OBJECTIVES
Over recent decades, meat has shifted from a status symbol of wealth to a daily staple, significantly impacting the environment, health, and animal welfare. This has prompted a growing move toward plant-based diets, with many adopting a flexitarian approach, focusing on reducing meat consumption. In response, the food industry has developed alternatives for animal-based proteins to meet this demand. The aim of this study was to examine consumer attitudes toward meat and plant-based alternatives, focusing on willingness to buy, sustainability, and naturalness, to identify factors influencing acceptance and market potential of meat alternatives.

METHODS
An online questionnaire was designed to explore the attitudes of Dutch consumers toward meat and meat alternatives. The survey consisted of four parts: in the first part participants answered questions about their grocery shopping behaviour and their health status. The second part included an online experiment in which participants evaluated their perceptions of eight products.: chicken, minced meat, burgers, sausages, and their plant-based counterparts. In the third part, participants were asked several questions about meat and meat alternatives to indicate their opinion on several statements about sustainability. In the final section, participants provided their demographic information. A total of 120 participants, recruited through Prolific, completed the questionnaire.

RESULTS
Participants showed a generally higher willingness to buy traditional meat products (e.g., chicken, minced meat, burgers, sausages) compared to their plant-based alternatives. However, for burgers, the willingness to buy is nearly identical for meat and meat alternatives, suggesting plant-based burgers may be more competitive and suggesting potential for greater acceptance. Plant-based alternatives were consistently rated as more sustainable than meat products across all categories, but meat products were generally rated as more natural than their plant-based counterparts.

CONCLUSIONS
While plant-based alternatives are viewed positively in terms of sustainability, they face challenges in terms of willingness to buy and perceived naturalness, where traditional meat still holds an advantage.

FOOD SYSTEMS INNOVATION TO NURTURE EQUITY AND RESILIENCE: EXAMPLES FROM THE WORK OF THE CANADA RESEARCH CHAIRS ON NUTRITION AND HEALTH INEQUALITIES

Malek Batal[1]
[1]Nutrition, Université de Montréal, Montreal, Canada

BACKGROUND AND OBJECTIVES
The concept of resilient food systems has gained increasing attention as a transformative framework aimed at addressing the vulnerabilities within the current food system. Resilience in food systems requires diversified strategies that ensure redundancy and stopgaps, allowing systems to adapt quickly to disruptions and prevent negative consequences to planetary and human health. Furthermore, for food systems to be resilient, they must also be equitable. The Canada Research Chair in Nutrition and Health Inequalities (CIENS) has been involved in several initiatives that investigate the link between traditional and alternative food systems and the health of humans, animals and the environment.

METHODS
Based on data from the First Nations Food, Nutrition and Environment Study in Canada, Ekomer-Redes in Ecuador and Utz K'aslemal in Guatemala, we explore the interactions between various disruptions to food systems and discuss potential responses to build resilience in the face of biodiversity collapse, climate change and political and security disruptions.

RESULTS
Food systems operate on a spectrum from local to global, and resilience is best achieved by linking and integrating these scales rather than treating them in isolation. Moreover, transformative food systems must go beyond individual actions in production and distribution to include a holistic view of the entire system, incorporating principles such as fairness, participation, and co-creation of knowledge, particularly through the lens of agroecology and the preservatiopn of traditional food resources for Indigenous people who traditionally relied and continue to favour hunting, fishing and gathering as a food source, such as for Indigenous Peoples in Canada. The importance of integrated approaches to human, animal, and environmental health reflects the interconnectedness of all elements within the food system for the adoption of integrated approaches to health and well-being (e.g., One Health, Planetary Health).

CONCLUSIONS
Achieving resilience requires collaboration across scales, sectors, and paradigms, with particular attention to equity and fairness. Agroecology and traditional land-based food systems offer valuable guiding principles for transforming dominant food systems, while integrated health frameworks provide a useful lens for understanding the broader implications of food system changes to face multiple crises globally.

ACCEPTANCE OF INSECTS AS FOOD: CAN THEY CRAWL ONTO POLISH PLATES?

Dominika Sikora[1, 2]; Piotr Rzymski[1]
[1]Department of Environmental Medicine, Poznan University of Medical Sciences, Poznan, Poland; [2]Doctoral School, Poznan University of Medical Sciences, Poznan, Poland

BACKGROUND AND OBJECTIVES
Edible insects are a sustainable alternative to conventional animal protein, offering significant environmental benefits. Compared to beef, insect farming has a lower water footprint, requires less land, and has a production cycle spanning only weeks. Furthermore, insects convert up to 88% of dietary protein into edible body mass and provide a nutritional density comparable to meat. Despite these advantages, public acceptance of edible insects remains a major challenge.

METHODS
This cross-sectional online study surveyed adult Poles (n=1553) to assess their familiarity with edible insects, their willingness to purchase them, and factors influencing these attitudes.

RESULTS
The vast majority of respondents (98%) were familiar with entomophagy; however, only 28% expressed a willingness to buy insects as food. The primary barriers were disgust (60%) and concerns over sensory properties (34%). Those willing to try insects were motivated mainly by curiosity (76%) and the perceived lower environmental impacts (61%). Ground insects (73%) and insect-based food products (77%) were preferred, while only 27% were open to consuming whole insects. Multiple logistic regression analysis revealed that the likelihood of rejecting edible insects was significantly higher among females (OR: 2.42; 95%: 1.61-3.65) and individuals with low openness to novel experience (1.57; 1.13-2.18). In contrast, respondents who acknowledged the adverse environmental effects of animal farming, such as impacts on air quality (OR: 0.42; 95% CI: 0.19–0.95) and water resources (OR: 0.30; 95% CI: 0.13–0.70), were less likely to reject edible insects.

CONCLUSIONS
Acceptance of edible insects as food in Poland is low but could improve with targeted information campaigns emphasizing their environmental benefits. To reduce disgust-related barriers, edible insects should be offered in ground form and incorporated into food products rather than presented whole.

EPO2_113

MONITORING THE PROTEIN INTAKE IN A BELGIAN CITY

Sofie Schryvers[1]; Gillis Fine[1]; Moyersoen Isabelle[2]; Jacxsens Liesbeth[1]; Carl Lachat[1]
[1]Department of Food Technology, Safety and Health, Faculty of Bioscience Engineering, Ghent University, Ghent, Belgium; [2]Lifestyle and chronic diseases Epidemiology and public health, Sciensano, Brussels, Belgium

BACKGROUND AND OBJECTIVES

Policy measures are implemented to promote a shift away from animal-source foods in favor of plant-based foods. In Belgium the proportion of animal-to-plant protein in the diet was 61% to 39% in 2014. The protein shift encourages a modification towards 60% from plant and 40% from animal. An efficient and accurate measurement of the protein consumption is important to monitor progress and guide policies.

METHODS

A Food Frequency Questionnaire (FFQ), developed by the Belgian public health institute, was used to measure the consumption of both animal- and plant-based protein sources in the population of a city with a long-standing urban food policy and protein strategy. The FFQ was developed so that at least 90% of the protein intake would be measured. Novel food categories that could contribute to the protein supply, e.g. plant-based meat and dairy alternatives or pulse-based foods (e.g. pasta) were added to the FFQ.

RESULTS

In total, 500 adults completed the online questionnaire in the period of May – June 2024. The sample was stratified by gender and age to ensure it was representative of the city's population. Upon removal of extreme responses, 456 respondents remained. The sample consisted of 61.5% omnivores, 36.8% flexitarians (i.e. people who don’t consume meat or fish at least one day a week, as derived by FFQ responses), 1.5% vegetarians (n=7) and 0.2% vegans (n=1). Overall, on average 51.4% of the protein intake was supplied by animal sources and 48.6% by plant sources. In flexitarians, the proportion of plant-to-animal source proteins were 56% and 44% respectively, while in omnivores this was 42% and 58%. Most important food groups in terms of protein intake were meat and meat products (26.7%), grains and grain products (26.7%), milk and dairy products (16.3%), fish and seafood (5.8%), while plant-based alternatives to meat and dairy supplied <5% of protein in the total population.

CONCLUSIONS

A shift in the frequency of consumption of animal products, such as meat, fish, eggs and dairy, as compared to the Belgian population, was clearly visible in this city. Flexitarians are an important driver for the protein transition here. Further analyses will assess whether this dietary profile is associated with the urbanised context or with the specific policy situation of this city.

CONFLICTS OF INTERESTS

ASSESSMENT OF THE ESTIMATED INTAKE OF PESTICIDE RESIDUES IN FOODS OFFERED IN INSTITUTIONAL MENUS

Priscilla Moura Rolim[1]; Ana Luiza Araújo Dias[1]; Angelita Americo Azevedo,[1]; Larissa Mont'alverne Jucá Seabra Seabra,[1]
[1]DEPARTMENT OF NUTRITION, Federal University of Rio Grande do Norte, Natal, Brazil

BACKGROUND AND OBJECTIVES
This study aimed to evaluate the estimated intake of pesticides through food provided in institutional food services in Brazil, which is based on the use of minimally processed and in *natura* foods, with few ultra-processed. The conventional agricultural production model in Brazil uses large amounts of pesticides, which can pose chronic toxicity risks, thus harming public health.

METHODS
The methodology for estimating pesticide intake through food, as outlined by the World Health Organization (WHO), was employed using the calculation of the Theoretical Maximum Daily Intake (TMDI), considering the Brazilian Maximum Residue Limits (MRL) for foods and the quantities consumed in institutional restaurant menus. The per capita food quantities offered in the menus were obtained from the preparation technical sheets. The percentage contribution of the Acceptable Daily Intake (ADI) was assessed by considering the estimated intake and a body weight of 60kg. A comparative analysis between the intake levels and the ADI of the respective active ingredient enabled the assessment of exposure risk. The study considered breakfast, lunch, and dinner meals, with MRL data for plant-based foods collected from the National Health Surveillance Agency, and for animal-based foods from the Codex Alimentarius database. Fourteen pesticide active ingredients were evaluated, including glyphosate, 2,4-D, abamectin, mancozeb, chlorpyrifos, acephate, methomyl, cypermethrin, bifenthrin, novaluron, lambda-cyhalothrin, tebuconazole, paraquat, and chlorothalonil. The foods analyzed included coffee, corn, banana, carrot, potato, tomato, rice, beans, grapes, eggs, milk, beef, and poultry.

RESULTS
The daily estimated intake of pesticide residues, considering breakfast, lunch, and dinner, revealed that TMDI >100% of the ADI for novaluron and mancozeb, assessing unacceptable risk. The active ingredients bifenthrin and chlorothalonil reached 95% and 76% of the acceptable daily intake, respectively, indicating health risks. It is noteworthy that only during lunch was an unacceptable exposure risk identified for the pesticides novaluron and mancozeb, with estimated daily intake surpassing the ADI (>100%).

CONCLUSIONS
The RESULTS showed that conventionally produced foods in Brazil are exposed to a range of pesticide active ingredients throughout their production chain. The study underscores the chronic risks of pesticide exposure and highlights the importance of quality food in promoting health and upholding the human right to adequate nutrition.

EPO2_116

NUTRITIONAL TRANSITION AND ENVIRONMENTAL SUSTAINABILITY: THE DIVERGENCE BETWEEN NORTHERN AND SOUTHERN MEXICO

FATIMA EZZAHRA HOUSNI[1]; Lares-Michel Mariana[1]; Saenz-Pardo-Reyes Erika[2]
[1]Instituto de Investigaciones en Comportamiento Alimentario y Nutrición (IICAN), University of Guadalajara, Guadalajara, Mexico; [2]Facultad de Ciencias Humanas, University of Baja California, Tepic, Mexico

BACKGROUND AND OBJECTIVES
Mexico is currently grappling with a severe environmental crisis, marked by a water scarcity that affects 85% of the territory and frequent droughts. This crisis is intricately linked to the nutritional transition, a shift from the traditional Mexican diet, rich in local products like corn and beans, to a Western diet. This transition has propelled Mexico to the top of the global charts for overweight and obesity and has also contributed to the country's substantial water and carbon footprints, averaging over 8,000 (l p–1 d–1) and 3.9 kg of CO2 per person per day. The nutritional transition has unevenly impacted the different regions of Mexico. In the northern states, greater progress is observed in this transition, while in the south, a diet more attached to the milpa tradition persists. A comparative study was conducted between Chihuahua, representing the north, and Oaxaca, representing the south, focusing on the impact of diets on the water footprint (WF) and carbon footprint (CF).

METHODS
A study of 84 adults (42 from Chihuahua and 42 from Oaxaca) assessed dietary patterns and environmental impacts using validated tools. Carbon and water footprints were calculated with LCA and WFA methods adapted to Mexico. Adjustments for food preparation were included, and statistical analyses used Stata 12.0.

RESULTS
The RESULTS showed similar dietary patterns in both states, with key differences. In Chihuahua, higher consumption of meat (136.1 g/d) and ultra-processed foods (165.6 g/d) was observed, while in Oaxaca, the consumption of traditional Mexican dishes (302.4 g/d) and low consumption of meat (19.3 g/d) predominated. In terms of environmental impact, the water footprint was 7,318.4 l p–1 d–1 in Chihuahua and 6,127.5 l p–1 d–1 in Oaxaca, with meat and Mexican dishes being the main contributors, respectively. Carbon footprints were 8.67 kg CO2 p–1 d–1 in Chihuahua and 6.64 kg CO2 p–1 d–1 in Oaxaca, with no significant differences between states.

CONCLUSIONS
Although the study did not find statistically significant differences between the states, the RESULTS underscore the significant impact of the nutritional transition. An increased consumption of meat and ultra-processed foods in North Mexico has a considerable environmental impact. In contrast, Oaxaca's diet, rooted in traditional products, is more sustainable. This stark contrast in environmental impact should serve as a wake-up call to the gravity of the situation.

NUTRITIONAL VALUE OF EUROPEAN FLAT OYSTER (OSTREA EDULIS)

Elena Dujmić; Greta Krešić[1]; Snježana Zrnčić[2]; Jelka Pleadin[3]
[1]Department of Food and Nutrition, Faculty of Tourism and Hospitality Management, Ika, Croatia; [2]Laboratory for Fish Pathology, Croatian Veterinary Institute, Zagreb, Croatia; [3]Laboratory for Analytical Chemistry, Croatian Veterinary Institute, Zagreb, Croatia

BACKGROUND AND OBJECTIVES
Among shellfish, the European flat oyster has long been known as a delicacy, and currently is the only oyster species native to Europe. Due to the spread of disease in the past century, native *Ostrea edulis* has largely been replaced by Pacific oyster. However, in the last years, renewed efforts have been made to reintroduce *O. edulis* along the European coast. With growing interest in its importance, this review aims to gather current knowledge on the nutritional properties of the European flat oyster.

METHODS
The comprehensive literature review was performed using Scopus database. The following keywords were used in the search: "European oyster", "Ostrea edulis", "nutritional", "biochemical", "composition", "fatty acid", "vitamin", and "mineral". In total, 150 studies were obtained. After screening and filtering, 16 scientific papers were reviewed, which involved studies from countries across Europe.

RESULTS
The literature review revealed significant differences in biochemical composition due to changes in environmental conditions, reproductive cycle, food quality or rearing conditions. Proteins were shown to be the main components of *O. edulis* (35.0 – 68.0 % dry weight, or 6.9 – 11.0 g/100 g), followed by carbohydrates (16.8 – 46.9 % dry weight, or 1.5 – 9.2 g/100 g) and fats (3.3 – 10.9 % dry weight, or 1.2 – 5.5 g/100 g). Studies on the fatty acid composition have produced mixed RESULTS with some reporting the highest proportion of saturated fatty acids (SFA) and others reporting the highest proportion of polyunsaturated fatty acids (PUFA). However, palmitic acid is considered the most abundant SFA, while EPA and DHA are the most present PUFAs. The lipid nutritional quality indices indicate that *O. edulis* may have a positive impact on consumer health. None of the studies investigated vitamins, and only a couple investigated mineral content.

CONCLUSIONS
The findings from this comprehensive review suggest that European flat oyster could be considered as a highly nutritious food contributing to healthy diet, with a high content of protein, omega-3 fatty acids and minerals, and a low content of total fat. It is worth to be more investigated in the future since the European Union recognizes bivalve aquaculture as part of sustainable food systems due to its low environmental impact.

CONFLICTS OF INTERESTS
The authors have no conflict of interest.

SUBSTITUTING CERTAIN ANIMAL-SOURCED FOODS WITH NOVEL PLANT-BASED ALTERNATIVES MAINTAIN NUTRITIONAL OUTCOMES AND LOWER ENVIRONMENTAL IMPACTS IN DIETS

Sarah Nájera Espinosa[1]; Arli G Zarate-Ortiz,[1]; Genevieve Hadida[1]; Jacqueline Tereza da Silva[2]; Alexander Vonderschmidt[3]; Edith Monica Esievo[1]; Tony Carr[1]; Anouk Reuzé[1]; Pauline Scheelbeek,[1]
[1]Population Health, London School of Hygiene & Tropical Medicine, London, United Kingdom; [2]Global Academy of Agriculture and Food Systems, The University of Edinburgh, Edinburgh, United Kingdom; [3]Global Academy of Agriculture and Food Systems, University of Edinburgh, Edinburgh, United Kingdom

BACKGROUND AND OBJECTIVES
Growing literature suggests dietary shifts from animal-sourced to plant-based foods. While the United Kingdom's (UK) meat and dairy consumption has decreased, further efforts are required to meet national environmental and health targets. Although novel plant-based foods (NPBFs) offer easy meat and dairy replacement without sacrificing sensory experience, their impact on health, the environment and cost remains uncertain. This study aimed to identify the potential trade-offs and co-benefits of substituting specific animal-sourced foods with comparable NPBFs in a UK healthy and affordable "basic basket" (baseline) for men and women.

METHODS
Nine new baskets were created to assess the nutritional, environmental and cost outcomes by substituting processed meat, milk or yogurt with the most consumed, healthiest, and affordable NPBFs. Food products from the basic basket were matched with the UK food composition table. NPBFs nutritional data were collected from UK supermarkets in 2023, using the Open Food Facts app. All foods were matched with dietary environmental footprints (greenhouse gas emissions, water and land use) from Clark et al. 2022, and prices were manually collected from UK supermarkets in 2023.

RESULTS
Dietary environmental footprints decreased by -0.39 to -6.94% in all new baskets. While nutritional outcomes varied between the basic and new baskets, most substitutions aligned with recommended daily allowance. When carefully selected, minimal nutrient changes were found—especially with the "healthiest" NPBFs—though important micronutrient reductions occurred when replacing milk with the most affordable alternative. Nearly all dairy alternatives substitutions lowered food basket costs, while the most consumed plant-based drink and all plant-based meats were more expensive.

CONCLUSIONS
If carefully selected, NPBFs present a powerful opportunity for health and environmental benefits, especially as replacements of processed meats. However, without policies to make NPBFs more affordable, this would represent a missed opportunity to drive progress towards net zero and health targets.

PROMOTING HEALTH AND SUSTAINABILITY IN FOOD SERVICES: A BRAZILIAN PERSPECTIVE ON NUTRITIONISTS' PRACTICES

Herbenny Hellen Medeiros De Brito Carvalho,[1]; Larissa Mont'alverne Jucá Seabra Seabra,[2]; Diogo Thimoteo Da Cunha,[3]; Priscilla Moura Rolim[2]
[1]Departament of Nutrition, Federal University of Rio Grande do Norte, Natal, Brazil; [2]Department of Nutrition, Federal University of Rio Grande do Norte, Natal, Brazil; [3]Nutrition, FCA/UNICAMP - Faculdade de Ciências Aplicadas da Universidade Estadual de Campinas, Limeira, Brazil

BACKGROUND AND OBJECTIVES
The study examined how nutritionists in food services adopt sustainable practices to contribute to Sustainable Development Goal (SDG3) on health and well-being. Two significant challenges in food service are: 1) Inadequately planned menus that fail to provide nutritionally balanced meals, hindering the prevention of chronic diseases; and 2) the neglect of worker health and safety, a critical oversight that compromises the well-being of a vital workforce.

METHODS
A validated questionnaire was used for the investigation, addressing the following factors: a) knowledge about sustainability (using a dichotomous scale) b) food quality, c) the health and well-being of foodservice workers, and d) health risk behaviors among these workers (using a Likert scale to measure the frequency of practice adoption - never, rarely, occasionally, frequently and very frequently). The study received ethical approval for research involving human subjects. A convenience sample (n=105) of nutritionists was recruited for this exploratory study. Participants were required to work or have worked in the foodservice sector to be included in the data analysis.

RESULTS
Key findings revealed that, regarding knowledge of sustainability, 52% of nutritionists reported promoting actions to achieve SDG 3. Regarding the dimension of health and food quality, the most nutritionists (85%) offer red meat in their menus, while 80% also reported diversifying sources of animal and plant-based protein. Additionally, 83% of nutritionists mentioned planning their menus considering seasonality, and only 17% referred to using ultra-processed food. The RESULTS showed that slightly more than half of the nutritionists (55%) control the use of critical nutrients (sugar, sodium, and oil). In terms of the health and well-being of workers in food services, only 36% of nutritionists assess the nutritional status of their workers; 74% provide personal protective equipment; 49% develop strategies to encourage teamwork; 69% promote effective communication within the team; and 45% manage environmental risks. In assessing health risk behaviors among foodservice workers, nutritionists identified factors such as low consumption of fruits and vegetables (39%), sedentary lifestyle (53%), stress (67%), hypertension (55%), and dyslipidemia (46%) as risks.

CONCLUSIONS
The RESULTS highlight the need for integrated efforts among nutritionists, health professionals, and occupational health experts to promote sustainable practices.

HARNESSING COMMUNITY-BASED SOCIAL AND BEHAVIOR CHANGE GROUPS TO ENHANCE FOOD AND NUTRITION SECURITY THROUGH INTEGRATED PROMOTION OF NUTRITION AND CLIMATE-SMART AGRICULTURE IN ZIMBABWE

Delilah Takawira[1]; Mutsa Tsvamuno[1]; Charity Chikwiriro[2]; Heather Chotvacs[3]
[1]SBC, FHI360, Harare, Zimbabwe; [2]SBC, Nutrition, Harare, Zimbabwe; [3]Social and Behavior Change, FHI 360, Durham, United States of America

BACKGROUND AND OBJECTIVES
Takunda, a resilience and food security project in Zimbabwe, seeks to enhance nutrition status of women and children, increase incomes and build resilience against shocks through innovative community-based interventions.

METHODS
Takunda leverages use of Social and Behavior Change (SBC) groups, like Care Groups (CG), Farmer Field and Business Schools (FFBS) and Village Savings and Loan Associations (VSLAs) to deliver layered and integrated interventions. SBC activities delivered through these groups use various communication channels to promote dietary diversity using locally produced foods FFBS integrates nutrition promotion into agricultural training, influencing farmers' selection of crops to grow and production methodologies in view of changing climate. CGs use edutainment, storytelling and cooking demonstrations to promote dietary diversification. In addition, CG participants are encouraged to participate in VSLAs and Income Generating Activities (IGAs) to diversify their income sources.

RESULTS
As a result of these interventions, nutrition outcomes have improved. Households with acceptable dietary diversity rose from 50% in 2022 to 74% in 2024, demonstrating increased economic access to a variety of nutritious foods despite the El Niño-induced drought. Similarly, women in Care Groups had an increase in dietary diversity from 19% in 2022 to 56% in 2024. At the same time the dietary diversity of children aged 6-23 months rose, with the proportion consuming Minimum Dietary Diversity (MDD) increasing from 38% in 2022 to 55% in 2024. Income diversification through small livestock and entrepreneurial activities provided additional financial security. Over 570,198 poultry were produced and generated cumulative sales of USD 1.74 million. This contributed to an average household income of USD 210 from poultry sales, supporting dietary diversity and adaptive capacity. The program supported development of 93 nutrition gardens producing vegetables such as green leafy vegetables, butternut and carrots on 58.8 hectares, generating USD 229,211 in gross revenue while also improving community dietary diversity.

CONCLUSIONS
By leveraging SBC activities through community established groups like Care Groups, FFBS and VSLA the project enhanced dietary diversity, food security, and resilience in the target population.

SUSTAINABLE EATING MADE EASY? A COMPARATIVE ANALYSIS OF THE NUTRITIONAL AND ENVIRONMENTAL FOOTPRINT OF READY-MEALS AND HOME-COOKED MEALS

Surbhi Agarwal[1]; Licida Giuliani[2]; Cristina Stewart[3]; Phoenix Andrews[1]; Michael Clark[4]; E. K. (Esther) Papies[5]; Eleonora Belfiore[6]; Graham Horgan[7]; Jennie Macdiarmid[8]; Pete Smith[2]
[1]The Rowett Institute, University of Aberdeen, Aberdeen, United Kingdom; [2]Institute of Biological and Environmental Sciences, University of Aberdeen, Aberdeen United Kingdom; [3]MRC/CSO Social and Public Health Sciences Unit, School of Health and Wellbeing, University of Glasgow, Glasgow, United Kingdom; [4]Smith School of Enterprise and the Environment, University of Oxford, Oxford, United Kingdom; [5]Behavioural Science Institute, Radbound University, Nijmegen, Netherlands; [6]Research Centre for Creative Economies, Coventry University, Coventry, United Kingdom; [7]Biomathematics & Statistics Scotland, (BioSS), Aberdeen United Kingdom; [8]The Rowett Institute, University of Aberdeen, Aberdeen United Kingdom

BACKGROUND AND OBJECTIVES

Young women aged 18–24 years are a key demographic for studying plant-based dietary patterns due to their inclination toward plant-based convenience foods, risk of iron deficiency, and role as future influencers of household dietary habits. Ready meals are popular due to convenience, but their nutritional quality and alignment with sustainability goals remain unclear. This calls for a deeper understanding of whether plant-based ready meals offer better nutritional quality and environmental sustainability compared to meat-containing ready meals and home-cooked options. The objective of this study was (i) to assess greenhouse gas (GHG) emissions and nutritional profiles (ii) to examine ingredient quality (using price as a proxy) to guide young women toward informed, sustainable choices.

METHODS

The ten most frequently purchased plant-based ready meals among households including at least one woman aged 18–24 were identified from Kantar WorldPanel data (05/2017 to 04/2021) and categorised into low, medium, and high-cost alternatives. Ready meals were prepared using packaging instructions, analysed for multi-elemental content (ICP-MS), and macronutrients quantified from back-of-pack information. Equivalent home-cooked meals, using low- and high-cost ingredients, were similarly analysed using ICP-MS and Nutritics software. GHG emissions were calculated based on estimated ingredient quantities and cooking processes to assess whether switching to convenient plant-based ready meals can be a sustainable dietary option for young women.

RESULTS

The most purchased ready meals were margherita and vegetable pizzas, macaroni cheese, cheese and tomato pasta, vegetarian tikka masala with rice, vegetable chilli with rice, vegetarian lasagne, vegetable biryani, mushroom risotto, and cottage pie, accounting for ~19% of ready meal purchases among the study population. Findings are expected to highlight trade-offs between adequate nutrition, convenience, and sustainability with the analysis to be completed by May 2025.

CONCLUSIONS

This analysis will provide information on whether ready meals can serve as a sustainable and nutritious choice for young women seeking convenient foods. Our findings will be used to inform consumers and policymakers, including Food Standards Scotland (FSS), about the trade-offs between plant-based ready meals, meat-based ready meals and home cooking. Through an artist co-op, we will create visual outputs to communicate trade-offs, making findings accessible for guiding sustainable and nutritious dietary strategies.

UNIVERSITY BASED ROOFTOP URBAN AGRICULTURE FOR SUSTAINABLE LIVELIHOODS (SL) AND SUSTAINABLE FOOD SYSTEMS (SFS): A CASE STUDY FROM AN IMPLEMENTATION SCIENCE IN NUTRITION (ISN) PERSPECTIVE

Fiona Yeudall[1]
[1]School of Nutrition and Centre for Studies in Food Security, Toronto Metropolitan University, Toronto, Canada

BACKGROUND AND OBJECTIVES
The role of urban agriculture in general, and rooftop urban agriculture in particular, has demonstrated potential to contribute to more socially, ecologically and economically SFS and SL outcomes, including food and nutrition security and a more sustainable use of the natural resource base. Anchor institutions such as Universities play a key role in their communities, including reducing opportunity costs associated with experimentation for less well resourced organizations, while simultaneously providing educational, research and employment opportunities. The history and activities of a university based Urban Farm Living Lab (UFLL), located in the downtown core of a capital city, will be explored from an ISN perspective.

METHODS
ISN aims to bridge the gap between knowledge and action by systematically considering five domains proven to impact implementation. Specifically, the intervention, implementing organization, enabling environment, communities of interest and strategies and decision making processes were considered. The case study conducted a systematic review of records, reports and documentation, in consultation with, and verified by, the UFLL team, key stakeholders and champions.

RESULTS
The intervention included two rooftop growing spaces, one retrofitted, and one purpose built for food growing. The UFLL facilitated experiential learning and research. On-campus food growing at the University (implementing organization) was initiated by students, provided with academic leadership from a University based research centre with additional human, physical and financial capital support from University administration and donors. Human and social capital of community engaged scholars facilitated engagement with community and governmental organizations (enabling environment), as did policy (Green Roof bylaw and Urban Agriculture Plan), and existing and emerging organizations (Black Food Sovereignty, Indigenous Education, Food Policy and Urban Growers). Communities of interest benefitted from food production, including pandemic related emergency food distribution, ecological services (stormwater and heat island effect mitigation) and social justice initiatives addressing historical AntiBlack and Indigenous racism. Strategies and decision making processes shifted as the initiative became embedded into university business services.

CONCLUSIONS
This case study demonstrates the potential of anchor institutions, supported by a range of sustainable livelihood assets and transforming structures, to contribute to SL and SFS.

BIOINTENSIVE BACKYARD PRODUCTION, A STRATEGY TO ACHIEVE FOOD SOVEREIGNTY IN THE MAZAHUA REGION OF THE STATE OF MEXICO

Cristian Angel Rosales Gómez[1]; Fabián Olvera Flores[1]; Eduardo Thébar Gómez[1]; Favio Vázquez Barrientos[2]; David Maldonado Cayo[2]
[1]Monitoreo, Evaluación e Investigación, Un Kilo De Ayuda, A.C., Ciudad de México, Mexico; [2]Programas, Un Kilo De Ayuda, A.C., Ciudad de México, Mexico

BACKGROUND AND OBJECTIVES
The current panorama of food security and the nutritional status of the Mexican population shows a reality of contrasts; the food supply is exceeded by demand, which limits access to nutritious food and creates a serious food security problem. The magnitude of this problem highlights the need to create biointensive production interventions to increase the availability and access to food. Our objective was to increase the availability of low-cost food in 30 Mazahua households in the State of Mexico that contribute to adequate food and nutrition.

METHODS
Participatory workshops on the biointensive production method and focus groups with 30 commissioners were facilitated. Production records were filled out to calculate the savings and family income produced.

RESULTS
A total of 5.4 tons of vegetables were produced in the 30 households. The main types produced were kale (33%), chard (31%), romaine lettuce (17%), and beetroot (6.3%). 33.5% of the production was for self-consumption and 46.5% for sale, generating an average monthly savings and income per household of 14.90 USD and 18.82 USD, respectively.

CONCLUSIONS
The RESULTS show that the biointensive method effectively contributes to food security and sovereignty by making available a greater variety of foods in quantity and quality. It may also be capable of generating additional family income that contributes to improving the quality of life of families.

EPO2_128

THE PROMOTION OF THE UTILIZATION OF INDIGENOUS FOODS' FRAMEWORK

Zoe Nomakhushe Nxusani[1]; Zuma Mthokozisi[2]; Mbhenyane1 Xikombiso[1]
[1]Division of Human Nutrition, Faculty of Medicine and Health Sciences, Stellenbosch University, Cape Town, South Africa; [2]Impact and Partnerships Division, Agricultural Research Council, Pretoria, South Africa

BACKGROUND AND OBJECTIVES
Indigenous plants grow naturally in the ecosystems and have been used by many generations as food and medicine in almost all societies. These foods and dietary diversity within an ecosystem are recognised as powerful sources of nutrients and are therefore more beneficial to health. This paper aims to present a validated framework for the promotion of the utilization of indigenous foods.

METHODS
Participatory action research was employed to engage participants when collaborating to understand social issues and identification of actions to bring about social change. The design logic model was informed by Theoretical Domain Framework delimiting to the four theoretical domains of knowledge, skills, environmental context and resources, and behavioural regulation). Key stakeholders, researchers, and experts were involved in consensus workshops which modelled the necessary activities and components as synthesized from the systematic review, quantitative and qualitative data, during designing of the Framework for the Promotion of the Utilization of Indigenous Foods. Modified Delphi Validation techniques included expert evaluation using evaluation questionnaires and focus group discussions with stakeholders. The framework is thought to be a practical and valuable artifact for the promotion of the utilisation of indigenous foods.

RESULTS
The validated framework suggests that major players—government officials, businesses, academic institutions, research institutes, communities, and the media—could cooperate to guarantee that indigenous foods are accessible and available to the communities. While the end users—communities, farmers, merchants, schoolchildren, patients, and prisoners— must promote the utilisation of these foods by consuming them. The framework also proposes that knowledge holders such as parents, elders, and women transmit indigenous food knowledge, harvesting, processing, preservation, and preparation skills to the younger generation.

CONCLUSIONS
The validated framework proposes that the promotion of the utilization of indigenous foods to improve health should include different stakeholders. The framework is targeted to those who have the power to implement it in their respective positions, with consequent goals of contributing to sustainable goals 1, 2, 3 and 12 of the United Nations.

EXPLORING THE LINKS BETWEEN ATTITUDES AND BEHAVIOURS CONCERNING FOOD USE AND WASTE WITHIN SCOTLAND – PERSPECTIVES ON RURALITY

Hattie Bracey[1]; Layla Alahmari[1]; Emilie Combet[1]
[1]Human Nutrition, School of Medicine, Dentistry and Nursing, University of Glasgow, Glasgow, United Kingdom

BACKGROUND AND OBJECTIVES
Food waste contributes 8-10% of global greenhouse gas emissions. In the UK, 61% of food waste is derived from households, costing ~£600 annually (1). Food habits, including waste, are influenced by identity, culture, and perceived norms (2). This study aimed to examine the role of rurality on food-related behaviours and intentions.

METHODS
We performed a secondary analysis of a cross-sectional survey of UK adults conducted in 2021, exploring food system understanding and diet in the context of both health and the environment. Food-related behaviours (n=9) and intentions (n=7) and the importance of sustainability when making food choices (n=1) were assessed using 7-point Likert scales. Cumulative scores for behaviours and intentions were calculated and transformed into percentages of the maximum possible score. Urban/rural classification was determined based on home postcode, using Office for National Statistics and Scottish Government classifications.

RESULTS
Respondents (n=297, 78% female) predominantly lived in urban areas (n=245, 82%) with a large median age difference between the rural group (64, IQR 29) and the urban group (36, IQR 30), $p<0.001$. Rural participants indicated buying seasonally (19% often/always for rural, 16% for urban $p=0.001$), local produce (58% often/always vs 31%, $p=0.027$) and eating leftovers (69% often/always vs 51% $p=0.008$) more frequently than urban participants. When making food choices, more rural participants agreed that sustainability was an important or very important consideration (46% for rural vs. 32% for urban, $p=0.001$). A greater proportion of rural participants reported already reducing consumption of animal products (38% vs 20%, $p=0.005$), acting to reduce food waste (65% vs 29%, $p<0.001$), limiting purchases in plastic packaging (35% vs 18%, $p=0.007$), buying locally (33% vs 15%, $p=0.002$) and seasonally (40% vs 16%, $p<0.001$), and purchasing animal products with higher production standards (37% vs 22%, $p=0.027$). Composite scores for pro-environmental behaviours and intentions were greater for the rural group (64% for behaviour, 78% for intentions) than the urban group (60% for behaviour, 67% for intentions). However, both groups had a significant intention-behaviour gap ($p<0.001$).

CONCLUSIONS
Rurality was associated with higher pro-environmental food-related behaviours and intentions, with an intention-behaviour gap highlighting opportunities to support both rural and urban residents in a place-specific fashion.

IMPROVING FOOD SUSTAINABILITY AND NUTRITION THROUGH PROMOTION OF A SIMPLE SOLAR FOOD DRYER IN A COMMUNITY BASED INTEGRATED NUTRITION AND FOOD SECURITY PROGRAM IN BANGLADESH, KENYA, SOMALIA AND TANZANIA

Asrat Tolossa[1]; Christina Nguyen[1]
[1]Health and Nutrition, World Vision Canada, Toronto, Canada

BACKGROUND AND OBJECTIVES

The Realizing Gender Equality, Attitudinal Change and Transformative Systems in Nutrition (REACTS-IN) program is a seven-year, multi-country program that aims to improve nutrition and gender equality for the most vulnerable women, adolescent girls, and children under 5 years of age. The project builds on previous impact achieved through ENRICH program in three countries, Bangladesh, Kenya, and Tanzania, and will aim to create impact in one new country, Somalia. The project is receiving $41 million from the Government of Canada, with World Vision Canada (WVC) contributing $3 million to the program.

METHODS

Solar food dryers offer a simple and cost-effective method of food preservation, preventing spoilage, fermentation, and contamination. The dehydration process also yields beneficial to reducing contamination by dust, insects, and other animals. They operate by harnessing passive solar heating, making them energy-efficient and environmentally friendly. The REACTS-IN program promoted a simple solar dryer made out of local materials such as card boxes, clear plastic sheet, and baskets made from split bamboo.

RESULTS

The technology was highly accepted by communities in the project target areas across the participating countries. The project identified early adopters to raise awareness about solar dryers and demonstrated how to construct them using locally available materials. These early adopters transferred their knowledge and skills to other community members, showcasing the cost-effectiveness and energy efficiency of the solar dryers, which help retain more nutrients in dried foods. The solar food dryers were found to be effective for drying fruits, vegetables, herbs, grains, and meat. However, in Somalia, adoption was slower as the project was implemented in Internally Displaced Persons (IDP) camps, where people primarily rely on food distribution rather than growing their own food. The dried foods were used as snacks for children, enhancing their nutrition and overall health. Women were also encouraged to sell the dried foods, contributing to increased household income and promoting economic empowerment and decision-making power.

CONCLUSIONS

Simple solar dryers contribute to global efforts in reducing food waste, mitigating climate change, and achieving the United Nations Sustainable Development Goals related to food security, sustainability, and climate action. Supportive policies and regulations are needed to increase adoption of solar food drying technologies.

UNDERSTANDING AND MITIGATING HOUSEHOLD FOOD WASTE: A MIXED-METHODS APPROACH TO BEHAVIORAL CHANGE

Ayşe Nur Songür Bozdağ[1]; Funda Pınar Cakıroğlu[2]
[1]Nutrition and Dietetics, Izmir Katip Çelebi University,Faculty of Health Sciences, İzmir, Türkiye; [2]Nutrition and Dietetics, Ankara University, Faculty of Health Sciences, Ankara, Türkiye

BACKGROUND AND OBJECTIVES
Food waste poses a critical challenge to global food system sustainability, with profound implications for food security, environmental degradation, and economic stability. Although losses occur at all supply chain stages, households in high- and middle-income economies are a major contributor to post-production food waste, accounting for 40–60% of total discards (FAO, 2019; UNEP, 2021). This study investigated the determinants of household food waste generation and assessed the efficacy of an intervention developed from these insights.

METHODS
A mixed-methods approach was employed across three phases:Phase 1: Households (n = 382) completed structured questionnaires to assess food waste practices, sociodemographic characteristics (e.g., age, income, education), and behavioral determinants.Phase 2: A stratified subset (n = 13) exhibiting sociodemographic predictors of high food waste behavior (FWB) participated in semi-structured interviews and 7-day waste diaries (documented via diaries and photography).Intervention: Insights from Phase 2 informed the development of tailored educational materials addressing key drivers (e.g., meal planning, portion sizing, storage techniques). Participants received training using these materials, and behavioral outcomes were evaluated through post-intervention waste diaries.

RESULTS
Higher Food Waste Behavior (FWB) scores were significantly associated with younger age (19–29 years), male sex, higher education attainment, employment, single marital status, income levels of 6500–7499 Turkish Liras, and households with one female ($p<0.05$). Intentions to reduce food waste were positively influenced by personal and environmental attitudes, perceived behavioral control, guilt, and recycling practices, whereas food safety concerns exhibited a negative impact on these intentions ($p<0.05$). The primary contributors to food waste included excessive portion sizes, food spoilage, and prolonged storage, with vegetables, fruits, leftovers, and bread identified as the most frequently wasted items. Post-intervention, the frequency of food waste decreased by 26.5%, and the total quantity of wasted food declined by 40.7%.

CONCLUSIONS
Household food waste behavior is shaped by multidimensional determinants, necessitating context-specific interventions across regional and national scales. Integrated approaches targeting behavioral, knowledge-based, and systemic barriers can enable effective mitigation of food waste and advance food system sustainability.

DAIRY CONSUMERS' READINESS TO ADOPT MILK PRODUCTS WITH IMPROVED NUTRITIONAL QUALITIES AND SUSTAINABILITY

Hattie Bracey[1]; Emilie Combet[1]; Stuart Gray[2]
[1]Human Nutrition, School of Medicine, Dentistry and Nursing, University of Glasgow, Glasgow, United Kingdom; [2]BHF Glasgow Cardiovascular Research Centre, School of cardiovascular and Metabolic Health, University of Glasgow, Glasgow, United Kingdom

BACKGROUND AND OBJECTIVES
Dairy intake offers nutritional benefits but also raises environmental and ethical concerns. Altering cows' diets is a potential strategy for improving animal health and productivity, thereby reducing the environmental burden whilst enhancing milk's nutritional qualities. This study examined consumer willingness to buy such improved milk products.

METHODS
Participants were recruited at community venues in Ayrshire and Glasgow. Habitual dairy purchasing and intake were assessed using a dairy-specific FFQ. Agreement with statements (n=5) related to sustainability and healthfulness of own diets, and the influence of diet on the environment were assessed using 5-point Likert scales (strong disagree to strong agree). We presented bottle packaging (n=4) providing different information about milk production and nutrition to participants, who ranked purchasing likelihood and factors (n=6) affecting their choices. Product A featured local production and omega-3 content, Product B featured "better for the planet" and "happy healthy cows" statements, natural enrichement with omega-3. Product C had no specific claims. Product D featured "happy healthy cows", enriched with omega-3, local production, fair trade standards, biodiversity protection, reduced methane emissions, and a novel quality assurance logo. A placebo taste test presented participants with four samples of the same milk, labelled to match the different packaging. Participants re-ranked the products from most to least likely to purchase, and were asked how much they would be willing to pay for each product compared to Product C.

RESULTS
Participants (n=26, 50% women, median age 54, IQR 25) had a median dairy intake of 3.7 portions per day (IQR 1.9-5.7), with 54% perceiving to consume a healthy diet, and 31% for sustainable diet. Although most participants (85%) agreed that food choices affect the environment, only 31% agreed that we should consume less dairy for the sake of the environment. Based on packaging, most ranked Product D first (77%) and Product C last (81%). After tasting, 42% selected product D first and 51% ranked Product C last (p=0.234, p=0.05 compared to pre-tasting), with participants willing to pay 15p (IQR 0-30p) more for Product D compared to C. Improved animal welfare was ranked most important (median 2, IQR 1-3), followed by fair trade standards (3 IQR 2-5), local production (3.5 IQR 2-5), environmental impact (4 IQR 3-5) nutrition (4 IQR 2-5) and quality assurance (5 IQR 3-6).

CONCLUSIONS
Participants would be willing to pay more for improved cows' milk, with statements about animal welfare being a critical factor.

EFFECTIVENESS OF "EPIDAURE MARKET": A GAME-BASED INTERVENTION TO TEACH NUTRITION IN MIDDLE SCHOOL

Florian Lecêtre[1]; Nicolas Marco[2]; Blanc Nathalie[3]; ; Sabrina Eymard-Duvernay[4]; Vanessa Cottet[5]; Florence Cousson-Gelie[6]

[1]Psychologie, Paul Valéry University Montpellier 3, Montpellier, France; [2]National Education (France), National Education Administration, Montpellier, France; [3]Epsylon, Paul Valéry University Montpellier 3, Montpellier, France; [4]MoISA, Univ Montpellier, CIHEAM-IAMM, CIRAD, INRAE, Institut Agro, IRD, Montpellier, France; [5]EPICAD Inserm CTM 1231, Chu Dijon, Dijon, France; [6]Epsylon, Université Paul Valéry Montpellier 3, Montpellier, France

BACKGROUND AND OBJECTIVES

Nutrition plays a crucial role in the overall health of populations. However, adolescents often adopt maladaptive dietary behaviors, which can shape their future eating habits. We developed a serious game intervention called **"Epidaure Market"**, a virtual supermarket designed to increase motivation for sustainable food choices (Lecêtre & al, 2024). The intervention consists of three school-based sessions, featuring interactive and engaging activities. This pilot study aims to evaluate the effectiveness of the intervention on adolescents' self-reported food choice motivations.

METHODS

A total of 583 middle school students (24 classes) from the Hérault region in France participated in the study. Twelve classes were assigned to the experimental group and twelve to the control group (which did not receive the intervention). Several factors were evaluated, including food choice motives, nutritional knowledge and skills, perceived social norms, outcome expectations, and self-efficacy. A cluster randomized controlled trial was conducted with three evaluation points: T0 (pre-intervention), T1 (1 month post-intervention), and T2 (4 to 6 months post-intervention).

RESULTS

Mixed-effects models were used, controlling for socio-demographic variables and class effects (clusters). The intervention was effective in improving adolescents' skills ($p < .001$), influencing their sustainable (i.e. including health, local and seasonal products, environmental impact, and ethics) motivations ($p < .05$), and increasing local and seasonal food motivation one month post-intervention ($p < .05$).

CONCLUSIONS

This intervention based on a serious game shows promising RESULTS in promoting sustainable motivations, particularly regarding local and seasonal aspects. However, limitations were observed concerning health-related outcomes, which will be discussed to refine and improve the intervention. A transferability study with the Academy of Dijon (France), a more rural area, is currently underway (Curnier et al., 2024). The preliminary RESULTS can be discussed in light of those already obtained.

CONFLICTS OF INTERESTS

THE INFLUENCE OF GENETIC AND BIOCHEMICAL DIVERSITY OF FOOD CROPS ON CLIMATE RESILIENCE, SUSTAINABILITY, AND NUTRITION

Eunice Amponsah[1]; Amma Larbi[1]
[1]Department of Biochemistry and Biotechnology, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana

BACKGROUND AND OBJECTIVES
Climate change significantly threatens global food security, underscoring the need for resilient, nutrient-dense crops within sustainable agriculture. Food crops, which are well-adapted to challenging environmental conditions, hold considerable promise for enhancing food security. Maintaining food security in low and middle-income countries like Ghana is very crucial because they are likely to suffer the most from exposure to climate shocks, to unsustainable food systems. It is essential to identify indigenous crops that are climate-resilient and have good nutritional quality to enhance food quality, sustainability and human health. This study aims to explore the genetic and biochemical diversity of selected indigenous crops, identifying traits that promote sustainability.

METHODS
This study focuses on three key food crops in Ghana: cassava, tomato, and Bambara groundnut. Samples were collected from local farms to analyze their genetic and biochemical diversity. Utilizing molecular markers and whole genome sequencing, the genetic profiles of these crops were, emphasizing traits related to yield, morphology, and environmental resilience. Moreover, biochemical profiling—including metabolomics, ionomics, and lipidomics—assessed their nutrient composition and bioactive compounds.

RESULTS
The outcomes will inform breeding programs aimed at enhancing crop resilience and nutritional quality, thereby advancing sustainable agriculture and food security.

CONCLUSIONS
In conclusion, leveraging the genetic and biochemical strengths of indigenous crops represents a promising approach to addressing the challenges posed by climate change and nutritional deficiencies, fostering a sustainable agricultural future.

ALMOND SOLIDS FROM ROASTED IN-SHELL ALMONDS AND PLANT-BASED DRINKS FROM ROASTED IN-SHELL ALMONDS AS A NOVEL FOOD AND POTENTIAL FUNCTIONAL FOOD

Tatiana Avellaneda,[1]; Christian Zimmermann,[1]; Tilo Hühn,[2]; Roland Laux,[1]; Hans Verhagen[3]
[1]-, RE-NUT AG, St. Gallen, Switzerland; [2]Centre for Food Composition and Process Design, ZHAW School of Life Sciences and Facility Management, Wädenswil, Switzerland; [3]-, Food Safety & Nutrition Consultancy, Zeist, Netherlands

BACKGROUND AND OBJECTIVES

Almond kernels have a long history of human consumption either raw, cooked, or dry roasted, sliced or whole, blanched or unblanched. Whereas the almond kernel has been the product of interest, the shell has been always removed and often also the skin. As such, the almond industry generates a large amount of by-products. The new RE-NUT® method processes the nuts «in-shell». This doubles the yield of nut flour, paste and milks. Moreover, this leaves in all the nutshells' valuable fiber and antioxidants. This patent-protected technology is now ready to be licensed by nut processors and food companies. Such food ingredients fall under the EU Novel Food Regulation (EU) 2015/2283. EFSA is currently evaluating the novel food dossier no. NF-2024-22731.

METHODS

Physical, chemical and microbiological specifications were established for almond solids from roasted in-shell almonds and plant-based drinks from roasted in-shell almonds. In addition, information and data obtained from the public domain on the components of almond shells (genotoxicity and human clinical studies) were collected.

RESULTS

Almond skin has been identified as a source of phenolic compounds. The shells are rich in fibers such as cellulose, hemicellulose, and lignin. As almond kernel and skin have a history of consumption, no toxicity tests were deemed necessary to further confirm their safety. Same applies to the plant-based drink from roasted in-shell almonds. The analytical data confirm that almond solids from roasted in-shell almonds and plant-based drink from roasted in-shell almonds are relatively low or below the level of detection of microbiological contaminants, heavy metals, and environmental contaminants such as pesticides, aflatoxins. Almond solids from roasted in-shell almonds and plant-based drink from roasted in-shell almonds contain only trace levels of polyphenols, and cyanogenic glycosides are below the level of detection. The potential allergenicity of almond solids from roasted in-shell almonds and plant-based drink from roasted in-shell almonds is considered to be not indifferent from allergy to almonds.

CONCLUSIONS

As per Regulation (EU) 2015/2283, the proposed novel food does not pose a safety risk to human health and does not mislead the consumer. On the contrary, it poses an alternative that can coexist with the current almond ingredients (in solid or liquid form) for different applications. Moreover, the bioactive constituents may provide for a possible unique and pleasant functional food.

EPO2_137

ASSESSING THE AFFORDABILITY OF SUSTAINABLE DIETS: A COMPARATIVE ANALYSIS OF THE COST OF DIETS IN THE URBAN FOOD ENVIRONMENT IN AUSTRIA

Pierre Ellssel[1]; Barbara Stadlmayr[2]; Ulrich Morawetz[3]; Lucia Diez Sanjuan; Ursula Truebswasser[4]
[1]Institute of Agronomy, Universität für Bodenkultur Wien (BOKU), Wien, Austria; [2]Institute for Development Research, Universität für Bodenkultur Wien (BOKU), Wien, Austria; [3]Institute of Sustainable Economic Development, Universität für Bodenkultur Wien (BOKU), Wien, Austria; [4]Institute for Health Sciences, University of Applied Science St. Pölten, St. Pölten, Austria

BACKGROUND AND OBJECTIVES

Inequalities within the agri-food system affect small-scale producers, workers throughout the value chain, and consumers (1). Recent reports on food poverty in Austria highlighted issues related to the affordability of sustainable and healthy diets (2). Consuming a healthy and sustainable diet is crucial to reduce diet-related diseases, addressing planetary health and issues of equity and fairness in the food systems (3, 4).

METHODS

This study investigated the minimum costs of adopting a healthy and sustainable diet (in line with the Austrian food-based dietary guidelines (FBDG)) (5) compared to a reference diet based on the Austrian nutrition report (6). We analysed the affordability of organic versus conventional food products for omnivore and vegetarian dietary patterns. Food price data from eight different supermarkets (ranging from discount to high end markets) and four alternative food networks were collected for 361 food items categorized into the food groups of the Austrian FBDG. For each food group the least expensive item was selected and the amounts (in calories and grams) of each group were calculated to meet the standard Austrian adult dietary energy intake target of 2029kcal/d (5, 7). Our analysis considered the economic implications for consumers, relating the food costs to income and overall food expenditure.

RESULTS

Our RESULTS will show the difference between organic and conventional food choices selected for recommended healthy and sustainable omnivore and vegetarian diets. Differences between different types of food outlets (discount, high-end as well as alternative. Our study will further show how affordable these diets are to different levels of income. The variety and geographic origin of food items will also be presented for selected food outlets.

CONCLUSIONS

Healthy and sustainable diets are associated with affordability issues. Important aspects of acceptability, preferences, and opportunity costs for meal preparation are important factors which should be considered in future studies. Furthermore, social aspects of sustainability including access to basic needs, justice, social inclusion and participation and right to food need to be part of discussions on food affordability.

TRANSCULTURAL ADAPTATION OF QUESTIONNAIRES ON KNOWLEDGE AND ATTITUDES OF HIGHER EDUCATION STUDENTS REGARDING FOOD SYSTEMS

Maria Costa Bittencourt[1]; Aline Rissatto Teixeira[2]
[1]Nutrição em Saúde Pública, Universidade de São Paulo, São Paulo, Brazil; [2]NUTRITION, University of Sao Paulo, School of Public Health, SÃO PAULO, Brazil

BACKGROUND AND OBJECTIVES
The growing discussion about the impacts of current hegemonic food systems on human and environmental health, such as the occupational risks faced by workers in the global agri-food system, the spread of unhealthy dietary patterns, environmental contamination, and the presence of contaminated, unsafe, and adulterated food, highlights the central role of global agendas that intersect discussions on Food Systems, Sustainability, and Food and Nutrition Security. This underscores the need to incorporate the topic into higher education, particularly in courses related to food, understanding that higher education should enhance the understanding of the human being and their surrounding environment and promote awareness of contemporary global challenges. Thus, the objective of this study is to carry out the transcultural adaptation of two international questionnaires, one on knowledge and the other on attitudes of undergraduate students regarding food systems and analyze their validity and reliability.

METHODS
This quantitative study follows a methodological approach consisting of transcultural adaptation and validity analysis of the U.S. "Food Systems Knowledge and Attitudes Survey for College Students," developed at the University of Tennessee. Two questionnaires, each composed of 11 items, are used: the first with dichotomous responses and the second using a Likert type scale. The transcultural adaptation will follow the guidelines of Beaton (2000) and PROMIS (2013), incorporating the following steps: a. Preconditions, b. Translation, c. Synthesis of translations, d. Back-translation, e. Review of back-translation, f. Expert committee, g. Pre-finalization, h. Finalization, i. Harmonization, j. Final review, k. Pilot test, and l. Submission of documentation. Additionally, psychometric tests will be employed, including validity analysis (content validity, response process, internal structure, relationship with other variables, and testing consequences, utilizing classical test theory and exploratory and confirmatory factor analysis) and reliability (using composite reliability tests).

RESULTS
This research will present the validated questionnaires for the Brazilian context, and so far, the translation and back-translation of the instrument have been completed. It is expected that by the time of the conference, the validated Brazilian version of the instrument will be presented.

CONCLUSIONS
These RESULTS will open opportunities for future research, with implications for public policies, changes in curriculum guidelines, and the epistemological foundations of higher education.

PERCEPTIONS AND CONSUMPTION OF PULSES, AND UNDERSTANDING AUSTRALIAN ADOLESCENTS' PERCEPTIONS OF HEALTHY AND SUSTAINABLE DIETS

Adeline Lanham[1, 2]; Ayesha Tulloch[3]; Jessica Bogard[4]; Jolieke Van Der Pols[1, 2]
[1]Centre for Agriculture and the Bioeconomy, Queensland University of Technology (QUT), Brisbane, Australia; [2]School of Exercise and Nutrition Sciences, Faculty of Health, Queensland University of Technology (QUT), Brisbane, Australia; [3]School of Biology and Environmental Science, Queensland University of Technology (QUT), Brisbane City, Australia; [4]CSIRO Agriculture and Food, Commonwealth Scientific and Industrial Research Organisation (CSIRO), Brisbane, Australia

BACKGROUND AND OBJECTIVES
IBACKGROUND AND OBJECTIVES: Increased consumption of pulses (the edible grains of legumes such as lentils and chickpeas) is recommended to promote healthy and sustainable dietary patterns. Dietary behaviours are influenced by consumers' perceptions of foods, and their capability, opportunity and motivation to make specific dietary choices. Adolescence is a period in which perceptions and behaviours develop that can impact lifelong dietary behaviours. This project aimed to understand how Australian adolescents perceive healthy, sustainable diets, and perceive and consume pulses.

METHODS
Highschool students (11-17 years old, n=33) in Brisbane, Australia participated in face-to-face focus groups to discuss their perceptions of, and barriers and enablers of healthy and sustainable diets, and pulses. Participants completed an online survey regarding their consumption patterns of pulses.

RESULTS
Adolescents' perceptions of healthy and sustainable dietary behaviours largely focused on the health aspects of food, and consideration of food waste behaviours. The main factors influencing the health and sustainability of their diet were a lack of perceived responsibility for the impact of their meal choices, and lack of knowledge of what constitutes a healthy and sustainable diet. Most adolescents were unfamiliar with the term 'pulses' and lacked a desire to consume pulses more often. Consumption of pulses was lower than recommended in national and international dietary guidelines. The main factors influencing pulse consumption related to adolescents' lack of skills and knowledge to prepare pulses, and the reduced accessibility and availability of appealing pulse-based foods.

CONCLUSIONS
Education and cooking classes, and increased availability of tasty pulse foods are recommended to increase adolescents' pulse consumption as part of a healthy and sustainable diet.

NUTRITIONAL LIFE CYCLE ASSESSMENT (LCA) OF SHIFTING TO PULSES FROM ANIMAL SOURCED FOODS: AN AUSTRALIAN CASE STUDY OF HUMMUS VS HAM SANDWICH

Adeline Lanham[1, 2]; Marguerite Renouf[3]; Jolieke Van Der Pols[1, 2]
[1]Centre for Agriculture and the Bioeconomy, Queensland University of Technology (QUT), Brisbane, Australia; [2]School of Exercise and Nutrition Sciences, Faculty of Health, Queensland University of Technology (QUT), Brisbane, Australia; [3]Lifecycles Australia, Lifecycles Australia, Brisbane, Australia

BACKGROUND AND OBJECTIVES
Increased consumption of foods with pulses (eg. lentils or chickpeas), which are a source of protein, is suggested due to their lower environmental impact than animal-sourced foods. However, Australian data for the environmental and nutritional trade-offs for such a dietary shift has been lacking. We therefore assessed the environmental and nutritional impact of consuming hummus or ham on a sandwich using Australian data.

METHODS
The environmental impact of two scenarios of ham (produced in Australia or imported from Europe) and three scenarios of hummus (produced commercially, or homemade with canned or dried chickpeas), within the meal context of a sandwich were evaluated using LCA. Impacts considered were climate change, water scarcity and eutrophication potential. Life cycle inventory data were adapted for the Australian context, from cradle to plate. The nutritional value of ham or hummus sandwiches were evaluated using the Nutrient Rich Foods Index (NRF9.3-including nine beneficial nutrients and three nutrients to limit).

RESULTS
Initial RESULTS indicate that the environmental impact of a hummus sandwich was lower than a ham sandwich across all environmental indicators, regardless of the production methods of ham or hummus. Quantitative environmental impact indicators for each of the ham and hummus scenarios will be presented at the conference. A sandwich with homemade hummus had the greatest positive nutritional value (NRF9=0.23 for boys (aged 14-18yo); NRF9=0.28 for girls (aged 14-18yo)), with less nutritional value from the commercial hummus (NRF9=0.17 for boys; NRF9=0.28 for girls), and from ham (NRF9=0.09 for boys; NRF9=0.11 for girls). The score for nutrients to limit was largest for a sandwich with ham (NRF3=-0.12 for boys; NRF3=-0.12 for boys) than homemade hummus (NRF3=-0.08 for boys; NRF3=-0.08 for girls) or commercial hummus (NRF3=-0.08 for boys; -0.02 for girls).

CONCLUSIONS
Using Australian data, this case study demonstrated that hummus, in comparison to ham, in a sandwich, has lower environmental impact, and healthier nutritional profile. Localised data should be used in LCA studies.

AGRICULTURE, FOOD AND NUTRITION SECURITY IN NIGER STATE, NIGERIA

Oluwaseun Ariyo; Victor Adejoh[1]; Godswill Aguiyi[2]; Toluwalope Emmanuel Eyinla[3]; Umar Alhassan[4]; U. I. Gbongan,[5]; Musa Isah Mohammed[5]; Oluwatomilola Aladesanmi[3]; Chioma Nnabugwu[3]
[1]Country Director, Synergos Development Innovations, Abuja, Nigeria, Abuja, Nigeria, Federal Republic of; [2]3. Alliance for Green Revolution Africa (AGRA), Abuja, Nigeria, 3. Alliance for Green Revolution Africa (AGRA), Abuja, Nigeria, Abuja, Nigeria, Federal Republic of; [3]Human Nutrition and Dietetics, University of Ibadan, Ibadan, Nigeria, Ibadan, Nigeria, Federal Republic of; [4]Agriculture, 4. Niger State Ministry of Agriculture and Rural Development, Minna, Nigeria, Minna, Nigeria, Federal Republic of; [5]Agriculture, Niger State Ministry of Agriculture and Rural Development, Minna, Minna, Nigeria, Federal Republic of

BACKGROUND AND OBJECTIVES

Agriculture remains a major driver of Nigeria's economy, yet malnutrition persists. This study was designed to evaluate agricultural diversification, food security and nutrition situation to inform policy reform and agricultural programme interventions in Niger state.

METHODS

The mixed-method study involved a two-stage cluster sampling of 451 households across 13 Local Government Areas. An interviewer-administered questionnaire was used to collect data including socio-demographic characteristics, dietary intake (Minimum Dietary Diversity classified as low (*<5*) and high (*≥5)*, *Household food insecurity access*, and agricultural output diversification (Herfindahl Index HHI lassified as low (<0.01), medium *(0.01 < HHI ≤ 0.18)* and high *(HHI > 0.18).* In-depth interviews were conducted with agriculture stakeholders, and focus group discussions with women's groups *to explore understanding of healthy diet, utilization of indigenous food crops and household food consumption practices*. Data analysis included descriptive statistics, and thematic analysis of qualitative data.

RESULTS

Households were largely male-headed (92.9%), medium-sized (4-6 members) (61.0%), and earned income below N500,000 (US$350) *annually (65.2%). Sugar/salt/spices (99.15%), fish/meat/egg/poultry group (97.44%), fruits and vegetable (92.02%), cereals and grain group (80.06%) were the most purchased food groups. About half (51.9%) of the households combined crop production and livestock, 65% had access to extension services, and only 33% practiced dry season farming. Majority (68%) had low, 12% had medium and 20% had high output diversification. About 65% were food insecure including mild/moderate (38.8%), and severe (26.5%). Coping strategies were reduction in consumption expenditures (64.7%) and reducing meals (63.2%).* Mean dietary diversity was 3.63 ± 1.08 and only 21.7% met MDDW. Women expressed fair understanding of the concept of healthy diet, however, food preparation is largely influenced by household food availability and the preference of the household head.

CONCLUSIONS

Food insecurity and poor diet quality characterise farming households in Niger state, and context-relevant food system interventions are required.

EXPLORING RAW VEGETABLE WASTE AND RESOURCE RECOVERY IN A INDONESIA NATIONAL NUTRITION PROGRAM

Ju Lan Phan[1]; Avita Usfar[2]
[1]Research, Dakra Consultant, Bekasi, Indonesia; [2]Research, Reconstra Utama Integra, Jakarta, Indonesia

BACKGROUND AND OBJECTIVES

In January 2025, the newly established National Nutrition Agency embarked on a transformative initiative to combat malnutrition and promote health among vulnerable populations. Over the span of five years, the agency aims to deliver one nutritious school meal per day to students in both public and private schools, every two days for children under the age of five, pregnant and lactating women, with a total of 83 million individuals. With budget of USD 4.4 million for the first year, each meal is valued at USD 0.62 and is designed to meet 20 to 35% of daily nutritional requirements, providing around 328 to 818 kilocalories. By the end of January 2025, the program seeks to establish 937 Nutrition Service Units (NSUs), each serving between 3,000 to 4,000 individuals. We would like to explore the potentials of raw vegetable waste resulted by this initiative.

METHODS

Our approach involved literature search and analysis. The search encompassed a review of the agency's site, news, and regulation of the program. The analysis included calculations of the potential value of vegetable waste into compost and other usage.

RESULTS

Assuming each person is served with 50 gram of green-leafy vegetables and 27% waste rate, each person contributes 18 g of raw vegetable waste per day. Each Nutrition Service Unit (NSU) that serves 3,500 people is estimated to generate around 65 kg of raw vegetable waste per day or 19 kg of compost. The compost will be able to enrich 9 green-leafy vegetable plants, assuming each plant needs about 2 kg of compost for its growth. Per month, there will be 380 kg of compost produced, with the ability to enrich all plants needed for one NSU for one month (159 plants or 476 kg of raw vegetables). The leftover compost can be sold for potential income of USD 17.00 per month that can be used to purchase the seeds and other necessitie

CONCLUSIONS

There is a potential self-sufficiency of the NSU in providing its monthly green-leafy vegetable need by managing its vegetable waste. These RESULTS highlight the potential for significant resource recovery and environmental benefits through effective waste management practices.

EPO2_146

NUTRITIONAL IMPACT OF FOOD LOSS AND WASTE IN THE PROCESSING, DISTRIBUTION AND RETAIL OPERATIONS OF MICRO, SMALL AND MEDIUM-SIZED FOOD-PROCESSING ENTERPRISES IN THAILAND: A COUNTRYWIDE SURVEY ON FIVE FOOD CATEGORIES

Nattapol Tangsuphoom[1]; Rosa S. Rolle[2]; Sueppong Gowachirapant[1]
[1]Institute of Nutrition, Mahidol University, Nakhon Pathom, Thailand; [2]Food and Nutrition Division, Food and Agriculture Organization of the United Nations, Rome, Italy

BACKGROUND AND OBJECTIVES
Reducing food loss and waste (FLW) in a sustainable manner offers considerable potential for improving food security and nutrition and generating economic and environmental benefits. Nevertheless, significant quantities of FLW are generated in micro, small and medium-sized food processing enterprises (MSMEs). Reducing FLW is not, however, a high priority for many MSMEs, and they often do not quantify FLW and consider its impact in their operations. Information on FLW in MSMEs is thus currently scarce. This study aimed to measure and reduce FLW and to determine nutritional impact in the operations of MSMEs in Thailand.

METHODS
FLW measurements were conducted following the Food Loss and Waste Protocol's Guidance on FLW Quantification Methods in 25 MSMEs in Thailand across 5 food categories, namely meat products, fish products, processed fruits, rice, and dairy products. Five representative MSMEs countrywide were purposively selected for each food category. Data was collected for 5 operation days at each enterprise in June-November 2022. The amount of FLW in processing, distribution and retail operations was quantified. Nutrient content was estimated using INMUCAL-Nutrients V.4.0 software.

RESULTS
The median (range) percentage of avoidable FLW in MSMEs was 11.10 (6.22-15.17) for meat products, 8.75 (4.18-36.75) for fish products, 7.60 (4.35-19.83) for processed fruits, 22.57 (6.21-41.65) for rice, and 2.61 (0.54-16.04) for dairy products. For each kg of raw material input (RM), the highest caloric loss due to FLW was found in rice processing enterprises (811.88 kcal/kg RM), while that of milk processors was the lowest (16.18 kcal/kg RM). Comparing with the recommended daily amounts of meat, fish, fruits, rice, and milk for healthy Thai adults, FLW generated from each 100 kg RM would be sufficient for 62, 65, 55, 38, and 13 persons, respectively.

CONCLUSIONS
This is the first study providing evidence-based information on FLW in food processing MSMEs in Thailand. The quantity of FLW and its associated nutrients varied among different food categories and enterprises. FLW not only negatively affects the profitability of MSMEs but also has an adverse impact on the availability of food to fulfill nutritional requirements of the population, which consequently threatens food security and sustainability.

THE ASSOCIATION BETWEEN SUSTAINABLE AND HEALTHY EATING BEHAVIORS AND DEPRESSION, STRESS, AND ANXIETY IN ADULTS

Gülsüm Kara[1]; Seda Nur Köktürk[2]; Hülya Yardımcı[1]
[1]Nutrition and Dietetics, Ankara University Faculty of Health Sciences, Ankara, Türkiye; [2]Nutrition and Dietetics, Ankara University Graduate School of Health Sciences, Ankara, Türkiye

BACKGROUND AND OBJECTIVES
The aim of this study is to determine the relationship between sustainable and healthy eating behaviors and depression, stress, and anxiety in adults.

METHODS
A questionnaire form including sociodemographic information, the Sustainable and Healthy Eating Behaviors Scale, and the Depression, Anxiety, and Stress Scale-21 was administered to the participants. The Kruskal-Wallis test was employed to determine differences among the groups.

RESULTS
The study included a total of 375 participants aged between 19 and 64 years. Among the participants, 25,3% were male, and 74,7% were female. The median age was 25 (19-62) years. In terms of education level, 53,9% of the participants graduated from high school, and 35,5% from university. When participants were grouped based on their depression scores, significant differences were observed in the scores of the sub-dimensions *Quality Labels*, *Seasonal Food* and *Avoiding Food Waste*, *Animal Welfare*, *Healthy* and *Balanced Diet*, *Local Food*, and *Low Fat* ($p < 0.05$). Similarly, grouping by anxiety scores revealed significant variations in the sub-dimensions of avoiding *Food Waste* and *Healthy And Balanced Diet* ($p < 0.005$). Conversely, no statistically significant differences were found between groups when categorized by stress scores ($p > 0.05$).

CONCLUSIONS
The RESULTS of this study suggest that depression scores are significantly associated with sustainable and healthy eating behaviours. These findings emphasise the importance of nutritional strategies that simultaneously improve mental health and promote environmental sustainability.

THE EFFECT OF ECO-LABELS AND PRICE DISCOUNTS TO PROMOTE SUSTAINABLE FOOD PURCHASES ON THE NUTRITIONAL CONTENT OF ONLINE GROCERY PURCHASES IN THE UK: A RANDOMISED CONTROLLED TRIAL

Helena Bentil[1]; Oyinlola Oyebode[2]; Edward Hillier[1]; Hamideh Borzadaran[3]; Peter Scarborough[4]; Martin White[5]; Claire Thompson[6]; Jessica Brock[6]; Michael Clark,[7]; Theresa Marteau[8]; Jean Adams[9]; Thijs Van Rens[1]
[1]Economics, University of Warwick, Coventry, United Kingdom; [2]Wolfson Institute of Population Health, Queen Mary University of London, London, United Kingdom; [3]Institute of Applied Health Research, University of Birmingham, Birmingham, United Kingdom; [4]Nuffield Department of Primary Care Health Sciences, University of Oxford, Oxford, United Kingdom; [5]Medical Research Council Epidemiology Unit, University of Cambridge, Cambridge, United Kingdom; [6]School of Health and Social Work, University of Hertfordshire, Hatfield, United Kingdom; [7]Smith School of Enterprise and the Environment, University of Oxford, Oxford, United Kingdom; [8]Behaviour and Health Research Unit, University of Cambridge, Cambridge, United Kingdom; [9]MRC Epidemiology Unit, University of Cambridge, Cambridge, United Kingdom

BACKGROUND AND OBJECTIVES
Effective interventions are needed to promote both sustainable and healthier food choices. However, interventions aimed at promoting sustainable food purchasing could also support better nutritional outcomes or have unintended negative side effects. Using an online grocery shop, which offers a way to study and evaluate these interventions on a large scale, we assessed the effect of eco-labels and price discounts on the nutritional content of shopping baskets in a real online supermarket in the UK.

METHODS
Participants were recruited from the UK Prolific panel and randomly assigned to one of six groups in a 2x3 factorial design. The interventions included: (i) eco-labels, which displayed the environmental impact of products on a scale from A (lowest impact, most sustainable) to G (highest impact, least sustainable), and (ii) price discounts (£1, £0.50, or no discount) offered on more sustainable alternative products that were in the same or a better category for fat (including saturated fat), sugar, and salt content on the traffic-light label for $\leq$3 items in their basket. Nutritional outcomes measured included energy (KJ/100g), fat, sugar, salt, and saturated fat (all in g/100g). Regression analysis was used to assess the effect of the interventions on these nutritional outcomes.

RESULTS
A total of 1,426 participants who shopped at least once were included in the analysis. The eco-labels had a very small, non-statistically significant effect on the nutritional content of baskets, with increases in sugar (b = 0.183, p = 0.39), fat (b = 0.053, p = 0.79), saturated fat (b = 0.107, p = 0.32), and energy (b = 10.461, p = 0.30), and small, non-significant decreases in salt (b = -0.017, p = 0.72). Similarly, the £0.50 discount showed small, non-significant effects on sugar (b = -0.263, p = 0.30), salt (b = -0.035, p = 0.49), saturated fat (b = -0.114, p = 0.34), energy (b = -10.594, p = 0.24), and fat (b = -0.054, p = 0.79). The £1 discount also did not appear to affect the nutritional content of purchases [sugar (b = 0.091, p = 0.73), salt (b = 0.025, p = 0.70), and fat (b = 0.023, p = 0.92)], except that energy purchased may have been slightly lower (b = -7.280) but this difference was also not statistically significant (p=0.07).

CONCLUSIONS
Eco-labels and price discounts did not lead to statistically significant changes in nutritional outcomes. These findings suggest that further research is needed to explore the potential effectiveness of such interventions in promoting healthier food choices.

CONFLICTS OF INTERESTS
The authors have no conflict of interest.

EFFECTS OF A CRICKET-BASED DIET ON GROWTH, BODY COMPOSITION AND BONE PARAMETERS IN PROTEIN-DEFICIENT MALE AND FEMALE JUVENILE SPRAGUE-DAWLEY RATS

Xin Qian Ng[1]; See Meng Lim[1]; Elvy Suhana Mohd Ramli[2]; Kok Yong Chin[3]; Siti Balkis Binti Budin[4]
[1]Centre for Community Health Studies (ReaCH), Faculty of Health Sciences, Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia; [2]Department of Anatomy, Universiti kebangsaan Malaysia Medical Center, Kuala Lumpur, Malaysia; [3]Department of Farmakologi, Universiti kebangsaan Malaysia Medical Center, Kuala Lumpur, Malaysia; [4]Centre for Diagnostic, Therapeutic and Investigative Studies (CODTIS), Faculty of Health Sciences, Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia

BACKGROUND AND OBJECTIVES
Protein-energy malnutrition is a major global health problem and contributes to stunted growth and impaired musculoskeletal development, particularly in children in low- to middle-income countries. Cricket (Order: Orthoptera) has a protein content comparable to that of meat while being environmentally friendly. This study aimed to investigate the effects of a cricket-based diet (CBD) on growth, body composition and bone parameters in protein-deficient juvenile Sprague-Dawley rats of both sexes.

METHODS
Three-week old male and female rats were first fed either a low-protein diet (LPD, 6% protein; n=24/group/sex) or a normal-protein diet (NPD, 18% protein from casein; n=8/group/sex) for 3-week to induce malnutrition in the LPD group. The LPD group was then divided into three subgroups for a 7-week intervention: LPD (maintaining LPD), treated protein diet (TPD; switching to NPD) and CBD (feeding CBD; 18% protein diet from cricket). The NPD group remained on the NPD.

RESULTS
Both the male and female LPD groups had significantly ($p<0.05$) lower body weight, body length, tail length and abdominal circumference than the male and female NPD groups after the 10-week feeding period. Both the male and female LPD groups also had significantly ($p<0.05$) lower femur and tibia weight, bone mineral density, bone mineral content, lean mass and fat mass than the NPD rats. However, no significant difference in these parameters was found between the male LPD, TPD and CBD groups. Similarly, no significant difference in these parameters was also found between the female LPD, TPD and CBD groups, except that female CBD group had lower body mineral content and fat mass than the female TPD and NPD groups. There were no significant differences between all groups in bone biomechanical strength, bone calcium content and serum IGF-1 levels in either sex.

CONCLUSIONS
Low protein diet exerts adverse effects on growth, body composition and bone parameters in both male and female rats. These adverse effects cannot be reversed by re-supplementation with casein or protein from cricket. Further studies should explore the long-term effects of consuming cricket as a sustainable protein on growth, body composition and bone parameters to combat malnutrition.

INDIGENOUS KNOWLEDGE AND SPIRITUALITY ATTACHMENTS TO THE GROWING, PROCESSING AND CONSUMPTION OF SELECTED GHANAIAN FOOD CROPS ACROSS THE VALUE CHAIN

FELIX OBENG[1]
[1]Sociology & Social Work, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana

BACKGROUND AND OBJECTIVES
Indigenous knowledge and spirituality fundamentally shape how communities interact with their environment, particularly regarding food systems. This research explores these connections in the context of Ghanaian food crops, examining how indigenous knowledge and spiritual beliefs influence growing, processing, and consumption practices.. The study aims to document indigenous knowledge systems in Kintampo and Techiman, Ghana, analyse the social significance of food practices, and investigate how spiritual attachments or beliefs impact food cultivation, processing, and consumption.

METHODS
Using a mixed-method approach with a Convergent Parallel Design, the study targets 384 respondents for quantitative data, while the qualitative sample size will be determined through saturation.

RESULTS
A preliminary analysis of 348 quantitative responses has been conducted to understand the relationships between spiritual beliefs, agricultural practices, and productivity outcomes. Initial findings indicate that demographic factors including age, sex, and religion have minimal influence on agricultural practices. However, specific spiritual beliefs, particularly trust in ancestral spirits guiding agricultural practices, significantly impact crop yields

CONCLUSIONS
The preliminary findings emphasise the cultural significance of spirituality in agricultural productivity and highlights the complex relationship between traditional beliefs and farming success in these communities.

FERMENTED TENEBRIO MOLITOR LARVAE EXTRACT MITIGATES OSTEOSARCOPENIA BY REGULATING THE CROSSTALK BETWEEN SKELETAL MUSCLE AND BONE THROUGH THE RANKL-NFKB/MAPK SIGNALING PATHWAY

Soo-Young Choi[1]; Se-Hwa Kim[1]; Mi-Kyung Lee[1]
[1]Department of Food and Nutrition, Sunchon National University, Suncheon, Korea, Republic of

BACKGROUND AND OBJECTIVES
Tenebrio molitor Larvae (mealworms) are recognized as a representative alternative protein source among edible insect for the future. When fermenting mealworms with yeast (FME), the amino acid content, particularly the branched-chain amino acid contents, increased approximately two-fold. Recently, osteosarcopenia (OS) has been found to increase the risk of mortality in older people. Our previous study demonstrated that FME simultaneously alleviates both osteoporosis and sarcopenia in ovariectomized mice. Therefore, the present study aimed to identify a baseline for improving OS by determining the effect of FME on the interaction between muscle and bone tissues.

METHODS
OS was induced through ovariectomy, and the mice were divided into five groups: sham, ovariectomy (OVX), OVX with two doses of FME (200 and 500 mg/kg, orally), and OVX with alendronate (positive control, 500 μg/kg, orally) for 15 weeks. Markers of crosstalk between skeletal muscle and bone were measured using western blot, RT-qPCR, and ELISA.

RESULTS
OVX decreased serum estradiol level, while increased the levels of RANKL, IL-6, and CTX-1. In contrast, the FME500 group was able to restore these levels. In both muscle and bone tissues, OVX upregulated the cytokines RANKL, IL-6, and TNF-α, while downregulated IGF-1, indicating that OVX promotes both muscle atrophy and bone resorption, simultaneously. However, the FME500 group significantly improved the levels of these cytokines. FME suppressed the phosphorylation of AMPK and increased phosphorylation of Akt in muscle tissue, thereby activating mTOR (which promotes protein synthesis) and inactivating FoxO3α (which is involved in protein degradation). Additionally, FME inactivated the RANKL-NFκB/MAPK pathway, leading to an increase in muscle protein synthesis markers (MyoD and MHC) and a decrease in muscle degradation markers (atrogin-1 and MuRF-1) compared to the OVX group. In bone tissue, FME inhibited osteoclast differentiation through the phosphorylation of Akt and inactivation of the RANKL-NFκB-cFos-NFATc1 and MAPK signaling pathways. This resulted in suppressed osteoclast activation (as indicated by cathepsin K) and reduced bone resorption (as indicated by TRAP) in OVX mice.

CONCLUSIONS
These RESULTS demonstrated that sustainable alternative protein FME has ameliorative effects in OS, simultaneously modulating the RANKL-NFκB/MAPK and Akt signaling pathways in both bone and muscle.

BACKGROUND AND OBJECTIVES
Food production has caused significant negative impacts on the environment, especially on natural resources such as soil, water and atmosphere. In this context, a balanced diet should benefit people's health and the planet. Dietary sustainability can be assessed by environmental indicators such as land use, greenhouse gas (GHG) emissions, eutrophication and freshwater use. Thus, the objective of this study was to validate the sustainability of the Meal Quality Index based on the evaluation of meal photos (MQI-photo) and to compare the quantification of land use, GHG emissions, eutrophication and freshwater use of meals with the final MQI-photo score.

METHODS
Secondary data from the “ClicPrato” project was used, which assesses meal quality through photographic records of lunch and/or dinner, based on nine components developed based on national and international recommendations. Ninety participants sent photos of their meals, recording food and respective quantities. Environmental indicators (land use, GHG emissions, eutrophication and freshwater use) were calculated using World Wide Fund for Nature (WWF) data. Statistical analyses were performed using STATA® software (version 14.0; College Station, Texas, USA), with a significance level of 5%, using Spearman correlation, Bland-Altman analysis and Kappa statistics to assess the agreement between the IQR-photo tertiles and the environmental indicators.

RESULTS
According to the final IQR-photo score categorized into tertiles, that is, the higher the tertile, the better the quality of the meal; it was possible to observe that the individuals who were in the first tertile presented the highest values referring to the environmental indicators when compared to the third tertile. There was no correlation between the IQR-photo score and the quantification of the environmental impact indicators ($p > 0.05$). The agreement between the tertiles of the IQR-photo score and the environmental impact indicators was also carried out. It was observed that the exact agreement between the tertiles ranged from 27.8% to 35.6%; however, it was not significant ($p > 0.05$).

CONCLUSIONS
Although no significant associations were identified, the literature suggests possible positive relationships between meal quality and sustainability. These RESULTS reinforce the need to improve the index and for new studies to explore these relationships in greater depth.

CLIMATE CHANGE-RELATED METABOLOMICS STUDY OF RAW MILK FROM THAI CATTLE FARMS

Wimonphan Chathiran[1]; Pattaraporn Morasin[1]; Jaruwan Chimasangkanan[1]; Saiyasombat Worakrit[1]; Warangkana Srichamnong[1]
[1]Institute of Nutrition, Mahidol University, Nakhon Pathom, Thailand

BACKGROUND AND OBJECTIVES

Dairy products are one of the conventional foods that are a crucial source of nutrients to promote the people's health at all ages. Meanwhile, climate change is a crucial issue worldwide that impacts planetary health, including dairy production. Previous research focused on heat-induced changes in cows' behavior and milk yield. However, few studies have addressed the global changes in metabolic pathways in milk, particularly in Thailand. To expand this matter, this project aims to explore the metabolomics profile in milk related to climate change.

METHODS

The study is conducting on a dairy farm in Thailand in which a sampling plan in different seasons. The biggest differences in temperature and humidity along the year were considered the main factors to collect the milk samples. The area of sampling was selected, which represents the biggest dairy cooperative center, the Dairy Farming Promotion Organization of Thailand (DPO). The milk samples in this study are from DPO production and cooperative cattle farms. The analysis was done with proximate composition and SB-Aq metabolomics using LC-qTOF/MS.

RESULTS

The preliminary data of the milk sample from the first batch showed that the nutrient composition of the samples were similar. And also the preliminary metabolomics profile was similar but different in some sources, as shown statistically by PCA analysis. Qualitative analysis of metabolites found that 405 compounds were discriminating up-down regulated in each group of samples. For further RESULTS, milk from different seasons was compared.

CONCLUSIONS

These research findings can support more in-depth research to explicate the milk-based changes in nutrient and metabolic pathways in dairy cows.

ADOLESCENTS' PERCEPTION OF "VEGETARIAN DAY" AND ITS ASSOCIATION WITH NUTRITIONAL STATUS IN SOUTH KOREA

Su-Ryeon Han[1]; Bo-Young Lyum[2]; Mi-Kyeong Choi[1]; Yun-Jung Bae[3]
[1]Dept. of Food and Nutrition, Kongju National University, Yesan, Korea, Republic of; [2]Major in Nutrition Education, Graduate School of Education, Kongju National University, Yesan, Korea, Republic of; [3]Major in Food and Nutrition, Korea National University of Transportation, Jeungpyeong, Korea, Republic of

BACKGROUND AND OBJECTIVES
In South Korea, schools have been implementing a regular “Vegetarian Day” in school meals to promote adolescent health and encourage sustainable dietary practices. However, research on adolescents’ perceptions of Vegetarian Day and its association with their nutritional status remains limited. This study aims to assess perception of sustainable eating habits and Vegetarian Day, as well as the overall quality of their diet, and to investigate their association in Korean adolescents.

METHODS
A survey was conducted in July 2023 among 372 middle and high school students (230 males and 142 females) in Daejeon, South Korea. The survey questionnaire was structured into four categories: general characteristics, Nutrition Quotient for Adolescents (NQ-A), sustainable eating education, and perception of Vegetarian Day.

RESULTS
Among the participants, 56.2% had received education on sustainable eating. The most relevant topics for sustainable eating education were ranked as follows: environmental impact (36.8%), health effects (33.3%), and animal welfare and ethical issues (12.7%). Perception of Vegetarian Day was assessed using a 5-point Likert scale, with an overall score of 3.21. The statement “I think Vegetarian Day will help students' health” received the highest score (3.67), while “I think the meat alternative food used in school is delicious” received the lowest score (2.80). Correlation analysis showed a significant positive association between perception of Vegetarian Day and the total NQ-A score ($r=0.166$, $P<0.01$) as well as the moderation NQ-A score ($r=0.203$, $P<0.001$). Furthermore, regression analysis indicated that perception of Vegetarian Day had a significant impact on the total NQ-A score ($P<0.01$), the balance NQ-A score ($P<0.05$), and the moderation NQ-A score ($P<0.001$), with explanatory power (R^2) values of 0.027, 0.012, and 0.038, respectively.

CONCLUSIONS
These findings highlight the importance of sustainable eating education for adolescents and provide foundational evidence for exploring the relationship between sustainable dietary practices and nutritional status.

BARRIERS THAT MEDIATE THE ASSOCIATIONS BETWEEN AN INDIVIDUAL'S VALUES AND CONSUMING LEGUMES SELDOM

Elviira Lehto[1]; Hanna Konttinen,[2]; Kirsi Korhonen,[3]
[1]Department of Food and Nutrition, University of Helsinki, Helsinki, Finland; [2]Department of Social Psychology, University of Helsinki, Helsinki, Finland; [3]Natural Resources Institute Finland, Natural Resources Institute Finland, Oulu, Finland

BACKGROUND AND OBJECTIVES

To promote health and sustainability, the New Nordic Nutrition Recommendations encourage increase in legume consumption. An individual's values are life guiding principles that are known to be associated also with consumption of plant-based protein sources. We examined what factors explain the associations between valuing power, achievement, hedonism, and tradition, and seldomly consuming legumes.

METHODS

18–75-year-old Finns (n=1000) completed an online survey in autumn 2020. Values were assessed with a Short Schwartz's Value Survey, barriers with thirteen questions, and legume consumption with a short Food Frequency Questionnaire. We examined the associations using mediation analyses (lavaan package, R), adjusting for gender, age, and education.

RESULTS

Individuals valuing power and tradition reported the most barriers to consuming legumes (Table 1). The most common mediator was considering legumes tedious to prepare, followed by not liking the mouthfeel of legumes and believing that their family would not eat them.

Table 1. Mediators of the associations of an individual's values and consuming legumes seldom (< once a month) (p<.05).

Barriers for legume consumption:	Power	Achievement	Hedonism	Tradition
Are not familiar				+
Don't like the taste	+		+	
Unpleasent mouthfeel	+		+	+
Don't know how to prepare		+		+
Preparing is tedious	+	+	+	+
Family doesn't want to eat	+	+		+
Cause stomach problems	+			
Don't satiete				+
Are not healthy	+			+
Are not sustainable	+			+

CONCLUSIONS

Individuals valuing power, achievement, hedonism, and tradition might benefit from diverse emphasis in the communication and interventions promoting legume consumption. Still, providing legumes that are ready-to-use and familiarizing individuals with the mouthfeel may help increase legume consumption among individuals with diverse values.

OILSEED CAKES AS SUSTAINABLE SOURCES OF AMINO ACIDS AND MINERALS

Vanja Todorovic[1]; Nevena Dabetic[1]; Bojana Vidovic[1]; Brizita Djordjevic[1]; Sladjana Sobajic[1]
[1]Department of Bromatology, University of Belgrade-Faculty of Pharmacy, Belgrade, Serbia

BACKGROUND AND OBJECTIVES
Oilseed cakes, the by-products of oil extraction processes, are traditionally used as compost, fertilizers, or animal feed due to their high protein, fiber, vitamin, mineral, and antioxidant content. With the increasing global demand for sustainable protein sources and environmental challenges, these nutrient-rich by-products are gaining attention for their potential in human nutrition. This aligns with the principles of the circular economy, promoting resource efficiency and waste reduction. The objective of this study was to characterize the amino acid and mineral profiles of pumpkin and sunflower oilseed cake flours, assessing their nutritional value and suitability for incorporation into innovative food products.

METHODS
To evaluate the nutritional composition of pumpkin and sunflower oilseed cake flours, amino acid profiling was conducted using ion chromatography with electrochemical detection. Mineral content analysis was performed using inductively coupled plasma mass spectrometry (ICP-MS).

RESULTS
The RESULTS revealed that, as expected, oilseed cake proteins lacked sulfur amino acids. In pumpkin oilseed cake flour L-glutamate was the most abundant (11.68%), followed by L-arginine (8.02%) and L-aspartate (5.11%). L-glutamate was the main amino acid in sunflower oilseed cake flour as well, but the percentage of it was lower (7.26%). When it comes to minerals, potassium was found in high concentrations in both oilseed cake flours (1915 mg/100 g and 1410 mg/100 g for pumpkin and sunflower, respectively). Also, sunflower oilseed cake flour was characterized by high amounts of calcium (1937 mg/100 g).

CONCLUSIONS
Based on these findings, it can be concluded that oilseed cakes represent rich sources of minerals and valuable amino acids. Their broader utilization for human consumption would contribute to the sustainable development of the food industry and open more opportunities for the development of innovative food products.

THE RELATIONSHIP BETWEEN SUSTAINABLE AND HEALTHY EATING BEHAVIORS AND THE TREND OF ORGANIC FOOD CONSUMPTION WITH THE ADHERENCE TO THE MEDITERRANEAN DIET IN EMERGING ADULTS

Emine Yassıbaş[1]; Hatice Bölkbaşı[2]; Ayşe Sena Ulugülyağcı[1]; Elif Akdeniz[1]; ÖZge Tunç[1]
[1]Nutrition and Dietetics, Gazi University, Ankara, Türkiye; [2]Nutrition and Dietetics, Süleyman Demirel University, Isparta, Türkiye

BACKGROUND AND OBJECTIVES
The Mediterranean diet is promising as a sustainable dietary model with its health and environmental benefits and encouragement of organic food consumption. The aim of this study was to identify emerging adults' sustainable and healthy eating behaviors and organic food consumption, and to evaluate their relationship with adherence to the Mediterranean diet.

METHODS
A questionnaire prepared by the researchers was administered to the participants through face-to-face interviews. The participants' sociodemographic characteristics and eating habits were questioned with the questionnaire form, the "Sustainable and Healthy Eating Behavior Scale" was used to evaluate sustainable and healthy eating behaviors, the "Organic Food Consumption Scale" was used to determine organic food consumption, and the "Mediterranean Diet Adherence Scale (MEDAS)" was used to evaluate adherence to the Mediterranean diet.

RESULTS
A total of 500 adults participated in the study, including 214 men and 286 women, with an average age of 21.7 ± 1.76 years. When the individuals' adherence levels to the Mediterranean diet were evaluated, it was determined that 61.4% had low adherence, 29.2% had moderate adherence, and 9.4% had high adherence. A weak, yet significant positive relationship was found between the individuals' MEDAS scores and the total score and all sub-dimensions of the Sustainable and Healthy Eating Scale. Similarly, there was a weak, yet significant positive relationship between the other sub-dimensions of the organic food consumption scale other than norms and health awareness and the MEDAS scores ($p<0.05$).

CONCLUSIONS
The RESULTS of the study emphasize the importance of promoting sustainable healthy eating behaviors and organic food consumption in emerging adults, as their adherence to the Mediterranean diet, considered a sustainable eating model, was found to be quite low.

SOLIDARITY KITCHEN AS A STRATEGY TO STRENGTHEN LOCAL SUSTAINABLE FOOD SYSTEMS - THE CASE OF DIRINEIA PINHEIRO KITCHEN IN THE AMAZON

Lia Thieme Oikawa Zangirolani[1]; Carla Bueno,[2]; Ivagno Brito,[3]; Cristiane Da Silva Cabral,[4]; Semíramis Martins Álvares Domene[5]

[1]Departamet of Public Policy and Public Health, Federal University of São Paulo, Rua Silva Jardim - Vila Matias - Santos-SP, Brazil, Santos, Brazil; [2]Production department, Movimento dos Trabalhores Sem Terra - MST - Alameda Barão de Limeira 1232, São Paulo-SP, Brasil, São Paulo, Brazil; [3]Latin America Institute of Agroecology - IALA Amazônico, Movimento dos Trabalhadores Sem Terra - Vicinal do Limão s/n, Palmares II, Parauapebas, Brasil, Parauapebas, Brazil; [4]Department of Health, Life Cycles and Society, Faculdade de Saúde Pública USP, São Brazil; [5]Health and Society Institute, Federal University of São Paulo, Santos, Brazil

BACKGROUND AND OBJECTIVES

The current scenario of global syndemic implies negative consequences for both human and planetary health, and poses challenges for the transformation of the global production processes, towards the creation of sustainable food systems. Solidarity Kitchens - CSol are a social technology that has spread throughout Brazil in the political and health context of the COVID-19 pandemic, and are a result of historical experiences of urban and rural social movements. The objective of this work was to identify the potential of CSol Dirineia Pinheiro, in order to characterize it as a resource to enable a local sustainable food system.

METHODS

This is a case study of a CSol in the Brazilian Amazon region, which employed Participant Observation as a research method. Data from field diary records and photoelicitation interviews were coded, recorded and transcribed, respectively. Descriptive and comprehensive analyses in dialogue with the literature enabled the identification of CSol's potential, as well as the challenges to establish it as a structuring equipment for local sustainable food systems.

RESULTS

The main potentialities identified were the possibilities from socio biodiversity ingredients, training in agroecology, the appreciation of food sovereignty and the healthy meals offered at CSol. The main challenges are the lack of regular and permanent access to public services and policies, such as garbage collection, public transportation in rural areas, maintenance of traffic conditions on access roads and unstable internet connections. Another challenge is the precarious working conditions of cooks.

CONCLUSIONS

It was possible to characterize CSol Dirineia Pinheiro as a structuring facility for sustainable local food systems, considering the potential identified in the territory and its historical and social constitution. Even so, there are challenges to be overcome, which require the strengthening of public policies in the country and the rapid implementation of the National Program of Solidarity Kitchens.

INNOVATIVE ENRICHMENT: ASSESSING MORINGA AND SPIRULINA AS ALTERNATIVES TO INDUSTRIAL, COMMERCIAL PREMIXES USED IN NUTRITION PROGRAMS IN AFRICA

Christophe Guyondet,[1]; Souheila Abbeddou[2, 3, 4]; Paolo Sarfatti[5]; Dimitrios Petalios[5]; Mélanie Broin,[6]; Carl Lachat[7]

[1]Food Technology, Safety and Health, Ghent University, Ghent, Belgium; [2]Public Health and Primary Care, Ghent University, Ghent, Belgium; [3]College of Medicine and Health Sciences, Arba Minch, Arba Minch, Ethiopia; [4]IMCAN, Infant, Maternal, Child, and Adolescent Nutrition, Ghent, Belgium; [5]Food Technology, Safety, and Health, Ghent University, Ghent, Belgium; [6]Nutrition Research Facility, Agropolis International, Montpellier, France; [7]Department of Food Technology, Safety and Health, Faculty of Bioscience Engineering, Ghent University, Ghent, Belgium

BACKGROUND AND OBJECTIVES

Complementary foods, particularly cereal-based, fall short of meeting infants' nutritional needs in many low-income African countries. Effective approaches, rooted in local food systems, are necessary to improve nutritional contents of complementary foods for children aged 6–23 months. This study explored the potential of using locally produced nutrient-rich foods, moringa leaves and spirulina, to achieve this goal. Findings will contribute to enhance the nutritional quality of complementary foods, and document the economic feasibility of using these alternatives to replace imported premixes.

METHODS

A scoping review was conducted to examine the nutritional composition of moringa and spirulina, assess the acceptability of foods enriched with these ingredients, and evaluate their effects on children's health and nutrition. Additionally, the nutrient contributions of moringa leaves and spirulina were estimated in relation to meeting the dietary requirements of children aged 6–23 months based on the World Health Organization's recommended micronutrient intakes. The economic analysis focused on Chad as a case study and estimated the incremental cost of fortification under two scenarios: using industrial premix and using a natural premix consisting of a 50/50 blend of moringa and spirulina. A standard infant flour recipe was used, with ingredient prices based on data collected in Chad in 2024.

RESULTS

Moringa leaves (5 g/day) provide high vitamin A and C but limited vitamin B2, iron, and zinc. Spirulina (10 g/day) is rich in protein and iron but covers only 3% of zinc requirements and up to 32.2% of folate requirements in infants and young children 6-23 months of age. Acceptability studies demonstrated a high acceptability and compliance of moringa, with less studies reporting on the acceptability of spirulina-enriched foods. A scoping review identified seven studies reporting on the nutritional effects of moringa- and spirulina-enriched foods. Findings showed moringa and spirulina enrichment resulted in inconsistent effects on haemoglobin status, ferritin concentrations and physical growth. Fortifying with industrial premix was more cost-effective, raising costs by less than 1% versus 8–10% with natural premix, due to high costs from Chad's underdeveloped moringa and spirulina value chains.

CONCLUSIONS

Both moringa and spirulina contribute to partially address nutrient gaps. Industrial premixes remain more cost-effective but moringa and spirulina show promises for enriching complementary foods while supporting local economies, sustainability, and resilience in Chad and similar contexts in sub-Saharan Africa.

TAX REFORM IN BRAZIL: A CASE STUDY ON THE IMPACT ON FOOD

Marilia Albiero,[1]; Priscila Diniz[1]; Paula Johns[1]
[1]Heatlh Feed Promotion, Associação de Controle do Tabagismo, Promoção da Saúde, São Paulo, Brazil

BACKGROUND AND OBJECTIVES
The tax reform on consumption in Brazil has emerged as a highly relevant topic, especially when considering its impact on food. Studying food taxes is crucial to understanding the cost and consequently, the access to healthier options, as the consumption of ultra-processed foods is associated with around 57,000 annual deaths in the country (NILSON,2023). Furthermore, the obesity epidemic is a growing global issue that not only affects public health but is also part of the global syndemic where diseases intertwine with environmental issues, including climate change (SWINBURN,2019). Therefore, this study aimed to analyze how the recently enacted tax reform in the country addressed the issue of food by comparing it with the previous tax system.

METHODS
This study employed a documentary and legislative analysis of the Brazilian tax system before and after the reform enacted in January 2025. The new system's food regulations, unified under a single complementary law to the constitutional amendment, were evaluated. For the previous system, a sample composed of one state from each of the five regions of the country, along with a list of food items based on the NOVA classification of processing (MONTEIRO, 2010), was used, for which federal and state regulations were analyzed.

RESULTS
The RESULTS reveal that the current tax system reduced complexity by adopting only four tax rate levels for food, in contrast to the previous system, which varied significantly between states and products. This standardization helped mitigate discrepancies and increase transparency, particularly regarding benefits granted to the food industries. The taxation levels now reflect the Brazilian Dietary Guidelines (BRASIL,2014) according to the NOVA classification, highlighting the creation of a basic food basket that consolidated the essential and healthy items most consumed by low-income populations. Nevertheless, only soft drinks were included in the highest and most burdensome tax level.

CONCLUSIONS
The tax reform represents a significant advancement by considering healthiness, sustainability, and social justice aspects, thereby aligning economic policy with the Brazilian Dietary Guidelines. However, it remains modest concerning the implementation of a more robust selective tax that could discourage the consumption of products detrimental to health and the environment, particularly ultra-processed products, indicating the need for improvement in the tax policy to effectively induce the necessary changes in the Brazilian food system.

ESTIMATING THE ENVIRONMENTAL COST OF THE DIETARY INTAKE OF ADULT SOUTH AFRICANS

Tyler Coates[1]; Rina Swart,[1, 2]
[1]Department of Dietetics & Nutrition, University of the Western Cape, Cape Town, South Africa; [2]DSI/NRF Center of Excellence in Food Security, University of the Western Cape, Cape Town, South Africa

BACKGROUND AND OBJECTIVES
Agriculture, the food system and human nutritional health are all linked, each having an extensive impact on one another. The objective of this project was to identify suitable metrics to quantify how much the South African adult diet impacts the environment.

METHODS
A quantitative multimethod design was used. Firstly, a scoping review was done to identify appropriate environmental impact factors of foods. Secondly, dietary intake data was extracted from a nationally representative dietary intake survey of adults aged 18-59 years.
Lastly, the dietary intake data was matched with the database on environmental impact factors in order to estimate the environmental cost of foods consumed by South Africans.

RESULTS
The adult South African daily intake is requiring an allocation of land and water daily, while releasing a considerable amount of carbon dioxide. Food retail data suggest an increase in per capita consumption of foods with a high carbon footprint.

CONCLUSIONS
The majority of research that explores the intersection between agriculture and human diets have been conducted in first world countries, thus there is an absence of literature on LMICs. South Africa will benefit from ensuring support is provided to the Agricultural sector to promote sustainable practices, which should be coupled with promotion of sustainable dietary practices.

FOOD MATRIX AFFECTS THE DIGESTION KINETICS AND POSTPRANDIAL METABOLISM OF PLANT-BASED PROTEINS: COMPARISON OF IN VITRO AND CLINICAL IN VIVO DATA

Moona Partanen[1]; Carlos Gómez Gallego[1]; Marjukka Kolehmainen[1]
[1]Institute of Public Health and Clinical Nutrition, University of Eastern Finland, Kuopio, Finland

BACKGROUND AND OBJECTIVES
To promote environmental sustainability, biodiversity conservation, and improve public health, it is crucial to reduce meat consumption and replace the intake of animal protein with plant protein. However, the interactions and structures, also known as the food matrix, of novel extracted plant proteins and fibers remain unexplored. Therefore, it is essential to study the impact of high protein plant1based foods and the effect of the food matrix on human health. Thus, this study aims to investigate the impact of fiber-protein interactions on plant protein digestion and metabolization.

METHODS
Seventeen participants with high risk for metabolic syndrome were recruited to eat three study products: Product A) Granola containing plant-based protein (10 g) with intrinsic fiber (17 g), meaning naturally occurring fiber within the undisrupted plant cell wall, Product B) porridge containing plant-based protein (10 g) with extrinsic fiber (17 g), meaning added fiber extracted from a plant cell wall, and Product C) cereal control product with minimal protein (2 g) and fiber (0.8 g). Plasma insulin, glucose, free fatty acids and triglycerides were measured at timepoints 0, 30, 60, 90, 180, and 240 minutes after ingesting the meal. The in vitro digestion of the products was done according to the INFOGEST protocol with minor modifications. In vitro degree of protein hydrolysis was calculated based on released amino groups in o-phthalaldehyde (OPA) measurement.

RESULTS
Plasma glucose and insulin levels were lower after ingestion of product B (6.66 ± 0.24 and 53.25 ± 8.24) compared to A (7.64 ± 0.43 and 81.79 ± 11.67) ($p = 0.0091$ and <0.001, respectively). These RESULTS suggest that the availability of protein and fiber varies depending on the food matrix, where the intrinsic fiber reduced the absorption of glucose that was shown as lower plasma concentrations. The in vitro analysis showed that Product B had a higher amount of free amino groups both before and after digestion. However, during digestion, Product A released free amino groups more quickly, though its total amount of free amino groups remained lower overall. This suggests that Product A undergoes faster initial protein breakdown, while Product B demonstrates a slower but overall, more efficient digestion process.

CONCLUSIONS
These differences in protein breakdown kinetics and fiber-protein interactions may be contributing to the lower glycemic response caused by plant-based protein with extrinsic fiber.

YOUTH ON THE PATH TO SUSTAINABLE EATING: UNVEILING BARRIERS AND FACILITATORS THROUGH FOCUS GROUP INSIGHTS

Soraya van Etten[1]; Lonneke Jansen[2]; Marijn Stok[2]; Brian Dermody[3]; John De Wit[2]; Eggo Müller[4]; Michèlle Bal[2]
[1]Dept. of Interdisciplinary Social Science , Utrecht University, Utrecht, Netherlands; [2]Dept. of Interdisciplinary Social Science, Utrecht University, Utrecht, Netherlands; [3]Copernicus Institute of Sustainable Development, Utrecht University, Utrecht, Netherlands; [4]Department of Media and Culture Studies, Utrecht University, Utrecht, Netherlands

BACKGROUND AND OBJECTIVES
The current food system plays a significant role in driving climate change, highlighting the urgent need for populations to adopt more sustainable food behaviours. Engaging young people in this shift is crucial, as dietary habits formed during adolescence often persist into adulthood, influencing the long-term transition to sustainable eating. To examine the factors that hinder or support the development of sustainable food behaviours among youth, we conducted focus group discussions guided by the Capability-Opportunity-Motivation-Behaviour (COM-B) model.

METHODS
Eleven focus group discussions were conducted with participants aged 12 to 16, recruited through football clubs in the Utrecht region, the Netherlands. Each group consisted of five to twelve participants and explored three key sustainable food behaviors: adopting a plant-forward diet, increasing the consumption of locally sourced and seasonal foods, and reducing food waste.

RESULTS
Adopting a plant-forward diet emerged as the most challenging behavior, while minimizing food waste was already seen as a common practice. Participants demonstrated a general awareness of sustainability and sustainable food, but misconceptions were common. The majority believed that meat is essential for health and that sustainable foods are more expensive. The taste of meat was cited as a key barrier to embracing plant-forward diets. Social influences played a substantial role, with family practices shaping eating habits and participants having limited autonomy over food choices. While most participants expressed a belief in the collective impact of sustainable eating and acknowledged its importance, they struggled to see its relevance on an individual level.

CONCLUSIONS
While reducing food waste is already normalized among youth, shifting towards a plant-forward diet presents significant challenges but also holds the greatest potential for meaningful change. Addressing misconceptions, promoting tasty alternatives, and empowering youth to feel personally connected to sustainable eating could pave the way for a broader transition.

INVESTIGATING THE DIFFERENCE BETWEEN MORE SUSTAINABLE PLANT-BASED PROTEINS AND ANIMAL-BASED PROTEINS ON INTESTINAL BARRIER FUNCTION USING IN VITRO MODELS

Lidwien Boven[1]; Paul De Vos[1]
[1]Pathology and Medical Biology, University Medical Center Groningen, Groningen, Netherlands

BACKGROUND AND OBJECTIVES
A more sustainable future requires a transition towards a plant-based diet due to the exhaustive effects animal-based proteins have on the environment. However, plant-based proteins generally have a lower variety in essential amino acid composition. Additionally, their structure RESULTS in proteins that are more difficult to digest and subsequently tend to end up lower in the digestive tract, making them prone to fermentation by the microbiome. This proteolytic fermentation can cause production of metabolites associated with negative health effects and additionally resulting in shortages in protein uptake. Proteolytic fermentation can potentially be steered towards more saccharolytic fermentation through the addition of non-digestible carbohydrates in the diet. Knowledge on this combination of plant-based proteins and non-digestible carbohydrates on colonic- and general health is limited. Current data suggest that a transition towards a more plant-based protein diet should be accompanied with a consumption of increased quantities and more complex structures of carbohydrates. This can reduce or prevent proteolytic fermentation which might consequently improve human health.

METHODS
We investigated the effect of combining plant-based proteins from fava bean, potato and pea and egg as an animal-based control and non-digestible carbohydrates inulin and pectin on IL-8 secretion and *TFF3*, *MUC2*, *GUSB*, *CHST5*, *GAL3ST2* and *MUC13* expression in intestinal mucus producing goblet cells. In addition, we treated these cells with different stressors (Tunicamycin, IL-13 and TNF- α) and IL-8 production in the supernatant was measured. Additional experiments are ongoing on the effect of these samples on Trans-Epithelial Electrical Resistance (TEER) and accompanying influence on gene expression.

RESULTS
Preliminary RESULTS show that cells treated with the animal-based control (egg) fermentation samples shows different RNA expression profiles as compared to the plant-based protein (fava bean) fermentation samples. TEER experiments will yield more information regarding barrier integrity and gene expression.

CONCLUSIONS
Supplementing plant-based proteins with non-digestible carbohydrates might help reducing the proteolytic fermentation that is generally associated with a more plant-based diet. Reducing the amount of proteolytic fermentation will help in the transition towards a more sustainable (plant-based) diet that is still nutritionally complete.

SUSTAINABILITY INDICATOR FRAMEWORK FOR COMMUNICATING RESPONSIBLE AQUAFOOD CONSUMPTION

Siân Astley[1]; Christine Absil,[2]; Michelle Boonstra,[3]; Paul Finglas,[1]; Tim Huntington,[4]; Sara Pittonet Gaiarin[5]
[1]Scientific Unit, EuroFIR AISBL Secretariat, EuroFIR, Brussels, Belgium; [2]Scientific Consultancy, Clupea, Enkhuizen, Netherlands; [3]Project Management Fisheries, Community Catch, Amsterdam, Netherlands; [4]Director, Poseidon Aquatic Resource Management Ltd, Portmore, United Kingdom; [5]Senior Project Manager, Trust-IT, Pisa, Italy

BACKGROUND AND OBJECTIVES
VeriFish (project no. 101156426) has developed a comprehensive indicator framework for the aquafood sector, addressing environmental, stock management, and nutritional dimensions. This initiative aims to simplify and standardise communication, fostering informed consumer choices and enhancing transparency. By integrating verifiable data into actors' communication strategies, the framework seeks to promote responsible consumption patterns, ensure the sustainability of aquafood systems, and support good communication practices tailored to diverse stakeholder needs.

METHODS
The indicators were identified through systematic review, focusing on core dimensions such as stock status, ecosystem impacts, climate footprint, governance, and nutritional attributes. The framework employs a tiered data approach: Tier 1 uses publicly available data ensuring broad availability, while Tier 2 incorporates value-chain-specific data to provide detailed, granular insights. This dual approach ensures flexibility and relevance across diverse operational contexts, facilitating adoption and integration by both small-scale and large-scale actors in the value-chain.

RESULTS
The framework provides measurable indicators for capture fisheries, aquaculture, and nutrition, enabling assessment of key sustainability metrics such as biodiversity conservation, carbon emissions, resource efficiency, and public health. These indicators form the basis of a prototype web application that will facilitate communication of sustainability by actors and enable consumers to make more informed decisions based on their priorities, such as environmental impact, nutritional quality, or responsible production.

CONCLUSIONS
By standardising sustainability reporting and enhancing value-chain communication, the VeriFish framework enables aquafood actors to align with global environmental and health objectives. Potentially, it can foster consumer trust and empowerment, promote responsible 'advertising' practices, and pave the way for diverse, sustainable consumption. This framework represents a step toward a more transparent, equitable, and environmentally responsible aquafood sector, benefiting producers, consumers, and the environment alike.

MAPPING STAKEHOLDERS INFLUENCING NEGLECTED UNDER-UTILIZED SPECIES (NUS) INCORPORATION INTO GHANA'S SCHOOL FEEDING PROGRAM

Phyllis Addo[1]; Kushitor Mawuli[2]; Afua Tetteh[3]; Akolaa Rosemary Anderson[4]; Charity Binka[5]; Savannah Dysard[6]; Samrat Singh; Francis Zotor[7]

[1]Family and Community Health Department, Fred N. Binka School of Public Health, University of Health and Allied Sciences, Ho, Ghana; [2]Health Policy, Planning and Program Management, University of Health and Allied Sciences, Hohoe, Hohoe, Ghana; [3]Department of Population, Family and Reproductive Health, School of Public Health, University of Ghana, Legon, Accra, Ghana; [4]School of Natural and Environmental Sciences, University of Environment and Sustainable Development, Somanya, Ghana; [5]WOMEC, Women, Media and Change, Accra, Ghana; [6]School Food Matters, School Food, London, United Kingdom; [7]Fred Newton Binka School of Public Health, University of Health and Allied Sciences, Ho, Ghana

BACKGROUND AND OBJECTIVES

Neglected Under-Utilized Species (NUS), indigenous climate-smart crops of Ghana, offer potential benefits for local agriculture, dietary diversity, and sustainable food systems if integrated into the Ghana School Feeding Programme (GSFP). This study examines the influence of national stakeholders on this integration process, recognizing that understanding stakeholder dynamics is crucial for effective implementation.

METHODS

In-person Net-Map interview was conducted with 14 representatives (10 females; 4 males) from the GSFP ecosystem. The interview audio-recording was transcribed verbatim and used in data entry in addition to the maps drawn. Ethical clearance was obtained, and informed consent was sought from all participants. Data analysis used VisuaLyzer version 2.2.

RESULTS

Sixty-eight stakeholders from nine categories were identified, connected by 730 links; formal command, technical assistance, funding, advocacy, and evidence dissemination. The network had a degree centralization of 70%, with 15 core and 53 peripheral actors. The network's density was 0.32, with an average stakeholder distance of 1.88. Government, academia, and development partners were the most influential groups, each scoring the highest influence level.

CONCLUSIONS

This study reveals the central influence of government, research/academia, and development partners on NUS integration into the GSFP. The identified stakeholder network provides a practical tool for policymakers, highlighting key actors to engage for successful and sustainable NUS incorporation into school meals, ultimately contributing to food system transformation.

HOW EXTREME TEMPERATURES ARE ASSOCIATED WITH MEASURES OF BREASTFEEDING AND CHILD NUTRITION IN GHANA

Jessie Pinchoff[1]; Gloria Odei Obeng-Amoako[2]; Evelyn Shu[3]; Olivia Otimpo[4]; Justina Owusu[2]; Gloria Ethel Otoo,[2]

[1]International Development , American Institutes for Research, Washington DC, United States of America; [2]Nutrition and Food Science, University of ghana, accra, Ghana; [3]International Development, American Institutes for Research, Washington DC, United States of America; [4]Nutrition, Ghana Statistical Serv, accra, Ghana

BACKGROUND AND OBJECTIVES

Progress on key breastfeeding and nutrition indicators are lagging across the world, with only 6 countries in Africa on course to meet childhood stunting targets (Global Nutrition Report). Climate change threatens progress made to date, as droughts and extreme temperatures lead to food insecurity and may shift infant feeding practices such as breastfeeding (IPCC 2023). Studies suggest that exposure to droughts may have adverse effects on feeding practices, for example reducing dietary diversity (Pinchoff et al, 2021), and also affecting anthropometric measures of nutritional status (Belesova et al, 2019). Our objectives are to integrate survey and satellite derived climate data to determine the association between heat, drought, and key nutritional outcomes among children in Ghana.

METHODS

Using the 2022 Ghana Demographic and Health Survey, we calculate indicators of child nutrition behaviors and nutritional outcomes (n=5,045 children under 5). Child health data is then integrated with remotely sensed data on maximum temperature and a measure of drought (normalized difference in vegetation index, NDVI). Child nutrition measures include exclusive breastfeeding among children under 6 months of age, stunting and wasting among children under 2 years, anemia, and measures of minimum dietary diversity, minimum meal frequency, and minimum acceptable diet for children ages 6-23 months. Our models adjust for key demographic factors such as income level, mother's educational attainment and household size. We also adjust for livelihood zone to reflect different household strategies for income and reliance on natural resources.

RESULTS

We have preliminary RESULTS, finding a strong association between extreme temperatures in the previous month with wasting and undernutrition (but not stunting). We also find that a higher proportion of hot days and heat waves days reduces the probability of meeting minimum dietary diversity guidelines, though an association with meal frequency was not found. With higher maximum temperatures and more hot days, we see a lower odds of currently breastfeeding, though the association with exclusive breastfeeding is less clear.

CONCLUSIONS

Our RESULTS suggest that extreme temperatures can affect measures of nutritional outcomes and child feeding behaviors, particularly short term nutritional indicators such as wasting. Our findings can inform nutrition policy to ensure consideration of climate risks, and improve targeting of programs to adjust for environmental changes.

EPO2_179

REDUCED RANK REGRESSION DERIVED DIETARY PATTERNS EXPLAINING INDICATORS OF ENVIRONMENTAL SUSTAINABILITY IN ADOLESCENT DIETS: ANALYSIS IN THE GERMAN DONALD COHORT STUDY

Karen van de Locht[1]; Ines Perrar[1]; Samuel Muli[1]; Juliana Minetto Gellert Paris[1]; Ute Alexy[1]; Ute Nöthlings,[1]
[1]Nutritional Epidemiology, Institute of Nutrition and Food Sciences, University of Bonn, Bonn, Germany

BACKGROUND AND OBJECTIVES
Shifting to dietary patterns that benefit human and planetary health is largely needed. We aimed to derive real-world dietary patterns that best explain variations in dietary greenhouse gas emissions (GHGE), land use (LU), and water use (WU) in adolescent diets, and their associations with nutrient adequacy.

METHODS
We analyzed dietary data of 415 adolescents (females: 9-15y, n=199; males: 10-16y, n=216) with at least two 3-day-weighed dietary records (n=2141; 2-7 per participant, median: 6) from the ongoing open DONALD (DOrtmund Nutritional and Anthropometric Longitudinally Designed) cohort study. A total of 23 food groups as well as GHGE, LU, and WU were assigned to all recorded foods. Reduced rank regression models with GHGE (kgCO2eq), LU (m² x year), and WU (L) per 1000kcal as response variables and consumption of food groups (g/1000kcal) as predictor variables were used to derive the dietary patterns. The Mean Adequacy Ratio (MAR = ∑(nutrient intake/recommended intake)/number of nutrients) was used to represent nutrient adequacy. Associations between the MAR and the dietary patterns were analyzed using multivariable linear regression models.

RESULTS
The first two dietary patterns (DP1, DP2) cumulatively explaining 10.1% variation in dietary intake and 68.5% joint variation in GHGE, LU, and WU were used. DP1 loaded positively for beef and lamb, pork, poultry, and ready-to-eat foods, and negatively for milk and grain products. DP2 loaded positively for vegetables, fruits, fruit and vegetable juices, and nuts and seeds, and negatively for milk, sweets and pastries, and ready-to-eat foods. DP1 was positively associated with GHGE, LU, and WU. DP2 was positively associated with WU and negatively with GHGE and LU. A higher MAR was associated with higher adherence to DP2 (ß=2.04, 95%CI: 1.42-2.67, p<0.0001). No significant association was found for MAR and DP1 (ß=0.2, 95%CI: -0.49-0.88, p=0.569).

CONCLUSIONS
Higher adherence to a more plant-based dietary pattern, which was characterized by lower GHGE and LU, but higher WU, was associated with higher nutrient adequacy. Adherence to a more animal-based dietary pattern showed no association with MAR.

CONFLICTS OF INTERESTS
The authors have no conflict of interest.

EPO2_180

ADEQUACY TO THE PLANETARY HEALTH DIET OF CURRENT DIETARY HABITS IN ITALIAN ADULTS

Giuseppe Grosso,[1]; Justyna Godos[1]; Marialaura Bonaccio[2]; Licia Iacoviello,[2]; Massimiliano Tucci[3]; Daniela Martini[3]
[1]Biomedical and Biotechnological Sciences, University of Catania, Catania, Italy; [2]Epidemiology and Prevention, IRCCS Neuromed Mediterranean Neurological Institute, Pozzilli, Italy; [3]Department of Food, Environmental and Nutritional Sciences (DeFENS), University of Milan, Milano, Italy

BACKGROUND AND OBJECTIVES
The Planetary Health Diet stands out as a dietary model suggested to merge both health benefits and environmental sustainability. However, only a limited number of studies have applied such a model to current dietary habits, while there is no univocal agreement on the most valid method to assess it. The aim of this study was to measure the adequacy to the Planetary Health Diet of current dietary habits in Italian adults.

METHODS
The dietary habits of 2000 individuals living in southern Italy were explored through a validated 110-item food frequency questionnaire. Adequacy to the Planetary Health Diet was assessed via application of five different scores already used in scientific literature. Validity for nutrient content was evaluated by estimating the macro- and micronutrient dietary composition. Also, the relation with level of food processing was investigated. Validity of environmental impacts was explored by estimating carbon and water footprint data. Energy-adjusted linear regression models were used to assess the associations between the scores, dietary content, and environmental impacts.

RESULTS
All scores predicted an adequate consumption of plant omega-3 polyunsaturated fatty acids (PUFA), total fiber, potassium, vitamin A, E, and C as well as lower intake of sodium and fats, including cholesterol and saturated fatty acids. However, protein, mono-unsaturated fatty acids (MUFA) and total PUFA intake resulted inversely associated with some but not all scores applied, revealing a different predictability of the tools used. When assessing the relation bewteen scores and the energy shares of ultra-processed foods (UPF), RESULTS showed an inverse association with all scores (mainly due to lower consumption of fast foods, biscuits/pastries/cakes and ice-cream). Concerning the relation with the environmental impacts, the increase in all scores was significantly associated with reduction of both environmental measures, with a difference by about 1.0 Kg CO2 eq./day and 100 L/day of greenhouse gas emission and water use between the extreme categories, respectively.

CONCLUSIONS
The application of a diet in line with the proposed Planetary Health Diet to the southern Italian population may reflect a lower environmental impact and a good nutritional quality diet. However, some concerns regarding an appropriate adequacy of protein intake as well as certain nutrients should be taken into account. Also, the tools used to assess the adequacy to the Planetary Health Diet may require an adaptation to improve their performance.

SAFETY, TOLERABILITY, AND PRELIMINARY EFFECTS OF CRICKET CHITIN FOR IBS: A RANDOMIZED CROSSOVER TRIAL

Alexandra Vita[1]; Shihning Teo[1]; Christine Murphy[1]; Afsana Khandakar[1]; Rania Hart[1]; Mathhews Paul; John Wilson[1]; Jacqueline Chaparro[2]; Thomas Aquilino[1]; Yuren Wei[1]; Tiffany Weir[1]; Valerie Stull[3]
[1]Food Science and Human Nutrition, Colorado State University, Fort Collins, United States of America; [2]Analytical Research Core, Colorado State University, Fort Collins, CO, USA, United States of America; [3]Department of Community & Environmental Sociology, University of Wisconson-Madison, Madison, United States of America

BACKGROUND AND OBJECTIVES

Background: Inflammatory bowel syndrome (IBS) is a gastrointestinal disorder affecting around 11% of the global population. Increased inflammatory mediators and altered gut microbiota are prevalent in IBS and may contribute to its' pathophysiology. Thus, sustainable dietary fiber sources accessble on a global scale are being investigated for their ability to improve functional gastrointestinal symptoms by remediating gut microbiota and reducing intestinal inflammation.

Objective: This study aims investigate the safety and tolerability of a unique and sustainable fiber source, cricket-derived chitin, in a sample of adults (n=18) diagnosed with IBS, as well as gather preliminary data regarding IBS management.

METHODS

Methods: In this randomized, double-blind, 2x2 crossover trial, participants consumed cacao patties containing either 4 grams of cricket-derived chitin (n= 10) or a maltodextrin comparator (n= 8) daily for 30 days, followed by a 14-day washout period and additional 30-day intervention period in the opposite treatment group. Assessments of the primary outcome of safety and tolerability (e.g., adverse events, metabolic biomarkers, quality of life) and secondary outcomes (e.g., inflammatory biomarkers, gastrointestinal symptoms, stool consistency, and gut microbiota) occurred before and after each intervention.

RESULTS

RESULTS: Saftey and tolerability outcomes were met; No serious adverse events, shifts in metabolic biomarkers outside normal range, or reduced quality of life were observed. While participants reported improved GI symptoms following both treatments ($p<0.05$), the relationship was more pronounced following the chitin intervention ($p<0.01$); The decrease in the inflammatory biomarker serum TNF-alpha was also significantly greater following the chitin intervention.

CONCLUSIONS

Conclusion: RESULTS suggest that while both chitin and cacao may be safe and tolerable in an IBS population and support symptom management, the chitin additive may provide an additional benefit for lowering inflammatory cytokines.

SUSTAINABILITY IN DIETETICS: A DIETETIC SURVEY INVESTIGATING THE REUSE OF PLASTICS AND ANCILLARIES WITH TUBE-FED PATIENTS IN THE UK

Emma Fisher,[1, 2]; Santosh Gaihre[1]
[1]Institute of Applied Health Sciences, School of Medicine, Medical Sciences and Nutrition (SMMSN), University of Aberdeen, Aberdeen, United Kingdom; [2]Nutricia Advanced Medical Nutrition, Nutricia, London, United Kingdom

BACKGROUND AND OBJECTIVES

The UK National Health Service (NHS) has set a goal to reduce single-use plastics where clinically appropriate, as part of meeting their ambitious net zero emissions goal [1]. Recent data [2] indicates that tube feeding plastics can be safely used over a 24-hour period without risk of bacterial contamination if handled properly. However, current practice involves high volumes of single use plastics [3]. Therefore, this study aimed to investigate current practice of reusing enteral tube feeding plastics across different patient groups and understand what drives this.

METHODS

The online surveyof enteral tube feeding dietitians recorded patient demographics, and plastic reuse over 24-hours during gastric/jejunal feeding, with decanted/commercial feeds. Qualitative questions on barriers and enablers of plastic reuse were asked and analysed using a coded frame as described by SAGE [4]. SPSS was used for statistical analysis, with *chi*-squared used to compare the plastic reuse between different groups.

RESULTS

A total of 58 dietitians from community and hospital settings responded, working with adults (83%), children (12%) or both (5%). Plastic reuse was reported in 45% of adults and children, but only 22% in infants (<1 year) ($p<0.05$). Additionally, plastic reuse was 42% when using commercial feeds, but only 27% with decanted feeds ($p<0.05$). 95% of dietitians listed microbiological contamination as a top 3 consideration, followed closely by home environment hygiene (88%) and patient convenience (52%). Thematic RESULTS showed top barriers to reuse were policy/guidance, patient choice, historic use and lack of education. Top enablers for reuse were environmental concern, cost, hospital guidance, and manufacturer training. Dietitians reported that current guidance on plastic reuse was varied, with sources being: ‘Plastic Manufacturer’ (69%), ‘Local Infection control’ (51%), ‘Feed Manufacturer’ (51%), ‘PENG’ (31%) and ‘NICE guidance’ (31%).

CONCLUSIONS

To meet the NHS’s ambitious net zero goals, change is required, with only relatively low numbers of patients reusing tube feeding plastics, particularly due to microbiological concerns. Focus on educating staff and patients on safe methods for reusing plastics, while highlighting the environmental benefits could improve tube feeding plastic reuse within the NHS, having both cost and sustainability benefits.

BRIDGING SILOS: A NEXUS FRAMEWORK FOR INTEGRATING NUTRITION, CLIMATE, AND GENDER TO BUILD RESILIENT FOOD SYSTEMS

Maximilian Ibing[1]; Juliane Friedrich[1]
[1]Independent, Independent, Bonn, Germany

BACKGROUND AND OBJECTIVES
Background: Nutrition, climate, and gender are critical global challenges, particularly in the Global South, where they shape food security and sustainability. Despite extensive research, interventions remain siloed, failing to address their interconnectedness.
Research Gap & Objective: Existing approaches primarily link two dimensions at a time, overlooking key interdependencies. This study develops a three-dimensional "Nexus Framework" to integrate nutrition, climate, and gender, guiding holistic policy responses and cross-sector collaboration.

METHODS
Methodology: A structured three-round framework analyzed bidirectional relationships. The first round examined nutrition's influence on gender equity and climate resilience. The second assessed climate change's impact on food security and gender disparities. The third evaluated gender-responsive policies in nutrition and climate adaptation. Findings were synthesized to identify key linkages and policy insights.

RESULTS
RESULTS: Siloed approaches hinder systemic efficiency. Climate disruptions disproportionately affect women's nutrition, exacerbating gender inequalities. Resource-intensive diets increase emissions, while gender-sensitive agricultural strategies enhance resilience. Gender-responsive interventions strengthen food security, improve environmental sustainability, and mitigate climate risks. Integrated approaches lead to more effective adaptation strategies and long-term resilience-building across sectors.

CONCLUSIONS
CONCLUSIONS & Policy Implications: The Nexus Framework provides a transformative model for integrating nutrition, climate, and gender. Dual-dimensional strategies are insufficient. Policies must incorporate gender-equitable, nutrition-sensitive strategies in climate action plans. Empowering women strengthens resilience and food security, while sustainable diets lower emissions. This framework helps policymakers amplify co-benefits and build equitable, sustainable food systems.

ENHANCING WHEAT TOLERANCE TO DROUGHT STRESS USING BACTERIAL EXOPOLYSACCHARIDES

Saliha Gharbi[1]; Hanae H'daidane,[1]; Mounir Hassani Zerrouk[1]; Amin Laglaoui,[1]; Mohammed Bakkali,[1]; Mostafa Lamhamdi[2]; Abdelhay Arakrak[1]; Ouiam El Galiou[1]
[1]Department of Biology, Biotechnology and Biomolecular Engineering Research Team, Abdelmalek Essaâdi University, Tetouan, Morocco, Faculty of Science and Technology, Tetouan, Morocco; [2]Laboratory of Applied Sciences for Sustainable Development, Higher School of Technology of El Kelaa Des Sraghna, Cadi Ayyad University, El Kelaa Des Sraghna, Morocco

BACKGROUND AND OBJECTIVES
Drought stress is one of the main factors limiting plant growth and productivity, disrupting their metabolic and physiological processes. The use of exopolysaccharides (EPS) produced by rhizobacterial strains represents a promising strategy to enhance plant tolerance. This study aimed to evaluate the effectiveness of EPS from strains *Bradyrhizobium cytisi* (B21) and *Rhizobium sullae* (BG15) in mitigating the effects of drought stress on wheat germination.

METHODS
Wheat seeds were germinated in Petri dishes for 10 days under drought stress induced by PEG-6000 at concentrations of 10% and 15%. EPS were applied at two concentrations (0.5 mg/mL and 5 mg/mL) during the germination process. Morphological parameters, including fresh and dry weight, were measured. Biochemical analyses were conducted to evaluate protein content, proline content, soluble sugars, and α-amylase activity.

RESULTS
Drought stress significantly reduced morphological parameters, including fresh and dry weight, in wheat plants. However, the application of EPS mitigated these effects. At a concentration of 5 mg/mL, fresh and dry weights were restored to levels close to non-stressed controls, demonstrating the protective effect of EPS. Biochemical analyses revealed notable improvements in key stress markers: protein content increased to 1.2 mg/g FW, while proline content rose to 30 µg/g FW, indicating enhanced osmotic adjustment. Additionally, the stabilization of soluble sugar levels and α-amylase activity further highlighted the capacity of EPS to support metabolic stability under stress.

CONCLUSIONS
The RESULTS confirm the protective role of EPS from B21 and BG15 strains in mitigating the negative effects of drought stress. EPS significantly improve metabolic stability and promote better tolerance in wheat plants under water stress conditions.

EPO2_189

DESIGN AND PRODUCTION OF A FUNCTIONAL AND SUSTAINABLE FOOD FOR THE NUTRITION OF MIGRANT COMMUNITIES: A PILOT STUDY

DANIELA GORDILLO-BASTIDAS[1]; Yareni Gutiérrez-Gómez[1]; Isis Nicole González-Balseca[1]; Danna Bribiesca-Jaramillo[1]; Gladis Anais Vargas-Ceballos[1]; Brisa Fernanda Yañez-Frias[1]
[1]Medicine and Heatlh Sciences School, Tecnológico de Monterrey, Monterrey, Mexico

BACKGROUND AND OBJECTIVES

Around of 9% of the total population in the world suffers hunger, and more than 582 million people are expected to suffer from chronic malnutrition by 2030. In Mexico and the world, a third of food is wasted (FAO 2023). In 2020, 3.6% of the world population were migrants, with Mexico being the 2nd country with the highest number of migrants (IOM 2020). The migrant population suffers from food insecurity, malnutrition and related diseases (FAO 2025). This pilot study aimed to design and produce a functional and sustainable food, low cost, custom-developed for an immigrant community to guarantee an adequate nutritional status during their journey to the final destination. Preliminary findings highlight the potential of this strategy to improve food security and well-being of populations in transit.

METHODS

A pilot study was carried out in which a clinical nutritional evaluation and an interview about eating habits and lifestyle were carried out with 16 migrants in transit. Based on the RESULTS obtained (nutritional needs and displacement conditions) the functional food (FF) was designed and produced. In a later phase, the FF will be produced on a large scale and distributed for free to migrants in transit; additionally we will teach the staff of a migrant shelter how to produce it, so that they teach the migrants and produce it continuously.

RESULTS

16 individuals who participated voluntarily, under informed consent, were evaluated. 62.5% were female and 37.5% male, aged between 18-70 years. According to the BMI, 7.1% were underweight, 50% normal weight, 7.1% overweight and 35.7% were obese. The main food source reported was rice or bread (25%), with limited availability of sources rich in protein. 50% reported weight loss since the beginning of their trip.

CONCLUSIONS

Food insecurity in the migrant population is linked to malnutrition. The migrant population faces limited access to rich sources of protein. The formulation of the FF developed in this study allows us to cover a significant part of the caloric and essential nutrient requirements of a day. The implementation and distribution of this FF has the potential to improve the health and well-being of migrants in transit, contributing to reducing the adverse effects of food insecurity in this vulnerable group, supporting SDGs 2, 3 and 12.

"NUTRIR +: A SUSTAINABLE MODEL FOR THE PRODUCTION OF PERSONALIZED FUNCTIONAL FOODS IN VULNERABLE COMMUNITIES"

DANIELA GORDILLO-BASTIDAS[1]; María José Rivas-Arreola[2]
[1]Medicine and Heatlh Sciences School, Tecnológico de Monterrey, Monterrey, Mexico; [2]Department of Science and Engineering, Universidad Iberoamericana, Puebla, Mexico

BACKGROUND AND OBJECTIVES
Globally, approximately 9% of the population suffers from hunger, and it is estimated that over 582 million people will experience chronic malnutrition by 2030 (FAO, 2023). Limited economic access to healthy diets remains a critical issue, affecting more than one-third of the global population (PAHO, 2023). Simultaneously, one-third of food produced in Mexico and worldwide is wasted (FAO, 2023). The aim of this study was to design and produce personalized functional foods (PFF) for vulnerable communities (VC), using ingredients sourced from food bank donations before being discarded.

METHODS
The "Nutrir +" project has been carried out annually since 2016, benefiting more than 700 people from VC in Mexico. The methodology consisting of the following phases: a)Nutritional assessment, b)Diagnosis: Nutritional deficiencies and key factors affecting food security, c)PFF design, d)Local food donations, e)Production, f)Distribution & training: The PFF is distributed, along with the RESULTS from a/b phases. Additionally, managers and kitchen staff training is conducted to enable the continuous production of the PFF, ensuring the project's long-term sustainability.

RESULTS
The "Nutrir +" methodology has been successfully replicated annually: 1) 2016, Functional soup for older adults; 2) 2017, Energy balls for migrants, 3) 2018 Functional candy for children, 4) 2019 Functional frozen popsicles for women with breast cancer, 5) 2020 Functional donuts for elderly, 6) 2023 Functional candy for children, 7) 2024 Energy bites for migrants in transit. Of the 7 VC involved, 3 continue to independently producing the PFF.

CONCLUSIONS
The methodology "Nutrir +" has been effective and replicable contributing to SDGs 2, 3, 12, and 13. The 43% of the VC have maintained autonomous production of PFF, highlighting the project's long-term sustainability. "Nutrir +" provides a scalable model to enhance food security and well-being in VC, with potential for expansion to other contexts.

INVESTIGATING LIVED EXPERIENCES OF FRUIT AND VEGETABLE ACQUISITION IN THE FOOD ENVIRONMENT OF ZIGUINCHOR, SENEGAL

Julia Liguori[1]; Ninon Sirdey[1]; Narcisse Diatta[2]; Benedict Sambou[2]; Aurélie Bechoff[3]; Arlène Alpha[1]; Christopher Turner[3]
[1]MoISA, Univ Montpellier, CIHEAM-IAMM, INRAE, Institut Agro, IRD, CIRAD, Montpellier, France, Montpellier, France; [2]Migration-Citoyennete-Developpement, GRDR, Ziguinchor, Senegal; [3]Food and Markets Department, Natural Resources Institute, University of Greenwich, Chatham Maritime, United Kingdom

BACKGROUND AND OBJECTIVES

Climate change, high rates of urbanisation and price inflation have modified traditional dietary patterns, especially among vulnerable populations who already experience food insecurity and malnutrition. This study aimed to understand the lived experience of the food environment among consumers from low-socioeconomic neighbourhoods in Senegal, specifically in relation to fruit and vegetable (F&V) acquisition as essential components of sustainable and healthy diets.

METHODS

Adults >18 years from a low socioeconomic neighbourhood of Ziguinchor were recruited by convenience sampling. Focus group discussions (FGDs) (n=4), participatory mapping, and participatory photography activities were implemented to investigate drivers of F&V acquisition practices. Data collection took place during the rainy season of 2022. Coding and analysis of transcripts, maps and photographs was conducted in NVivo14 software, informed by the Turner et al., (2018) food environment framework to capture dimensions of the external and personal food environment that shape food acquisition and consumption practices. Additional *in-vivo* themes emerging from the data were also included in an iterative process.

RESULTS

FGD participants (n=42) included food vendors, including vendors of prepared meals (e.g. couscous) and small-scale F&V vendors – with the majority being female (76%). Key drivers of food acquisition practices included high food prices and limited seasonal availability during the rainy season. Infrastructural challenges restricting transportation and mobility and the limited affordability of vegetables were emphasised narratives in the participatory photography activity. Participants called for improved accessibility and affordability of vegetables used in traditional meals, which were often forgone to purchase staple food items like rice, oil and fish. Participants recommended investment in the built environment (e.g. roads and market infrastructure) in addition to food environment policies to regulate food prices and reduce intra-annual price variation.

CONCLUSIONS

This study contributes to growing evidence on urban food environments in Africa and how they shape F&V acquisition and consumption practices. Policies to improve the built environment are needed to increase the accessibility and affordability of sustainable and healthy diets among consumers in low-income neighbourhoods in Senegal, particularly during rainy seasons when food environment challenges are exacerbated.

BRIDGING THE GAP: ASSESSING CHILD HUNGER AND MALNUTRITION IN NATIONAL CLIMATE STRATEGIES UNDER THE PARIS AGREEMENT

Andrea Galante[1]; Carmen Tse[2]; Yukiko Morovic[3]
[1]Global Center, World Vision International , Rome, Italy; [2]Global Health and Nutrition Team, World Vision International, Vaughan, Canada; [3]Technical Director, ESCA • Sponsorship, World Vision Foundation International, Madrid, Spain

BACKGROUND AND OBJECTIVES
The Paris Agreement mandates periodic updates to Nationally Determined Contributions (NDCs), which outline countries' climate action plans. However, children—who are disproportionately affected by climate change, mainly through hunger and malnutrition—are often overlooked in these strategies. This review, conducted with a sense of urgency, assesses the integration of child hunger and malnutrition into NDCs and National Adaptation Plans (NAPs), identifying key gaps, evaluating current commitments, and exploring advocacy opportunities. The objectives were to examine child-specific considerations, pinpoint policy deficiencies, and propose strategies to enhance child-sensitive climate action.

METHODS
Desk research was conducted on NDCs and NAPs from countries where World Vision operates. Proxy indicators, including stunting, wasting, and food security measures, were used to assess the integration of child hunger and malnutrition into climate strategies. The analysis categorized commitments and actions by specificity, budgets, and timelines while examining the extent of child participation in NDC development processes.

RESULTS
The review revealed substantial gaps in addressing child-specific issues within climate frameworks. While 85.9% of regions acknowledged hunger and malnutrition, only 65.9% included measures targeting child hunger and malnutrition. Child participation in NDC processes was notably low (31.8%), and no country explicitly identified child hunger as a critical issue.

Region	Action on Hunger (%)	Action on Child Hunger (%)	Child Participation (%)
East Asia	100	75	37.5
Latin America & Caribbean	100	93.3	46.7
Southern Africa	55.6	22.2	11.1

CONCLUSIONS
This study highlights gaps in addressing child hunger and malnutrition in climate plans. Proposed strategies could bring positive impacts. Advocacy should prioritize child-sensitive policies, budgets, and participation. These findings can be used to push for more substantial government commitments to address children’s needs in NDCs and NAPs

DETERMINANTS OF FOOD CHOICE MOTIVES AMONG ADULTS IN A UNIVERSITY SETTING: THE ROLE OF SOCIODEMOGRAPHIC AND ANTHROPOMETRIC FACTORS

Souzan Zidan[1]; Serene Hilary[1, 2]; Carine Platat[1, 2]
[1]Department of Nutrition and Health, United Arab Emirates University, Al Ain, United Arab Emirates; [2]ASPIRE Research Institute for Food Security in the Drylands (ARIFSID), United Arab Emirates University, Al Ain, United Arab Emirates

BACKGROUND AND OBJECTIVES
Food choices is complex and influenced by many motivating factors. Therefore, understanding factors behind food choices may be important in designing dietary interventions aimed at improving human health as well as environmental sustainability. The aim of this study to explore food choice motives and to identify whether sociodemographic and anthropometric factors influence them in adults at UAEU community.

METHODS
The English and Arabic-adapted versions of the Food Choice Questionnaire (FCQ) were used to measure FCMs. Mann-Whitney U and Kruskal Wallis tests were utilized to compare differences in FCMs among 894 adults with varying sociodemographic and anthropometric factors. Further analysis was conducted using multiple linear regression.

RESULTS
Sensory appeal emerged as the most important food choice motive, followed by price, convenience, and health motives, whereas familiarity and eco-ethics were ranked as the least important. Statistically significant differences in FCMs were observed among adults based on sociodemographic and anthropometric factors ($p < 0.05$). However, a small proportion of the variability in FCMs (3.7% - 12.6%) was explained by the sample characteristics included in the multivariate analysis. Gender was the most consistently associated factor with variations in FCMs. Specifically, females rated all FCMs, except for price, as significantly more important compared to males.

CONCLUSIONS
Food choices among adults are shaped by several factors, with sensory appeal being the most important motive. Future interventions targeting health and environmental sustainability should align with adults' sensory preferences. Although sociodemographic and anthropometric factors influenced FCMs in a limited extend, they should still be considered in tailored interventions.

SHIFTING FROM DAIRY MILK TO PLANT-BASED MILK ALTERNATIVES: IMPACT ON % DAILY VALUES ON MACRONUTRIENTS

Airisse Rae Basinang[1]; Casiana Blanca Villarino,[1]; Gerieka Anapi[1]; Jin Mark Pagulayan,[1]
[1]Department of Food Science and Nutrition, College of Home Economics, University of the Philippines Diliman, Quezon City, Philippines

BACKGROUND AND OBJECTIVES
With the growing demand for plant-based milk alternatives (PBMiA), there is a need to assess the nutritional profile and its impact on the % daily values (%DV) of nutrients to maximize the potential benefits of shifting from dairy milk (DM) to PBMiA. This study measured the impact on the %DV per macronutrient per age group with the substitution of PBMiA (i.e., cereal-based = CEB; coconut-based = COB; legume-based = LEB; nut-based = NUB) to DM.

METHODS
Nutritional information from labels of PBMiAs and DM sold in Metro Manila, Philippines was collected. The %DV for each macronutrient was calculated per age group as categorized in the Philippine Dietary Reference Intakes (PDRI).

RESULTS
RESULTS showed the %DV for energy will significantly decrease ($p<0.05$) by 0.49-2.14% if adults shift to PBMiA, except when CEB is consumed by male adults. Similarly, energy %DV for children will significantly decrease ($p<0.05$) by 2.22-2.48% when DM is substituted by NUB. The %DV for protein and fat for all groups will significantly decrease ($p<0.05$) by 1.06 - 9.67% and 2.06 - 5.00%, except when LEB and COB are consumed by male children, respectively. Meanwhile, the %DV dietary fiber will increase significantly ($p<0.05$) by 1.78 - 5.23% for all groups except for COB and NUB consumption of male and female adults.

CONCLUSIONS
These shifts in %DV indicate potential health implications, including increased dietary fiber but reduced energy, fat, and protein intake, underscoring the need for nutritional balance when adopting sustainable, alternative diets through PBMiA consumption.

STUDIES ON THE ENRICHMENT OF Γ-AMINOBUTYRIC ACID IN AMAZAKE BY LACTIC ACID FERMENTATION

Takahiro Kashima[1]; Midori Udoyama[2]; Shingo Udoyama[3]; Shin-Ichiro Yokoyama[4]
[1]Research & Testing Department, Gifu Prefectural Research Institute for Food Sciences , Gifu, Japan; [2]Researcher, Sho-kawa Research Centre, Nihon Shizen Hakko, Co. Ltd., takayama, Japan; [3]Director, Sho-kawa Research Centre, Nihon Shizen Hakko, Co. Ltd., takayama, Japan; [4]Industry-academia collaboration department, Gifu Prefectural Research Institute for Food Sciences , Gifu, Japan

BACKGROUND AND OBJECTIVES
It has been reported that continuous intake of foods rich in γ-aminobutyric acid (GABA) provides tranquilizer and hypotensive effects. For example, in the case of defatted rice germ enriched with GABA, intake of 9 g (GABA 26.4 mg)/day for 8 weeks was observed to improve sleeplessness and depression during the menopause or presenile period.1) Also, in a GABA-enriched fermented milk drink, hypotensive effects have been confirmed by intake of 100 ml (GABA 10 mg)/day for 4 weeks or more, and it is marketed as Food for Specified Health Uses(FOSHU) in Japan.2) In this study, we investigated lactic acid fermentation by *Lentilactobacillus buchneri* TS-25 strain in order to enrich GABA in *Amazake* (made by saccharifying rice with *rice-koji*), a traditional and popular beverage in Japan.

METHODS
Amazake was prepared according to the conventional method. Specifically, washed rice was watered and heat gelatinised (90°C, 30 min), then *rice-koji*(neutral protease activity: 33 units/g) was added at 55°C and followed by saccharification for 18 h (control). On the other hand, in the lactic acid fermentation, after adding *rice-koji*, the TS-25 strain was inoculated at 35°C, followed by saccharification and fermentation in parallel for 18-42 h(test). Some of them were picked over time (after 18, 24 and 42 h) and analysed quantitatively by HPLC (labelling with NBD-F) for free glutamic acid (L-Glu) generated by *rice-koji* and GABA converted by the TS-25 strain. The weight of the supernatant collected by centrifugation (12,070 x g, 15 min) of the *Amazake* was used as the liquefaction rate (%).

RESULTS
In the control, the saccharification at 55°C, 18 hours, yielded 62 mg/100 g of L-Glu, but only 6 mg/100 g of GABA. On the other hand, in the test, saccharification and lactic acid fermentation at 35°C, 42 hours yielded 83 mg/100 g of GABA, while L-Glu was reduced to 4 mg/100 g. The liquefaction rate (%) was similar in the control and test, 76.9% and 76.7%, respectively, and the liquid state was suitable for beverages.

CONCLUSIONS
As a result of applying lactic acid fermentation by *Lentilactobacillus buchneri* strain TS-25 to the manufacturing of *Amazake*, GABA increased more than 13-fold(6 mg → 83 mg/100g), while L-Glu, which has antagonistic effects, was reduced to less than 1/15 (62 mg → 4 mg/100g). The resulting lactic acid fermented *Amazake* provided 10 mg of GABA in just 13 g of drinking, thus contributing to a reduction in calorie intake. In addition, it had a sweetness and sourness close to that of sweetened yogurt (lactic acid content around 660 mg/100 g), making it suitable for daily enjoyment as an animal-free yogurt-like beverage.

ALTERNATIVE USE OF GRAIN AND LEGUME FLOURS IN MUFFIN-MAKING: A SENSORY ANALYSIS FROM CONSUMER POINT OF VIEW

Nesli Ersoy[1]
[1]Nutrition and dietetics, Hacettepe Üniversitesi Sıhhıye Kampüsü, Ankara, Türkiye

BACKGROUND AND OBJECTIVES
Legumes, which are a sustainable alternative protein source with high energy and nutrient density, can be used in various ways beyond meal preparation. The aim of the study was to evaluate legume flours used in muffins as an alternative to grain flours.

METHODS
Muffin samples were prepared by eight fours; 3 grains (wheat, buckwheat, and whole wheat) and 5 legumes (lentil, chickpea, white sorghum, black gram, and bean) by standard recipe. The grain and legume muffins were evaluated in terms of physical property analysis (baking loss (%) and baking volume (mm)), sensory analysis and nutritional value (energy, carbohydrate, protein, fat, fiber, calcium, magnesium, iron, and zinc). Sensory analysis were evaluated according to taste, flavour/aroma, colour, internal texture and overall acceptability by the panellist (10 cm VAS scale and hedonic scale).

RESULTS
White sorghum muffins were reported as the most liked after wheat flour and whole wheat muffins according to all sensory analysis. Buckwheat (4.1±0.7) and Lentil (2.7±0.6) muffins have the lowest overall acceptability score of all the muffin samples. Wheat (19.2 mm) had most baking volume and then lentils' baking volume was 15.8 mm, baking volumes of grain and legume muffins were similar ($p=1.000$). Energy and nutrient ingredients of legumes muffins were higher than grain muffins except carbohydrate ($p>0.05$). Chickpea (22.2mg), lentils (19 mg) and black gram (18.0 mg) had higher iron than grain flour muffins ($p=0.025$).

CONCLUSIONS
Legumes are a source of plant-base sustainable protein that can be easily used not only in food preparation but also in the production of sweet-tasting bakery products. Whole wheat flour and white sorghum flour were found to be the closest to wheat flour as a result of sensory analysis. In terms of nutritional value, whole wheat flour is a much better alternative to purified wheat flour, while white sorghum flour is a better choice for individuals with gluten sensitivity such as celiac disease. In this study, the muffins were made with a single type of flour, but the flours can be used in different ratios with each other or in mixtures with wheat flour to increase the nutritional density of the product.

STABILITY OF HONEY FROM THE BRAZILIAN STINGLESS BEE SCAPTOTRIGONA BIPUNCTATA AFTER TWO YEARS OF STORAGE

Aline Danielle Di Paula Silva Rodrigues[1]; Suelen Avila[1]; Sila Mary Rodrigues Ferreira[1, 2]
[1]Postgraduate Program in Food and Nutrition, Federal University of Parana, Curitiba, Brazil; [2]Nutrition Department, Federal University of Parana, Curitiba, Brazil

BACKGROUND AND OBJECTIVES

Stingless bee honey (SBH) differs from conventional honey (*Apis mellifera*) in having higher moisture and acidity and lower sugar content, as well as better antimicrobial, antioxidant and anti-inflammatory properties [1]. Among the honey-producing species, *Scaptotrigona bipunctata* (known as Tubuna bee) stands out, native to Brazil and of great ecological and economic importance. However, the effects of prolonged storage on the quality of SBH are still poorly known, limiting its commercial and scientific potential [2]. Therefore, the aim of this study was to evaluate the physicochemical and microbiological parameters of fresh and thermic treatment of *Scaptotrigona bipunctata* honey after two years of storage.

METHODS

Three samples of Tubuna bee honey were collected in April 2022 in the Metropolitan Region of Curitiba, Paraná, Brazil. Each sample was subdivided into two parts: one was stored fresh (Fr), and the other underwent thermal treatment (TT) at 65ºC/3 min before storage. The analyses of free acidity, pH, hydroxymethylfurfural (HMF), molds and yeasts were performed in triplicate at the time of collection (April 2022) and after two years of storage at room temperature (19ºC ± 6.2ºC) in sealed bottles (April 2024).

RESULTS

After two years, the free acidity (mEq/Kg) increased in both Fr honey (from 41.2 ± 6.4 to 88.5 ± 12.5) and TT honey (from 40.4 ± 8.1 to 57.3 ± 2.0). The pH value decreased in all samples (from 3.7 ± 0.3 to 3.5 ± 0.3). The HMF content (mg/Kg) increased from 1.8 ± 0.9 to 4.1 ± 0.9 in Fr honey and from 1.0 ± 0.3 to 3.1 ± 2.7 in TT honey. The molds and yeasts count (CFU/mL) decreased in Fr honey (from 5.3 x 10^2 to 5.0 x 10^2) and TT honey (from 2.8 x 10^2 to 1.5 x 10^2).

CONCLUSIONS

Despite the changes observed, the thermally treated honey (65ºC/3min) remained within the quality limits established by the legislation of the State of Paraná for stingless bee honey [3], including free acidity (< 60 mEq/Kg), pH (< 4.7), HMF (< 40 mg/Kg) and molds and yeasts (< 1 x 10^4 CFU/mL). The RESULTS provide a scientific basis for international regulations on the quality of thermally treated SBH, which do not yet exist. In addition, SBH is a sustainable product that can improve Brazilian biodiversity, promote environmental conservation practices and drive the expansion of the market by helping to generate income for small producers and rural communities.

KETONE BODY INTAKE DURING PREGNANCY IMPROVES GLUCOSE AND LIPID METABOLISM IN OFFSPRING IN MICE

Yuki Hirabayashi[1]; Asahi Tarui[1]; Shu Takeda[1]; Fuyuka Murase[1]; Wataru Machida[1]; Kohei Yamaguchi[1]; Yukari Egashira[1]; Shizuka Hirai[1]

[1]Laboratory of Food Nutrition, Applied Biological Chemistry, Graduate School of Horticulture, Chiba University（Matsudo campus）, Matsudo, Japan

BACKGROUND AND OBJECTIVES

It has been reported that fetal malnutrition increases the risk of developing metabolic syndrome after birth. In our previous study using mice, we found that dietary restriction during pregnancy exacerbated obesity and abnormal glucose and lipid metabolism in the offspring, whereas restriction of only carbohydrate during pregnancy improved obesity and glucose metabolism in the offspring. We also found that transplantation of the intestinal microbiota at weaning from either fetal nutritional restricted mice into germ-free mice improved glucose and lipid metabolism. In this study, we focused on ketone bodies, which are produced in the liver when glucose is not readily available, as a mechanism that can induce similar changes in the intestinal microbiota during pregnancy and improve glucose and lipid metabolism in the next generation. We investigated the effects of administration of β-hydroxybutyrate (BHB), a ketone body, during late pregnancy in mice on high-fat diet-induced abnormal glucose and lipid metabolism in the offspring.

METHODS

Pregnant female C57BL/6J mice were divided into three groups and administered with water (control group), 150 (low-dose group), or 300 (high-dose group) mg/mouse/day of BHB from day 10.5 of gestation to the day before delivery. The pups were fed a 60 kcal% high-fat diet from 5 weeks of age, and subjected to an oral glucose tolerance test at 19 weeks of age and dissection at 20 weeks of age.

RESULTS

The high-dose group showed a significant decrease in liver and white adipose tissue weights, liver triglyceride content, and fasting plasma glucose level compared to the control group. The high-dose group also showed a significant decrease in HOMA-IR and increase in QUICKI compared to the control group. In addition, the mean adipocyte area in perirenal adipose tissue was significantly lower in the high-dose group compared to the control group.

CONCLUSIONS

Administration of ketone body during late pregnancy improved glucose and lipid metabolism in the offspring. Improvement of insulin resistance and the enhancement of insulin sensitivity by suppressing adipocyte hypertrophy in the pups were suggested as one of the mechanisms of improved glucose metabolism in the offspring.

EFFECTS OF A TWO-WEEK INTERVENTION WITH PROBIOTICS GUMMIES ON GASTROINTESTINAL DYSFUNCTION IN WHITE-COLLAR EMPLOYEES: A RANDOMIZED CONTROLLED TRIAL

Yanyi Zheng[1]; Yujie Peng[1]; Lianjing Wang[1]; Jingya Huang[1]; Chaoran Zhang[1]; Hua Zhang[1]; Lingling Zhao[1]
[1]Family Nutrition and Care, H&H Group, Guangzhou, China

BACKGROUND AND OBJECTIVES
Abnormalities in Gastrointestinal (GI) function, typically manifested as dyspepsia, abdominal pain, bloating, constipation, and diarrhea, are prevalent concerns among sedentary white-collar employees. GI dysfunction is often induced by gut microbiota disorder and probiotic supplements are known to be an effective intervention. Gummies are more popular with consumers than capsules, but the processing method is unsuitable for common probiotics. *Bacillus coagulans* BC30 (BC30) exhibits remarkable resistance to high temperature, and can be produced in the form of gummies, while its health benefits remain unexplored. Therefore, our study aims to evaluate the effects of gummies containing BC30 on improving defecation habits and digestive function.

METHODS
Sixty white-collar employees, reporting self-perceived GI dysfunction, were recruited and randomly assigned equally to the low-dose (LG, 1 billion CFU/day) and high-dose (HG, 2 billion CFU/day) groups for the clinical trial. Participants were further categorized into constipation and diarrhea subgroups based on self-reported stool characteristics. Stool characteristics were assessed using the Bristol Stool Form Scale (BSFS), and the severity of constipation was evaluated through the Constipation Scoring System (CSS). The frequency and severity of GI symptoms—including bloating, abdominal pain, early satiety, belching, poor appetite, heavy stomach, indigestion, nausea or vomiting, poor GI motility, and dissatisfaction with digestive function—were rated using a 5-point Likert-type scale.

RESULTS
After two weeks of BC30 gummies consumption, the prevalence of constipation among the participants decreased from baseline levels (LG: 36.7% vs 20.0%, HG: 43.4% vs 6.7%). The mean CSS for LG decreased by 27.5% compared to baseline ($p > 0.05$), whereas that for HG reduced by 47.5% ($p < 0.01$). Analysis of stool consistency between subgroups revealed that the BSFS scores increased from 3 to 4 in the constipation subgroup, and decreased from 6 to 4 and 5 in the diarrhea subgroup. Additionally, the GI symptom scores of LG decreased by 43.1% after two weeks ($p < 0.01$), while a significant reduction was observed in HG after only one week ($p < 0.05$), with further decline noted after two weeks ($p < 0.001$).

CONCLUSIONS
Overall, supplementation with the BC30 gummies may help to regulate bowel movement, enhance stool consistency, and alleviate various digestive discomforts among sedentary people experiencing GI dysfunction.

EFFECTS OF COMBINED INTAKE OF FOOD COMPONENTS ACTIVATING THERMORECEPTORS ON ENERGY METABOLISM

Noriyuki Mori[1]; Mahiro Oku[1]; Yuna Takeuchi[1]
[1]Department of Food Science and Nutrition, DWCLA, Kyoto, Japan

BACKGROUND AND OBJECTIVES
Menthol and capsaicin are compounds known to activate cold receptors (TRPM8) and heat receptors (TRPV1), respectively, and their intake has been reported to enhance lipid metabolism. However, the mechanisms of action differ between these compounds, and the potential synergistic effects of their combined administration remain unclear. This study aimed to evaluate the effects of combined menthol and capsaicin intake on energy metabolism and lipid accumulation, as well as to elucidate the underlying mechanisms.

METHODS
Six-week-old male C57BL/6J mice were divided into four groups and fed specific diets for four weeks: a normal diet group (N group), a 0.25% menthol-supplemented diet group (M group), a 0.03% capsaicin-supplemented diet group (C group), and a combined 0.25% menthol and 0.03% capsaicin-supplemented diet group (MC group). Due to reduced feed intake observed in the MC group, the diet concentrations were adjusted to 0.125% menthol and 0.015% capsaicin after six days.

RESULTS
Final body weight did not differ significantly between the N and M groups, while the C group showed a decreasing trend, and the MC group exhibited a significantly lower value. Epididymal fat weight was significantly reduced in the M, C, and MC groups compared to the N group. Hepatic triglyceride content was significantly higher in the M group and significantly lower in the C group relative to the N group, with no significant differences observed in the MC group.

CONCLUSIONS
The findings of this study suggest that menthol intake may disrupt lipid transport from the liver, whereas capsaicin intake enhances lipid metabolism in both hepatic and peripheral tissues. Moreover, the combined intake of menthol and capsaicin demonstrates a greater capacity to suppress peripheral lipid accumulation, likely due to their distinct yet complementary mechanisms of action. These RESULTS underscore the potential of combining menthol and capsaicin as a dietary strategy to improve energy metabolism and mitigate lipid accumulation.

ANTIOXIDANT EFFECTS OF THE ACIDIC ETHANOL EXTRACT OF PURPLE CAULIFLOWER (BRASSICA OLERACEA L. VAR. BOTRYTIS)

Miki Hiemori-Kondo[1]; Yu Kayaki[1]
[1]Health and Nutrition, University of Kochi, Kochi, Japan

BACKGROUND AND OBJECTIVES
Purple cauliflower (Brassica oleracea L. var. botrytis) is a vegetable rich in anthocyanins. Previous our studies have identified six anthocyanins and L-ascorbic acid as antioxidant compounds in purple cauliflower based on a 2,2-diphenyl-1 picrylhydrazyl (DPPH) radical scavenging activity. However, the antioxidant effect of purple cauliflower in vivo remains to be elucidated. The objective of this study is to examine the antioxidant effect of purple cauliflower extract using iron induced acute oxidative injury in an animal model.

METHODS
To prepare the test samples, purple and white cauliflowers were freeze-dried and milled to produce powders, which were extracted with acidic ethanol. DPPH radical scavenging activity of the purple and white cauliflower extracts (P-Ex and W-Ex) was evaluated. Six-Week-old male ICR mice were randomly assigned to five ferric nitrilotriacetate (Fe-NTA)-treated groups (n=4-6), which included a phosphate buffered saline group (PC) and four extract groups: low dose P-Ex, high-dose P-Ex and W-Ex, and L-ascorbic acid. In addition, three Fe-NTA-untreated groups administered with P-Ex, W-Ex, and phosphate-buffered saline were designed to investigate the potential adverse effects of extracts. The mice were fasted for 12 h and the extract was administered orally 15 min before the intraperitoneal injection of Fe-NTA. Subsequently, the mice were dissected 60 min following the administration of Fe-NTA, and blood and kidney were obtained. Thiobarbituric acid reactive substances (TBARS) in plasma and renal homogenate were quantified as an indicator of lipid peroxidation.

RESULTS
The antioxidant activities of the purple and white cauliflower extracts were 129 ± 2 μmol Trolox equivalent (TE)/g and 59 ± 1 μmol TE/g, respectively. The Fe-NTA-treated P-Ex group exhibited a markedly elevated plasma TBARS value (80.7 ± 38.7 nmol MDA/ml) in comparison to the untreated group (7.6 ± 1.9 nmol MDA/ml). In contrast, the Fe-NTA-treated P-Ex high-dose group exhibited significantly reduced plasma TBARS levels (23.4 ± 24.1 nmol MDA/ml) compared to the PC group. This suggests that oral administration of the extracts prior to Fe-NTA injection markedly suppressed TBARS production. A similar result was observed in renal homogenates. Furthermore, administration of P-Ex-H did not demonstrate any adverse effects in Fe-NTA-untreated mice.

CONCLUSIONS
These RESULTS indicate that the purple cauliflower extracts have greater antioxidant effects than the white cauliflower extract, both *in vitro* and *in vivo*. Purple cauliflower could therefore be beneficial as a food for the prevention of oxidative stress-related disorders.

BACKGROUND AND OBJECTIVES
Neglected and underutilized species (NUS) can play an important role in nutrition and food security. This study aimed to promote the consumption of two NUS, *Ocimum gratissimum* and *Adansonia digitata*, by improving recipes that are traditionally consumed by children aged 6-23 months in the Atacora department.

METHODS
Two (02) improved recipes were formulated: baobab pulp-enriched porridge (BPP) and *egusi* sauce with african basil leaves and red palm oil (ESBR). Formulation was initially carried out using *MINITAB 19* mixing software. For each recipe, two factors (two main ingredients of the recipe) were considered for the formulation. The optimized recipes were then tested through a hedonic test with a sample of 66 children in three (03) communes. The nutritional densities of accepted recipes were then determined.

RESULTS
RESULTS showed that most of the children liked both recipes formulated. The energy densities of both recipes (1.24 ± 0.03 kcal and 1.89 ± 0.05 kcal/g respectively for BPP and ESBR) met the recommended standards. As for nutritional densities, only iron recommended density was achieved for BPP (4.86 ± 0.12 mg/100 kcal) while for ESBR, in addition to iron density, zinc and vitamin A densities were also achieved. The BPP recipe covered good levels of daily nutritional requirements for one single feed for iron (46.42 %) and energy (13.49%) considering the amount consumed by children, whereas the ESBR recipe covered levels of 26.61% for energy, 399.32% for vitamin A, 94.11% for iron and 17.44% for zinc.

CONCLUSIONS
A better valorization of these species through cooking demonstration sessions addressed to mothers is necessary to ensure the consumption of recipes formulated by communities in general and children in particular.

A NOVEL STRATEGY FOR ALLERGY PREVENTION AND TREATMENT: SYNERGISTIC MODULATION OF GUT MICROBIOME BY COMBINED FRUCTAN INTAKE

Hideaki Takahashi[1, 2, 3]; Chikako Yamada[1]; Kotoyo Fujiki[1]; Kento Kuramitsu[4]; Tadashi Fujii[2, 5, 3]; Yoshiki Hirooka[2, 5, 3]; Takumi Tochio[2, 5, 3]

[1]Graduate School of Nutritional Sciences, Nagoya University of Arts and Sciences, Nisshin, Japan; [2]Department of Gastroenterology and Hepatology, Fujita Health University, Toyoake, Japan; [3]Research and development, BIOSIS Lab. Co., Ltd., Toyoake, Japan; [4]Department of Applied Biosciences, Graduate School of Bioagricultural Sciences, Nagoya University, Nagoya, Japan; [5]Department of Medical Research on Prebiotics and Probiotics, Fujita Health University, Toyoake, Japan

BACKGROUND AND OBJECTIVES

The gut microbiome plays a key role in food allergies. This study investigated the combined effects of short-chain fructan (1-Kestose [Kes]) and long-chain fructan (Inulin [Inu]) on preventing or improving food allergies in an ovalbumin (OVA)-induced allergy mouse model, with a focus on gut microbiome composition.

METHODS

In the pre-sensitization trial (prevention study) and post-sensitization trial (treatment study), the groups were divided as follows: the control group (Ctrl group) was fed AIN-93G without OVA allergy induction, while the OVA allergy-induced groups received AIN-93G (OVA group), Kes 5% (Kes group), Inu 5% (Inu group), or Kes 2.5% + Inu 2.5% (Kes+Inu group).In the prevention study, diets were introduced 2 weeks prior to OVA sensitization and continued until autopsy, while in the treatment study, diets were administered for 4 weeks after allergy induction. Measurements included allergy symptoms, rectal temperature, serum OVA-specific IgE levels, gut microbiome composition, and cecal metabolite levels. Enzyme assays were also performed in the prevention study using *E. coli* expressing fructan-degrading GH32 enzymes.

RESULTS

In the prevention study, the Kes+Inu group significantly reduced allergy indicators. Gut microbiome analysis revealed increased abundances of *Parabacteroides distasonis* and *P. goldsteinii*, while metabolic analysis showed elevated levels of acetate and lactate in cecal contents. Enzyme assays further confirmed that GH32 enzymes from these bacteria actively degraded Kes and Inu in vitro.

In the treatment study, the Kes+Inu group demonstrated the greatest improvement in allergy symptoms. Gut microbiome analysis revealed an increased abundance of *UBA7173* within the *Muribaculaceae* family, and metabolic analysis showed elevated acetate levels in cecal contents.

CONCLUSIONS

The combined intake of Kes and Inu exhibited strong allergy-suppressive effects in both prevention and treatment trials. In the prevention study, the increased abundance of *P. distasonis* and *P. goldsteinii*, attributed to fructan degradation, was thought to contribute to allergy alleviation through elevated acetate and lactate production. In the treatment study, *UBA7173* and its presumed acetate production played key roles in improving allergy symptoms. These findings highlight the potential of Kes and Inu as functional food components for allergy prevention and treatment, with promising clinical applications.

THE TRANSCRIPTIONAL CO-ACTIVATOR PGC1A IN SKELETAL MUSCLE MEDIATES THE ANTI-OBESITY EFFECTS OF SOY ISOFLAVONES

Takumi Sugimoto[1]; Tokushi Kimura[1]; Mamoru Oyabu[1]; Ran Uchitomi[1]; Shiho Nakai[1]; Yasutomi Kamei[1]
[1]Laboratory of Molecular Nutrition, Graduate School of Life and Environmental Sciences, Kyoto Prefectural University, Kyoto, Japan

BACKGROUND AND OBJECTIVES

Obesity, a factor increasing the risk of metabolic diseases such as type 2 diabetes, dyslipidemia, and hypertension, can be reduced by the intake of soy isoflavones. Peroxisome proliferator-activated receptor γ coactivator 1α (PGC1α) is a transcriptional coactivator whose expression increases in skeletal muscle during exercise and co-activates a variety of transcription factors. In this study, we investigated whether skeletal muscle PGC1α is involved in the anti-obesity effects of soy isoflavones using skeletal muscle-specific PGC1α knockout mice.

METHODS

- Skeletal muscle-specific PGC1α-deficient (PGC1α-KO) mice were used for voluntary exercise in a rotating cage. In addition, they were fed a high-fat diet containing soy isoflavones for 4 weeks.
- Gene expression analysis was performed by qRT-PCR in skeletal muscle, white adipose tissue and liver.
- Gene expression analysis was performed by qRT-PCR in C2C12 myoblasts overexpressing PGC1α and supplemented with soy isoflavones.

RESULTS

In PGC1α-f/f mice, a decrease in white adipose tissue weight was observed after a combination of exercise and soy isoflavone intake. In contrast, no significant changes were observed in PGC1α-MKO mice. Gene expression analysis of skeletal muscle revealed that gene expression of energy metabolism-related genes such as mitochondrial function, lipolysis, and fatty acid oxidation, which are increased by soy isoflavone intake, were not observed in PGC1α-MKO mice. In white adipose tissue, beige adipose tissue markers including *Ucp1* gene expression appeared to be increased by the combination of soy isoflavones and exercise in both PGC1α-flox/flox and PGC1α-MKO mice, but not significantly. In addition, gene expression related to lipolysis was similar. In C2C12 myoblasts overexpressing PGC1α, soy isoflavone treatment increased genes related to energy metabolism.

CONCLUSIONS

PGC1α in skeletal muscle may be involved in some of the anti-obesity effects of soy isoflavones.

SLOW-DIGESTIBLE GLUCANS ENHANCE GLP-2 SECRETION AND PROMOTE ILEAL VILLI ELONGATION IN RATS

Rikako Nishina[1]; Tomoya Goto[2]; Shingo Hino[3]; Naomichi Nishimura[3]
[1]Course of science of Biological Resources, The United Graduate School of Agricultural Science, Gifu University., Gifu, Japan; [2]Faculty of Agriculture, Shizuoka University, Shizuoka, Japan; [3]Academic Institute, Shizuoka University, Shizuoka, Japan

BACKGROUND AND OBJECTIVES
Due to limited nutrient supply, the ileal villi are shorter than those in the jejunum, resulting in reduced barrier function. Villi elongation, mediated by glucagon-like peptide-2 (GLP-2), is crucial for maintaining intestinal integrity. GLP-2 is secreted by nutrient-stimulated L cells, which are predominantly located in the distal small intestine. Slow-digestible nutrients have the potential to increase nutrient delivery to the ileum, thereby stimulating GLP-2 secretion. This study aimed to investigate whether glucose delivery to the ileum via slow-digestible glucans (SDGs) could enhance GLP-2 secretion and promote ileal villi elongation.

METHODS
Expt. 1: Rats were fed either a control diet (C) or a 10% SDGs diet for 10 days. Isomaltodextrin (IMD) and resistant maltodextrin (RMD) were used as SDGs sources. **Expt. 2**: To induce atrophy of small intestinal villi, rats were administered 5-fluorouracil (5-FU, 20 mg/kg). The rats were simultaneously fed the same diets as in Expt. 1 for 10 days. **Expt. 3**: Following villus atrophy induced by 5-FU, rats were subsequently fed the same diets as in Expt. 1 for either 3 or 6 days.

RESULTS
Expt. 1: Rats fed the RMD diet exhibited significantly higher portal GLP-2 levels and longer ileal villi compared to the control group. These findings suggest that RMD facilitates glucose delivery to the ileum, thereby enhancing GLP-2 secretion and promoting villi elongation. In contrast, IMD, presumed to be more rapidly digestible compared to RMD, resulted in weaker GLP-2 secretion and villi elongation. **Expt. 2**: Under conditions of inhibited cell proliferation induced by 5-FU, no significant changes in GLP-2 secretion or villi length were observed in rats fed SDGs. **Expt. 3**: After 5-FU-induced atrophy of ileal villi, rats fed SDGs showed significantly enhanced GLP-2 secretion and significant recovery of villi length after both 3 and 6 days of feeding.

CONCLUSIONS
This study demonstrates that SDGs, such as RMD, enhance glucose delivery to the ileum, stimulate GLP-2 secretion, and promote ileal villi elongation. These findings highlight the potential of SDGs as dietary interventions for improving intestinal health.

CHARACTERIZATION OF SUMASHI-JIRU (JAPANESE CLEAR SOUPS) WITH VARIOUS INGREDIENTS USING COOKING METABOLOMICS

Tomomi Asano[1]; Tomoya Matsuda[2]; Shunsuke Yamamoto[3]; Kei Zaitsu[3, 2]
[1]Food and Nutritional Environment, Kinjo Gakuin University, Nagoya, Japan; [2]Graduate School of Biology-Oriented Science and Technology, Kindai University, Wakayama, Japan; [3]Computational Systems Biology, Kindai University, Wakayama, Japan

BACKGROUND AND OBJECTIVES

Low-sodium foods (LSF) are widely recognized for their ability to reduce the risk of lifestyle-related diseases. However, some LSF are often perceived as lacking “salty”, which can leave a negative impression. To address this challenge, it is essential to scientifically evaluate and enhance “taste” particularly in prerared dishes. Cooking metabolomics, a novel approach to profiling food components, offers significant potential for optimizing “taste” of cooked foods. In this study, we applied cooking metabolomics to perform a metabolic profiling of *sumashi-jiru*, a traditional Japanese clear soup, with various ingredients. We also assessed whether metabolic profiles can effectively capture and characterize the unique features of each soup.

METHODS

Sumashi-jiru was prepared by seasoning dashi (bonito stock) with soy sauce and adjusting the salt concentration to 0.7%. Vegetable soup was made by thoroughly cooking vegetables in the prepared *sumashi-jiru*. Fried-tofu soup was created by adding fried-tofu to the vegetable soup, and chicken soup was prepared by thoroughly cooking chicken in the vegetable soup. Metabolic profiles of each soup (n=5) were analyzed using a novel metabolomics platform, PiTMaP (Anal. Chem., 2020). Multivariate analyses, including PLS-DA, were performed using R software.

RESULTS

Aproximately 60 metabolites were detected in each soup. In the PLS-DA score plots, the chicken soup group was distinctly separated from the others along the first principal component axis, while the *sumashi-jiru* group was separated along the second principal component axis. In contrast, the vegetable soup and the fried-tofu soup groups showed no clear separation. Key metabolites contributing to group separation included 10 amino acids, 4 sugar phosphates, 3 organic acids, 2 fatty acids, 2 nitrogen-containing compounds, 2 nucleotide derivatives, and 1 sugar. These findings suggest that components eluted from chicken had a strong impact on the metabolic profiles of the *sumashi-jiru*-based soups, whereas the contributions of heated vegetables and fried-tofu were comparatively limited.

CONCLUSIONS

Cooking metabolomics successfully identified the metabolic profiles of *sumashi-jiru*-based soups. These findings highlight the potential of cooking metabolomics as an analytical approach for evaluating the taste of prepared dishes.

FORMULATION AND CHARACTERIZATION OF FUNCTIONAL BISCUITS OBTAINED BY INCORPORATING PAPAYA (CARICA PAPAYA), PINEAPPLE (ANANAS COMOSUS) AND BEETROOT (BETA VULGARIS) POWDER

Marlyne Mananga[1]; Kesnel Dtsayo Immata[2]; Nicolas Polycarpe Nolla[3]; Elie Fokou[2]
[1]Department of Biochemistry/Faculty of Sciences, Université de Yaoundé 1- NGOA EKELLE, Yaoundé, Cameroon; [2]Biochemistry, Univer, Yaounde, Cameroon; [3]Biochemistry, University of Douala, Douala, Cameroon

BACKGROUND AND OBJECTIVES

Beetroot (*Beta vulgaris*), pineapple (*Ananas comosus*) and papaya (*Carica papaya L*) are important natural fruits and legumes in producing functional foods due to the presence of bioactive (vitamin C, β-carotène) and antioxidant compounds. This study was undertaken to formulate and evaluate the physicochemical composition and antioxidant properties of biscuits incorporated with papaya, pineapple and beetroot powder at the rates of 10%, 15%, 20% and 25% (w/w).

METHODS

The hardness, pH, water absorption, proximate composition, mineral analysis and in vitro antioxidant profile (DPPH, FRAP) were analyzed using standard methods. Sensory analysis was conducted by applying a hedonic scale test using the technique of a 9-point.

RESULTS

The RESULTS showed that the hardness varied from 92.02 ± 4.29 N for biscuits with 25% of fruit powder to 104.66 ± 2.98 N for biscuits with 10% of fruit powder. The pH values decreased for all the enriched samples compared to the control (5.90-7.4), but this was more relevant for the samples enriched with 20 and 25% fruit powder. The use of beetroot, pineapple and papaya flour resulted in a slight increase in water absorption (33.32-160.53%). Moisture, fat, protein, fibre, ash, and available carbohydrate content ranged from 4.79-9.92%, 17.02-21.65g/100g, 7.94-9.89g/100g, 2.46-14.86g/100g, 2.39-3.55g/100g, 42.14-56.85g/100g respectively. Soluble sugars varied from 3.16-13.82g/100g. The micro minerals (Fe, Zn and Mg) ranged from 4.28-8.39%, 4.82-5.74% and 20.41-62.31% respectively. The total polyphenols flavonoids, and antioxidant activity increased with fruit powder content incorporated. Antioxidant properties such as total carotenoids and total phenolic contents were improved with the addition of fruit powder to the biscuits. Among the treatments, the biscuits prepared with 10% of papaya, pineapple and beetroot powder had the highest nutritional and sensory quality, having an overall acceptability score of 6.71 on a 9-point hedonic scale.

CONCLUSIONS

This study highlights the potential of utilizing papaya, pineapple and beetroot in functional biscuits, hence it can serve as relief for malnutrition.

EFFECTS OF GUAR GUM ON FATTY LIVER AND BRAIN INFLAMMATION IN MICE FED A HIGH-FAT DIET

Hitomi Yako[1]; Takayuki Tateishi[1]; Ayumu Sasaki[1]; Shizuka Hirai[1]; Yukari Egashira[1]
[1]Laboratory of Food Nutrition, Applied Biological Chemistry, Graduate School of Horticulture, Chiba University, Matsudo, Japan

BACKGROUND AND OBJECTIVES
Neuroinflammation is an activation of the immune response in the brain and spinal cord caused by neurotoxins. Neuroinflammation activates the immune cells, microglia, which secrete inflammatory cytokines. In chronic neuroinflammation, abnormal production of inflammatory cytokines causes neurotoxicity and contributes to the progression of neurodegenerative diseases. Guar gum is a soluble dietary fiber obtained from the endosperm of guar beans. Epidemiological studies have reported that dietary fiber intake affects brain function through changes in the intestinal microbiota. In this study, we examined the effects of guar gum on fatty liver and brain inflammation in mice fed a high-fat diet.

METHODS
C57BL/6J mice were obtained and bred. The mice were divided into three groups: S (Standard : S) group, H (High Fat Diet : H) group, and Guar Gum (High Fat Diet + Guar Gum : HG) group. The animals were divided into three groups. The final body weight was measured on the day before dissection, and tissue weight, liver triglycerides, and gene expression levels in several tissues were measured after dissection.

RESULTS
Body weight and liver triglyceride levels were significantly lower in the HG group than in the H group. White fat weight showed a tendency that guar gum administration suppressed the increase caused by the high-fat diet. Cecum weight was significantly increased in the HG group compared to the H group. In the hippocampus, the expression levels of inflammatory cytokines TNF-α, IL-6, and indoleamine-2,3-dioxygenase (IDO), a key enzyme in tryptophan metabolism, were lower in the HG group than in the H group. In addition, the expression level of PPAR-α, which promotes β-oxidation in the liver, was significantly increased in the HG group compared to the H group. The lipid content of feces was also significantly increased in the guar gum treatment.

CONCLUSIONS
Guar gum suppressed obesity and fatty liver caused by high-fat diet intake. IDO is known to be activated by inflammation and to affect the production of quinolinic acid (QUIN), which has neurotoxic effects. Inflammatory cytokines and IDO were decreased by guar gum treatment, suggesting that guar gum suppresses brain inflammation induced by obesity. As a possible mechanism of action, suppression of fatty liver and changes in the intestinal environment improvement may suppress the expression of inflammation-related factors in the brain.

IMPROVING KOUGLOF, A SWEET BREAD, USING GRAPE SEED OIL AND LACTIC ACID BACTERIA: A QUALITY EVALUATION FOR USE AS FOOD IN NURSING CARE

Yoshiko Fukushima[1]; Toshikazu Suzuki[1]; Noriko Komatsuzaki[2]
[1]Graduate School of Human Ecology, Wayō Women's University, Ichikawa, Japan; [2]Human Nutrition, Seitoku University, Matsudo, Japan

BACKGROUND AND OBJECTIVES

Kouglof, a traditional fermented confectionery resembling brioches and containing raisins, originates from the Alsace region of France. Although kouglof includes a high amount of butter, the process of making it is similar to that of making ordinary bread. Its rich nutrient content makes it a suitable staple food for older people who eat less. However, high consumption of saturated fats in butter increases the risk of cardiovascular diseases. In addition, its slightly stiff texture may make swallowing difficult in older people with decreased salivation. To address these issues, we investigated the improved preparation of kouglof using high-quality grape seed oil (GO) as a butter substitute and lactic acid bacteria (LAB) to soften the texture and evaluated its quality.

METHODS

We investigated the quality of kouglof using GO and some LAB. Furthermore, we carried out the color analysis, the 3/2D image analysis, and the physical properties tests of kouglofs.

RESULTS

Quality analysis of kouglof prepared using GO instead of butter showed that the height and specific loaf volume of kouglof made with GO (GO kouglof) were higher than those of ordinary kouglof made with butter. Textural analysis RESULTS showed that the hardness of the GO kouglof was lower than that of ordinary kouglof. The 3/2D image analysis showed that the bubble volume ratio was higher than the ordinary ratio, and the bubble-structure model index value was nearly oval. The linoleic acid content of the GO kouglof did not decrease after baking. Subsequently, we added different amounts of LAB to check if it affected dough softness when kneading the GO kouglof. The moisture content in the kouglof increased with the addition of LAB, with the highest moisture content observed in kouglof containing 32% LAB. In physical properties tests, the softness was in the following order: 16% LAB, 32% LAB, and no LAB.

CONCLUSIONS

The GO kouglof is softer and more elastic than ordinary kouglof, and the addition of LAB further improves its softness. We successfully optimized the amount of LAB required to soften the dough, providing a solid foundation for developing nursing-care food for older adults with difficulty in chewing and swallowing.

IMPROVING DIET QUALITY OF 6-23 MONTH-OLD SENEGALESE CHILDREN THROUGH THE DEVELOPMENT OF INNOVATIVE COMPLEMENTARY FOODS BASED EXCLUSIVELY ON LOCAL HIGH NUTRITIONAL VALUE PRODUCTS

Papa Mamadou Dit Doudou SYLLA[1, 2]; Christèle Icard-Vernière[3]; Bassama Joseph[1, 2]; Morgane Chapron[3]; Alé Kane[2, 1]; Claire Mouquet-Rivier[3]
[1]Departement de Technologies Agro-alimentaires, Université Gaston Berger, Saint-Louis, Senegal; [2]Laboratoire des Sciences Biologiques, Agronomiques, Alimentaires et de Modélisation des Systèmes, Université Gaston Berger, Saint-Louis, Senegal; [3]UMR QualiSud, Equipe 6 - Aliments, Nutrition et Santé, Institut de Recherche pour le Développement (IRD), Montpellier, France

BACKGROUND AND OBJECTIVES
Most of the complementary foods available in Senegal, particularly in rural areas, are essentially cereal-based and are therefore undiversified. They are poor in the essential nutrients required to prevent malnutrition in 6–23-month-old children. The aim of this work was to propose formulations of blended flour made from local nutritionally key foods well adapted to the local population's tastes and eating habits.

METHODS
Raw materials selected included millet biofortified with iron and zinc, orange-fleshed sweet potato rich in provitamin A carotenoids, cowpea flour or powdered dried fish muscle as a source of proteins, and groundnut flour or paste for their essential fatty acid. Flours were characterized according to their macro (proteins, lipids, ashes and total carbohydrates) and micronutrient (iron, zinc, Ca, Mg, etc.) contents to select the optimum combinations, through laboratory analyses or using data from food composition tables. Formulations were calculated in line with the Senegalese standards for infant flours based on 2 meals served per day to meet energy requirements, as well as iron and zinc levels of more than 5 mg/100 kcal and 2 mg/100 kcal respectively.

RESULTS
Iron and zinc contents in biofortified millet flour was 7.38 ± 0.35 mg/100 g DM and 6.12 ± 0.22 mg/100 g DM respectively. Thiamine levels were 5 times higher in groundnut flour (5.75 ± 0.14 µg/ g DM) than in groundnut paste (0.19 ± 0.01 µg/ g DM). Fishmeal-based formulas provided an average of 408.8 kcal/100 g DM, whereas cowpea-based formulas provided 394.14 kcal/100 g DM. Distribution of energy percent by macronutrients was in line with WHO recommendations for healthy diet. All formulations contained between 3.35 and 3.51 g of digestible protein per 100 kcal. They provided all the essential amino acids at adequate levels (more than 100% of estimated values). However, iron and zinc levels were around 30% and above 60% of the targeted values respectively.

CONCLUSIONS
The proposed formulations will considerably increase macro and micronutrients intake.Their consumption could contribute to a significant increase in infant’s diet diversity, through the introduction of four new food groups in addition to the cereals, and the breastmilk. Sensory and acceptability tests on porridges based on these formulations are ongoing.

EVALUATION OF THE DPP-IV INHIBITORY AND ANTIOXIDANT ACTIVITY OF MILKFISH FRAME (CHANOS CHANOS) HYDROLYSATES

Yu-Wei Chang[1]; Anastacio Iii Cagabhion,[2, 1]; Shao-Fu Tsou[1]; Ting-Jui Chuang[1]; Wen-Ling Ko[1]
[1]Department of Food Science, National Taiwan Ocean University, Keelung, Taiwan; [2]Department of Home Economics, Western Philippines University, Aborlan, Philippines

BACKGROUND AND OBJECTIVES
Diabetes has become one of the most critical public health issues in the world in the 21st century. Fish by-products particularly from milkfish are known to produce bioactive peptides which helps regulate blood sugar and possesses antioxidant capacities. Hence, the study utilized milkfish frame which is a by-product of the milkfish industry to assess its dipeptidyl peptidase IV [DPP-IV] inhibitory and antioxidant activity.

METHODS
The study employed milkfish frames hydrolyzed by pepsin, papain, and bromelain at different enzyme-substrate ratios for 8 hours to produce peptides with high DPP-IV inhibitory activity. Antixodant assay using DPPH free radical scavenging activity, ABTS antioxidant capacity and ferric reducing antioxidant power [FRAP] was also employed.

RESULTS
RESULTS revealed that two percent (2%) pepsin has the highest peptide content (283.64 mg/g) and has the highest DPP-IV inhibitory rate (68.47%) to produce the milkfish frame hydrolysates. RESULTS also showed that the DPPH free radical scavenging activity, ABTS antioxidant capacity and FRAP has improved after enzymatic hydrolysis, with papain hydrolysate exhibiting the highest activity with values of 23.04%, 33.90% and 43.72 μg/mL, respectively. Furthermore, RESULTS of the study showed that DPPH free radical scavenging activity, ABTS antioxidant capacity and FRAP improved during further ultrafiltration and in vitro simulated gastrointestinal digestion.

CONCLUSIONS
From these RESULTS, it shows the potential of the milkfish frame to be used as a multifunctional food ingredient given it DPP-IV inhibitory and antioxidant ability.

PREVALENCE OF ANEMIA AMONG THE ELDERLY AGED 60 AND ABOVE IN CHINA IN 2015

Li He[1]; Pengfei Wang[1]
[1]Nutrition and health education, National Institute for Nutrition and Health, Chinese Center for Disease Control and Prevention, Beijing, China

BACKGROUND AND OBJECTIVES
Elderly age is associated with a higher incidence of anemia. As China faces a demographic shift towards an aging population, which indicates that anemia among the elderly is a common health concern for us. The aim of this study was to analysis the prevalence of anemia and provide a scientific basis for reducing anemia rate in the elderly.

METHODS
The data were obtained from the 2015 China Adults Chronic Diseases and Nutrition Surveillance (2015 CACDNS), a multi-stage stratified cluster random sampling method was adopted. In order to improve the representativeness of the sample, the data were adjusted using post-stratification weighting.

RESULTS
A total of 48,955 elderly individuals were included in the study, with the prevalence of anemia was 9.2% in males and 9.1% in females. And the prevalence of anemia increased with age, with the rate in the 85 and older age group being twice that of the 60-64 age group. Females had a high prevalence of anemia due to pregnancy or menstrual bleeding, which had received widespread attention. However, our study found that the prevalence of anemia in the males aged 60 and above was higher than that in females.

CONCLUSIONS
The increased anemia risk in males can be partly attributed to dietary habits, lifestyle factors, sociodemographic conditions, hormonal changes, and a higher susceptibility to chronic diseases such as chronic kidney disease. Therefore, while paying attention to anemia in females, the issue of anemia in elderly males was also a cause for concern, especially the very elderly.

EFFECT OF FOOD ADDITIVES ON THE INVERTEBRATE ALLERGENS

Cai-Yi Chen,[1]; Yi-Tien Chen[1]
[1]School of Food Safety, Taipei Medical University, Taipei, Taiwan

BACKGROUND AND OBJECTIVES

Crustaceans, mollusks, and edible insects are categorized as invertebrates. In the European Union and many other countries, crustaceans and mollusks are recognized as statutory food allergens. Recently, edible insects have been introduced to the global market as novel and sustainable food. However, the studies indicate that edible insects may trigger allergic reactions in individuals with crustacean allergy. Food additives, including pH-adjusting agents and enzymes, may affect the activity and stability of proteins. Therefore, the objective of this study is to investigate the effects of food additives on the common allergenic proteins among invertebrates.

METHODS

The selected crustaceans (shrimp), mollusks (squid), and edible insects (cricket) were processed with various alkaline or acidic pH-adjusting agents and enzymes. The proteins of processed samples were extracted. Gel electrophoresis and western blot were used to analyze the immunoreactivity of allergenic proteins.

RESULTS

The immunoreactivity of tropomyosin, a major allergenic protein in invertebrates, was either unaffected or showed a slight increase in alkali-treated samples. In contrast, enzymatic and acidic treatments demonstrated varying degrees of reduction in the immunoreactivity of tropomyosin, with the degree of reduction varying by species.

CONCLUSIONS

Common food additives may either increase or decrease the immunoreactivity of invertebrate allergenic proteins, with the extent of reduction being species-dependent. This study provides further insight into the effects of food additives on food allergens.

IN VITRO PROTEIN DIGESTIBILITY OF RUBISCO-ENRICHED WHEAT DOUGHS

Valérie Micard[1]; Maude Ducrocq[2]; Adeline Boire[3]; Claire Bourlieu Lacanal[4]; Marie-Hélène Morel[2]; Marc Anton[3]
[1]SABP, Institut Agro Montpellier, Montpellier, France; [2]IATE, Inrae Centre Occitanie-Montpellier, Montpellier, France; [3]BIA, INRAE, Nantes, France; [4]IATE, INRAE occitanie, Montpellier, France

BACKGROUND AND OBJECTIVES
As the demand for sustainable, plant-based protein sources continues to grow, there is increasing interest in identifying new ingredients for food enrichment. This research explores the nutritional and digestive impacts of adding RuBisCO to wheat dough, comparing to pea protein or gluten addition.

METHODS
Wheat doughs were fortified with 10% external proteins and thermally treated to mimic bread food. Amino acid composition, COST standardized static in vitro digestion, degree of hydrolysis, and nitrogen/protein solubility, were conducted to assess the quality and digestibility of these enriched doughs.

RESULTS
RuBisCO and pea proteins enhanced the chemical score and the in vitro PDCAAS (IV-PDCAAS) score of the wheat dough compared to the gluten control. Digestibility assessments indicated that RuBisCO modified the kinetics of protein hydrolysis: nitrogen release was lower during gastric digestion but higher during intestinal digestion than in other samples. Size-exclusion chromatography of the digesta's soluble and insoluble parts showed that the protein network in RuBisCO-enriched dough was more resistant to gastric hydrolysis than in other doughs. These findings are analyzed considering the sites of enzymatic cleavage, the presence of enzyme inhibitors, the state of protein aggregation, and the secondary structures within the protein network of each dough type.

CONCLUSIONS
RuBisCO appears as a promising protein to enhance the protein nutritional quality ofwheat-based products. Its aggregation properties, beneficial for viscoelastic dough properties,modifies its protein digestion kinetic and the peptide profile after digestion remains to be cahracterized.

BACKGROUND AND OBJECTIVES
Strawberry fruit has been reported to have physiological functions such as antioxidant, anti-inflammatory and anti-allergic effects. However, there are no reports on functional actions specific to strawberry leaves. In this study, the effects of strawberry leaf extract and its polyphenolic components on atopy were investigated.

METHODS
Strawberry leaf extract (SLE) and its polyphenol components (SLP) used in the experiment were extracted and prepared using 50% (v/v) ethanol. Four-week-old female HR-1 mice were pre-fed for one week and then fed each test diet for seven weeks. The atopy-induced group was fed an atopy-induced diet (HR-AD), the SLE group was fed HR-AD with 1% and 5% SLE, and the SLP group was fed HR-AD with 0.2% and 1% SLP. The atopy-uninduced group was fed a standard diet (Lab M R stock diet). Body weight, keratin water content and transdermal water transpiration of the mice were measured every week from the start of feeding. Seven weeks after the start of the study, blood samples were taken under isoflurane aspiration anaesthesia and serum IgE, IgA, IgG, IgM and histamine levels were measured by enzyme-antibody methods. Antibody and cytokine mRNA expression levels in the spleen were also analyzed by RT-qPCR.

RESULTS
Compared to the HR-AD mice, the skin keratin water content increased in HR-1 mice treated with SLE. In addition, the allergic markers serum IgE and histamine levels were significantly reduced in the SLE and SLP-treated groups. On the other hand, no changes were observed in serum IgA, IgG and IgM concentrations. RT-qPCR analysis of splenocytes showed a significant decrease in IgE mRNA expression in the SLE- and SLP-treated groups compared to the atopy-induced control group. On the other hand, there were no differences in IgA, IgG and IgM mRNA expression levels in the groups. Compared to the atopy-induced control group, the SLE- and SLP-treated groups resulted in a significant reduction in IL-4 mRNA expression, which is involved in the enhanced production of Ig E.

CONCLUSIONS
The present study suggests that strawberry leaf extract and its polyphenol components have preventive and ameliorative effects on atopic symptoms and type I allergic reactions.

EVALUATION OF THE EFFECT OF NACRE EXTRACT ON DIABETIC ENCEPHALOPATHY USING KK-AY MICE

Heng Zhang[1]; Yamato Yotsuya[1]; Tomoki Omachi[1]; Yasushi Hasegawa[1]
[1]Engineering major, Muroran Institute of Technology, Muroran, Japan

BACKGROUND AND OBJECTIVES
Pearls are widely used as natural remedies in traditional medicine and in cosmetics and functional food. Previously, nacre extract derived from pearl shells significantly improved the memory in cognitive impairment model mice. In this study, we aimed to assess the effects of orally administered nacre extract on cognitive dysfunction, specifically diabetic encephalopathy, in genetically diabetic KK-Ay mice.

METHODS
ICR and KK-Ay were fed a AIN93G basal diet without or with 125,250 mg/kg nacre extract for 3 months. Blood glucose level and insulin resistance were evaluated by OGTT and ITT. Diabetic encephalopathy was evaluated by behavior tests. Real-time PCR was used to evaluate the mRNA expression levels ofsirtuin-1(Sirt1),glucose transporter-4(GLUT4), and brain-derived neurotrophic factor(BDNF) in mouse brains.

RESULTS
Various behavioral tests, including the Y-maze, novel object recognition, open field, and elevated plus maze tests, revealed that the nacre extract effectively alleviated the memory deficits and anxiety-like behaviors in diabetic mice. Moreover, the extract improved glucose tolerance by enhancing insulin sensitivity. It also exhibited cognitive and metabolic benefits by upregulating the Sirt1,GLUT4, and BDNF expression levels in the brain.

CONCLUSIONS
This study suggests that the nacre extract ameliorates diabetic encephalopathy by enhancing glucose metabolism and protecting neuronal cells in the brain.

EFFECT OF PROTEASE TYPE ON THE ANTIOXIDANT AND ENZYME INHIBITORY PROPERTIES OF CHICKPEA PROTEIN HYDROLYSATES

NILAKSHI ABEYSINGHE[1]; Rotimi E Aluko[2]
[1]Department of Food and Human Nutritional Sciences, University of Manitoba, Winnipeg, Canada; [2]Food and Human Nutritional Science, University of Manitoba, Winnipeg, Canada

BACKGROUND AND OBJECTIVES
Protein-derived peptides have gained attention for their potential health benefits such as antioxidant (AO) & enzyme inhibition (EI) properties. The objective of this study was to compare AO & EI activity of protein hydrolysates obtained from enzymatic hydrolysis of chickpea protein concentrate.

METHODS
The chickpea protein concentrate was isolated using alkaline solubilization coupled with isoelectric pH precipitation. The protein concentrate was digested using each of the following enzymes: alcalase, flavourzyme, pepsin + pancreatin, trypsin, and chymotrypsin. Obtained hydrolysates were then characterised for AO and EI properties.

RESULTS
Comparatively the hydrolysates obtained from chymotrypsin showed significantly ($p<0.05$) highest protein content (65.46 ± 0.56%). The reducing power of DPPH scavenging, hydroxyl inhibition, ferric-reducing & metal-chelating activities exhibited significant ($p<0.05$) variations across different proteases. Flavourzyme hydrolysates demonstrated the highest ($p<0.05$) reducing power of 59.4 ± 2.03% for DPPH scavenging. Highest hydroxyl radical scavenging activity ($p<0.05$) was also observed in flavourzyme hydrolysates, with an inhibition rate of 40.71 ± 0.00%. Alcalase hydrolysates recorded significantly ($p<0.05$) higher ferric-reducing activity rate of 0.13 ± 0.0%. And, trypsin hydrolysates exhibited the highest metal-chelation activity ($p<0.05$) at 18.77 ± 0.75%. Enzyme inhibition activities of hydrolysates were found to be dose-dependent, with varying levels of inhibition observed at different concentrations. Hydrolysates from trypsin & flavourzyme exhibited significantly ($p<0.05$) higher enzyme inhibition against chymotrypsin, with inhibition rates of 60.92 ± 1.6% and 58.75 ± 4.2%, respectively. In comparison, flavourzyme & pepsin + pancreatin hydrolysates demonstrated the highest ($p<0.05$) inhibition of trypsin, with inhibition rates of 60.79 ± 1.04% & 58.93 ± 1.4%, respectively. All protease-derived hydrolysates showed strong 92% inhibition of α-amylase activity while up to 99% activity of α-glucosidase was inhibited. Pepsin + pancreatin & chymotrypsin hydrolysates recorded significantly ($p<0.05$) highest inhibition rates of 69.26 ± 0.7% & 68.81 ± 1.47% against pancreatic lipase.

CONCLUSIONS
Based on these RESULTS, we conclude that flavourzyme hydrolysis most effectively enhanced AO & EI properties of chickpea protein hydrolysates compared to other proteases. However, some of these hydrolysates hold the potential for use as ingredients to formulate functional foods & nutraceuticals suitable for managing diseases related to oxidative stress & diabetes.

LIFESTYLE, DENTAL PLAQUE MICROBIOTA, AND PERIODONTITIS: A COMMUNITY-BASED STUDY

Nuo Xu[1, 2]; Ningxin Chen[1, 2]; Simayi Halizere[1, 2]; Jialing He[1, 2]; Yating Yang[1, 2]; Yuwen Shi[1, 2]; Weifang Zheng[3]; Fei Yang[1, 2, 4]; Shankuan Zhu[1, 2, 4]

[1]Department of Nutrition and Food Hygiene, Children's Hospital, Zhejiang University School of Medicine, National Clinical Research Center for Child Health, Hangzhou, Zhejiang, China; [2]Chronic Disease Research Institute, School of Public Health, School of Medicine, Zhejiang University, Hangzhou, Zhejiang, China; [3]Lanxi Hospital of Traditional Chinese Medicine, Lanxi Hospital of Traditional Chinese Medicine, Lanxi, China; [4]Binjiang Institute of Zhejiang University, Zhejiang University, Hangzhou, Zhejiang, China

BACKGROUND AND OBJECTIVES

Periodontitis is a serious oral disease, which is the main cause of tooth loss. Understanding the influence of lifestyle on periodontitis and the role of dental plaque microbiota in them is a key to prevent and control periodontitis.

METHODS

This study included 2,184 Chinese adults from Lanxi Cohort. Lifestyle score specifically included waist circumference, drinking status, smoking status, diet and physical activity, which later divided participants into healthy and unhealthy lifestyle groups. Periodontitis was defined according to the diagnostic criteria of the American Academy of Periodontology (AAP). 16S rRNA sequencing was performed on dental plaque samples from 1,747 participants. Multivariable linear regression and logistic regression models were used in all analyses.

RESULTS

The prevalence of periodontitis decreased with the increase of healthy lifestyle score. Compared toparticipants with unhealthy lifestyle, those with healthy lifestyle had a lower prevalence of periodontitis (OR = 0.76, 95%CI = 0.62-0.94, p = 0.013), and this phenomenon was more pronounced in men. Dental plaque microbial analyses showed that participants with healthy lifestyle exhibited enriched α-diversity and altered β-diversity. Nineteen genera were found to be linked to lifestyle and nine of them significantly increased the risk of periodontitis. Dental plaque microbiota played a mediating role of 18.61% in the influence of lifestyle on periodontitis (p < 0.001).

CONCLUSIONS

Healthy lifestyle is associated with a lower prevalence of periodontitis, and dental plaque microbiota may play a mediating role in them. Furthermore, this study may provide a viable combination of healthy lifestyle for preventing periodontitis.

INFLUENCES ON SWALLOWING BY BOLUS VOLUME, BOLUS VISCOSITY, SEX, AND AGE: ANALYSES BY A NOVEL METHOD FOR SWALLOWING FUNCTION MEASUREMENT BY SWALLOWING SOUNDS

Yuka Konoike[1, 2]; Kei Naramura[3]; Takahiro Hasegawa[3]; Izumi Tsukayama[1]; Saya Maruoka[1]; Takayo Kawakami[1]; Kayoko Ishii[2]; Tomoya Yoshida[3]; Masaki Hokari[3]; Toshiko Suzuki-Yamamoto[1]
[1]Department of Nutritional Science, Okayama Prefectural University, Soja, Japan; [2]Department of Nutrition and Health Science, Fukuyama University, Fukuyama, Japan; [3]Department of Human Information Engineering, Okayama Prefectural University, Soja, Japan

BACKGROUND AND OBJECTIVES
Acoustic analysis of pharyngeal sounds during swallowing may capture physiological functions, providing a noninvasive method for measuring swallowing capability. This approach could be valuable for early screening of swallowing declines and dysphagia, contributing to aspiration prevention. Quantifying the acoustic characteristics of swallowing through parameter analysis is essential for developing an objective measurement tool. Herein, we aimed to construct a noninvasive method for evaluating swallowing function using pharyngeal sounds during swallowing as indicators of performance.

METHODS
Healthy adults participated in the study, with no reported issues specific to chewing or swallowing functions. They were categorized into the younger group (aged 20–25 years) and older group (aged 50–65 years). We analyzed changes in swallowing function across variations in bolus volume, bolus viscosity, sex, and age using parameters such as swallowing duration, average voltage, and swallowing power derived from swallowing sounds.

RESULTS
Average voltage and swallowing power were significantly higher in men, both in younger and older groups, regardless of bolus volume and viscosity. These parameters generally decreased as bolus viscosity increased, with significant differences observed between men and women, except in older men. An age-related difference in swallowing function between men and women was noted in swallowing duration: older men took significantly longer to swallow a high-viscosity bolus compared to younger men, a pattern not observed in women. This finding suggests that men experience greater deterioration in swallowing with age than women.

CONCLUSIONS
This convenient and noninvasive method for swallowing function appears effective as an objective evaluation tool, indicating that swallowing varies by sex, aging, food physical property.

TRENDS IN BMI AND OVERWEIGHT/OBESITY AMONG CHINESE ADULTS FROM 1982 TO 2015 AND PREDICTIONS FOR OVERWEIGHT AND OBESITY

Hongyun Fang[1]; Aidong Liu[2]; Jiguo Zhang[3]
[1]Student Nutrition, National Institute for Nutrition and Health, Chinese Center for Disease Control and Prevention, Beijing, China; [2]Nutrition, National Institute for Nutrition and Health, Chinese Center for Disease Control and Prevention, Beijing, China; [3]Nutrition Monitoring Department, National Institute for Nutrition and Health, Chinese Center for Disease Control and Prevention, Beijing, China

BACKGROUND AND OBJECTIVES
Over the past few decades, the prevalence of overweight and obesity among Chinese adults has increased dramatically. Data indicates that the overweight rate has surpassed 50%**.** This study analyzes the trends in Body Mass Index (BMI), overweight rates, and obesity rates among Chinese adults from 1982 to 2015. And based on linear regression models, presents estimates of the overweight and obesity rates among adults in China for 2025 and 2030.

METHODS
Data on height and weight of adults from five China Nutrition Surveys/Monitoring conducted between 1982 and 2015 were analyzed to assess the current status and trends of BMI among Chinese adults. Obesity and overweight were defined according to the criteria of China. Linear regression model was used to predict the overweight rate and obesity rate among adults in China for the years 2025 and 2030.

RESULTS
In 1982, the average BMI for adult males and females in China was 21.06 and 21.32, respectively. By 2015, the average BMI for adult males and females had risen to 24.25 and 23.89, respectively. The increase in BMI was greater for males than for females, particularly among young and middle-aged males. For females, the increase in BMI was more pronounced with age, especially in women over 60. Before 2000, adult men had a lower BMI than women, but this trend began to change after 2000, and by 2015, the average BMI of men aged 18-45 was higher than that of women. The overweight rate and obesity rate among adults in China increased from 11.0% and 1.9% in 1982 to 33.3% and 14.1% in 2015. Using a linear regression model to make predictions for 2025 and 2030, it is estimated that by 2025, the overweight rate and obesity rate among adults in China will be 39.1% and 16.8%, respectively, and by 2030, these rates will rise to 42.4% and 18.6%.

CONCLUSIONS
The BMI of males and females in China has been steadily increasing, with a greater rise observed in males than in females. Chinese adults are indeed facing a serious problem with overweight and obesity, with projections indicating that by 2025, over 55% of adults will be overweight or obese, and by 2030, this figure is expected to exceed 60%.

FORMULATION AND CHARACTERIZATION OF A COMPOSITE INFANT FLOUR WITH LOCAL INGREDIENTS OF SOUTH KIVU: IRON AND ZINC ENRICHMENT STRATEGY

Marie AMELIE NABUHOLO[1]; Olouwafemi Mistourath Mama[1]; Mane Hélène Faye[1]; Adama Diouf[1]; Esto Bahizire[2]; Nicole Idohou-Dossou[1]
[1]Laboratoire de Recherche en Nutrition et Alimentation Humaine, Faculté Sciences et Techniques, Universite Cheikh Anta Diop (UCAD), Dakar, Senegal; [2]Center for Tropical Diseases and Global Heath, Université Catholique de Bukavu, Bukavu, Congo, Democratic Republic of the

BACKGROUND AND OBJECTIVES
Micronutrient deficiencies are a global nutritional problem. They are particularly prevalent among children living in areas where the diet is monotonous and based on cereals. Stunting and wasting affect 48% and 3% of children under five in South Kivu, in the eastern Democratic Republic of Congo. The infant formulas produced in the region do not always meet the standards recommended by the World Health Organisation (WHO). Our preliminary data show that children's first complementary food is porridge made from simple cereal flours (maize, soya, sorghum) or cereal flour/water mixtures. This study aimed to formulate iron and zinc enriched infant flours in line with international standards.

METHODS
The matrix formulation method was used to generate proportions of ingredients (maize, soybean, sorghum, fish powder) to be blended to achieve the required nutrient content. Three formulas, including a control formula (FC), formulas F1 (FE40) and F2 (FE20) enriched with 40% and 20% fish powder respectively, were prepared with fixed proportions of ingredients. The contents of macronutrients (proteins, lipids, carbohydrates, total sugars) and micronutrients (iron, zinc, calcium, magnesium) were measured using standard protocols. A 7-point hedonic scale was used to assess the overall acceptability (DOL) of the porridges prepared with the two formulas (FC and FE40) to mother-child pairs.

RESULTS
All formulas meet WHO standards for nutrient composition (carbohydrates, proteins, lipids and energy) with high levels of magnesium (129.2 - 202.2 mg/100g). The addition of fish powder in proportions of 40% and 20% contributed to the enrichment of zinc and iron, resulting in concentrations of 6.5 mg/100 g and 11.8 mg/100 g for FE40 and 4.52 mg/100 g and 10.13 mg/100 g for FE20. The concentration values reach 150% and 93% of the recommended zinc and iron intakes respectively for FE20. The fortified formulas have a high calcium content, with values ranging from 427.2 to 820.6 mg/100 g. Based on the overall average DOL values, both (FC and FE40) formulas were acceptable to most infants (over 75%), with an acceptability index greater than or equal to 70%.

CONCLUSIONS
This formulation strategy could be used locally to produce a high nutritional value infant formula. EF40 is well accepted by children and could be an appropriate local complementary food. Furthermore, timely introduction of food tastes and textures are the best predictors of child acceptance.

STRUCTURAL CHANGES OF HUMAN MILK UNDER SIMULATED INFANT GASTRIC CONDITIONS AFFECT INTESTINAL NUTRIENT BIOACCESSIBILITY

Ilona E. Kłosowska-Chomiczewska[1]; Paulina Żmuda-Trzebiatowska,[1]; Gabriela Burakowska,[1]; Adam Macierzanka,[1]
[1]Department of Biotechnology and Microbiology, Gdańsk University of Technology, Gdańsk, Poland

BACKGROUND AND OBJECTIVES
A series of extensive studies undertaken over the recent years by our research group has provided a comprehensive analysis of the influence of human milk (HM) composition on the structural changes observed during *in vitro* gastric infant digestion, affecting the bioaccessibility of proteins, fats and carbohydrates, and their further small intestinal hydrolysis. The studied variations in HM composition were due to the gestation length and the lactation period; and colostrum and mature HM samples were examined against cow's milk and selected commercially available milk formulas.

METHODS
The digestion progress and nutrient bioaccessibility were simulated using a miniaturised *in vitro* semi-dynamic digestion model and by applying conditions representative of the infant digestive system. Gastric emptying was imitated by collecting samples of gastric content at regular time intervals. Phase separation of the digesta was monitored by laser light scattering measurements at various stages of the digestion experiment.

RESULTS
The kinetics of digestion and the release of nutrients from HM were closely related to the structural changes the milk was undergoing under gastric conditions. Low pH has led to flocculation of fat droplets and coagulation of milk proteins, which resulted in fat creaming and/or sedimentation of coagulated proteins, while a progressive digestion of proteins and lipids was observed too. This phase separation affected the amounts of lipids, proteins and carbohydrates removed from the stomach at various stages of digestion, and their further degradation under small intestine conditions.

CONCLUSIONS
Our studies are crucial in revealing the complex structural changes that HM undergoes in the stomach. Experiments of this type remain a challenge, not only due to small volumes of some milk samples, particularly colostrum, that can be obtained for research purposes, but also because of the complexity of digestion processes they intend to replicate. Our findings highlight the critical importance of accurate nutritional strategies for the new-borns, especially when HM substitutes are required.

CONFLICTS OF INTERESTS

IMPACT OF MALTING AND GERMINATION ON RETENTION OF CALCIUM, IRON, ZINC, PHYTIC ACID AND SENSORY PROPERTIES OF THE TAKE HOME RATION COMPLEMENTARY FOOD MIXES OPTIMIZED TO MEET THE REVISED NATIONAL FOOD SECURITY ACT STANDARDS, FOR UNDER 2 YR CHILDREN OF INDIA

Sangita Thenarangam[1]; Prasanthi P S[1]; Shally Vishnoi[1]; Shrunga Shree S[1]; Pavithra R C[1]; Prathyusha Vasireddy[1]; Srinivas E[1]; Ananthan Rajendran[2]; Naveen Kumar R[3]; Radhika Madhari[1]
[1]Department of Dietetics, ICMR - National Institute of Nutrition, Hyderabad, India; [2]Food Chemistry, National institute of nutrition, Hyderabad, Telangana, India, India; [3]Microbiology Division, ICMR - National Institute of Nutrition, Hyderabad, India

BACKGROUND AND OBJECTIVES

Complementary feeding is essential for growth and development after 6 months. Many traditional complementary foods lack sufficient nutrient density, leading to micronutrient deficiencies. This study assesses how processing techniques affect the nutritional profile and sensory acceptability of complementary food mixes, aiming to develop optimized formulations that align with the revised 2023 National Food Security Act standards for children 6–35 months in India.

METHODS

This study built upon a previously optimized complementary food formulation, developed using a Mixture Design approach, to create nutrient-dense food mixes for children. The base formulation included wheat, pulses, milk powder, groundnuts, gingelly seeds, and plant-based oil, with locally sourced ingredients processed through malting and germination. Processed ingredients were incorporated into the optimized proportions. Nutrient levels were assessed pre- and post-processing. The processed optimized formulation was used to create three variations. Variations include: “Dry Dates Powder”, “ Low Refined Sugar (as per WHO guidelines)”, and Spices/Condiments”. Sensory evaluation with 20 semi-trained panelists using a nine-point hedonic scale (acceptability >6) compared the variations to Telangana’s Take Home Ration “Balamrutham.”

RESULTS

Processing raw ingredients through malting and germination enhanced their nutrient profile. Malting wheat increased calcium (50.64 to 52.97 mg/100g), iron (4.06 to 4.97 mg/100g), and zinc (2.97 to 3.13 mg/100g), while reducing phytic acid (643.79 to 318.10 mg/100g). Germinated Bengal gram contained 173.73 mg calcium, 6.93 mg iron, 3.78 mg zinc, and 231.5 mg phytic acid per 100g, while green gram provided 99.53 mg calcium, 4.96 mg iron, 2.87 mg zinc, and 196.96 mg phytic acid. The developed formulation contained 4.73 mg iron (78.8% Estimated Average Requirement, EAR), 219.37 mg calcium (54.8% EAR), and 2.78 mg zinc (103% EAR). Sensory evaluation showed high acceptability for variations with low refined sugar and spices/condiments (score 7.6), compared to the control product "Balamrutham" (score 7.8 score).

CONCLUSIONS

In conclusion, malting and germination improved the nutrient composition, while reducing phytic acid. The optimized complementary food mix showed enhanced nutrient density and acceptability, demonstrating the potential of processing techniques to enhance complementary foods and support child health.

IN VITRO DIGESTION OF A KIND OF WHOLE GRAIN BLEND AND ITS EFFECT ON GUT MICROBIOTA IN DIABETIC PATIENTS

Qian Du[1]; Ming Zhao[2]; Ruisheng Fu[1]; Meihong Xu[1]
[1]Department of Nutrition and Food Hygiene, School of Public Health, Peking University, Beijing, China;
[2]Institute of Biotechnology and Health, Beijing Academy of Science and Technology, Beijing, China

BACKGROUND AND OBJECTIVES
The glycemic index (GI) of common refined white rice (WR) is high, posing challenges for blood glucose control in diabetic patients. This study investigated the *in vitro* digestibility of a whole grain blend (WGB, composed of black rice, red rice, and brown rice) and its effects on the gut microbiota of elderly individuals with diabetes, aiming to evaluate its potential as a substitute for WR in diabetic diets.

METHODS
The WGB and control WR were cooked, and their total starch and amylose contents were measured. The INFOGEST *in vitro* digestion model was used to compare the starch hydrolysis rates and estimated glycemic index (eGI). Fecal samples from 20 elderly diabetic patients (aged 68.4±5.16 years) were collected, and *in vitro* fermentation was conducted with the digestive products for 24 h. The fermentation process was evaluated by measuring pH, short-chain fatty acid (SCFA) concentrations, non-starch polysaccharide (NSP) degradation, and microbial composition.

RESULTS
The final starch hydrolysis rates of WGB and WR were 69.76±5.71% and 73.02±6.16%, respectively, with corresponding eGI values of 73.43±4.49 and 77.55±2.64. WGB exhibited lower starch digestibility and a reduced eGI compared to WR, likely due to its higher amylose content (P<0.05). WGB fermentation increased *Bifidobacterium* and *Lactobacillaceae*, reduced pro-inflammatory *Bacteroides fragilis* and *Enterocloster bolteae*, and released more arabinose and xylose. Additionally, WGB yielded higher isobutyrate, while WR contained more glucose and fructose in structure, leading to increased acetate production and a more acidic environment, potentially boosting dysbiosis and inflammation. Functional analysis revealed that WGB upregulated pathways related to fatty acid elongation and fiber fermentation.

CONCLUSIONS
WGB demonstrated a lower GI in a simulated *in vitro* digestion model and exerted beneficial effects on gut microbiota composition. These findings suggest that WGB is a viable and health-promoting alternative staple food for diabetic patients, offering dual benefits in glycemic control and gut microbiome.

EGG WASTE IN MEDICINE: A NOVEL APPROACH TO SUSTAINABLE HEALTHCARE

Tsvetelina Vitkova[1]; Zdravka Radionova[2]; Plamen Saraliev[3]; Nikolaj Kolev[3]; Vanya Birdanova[1]; Ivelina Ruseva[1]
[1]Department of Hygiene, medical ecology and occupational diseases and DM, Medical University - Pleven, Плевен, Bulgaria; [2]Department of Social Medicine and Health Management, Medical University - Pleven, Плевен, Bulgaria; [3]Department of Meat and Fish Technology, University of Food Technologies, Plovdiv, Bulgaria

BACKGROUND AND OBJECTIVES
Eggs are a daily staple in many diets worldwide. During their usage and processing, significant amounts of waste are generated. Annually, at least 7,894,962 tons of egg processing waste are produced globally, of which 777,000 tons are within the European Union. The utilization of these byproducts could lead to substantial economic, social, and health benefits. The objective of the study was to provide an updated review of the scientific literature regarding the medical use of waste products derived from egg production

METHODS
A comprehensive literature review and systematic analysis were conducted using various databases, including PubMed, Scopus, Web of Science, Scielo, ISI, and Ovid MedLine. The focus was on highlighting the significance and the vast quantity of egg waste products in human nutrition, as well as their preventive and clinical applications.

RESULTS
The processing of eggs and the production of egg-based products generate considerable amounts of animal byproducts, which can be categorized into two groups: solid (shells and membranes) and liquid (technical egg white). These byproducts are a rich source of biologically active substances and are of interest for preventive and clinical medicine. Egg white contains proteins and hydrolysates with antibacterial, anticoagulant, and antioxidant properties. Additionally, they exhibit ACE inhibitory activity. Eggshell membranes contain collagen, keratin, glycosaminoglycans, including hyaluronic acid. For these reasons, they find applications in medicine for the prevention and treatment of various diseases, such as osteoarthritis, eye diseases, wound healing, tissue engineering, cardiovascular health, pulmonary conditions, and more.

CONCLUSIONS
The valuable properties and components of egg membranes and egg white, combined with the development of novel technologies and methods, make them highly applicable and effective in medicine.

CONFLICTS OF INTERESTS

RETENTION OF ANTHOCYANINS IN GRAPE PEEL EXTRACT MICROENCAPSULATED WITH AMAZONIAN BUTTERS USING SPRAY CHILLING

Jayne de Abreu Figueiredo[1]; Matheus Felipe Oliveira Souza[1]; Soraia Vilela Borges[1]; Diego Alvarenga Botrel,[1]; Pedro Henrique Campelo,[2]
[1]Food Science, Federal University of Lavras, Lavras, Brazil; [2]Food Science, UFV, Viçosa, Brazil

BACKGROUND AND OBJECTIVES
Grape peel extracts are rich in polyphenolic compounds, with anthocyanin (malvidin-3,5-diglycoside) as the main pigment, offering applications as natural dyes in food systems such as dairy, confectionery, and meat substitutes. These phenolic compounds provide significant health benefits, including antioxidant, antimicrobial, and antiviral properties. This study aimed to encapsulate grape peel extracts using the spray-chilling technique with Amazonian butters (Murumuru, Tucumã, and Cupuaçu) as encapsulating agents.

METHODS
For the production of microparticles by spray chilling, the blends containing Amazonian butters (60 %) and fully hydrogenated palm oil (HPF) (40 %) were melted in a water bath at 70°C. Regarding the microparticles produced with 60% murumuru butter, tucumã, and cupuaçu, and 40% HFP. Once fully melted, the blends were homogenized on a magnetic stirrer for 1 minute at 750 rpm to incorporate the PGPR (polyglycerol polyricinoleate) emulsifier (4 g by weight relative to lipid materials). The mixture was then fed into the atomizer nozzle (double-fluid model with 3.0 mm diameter) at a flow rate of 10 ml/min. The air flow rate was 35 L/min, and the cooling air temperature was 1°C.

RESULTS
The RESULTS of this study showed total monomeric anthocyanins and encapsulation retention values of 1006 ± 0.05, 920 ± 0.72, and 972 ± 0.12 mg malvidin-3-glucoside per 100 g, with retention efficiencies of 92%, 84%, and 88% for MM_P, TC_P, and CP_P, respectively. These values were found to be statistically different ($p < 0.05$). The RESULTS suggest that the use of different butters as encapsulating materials influenced both the levels of anthocyanins and the encapsulation efficiency.

CONCLUSIONS
Murumuru butter showed the highest encapsulation efficiency, followed by Cupuaçu and Tucumã. These RESULTS highlight the potential of Amazonian butters as effective encapsulating materials. However, further studies on storage stability are necessary to evaluate long-term protection due to potential lipid matrix reorganization.

ASSESSING THE AVAILABILITY AND QUALITY OF IODIZED SALT IN SENEGAL, WEST AFRICA

Marie Madeleine Adjigueleu DIEME[1]; Mane Hélène Faye[1]; Olouwafemi Mistourath Mama[1]; Phillip Makhumula Nkhoma[2]; Abdou Badiane[1]; Dora Panagides[2]; Adama Diouf[1]; Marielle Atala De Souza[1]; Becky Tsang[3]; Nicole Idohou-Dossou[1]

[1]Laboratoire de Recherche en Nutrition et Alimentation Humaine, Faculté Sciences et Techniques, Universite Cheikh Anta Diop (UCAD), Dakar, Senegal; [2]USAID Advancing Food Fortification Opportunities to Reinforce Diets (USAID AFFORD), TechnoServe, Arlington, Virginia, United States of America; [3]USAID Advancing Food Fortification Opportunities to Reinforce Diets (USAID AFFORD), Food Fortification Initiative (FFI), Atlanta, Georgia, United States of America

BACKGROUND AND OBJECTIVES

In Senegal, salt fortification with iodine is mandatory to address iodine deficiency and its' associated disorders. The impact of mandatory fortification on public health depends, in part, on the availability of food vehicles that meet fortification standards (FS). The objective of this study was to determine to what extent salt was iodized, and what proportion conforms with the Senegalese FS to help inform programming efforts.

METHODS

A cross-sectional market survey was conducted in Dakar and Thies. All salt brands available on the market were collected. Samples were first qualitatively tested for potassium iodate using a rapid test kit. Negative samples for potassium iodate were then analyzed for potassium iodide by a colorimetric assay. Composite samples (CS) were prepared from positive samples by brand/type and analyzed by titration. Iodine content was compared with FS, which requires fortification with 20-60 mg of iodine per kg of salt (mg/kg). CS RESULTS were extrapolated to native samples to account for the market share of brands and to allow analysis by relevant characteristics.

RESULTS

Overall, 141 salt samples were collected, of which 75.9% were fortified according to the qualitative test. The iodine content of 42 CS of 25 brands was determined. The median iodine content was 33.6 mg/kg [IQR: 18.5-61.3]. Less than half of the CS were within the FS range (45.2%). When the CS RESULTS were extrapolated to the native samples, only 36.4% were within the FS range. The proportion of adequately fortified salt was significantly higher in hypermarkets than in retailers (42.3% vs. 11.1%, $P<0.05$). The proportion of salt fortified below the standards was significantly higher for domestically produced salt (21.7%) than for imported one (3.7%), $P<0.05$.

CONCLUSIONS

Only 36.4% of salt in the Senegalese marketplace is fortified to standards. Further action is needed to close the fortification gap and ensure compliance with mandatory fortification standards.

CONFLICTS OF INTERESTS

The authors have no conflict of interest.

INFLUENCE OF COW BREED AND LOCATION ON MILK QUALITY PROPERTIES AND WEST AFRICAN SOFT CHEESE YIELD

Matthew Atongbiik Achaglinkame[1, 2]; Linda Dari[3]; Daniel Mörlein[2]
[1]Faculty of Agriculture, Food and Consumer Sciences, University for Development Studies, Tamale, Ghana; [2]Department of Animal Sciences, University of Göttingen, Göttingen, Germany; [3]Department of Agricultural Engineering, University for Development Studies, Tamale, Ghana

BACKGROUND AND OBJECTIVES

Ghana has diverse cow breeds, yet there is a notable paucity of information on how these breeds differ in milk quality and cheese yield. This study explored the impact of cow breed and farm location on milk composition and indigenous cheese ("Wagashi") yield.

METHODS

Two samples (three litres) of fresh milk per breed were collected from four main breeds: ("Boboji" (Ghana shorthorn), "Degeji" (a *Bos indicus* x *Bos taurus* breed), "Mossiji" (a Sanga breed), and "Yakanaji" (a zebu breed), at two different locations in Ghana – Achubunyor (Savanna Region) and Kasalgu (Northern Region). The milk samples were analysed in triplicate for fat, protein, lactose, ash, total solids and density using an SP lactoscan ultrasonic milk analyser. Subsequently, the milk was processed into "Wagashi" using 3% w/w fresh *Calotropis procera* leaves as a coagulant and an induction cooking plate (80°C) for heating for about 30 minutes.

RESULTS

The findings indicate that the milk compositions and cheese yields of the breeds generally varied considerably ($p<0.05$) within and across the locations. The breed-location interactions had mean ranges of 4.12-5.83% fat, 3.05-3.16% protein, 4.60-4.77% lactose, 0.69-0.71% ash, 12.71-14.32% total solids and 1027.03-1028.98 kg/m3 density, with cheese yield between 31.10-39.85%. The "Mossiji" breed from Achubunyor had the highest milk fat (M=5.83%, SD=0.01%), total solid (M=14.32, SD=0.01%), and cheese yield (M=39.85%, SD=0.21). The "Boboji" breed from Achubunyor had the highest milk protein (M=3.16%, SD=0.05%), lactose (M=4.77%, SD=0.07%), (M=0.71, SD=0.01%), and the second highest (M=38.05%, SD=2.33%) cheese yield. Achubunyor's "Yakanaji" milk is the densest (M=1028.98 kg/m3, SD=0.01), second highest (M=3.13%, SD=0.00) protein and lactose (M=4.72%, SD=0.00%), and the lowest fat and total solid contents, with a cheese yield averaging 37.55%. The compositional traits are moderately correlated ($0.44>r<0.60$) with the cheese yield. The milk compositions fell within the recommended ranges for fresh cow milk while the cheese yields were relatively higher than those reported in literature.

CONCLUSIONS

The findings show breed and location influence cow milk composition, and "Wagashi" yield and potentially its nutritional and sensory properties. They also point to management/diet effects and individual animal effects. Cow milk can help improve food security and dietary diversity in Ghana if its production is sustainably intensified. The high cheese yields obtained herein point to best practices that could improve cheese processors' income.

EPO3_046

CHARACTERIZATION OF THE USE OF NON-SUGAR SWEETENERS IN ULTRA-PROCESSED FOODS LAUNCHED IN BRAZILIAN RETAIL IN THE FIRST YEAR OF IMPLEMENTATION OF DIRECTORS' COLLEGIATE RESOLUTION (RDC) 429/2020

Ana Furtado[1]; Camila Borges,[1]
[1]Department of Food Science and Technology, Escola Superior de Agricultura Luiz de Queiroz da Universidade de São Paulo - USP, Piracicaba, Brazil

BACKGROUND AND OBJECTIVES
Non-sugar sweeteners present in food are widely used by the industry, but they raise concerns regarding their form of use and regulation in several products. Ultra-processed foods highly consumed by the Brazilian population contain in their composition, critical nutrients and cosmetic additives that stimulate their consumption. Among these additives are the presence of non-sugar sweeteners. Objective: To identify and classify the main non-sugar sweeteners used in the manufacture of ultra-processed foods available for sale in Brazil in 2022/2023 (beginning of the implementation of Directors' Collegiate Resolution 429/2020 in Brazil).

METHODS
The non-sugar sweeteners present in a sample of foods and beverages launched in Brazilian retail in the year 2022-2023 were identified from a database (Mintel-GNPD). Non-sugar sweeteners were identified through the list of ingredients and classified into 17 types according to the National Health Surveillance Agency (ANVISA). Ultra-processed foods were grouped according to retail sales categories. The frequencies of non-sugar sweeteners were calculated according to the categories of ultra-processed foods. In addition, the amount of non-sugar sweeteners and the frequency of their use in combination with added sugar were calculated. The main combinations of non-sugar sweeteners in the product sample were also observed through a Pearson correlation analysis ($p<0.01$).

RESULTS
The study revealed that 11.35% of ultra-processed foods contained at least 1 non-sugar sweetener, even when there was added sugar (591 had both non-sugar sweetener and added sugar). The categories of ultra-processed foods with the highest presence of non-sugar sweeteners were “bakery products”, “dairy products” and “chocolate products”. The most commonly used sweetener in the product sample was sucralose. It was found that 20.18% of nutritional beverages had 4 different non-sugar sweeteners, 1.03% of sweet fillings for breads had 5 sweeteners and 0.76% of candies and chewing gums had 8 different non-sugar sweeteners in their composition. The most common sweetener combinations found in foods were cyclamate and saccharin(significant positive correlation $p<0.01$).

CONCLUSIONS
The study showed the frequent use of sweeteners alone and in combinations in a sample of ultra-processed foods sold in Brazilian retail in the first year of implementation of RDC 429/2020. Furthermore, the concomitant use of sweeteners and added sugar reflects a possible reformulation trend driven by the implementation of RDC 429/2020 in the country.

VARIABILITY IN THE NUTRITIONAL COMPOSITION OF FLOUR AND BREAD FROM DIFFERENT TRITICALE CULTIVARS

Georgiana Gabriela Codină[1]; Sergiu Paiu[2]; Rumeus Iurie,[2, 3]; Aliona Ghendov-Mosanu,[2]; Atudorei Denisa,[1]
[1]Faculty of Food Engineering, Stefan cel Mare University, Suceava, Romania; [2]Faculty of Food Technology, Technical University of Moldova, Chișinău, Moldova; [3]Moldova, Cahul State University, Chișinău, Moldova

BACKGROUND AND OBJECTIVES

Triticale production increases worldwide, especially in Europe which generates over 80% of the world's quantity. Its popularity is due to its high crop yield and tolerance to adverse environmental conditions such as acidic soils or drought. Given the growing demand for food resources and interest in using new raw materials for food products, triticale can become a sustainable and innovative solution in bread-making. This study analyzed triticale cultivars from the Republic of Moldova Ingen 33, Ingen 93, Ingen 40, Ingen 35, Ingen 54, Fanica, and Costel in order to evaluate the nutritional quality of flour and bread obtained from its.

METHODS

The moisture, fat, ash, protein content was determined according to the ICC 110/1, ICC 105/2, 104/1, ICC 136. For triticale flour the wet gluten has been determined according to SR 90:2007 whereas bread loaf volume, porosity and elasticity were analyzed according to SR 91:2007 method. The total polyphenol content (TPC) as well as the content of individual polyphenols was evaluated at an extraction temperature of 60 °C using an HPLC - DAD.

RESULTS

For triticale flours, the moisture content was less than 14% for all triticale varieties, indicating a long shelf life during its storage. The ash content varied between 1.5 and 1.73% whereas the protein content was higher than 13% for all triticale cultivars. The wet gluten content was in a lower amount for Ingen 93, Ingen 54 and Ingen 40 varieties. The fat content was not in a high amount whereas the carbohydrates content was higher than 70% for all triticale varieties. The value of TPC varied between 275.95÷591.6 mg/kg, the 4-hydroxybenzoic acid content varied between 1.20÷3.22 mg/kg, the vanillic acid content varied between 0.70÷1.70 mg/kg, the caffeic acid content varied between 0.15÷2.27 mg/kg, the chlorogenic acid content varied between 0.08÷0.40 mg/kg, the *p*-coumaric acid content varied between 0.18÷18.22 mg/kg and the rosmarinic acid content varied between 0.61÷2.67 mg/kg. Bread technological quality characteristics varied between 228÷265 cm3/100 g for specific volume, between 51.3÷62.4% for porosity and between 70.1÷83.4% for elasticity. From the nutritional point of view, the triticale bread humidity varied between 43÷45%, protein between 8.5÷9.2%, fat between 0.8÷1.2%, ash between 1.0÷1.2% and carbohydrates between 46.4÷47.3%.

CONCLUSIONS

According to the data obtained it may be concluded that triticale flour has a high nutritional value being a valuable source of phenolic acids which possess antioxidant properties and may lead to bakery products of a high nutritional and technological quality.

ASSESSMENT OF FOOD AND NUTRITIONAL SECURITY AMONG WORKERS IN AN INDUSTRIAL COMPLEX IN A COUNTRYSIDE MUNICIPALITY OF SÃO PAULO STATE: A CROSS-SECTIONAL STUDY

Flavia Aranha[1]; Murillo Cesar Holtz Dorta[1, 2]
[1]Department of Human Sciences and Nutrition and Food Sciences, São Paulo State University (UNESP), Institute of Biosciences, Botucatu, Botucatu, Brazil; [2]Institute of Biosciences, Botucatu, São Paulo State University (UNESP), Botucatu, Brazil

BACKGROUND AND OBJECTIVES

In Brazil, the Workers' Food Program (PAT), linked to the Ministry of Labor and Employment, is considered the longest-lasting and most successful socioeconomic program in the country, benefiting around 21.9 million workers in 2024, 86% of whom have an income of up to 5 minimum wages (BRASIL, 2024). Although not originally designed for this purpose, the program has a significant impact on promoting Food and Nutrition Security (FNS) and on workers' health (GUILHERME et al., 2020). Food in the workplace has a direct influence on eating habits and health, in line with the guidelines of the World Health Organization's “Global Strategy on Diet, Physical Activity and Health” (WAXMAN, 2004). This study aims to verify the perception of FNS and the relevance of meals eaten in the workplace to the daily diet of workers in an industrial complex served by the Food Service (FS).

METHODS

This is a cross-sectional study of workers at an industrial complex in a large municipality in the state of São Paulo. The research was conducted with workers who attend the site's Food Service. Of the 260 individuals present at the SA, 175 chose to participate. The form was based on the Brazilian Food Insecurity Scale (EBIA), a short eight-point version (PENSSAN, 2022), and included a sociodemographic section. The EBIA classifies food insecurity (FI) as: food security, mild FI, moderate FI and severe FI (SPERANDIO; MORAIS; PRIORE, 2018). FI was graded by adding up the positive answers, given as “1”, and the negative answers, as “0”. The data was tabulated in Microsoft Office Excel® and analyzed in R software, with the creation of graphs and statistical analysis (TEAM, 2024).

RESULTS

The characterization of the participant population revealed that 88% were men (n=154) and 12% women (n=21). In terms of age, 42.3% of the participants were up to 30 years old, 33.1% were between 31 and 40 years old, and 24.6% were over 40. As for color/race, 57.14% identified themselves as white, followed by brown (20.57%), black (20%), indigenous (1.71%) and yellow (0.57%). had mild IA, 5.14% moderate and 1.14% severe. Thus, the majority (n=123) were food secure, and 29.7% (n=52) had some degree of FI.

CONCLUSIONS

The vast majority of the population surveyed is food insecure. It is necessary to carry out evaluations of institutional SA in order to obtain data on the nutritional quality of the meals, as well as the nutritional status of the workers and the state of FNS.

CHANGES OF EATING PATTERNS AMONG INTERNATIONAL MEDICAL STUDENTS IN BULGARIA

Rosica Popova[1]; Ludmila Ivanova[1]
[1]Faculty of Medicine, Sofia University St. Kliment Ohridski, Sofia, Bulgaria

BACKGROUND AND OBJECTIVES

International mobility of young people affects their lifestyle and alongside their routine everyday life including the eating habits and food selection. In recent years more international medical students coming from neighboring countries selected Bulgaria to live and to receive their medical training. Although some similarities with Bulgarian, the new setting changes their traditional nutrition patterns.
The aim of our study is to assess the perception and the attitude towards changes in food and dietary habits of International Medical students from 3rd and 4th grade, influenced by the new environment in Bulgaria.

METHODS

The study was conducted during September-October 2024 among international students from 3rd and 4th grade at Medical Faculty, Sofia University, Bulgaria. The total number of 85 international students completed the study. Data was collected by specially designed pre-tested questionnaire with 25 questions, divided into 2 parts. The first part was related to demographic characteristics. The second part of the questionnaire was to assess the perception and the attitude of the students towards food and nutrition in general, and related to the new environment, to evaluate the changes of their dietary patterns in the new country, and how these changes reflect on their body weight.

RESULTS

The majority of the international students were from neighboring countries of Bulgaria - Turkey and Greece. More than half of them didn`t describe significant changes in their eating patterns as they share some similarities between the cuisine of their own countries and Bulgarian cuisine. The Turkish students reported some problems with the finding and selection of some kind of meats, related to their religious culture but they take advantage of the availability of plenty of restaurants with ready-to-eat Turkish meals in Sofia. One of the most significant differences among all the students was a lower fish consumption which is influenced by the availability on the market. Also, there are lack of time and some ingredients to prepare their national meals at home.

CONCLUSIONS

The eating pattern and food selection of international students were not substantially influenced by the new environment most probably because of many geographical and cultural commonalities including culinary traditions.

EVALUATION OF KNOWLEDGE, ATTITUDES, SELF-REPORTED PRACTICES, AND RISK PERCEPTION OF FOODBORNE DISEASES AMONG FOOD HANDLERS IN A FOOD SERVICE UNIT IN BOTUCATU: A PILOT STUDY

Flavia Aranha[1]; Bárbara Alessandra Leão Matias[2]; Isabela Magrini Brandão[2]
[1]Department of Human Sciences and Nutrition and Food Sciences, São Paulo State University (UNESP), Institute of Biosciences, Botucatu, Botucatu, Brazil; [2]Institute of Biosciences, Botucatu, São Paulo State University (UNESP), Botucatu, Brazil

BACKGROUND AND OBJECTIVES

Collective feeding in Food and Nutrition Units (UANs) includes institutional services that meet a fixed demand from clients. The UAN is geared towards the operationalization of the nutritional supply to specific groups. It is an organized service that involves a series of activities designed to offer balanced meals, in line with dietary and hygienic standards, with the aim of meeting the nutritional needs of its clients, while respecting the financial limits of the institution (ABREU, SPINELLI, PINTO, 2011). The correct administration of these activities is fundamental to preventing Food and Waterborne Diseases (FWD), which are caused by ingesting water and/or food contaminated by bacteria, viruses, parasites or chemical substances. An AWD outbreak is identified when two or more people present similar symptoms after consuming the same food source or water from the same origin, usually in the same place. Common symptoms include nausea, vomiting, abdominal pain, diarrhea, lack of appetite and fever (BRASIL, 2024). A crucial strategy for assessing the hygiene and sanitation aspects of food handling is to carry out a diagnosis of food handlers' knowledge, attitudes, self-reported practices (CAP) and perception of risk of AWD. Even with periodic training, these measures are often not enough to guarantee correct adherence to hygiene practices, as they fail to effectively transform knowledge into appropriate attitudes and practices (LEANDRO et al, 2024). To analyze the knowledge, attitudes, self-reported practices and perception of risk of HAWD among food handlers in a large Food and Nutrition Unit (FNU) in the municipality of Botucatu/SP - Brazil.

METHODS

This was a descriptive cross-sectional study, carried out in July 2024, using questionnaires in a UAN in the municipality of Botucatu-SP. The initial sample consisted of 25 handlers and the questionnaires were designed for 7 areas of the UAN (stock, salad, butchery, cooking, dessert, distribution and hygiene).

RESULTS

The final sample consisted of 18 food handlers, the majority of whom were female, with an average age of 36.7±10 years, brown and with a high school education. The disconnection between the CAPs was identified in a considerable number of the questions, with emphasis on the validity of the food, the use of gloves and the handling of food with cuts and/or diseases.

CONCLUSIONS

Self-reported practices often do not correspond to observed practices, suggesting that handlers may omit their true beliefs and practices or carry out their tasks automatically. It is therefore crucial that further studies are carried out to identify the reasons why not all knowledge translates into practice. However, possible limitations such as lack of time were identified.

POSSIBILITIES OF PRODUCING PASTA OBTAINED FROM DIFFERENT TRITICALE VARIETIES AND FERMENTED LIGHT BREWERS SPENT GRAIN

Denisa Atudorei[1]; Olesea Saitan[2]; Aliona Ghendov-Mosanu,[2]; Georgiana Gabriela Codină[1]
[1]Faculty of Food Engineering, Stefan cel Mare University, Suceava, Romania; [2]Faculty of Food Technology, Technical University of Moldova, Chișinău, Moldova

BACKGROUND AND OBJECTIVES

Interest in the cultivation of *Triticale* grains has grown more and more. Nowadays it has also found applicability in the food industry. For this study were used seven different cultivars of *Triticale* from the Republic of Moldova, namely: Ingen 33, Ingen 93, Ingen 40, Ingen 35, Ingen 54, Fanica and Costel. Also, was used the brewers spent grain (BSG) in a fermented form in order to be incorporated in percentages of 10% and 17.5% in *Triticale* flour, to obtain pasta products. BSG was provided from pale (blonde) beer. The objectives of this study are to evaluate the quality of the pasta samples obtained.

METHODS

The pasta technological characteristics were characterized using AACC International Approved Method 66-50.01. For the characterization of the dry pasta fracturability and the pasta textural properties a Perten TVT-6700 device was used. The color evaluation of pasta samples was made using Konica Minolta Chroma Meter CR-400. The sensory evaluation of pasta samples was performed applying the nine-point hedonic scale.

RESULTS

The optimal cooking time varied between 11.30 min and 13.35 min, the lowest value being recorded for the sample obtained from the Costel variety and 10% BSF. Water absorption parameter increased at an addition of 10% BSF and decreased at an addition of 17.5% BSF. Cooking loss was generally enhanced by the addition of BSF, but this depended on the variety of *Triticale* used. The samples obtained with Ingen 93 and Ingen 35 had the lowest cooking loss, which ranged between 0.16% and 0.20%. Swelling index increased in the case of the samples with the addition of BSF. The value of 2.12, obtained with the Costel variety, with the addition of 17.5% BSF, was the highest. The addition of BSF had the effect of decreasing the brightness of the pasta samples, the lowest value of the L^* parameter being 48.47, in the case of the sample obtained with the Costel variety, without addition of BSF. From a textural point of view, it can be said that the value of the fracturability parameter decreased due to the addition of BSF, being the lowest in the case of Ingen 54 samples, when it had a value of 54.55 N, at a 10% BSF addition. The sensory analysis of the pasta showed that the tasters appreciated the best the pasta with an addition of 10% BSF.

CONCLUSIONS

The evaluation of how the addition of BSG influenced the quality of the pasta samples highlighted the fact that it is possible to successfully obtain pasta using whole wheat flour obtained from different *Triticale* varieties and BSF. It is gratifying to note that the seven types of different *Triticale* varieties are finding applicability in the food sector.

EPO3_052

PHYSICO-CHEMICAL AND CONSUMER ACCEPTANCE OF WHITE BREAD WITH DIFFERENT LEVELS OF GERMINATED BUCKWHEAT FLOUR ADDITION (FAGOPYRUM ESCULENTUM)

Olivia Atudorei[1]; Georgiana Gabriela Codină[1]
[1]Faculty of Food Engineering, Stefan cel Mare University, Suceava, Romania

BACKGROUND AND OBJECTIVES

White bread is consumed the most, but it is known that the refining process leads to a considerable loss of nutritional compounds. Thus, it is necessary to optimize the nutritional profile of this food product. Germinated buckwheat flour (BGF) can be used as an addition ingredient to white bread recipe because they have a valuable nutritional profile. The objectives of this study are to establish the optimal percentage of addition.

METHODS

To evaluate the bread physical characteristics, the following were determined: specific volume, porosity and elasticity. A Konica Minolta CR-400 colorimeter was used to highlight the crust and the crumb color. The textural characteristics were evaluated using a Perten TVT-6700 device. The microstructure of bread was analyzed with a Motic SMZ-140 stereo microscope, with the 20 x objective. The 9-point hedonic scale was used as a sensory method of analysis.

RESULTS

The specific volume of bread obtained by adding flour from buckwheat germinated for two days, without radicles, increased at the same time as the percentage of BGF increased. From a value of 163.78 cm^3/100 g, the specific volume increased to 193.86 cm^3/100 g (5% BGF). At four days, increasing the percentage of BGF produced a decrease in specific volume. Porosity also increased, from 70.54% to 76.54%, and at 7% addition it decreased to 73.37%. Elasticity increased from 91.92% to 93.67% and decreased to 91.53% at 7% addition. The crust color parameter L^* varied between 76.51÷ 62.96 in the second day of germination. The values of the parameter a^* ranged from 3.91 to 9.46 and for b^*, from 26.97 to 30.80. From the textural point of view, the value of gumminess decreased from 8.68 to 5.26. Cohesiveness and resilience have also decreased. Regarding the crumb microstructure of bread samples, it was deduced that the supplementation with BGF changed the size of the pores, but also their distribution in the structure of the bread crumb. The sensory analysis made it possible to highlight the fact that BGF did not negatively influence the opinion of the tasters in terms of quality taste indices. The samples with the addition of BGF without radicles have a higher quality compared to those obtained with radicles.

CONCLUSIONS

The study made possible to highlight the fact that the addition of BGF can be successfully used in the recipe for the manufacture of white wheat bread, without negatively affecting the quality indicators and consumer perception. An optimal supplementation level of 5% BGF was established at the end of the study.

FOOD FUNCTIONALITY TARGETING THE SYNTHETIC PATHWAY OF PRO-INFLAMMATORY LIPID MEDIATORS FOR THE PREVENTION OF CHRONIC INFLAMMATION

Toshiko Suzuki-Yamamoto[1]; Izumi Tsukayama[1]; Yuki Kawakami[1]; Keisuke Toda[1]; Hideyuki Ito[1]; Yoshitaka Takahashi[1]
[1]Department of Nutritional Science, Okayama Prefectural University, Soja, Japan

BACKGROUND AND OBJECTIVES

Chronic inflammation is an underlying pathological condition of lifestyle-related diseases or chronic diseases. Consequently, prevention and improvement of chronic inflammation are important for extending healthy life expectancy. Pro-inflammatory lipid mediators, prostaglandin (PG) E_2 and leukotrienes (LTs), induce and exacerbate chronic inflammation. Although inhibitors on cyclooxygenase (COX) catalyzing the first step of PGE_2 synthesis and 5-lipoxygenase (5-LOX) catalyzing the first step of LTs are already in clinical use, long-term preventive use is difficult due to the development of side effects. Therefore, we explore novel functional food ingredients targeting the synthetic pathway of PGE_2 and LTs, which can be used safely and continuously to prevent chronic inflammation.

METHODS

Changes in the expression of COX-2 and microsomal PGE synthase-1 (mPGES-1) which is the final enzyme of PGE_2 production were analyzed by real-time PCR and western blotting. Inhibitory effects on mPGES-1 activity from the substrate PGH_2 to PGE_2 and 5-LOX activity from arachidonic acid to the product were investigated, and the metabolites were analyzed by reverse phase-ultra performance liquid chromatography. The pathological amelioration was validated using some chronic inflammatory model mice such as psoriasis, colitis, and metabolic dysfunction-associated steatohepatitis.

RESULTS

We propose novel food functions with chronic inflammation-preventing effects: cell-selective effect, dual inhibitory effect, and final PGE_2 synthase (mPGES-1)-targeting effect that suppress the production of PGE_2 and LTs. 1) Cell-selective effect: diosgenin as a plant steroidal saponin down-regulated COX-2 and mPGES-1 in infiltrated macrophages of hepatic inflammation without influences on homeostatic COX-2 expression in endothelial cells and ameliorated acute and chronic liver injury. 2) Dual inhibitory effect: red rice proanthocyanidin and malabaricone C derived from nutmeg inhibited 5-LOX and mPGES-1, and ameliorated LTs-related inflammatory diseases such as psoriasis-like skin inflammation and asthma-like airway inflammation. 3) mPGES-1-targeting effect: ellagitannins, ganatin A and granatin B, down-regulated mPGES-1 without influence on COX-2 expression in macrophage and lung cancer cell lines and had tissue repair effects on chronic colitis.

CONCLUSIONS

We have discovered functional ingredients with new concepts that target the synthetic pathway of PGE_2 or LTs. The functional ingredients may contribute to the prevention of chronic inflammation, avoiding the side effects generated by existing drugs.

EFFECT OF ACIDIC TREATMENT ON THE ALLERGENIC PROTEIN (TROPOMYOSIN) OF MEALWORM

Cai-Yi Chen[1]; Yi-Tien Chen[1]
[1]School of Food Safety, College of Nutrition, Taipei Medical University, Taipei, Taiwan

BACKGROUND AND OBJECTIVES
Mealworm (*Tenebrio molitor*) is recognized as an eco-friendly and sustainable source of protein, approved as a novel food by the European Union in 2021. Despite its benefits, allergenicity remains a potential concern associated with the consumption of edible insects. A muscle fibril protein, tropomyosin, has been identified as a major allergenic protein in mealworms. The pH plays an important role in the property and integrity of proteins. This study aims to examine the stability and immunoreactivity of mealworm tropomyosin to understand its characteristics under acidic treatment.

METHODS
Mealworms were subjected to various acidic treatments using different vinegars and acidic food additives, each conducted at different pH and soaking conditions. Proteins were extracted from the processed samples, and their profiles were analyzed using gel electrophoresis and western blot to assess changes in integrity and immunoreactivity.

RESULTS
Analysis using gel electrophoresis demonstrated that the integrity of major proteins was affected by acidic treatment. Furthermore, RESULTS from western blot analysis revealed that the immunoreactivity of mealworm tropomyosin was dramatically reduced following acidic treatment.

CONCLUSIONS
Acidic treatment reduced the immunoreactivity of mealworm tropomyosin by altering its structural integrity. This approach may serve as a potential food processing method to modify the immunoreactivity of food allergens.

PHARMACOKINETIC ANALYSIS AND MODELING TO EXPLAIN LONG-TERM INTAKE OF THE FOOD-CONTAINING AMINO ACID ERGOTHIONEINE NECESSARY FOR COGNITIVE FUNCTION IMPROVEMENT

Yudai Araragi[1]; Reiya Yamashita[1]; Takahiro Ishimoto[1]; Yukio Kato[1]
[1]Faculty of Pharmacy, Kanazawa University, Kanazawa, Japan

BACKGROUND AND OBJECTIVES

A food-derived amino acid ergothioneine (ERGO) is currently used as a functional food that aims to maintain learning and memory in elderly people. ERGO is distributed to the brain after oral ingestion, and recognition by its specific transporter SLC22A4/OCTN1 may explain such efficient oral absorption and brain distribution. On the other hand, repeated oral intake of ERGO for 2 and 12 weeks in mice and humans is required for the improvement effect in cognitive function to appear, but the reason for this is unknown. The present study aimed to clarify details in ERGO pharmacokinetics to develop a physiologically based pharmacokinetic (PBPK) model that quantitatively explains the factors essential for the long-term ingestion of ERGO necessary in brain function improvement.

METHODS

Deuterium-labeled ERGO (d9-ERGO) was administered in mice at 1-10 mg/kg. ERGO concentration in the body was measured by LC-MS/MS. A mathematical model was constructed using the Napp program.

RESULTS

The terminal half-life of d9-ERGO after intravenous administration in plasma was ~24 days. Distribution of d9-ERGO to the adipose, muscle, and skin was rapid whereas that to the brain and blood cells was slow, compared to other organs. Thus, the brain distribution phase may be a rate-limiting in cognitive improvement by ERGO. The PBPK model was constructed to quantitatively explain the nonlinear pharmacokinetics of ERGO, revealing that the major critical factors in the brain distribution of ERGO are membrane permeability in the brain, distribution to erythrocyte precursor cells, and nonlinear kinetics of ERGO reabsorption in the kidney. The increase in neurogenesis after repeated ERGO administration was slowly increased, and this could be another critical factor for long-term administration necessary for cognitive improvement.

CONCLUSIONS

The PBPK model constructed can successfully describe the nonlinear disposition of ERGO after repeated oral administration and elucidate the critical factors in its improvement effect on brain function.

OPTIMISING 'GREEN' SOLVENTS AND TECHNOLOGIES TO PRODUCE ALGINATE, A PLANT-BASED FUNCTIONAL FOOD INGREDIENT

Heather Kenny[1]; Clare Reynolds[1]; Emma Feeney[1]; Marco Garcia-Vaquero[1]
[1]Institute of Food and Health, University College Dublin, Dublin, Ireland

BACKGROUND AND OBJECTIVES

To meet the demands of sustainable and healthy foods, more sustainable practices and technologies are required to produce food ingredients. Alginate is a polysaccharide derived from brown seaweed that is becomingly increasingly used in the food industry. Alginate is a popular plant-based food ingredient, with a wide variety of functions including thickening, stabilizing and emulsifying. Due to this versatility, alginate is used in many foods, such as sauces, jams, ice creams, syrups, instant desserts, and jellies. Beyond these traditional uses, emerging applications include edible films, fat replacers in foods, nutraceutical delivery agents and food scaffolds. However, current alginate processing is resource-intensive and tends to use harmful solvents. This study aims to apply response surface methodology (RSM) to optimise the extraction conditions of alginate from *Alaria esculenta* using ultrasound-assisted extraction and citric acid to improve the environmental footprint of the extraction process.

METHODS

A series of alginate extractions were conducted in a box Behnken design (n=17). *A.esculenta* was pre-treated with 1:10 (w/v) 3% citric acid solution and subject to ultrasound treatment (30-70 minutes, amplitudes 60%-100% and temperatures 20°C-80°C). The full biomass from this step was subjected to 0.1 % sodium bicarbonate solution 1:20 (w/v) at 64 % amplitude, 23°C for 32 min using an ultrasonic processor (UIP500hdT, Hielscher Ultrasonics GmbH, Teltow, Germany). The supernatant was then precipitated with IPA at a ratio of 1:3 overnight at 4°C, centrifuged and freeze-dried to record alginate yields.

RESULTS

The highest yield of alginate was 3.7% (US treatment: 80°C, 50 min and 60% amplitude). This was more than three times higher than the lowest yield of 1.2% obtained at 50°C, 50 minutes, and 80% amplitude. Overall, higher temperatures (80°C) produced greater alginate yields.

CONCLUSIONS

Ultrasound-assisted extraction and citric acid can be utilized in alginate extraction processes. Temperature had a critical role in enhancing the extraction efficiency. Future analysis will incorporate the purity of the extracts to further optimise the extraction conditions.

COLOR STABILITY OF ENCAPSULATED ANTHOCYANIN EXTRACT FROM BORDÔ GRAPES BY SPRAY CHILLING APPLIED TO GELATIN GUMMIES

Jayne de Abreu Figueiredo[1]; Matheus Felipe Oliveira Souza[1]; Soraia Vilela Borges[1]; Diego Alvarenga Botrel,[1]; Pedro Henrique Campelo,[2]
[1]Food Science, Federal University of Lavras, Lavras, Brazil; [2]Food Science, UFV, Viçosa, Brazil

BACKGROUND AND OBJECTIVES
The increasing demand for healthier food ingredients has driven the use of natural colorants. Grape skins, agro-industrial byproducts from winemaking, present a sustainable solution for obtaining anthocyanins, bioactive compounds widely used as natural colorants. However, these compounds are highly sensitive to processing and storage conditions, which may compromise their effectiveness. Spray chilling encapsulation emerges as a promising strategy to protect anthocyanins, enhancing their stability. This study evaluated the coloring efficiency and stability of gelatin gummies containing spray-chilling-encapsulated anthocyanins over 30 days of storage.

METHODS
Binary mixtures comprising fully hydrogenated palm oil (FHPO) combined with cocoa butter (CB) or Amazonian butters such as murumuru (MM), cupuaçu (CU), and tucumã (TU) were used as encapsulating materials. The emulsions, consisting of 60% butters, 40% FHPO, emulsifiers, and grape skin extract, were atomized to produce microparticles with coloring potential. Gelatin gummies were prepared using maltodextrin, unflavored gelatin, distilled water, sweetener, microparticles (natural colorant), citric acid, PGPR, and flavoring agents. The mixture was microwaved, homogenized using a magnetic stirrer with heating plates, and then refrigerated to solidify the gummies. The colorant efficiency was assessed through color parameters (L*, a*, b*), total color difference (ΔE), and hexadecimal (HEX) color standards. RESULTS, analyzed on days 0, 6, 13, 20, and 27, showed efficient color transfer to the gummies despite variations in ΔE during storage.

RESULTS
Anthocyanin degradation, evidenced by increased L* and decreased a*, was more pronounced in the CB treatment, which exhibited the highest ΔE and significantly differed from the other treatments ($p < 0.05$). The MM treatment presented the lowest ΔE, while CU and TU showed no significant differences ($p < 0.05$). Despite the perceptible changes indicated by ΔE, visual variations observed in HEX standards did not negatively impact the gummies' appearance.

CONCLUSIONS
, spray-chilling-encapsulated colorants utilizing Amazonian butters are viable and sustainable alternatives for the food industry, showing significant potential for application in gelatin gummies. Moreover, replacing conventional fats such as palm oil and cocoa butter with Amazonian butters enhances the sustainability of the process.

A COMPREHENSIVE INSIGHT IN SOY FOODS: CONSUMPTION PATTERNS IN THE CENTRAL BALKANS REGION, HEALTH BENEFITS ASSOCIATED WITH ISOFLAVONES, AND SAFETY CONCERNS

Maja Amidžić[1]; Mira Mikulić[1]; Ljilja Torović[1]
[1]Department of Pharmacy, Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia

BACKGROUND AND OBJECTIVES
The increasing global consumption of soy-based foods, attributed to their nutritional value and associated health benefits, underscores the significance of soy isoflavones (daidzein, glycitein, and genistein) for various nutritional and health-related applications.

METHODS
In this research, a comprehensive analysis of 94 soy-based food products and 21 food supplements (FS) marketed in the central Balkans region (Republic of Serbia and Republic of Srpska), included isoflavone and biogenic amine (BA) profiling by high-performance liquid chromatography as well as toxic metal(loid)s determination by inductively coupled plasma with mass spectrometry.

RESULTS
The isoflavone content varied significantly across food groups, with an average of 611 mg/kg. Soybeans, flours, and flakes exhibited the highest isoflavone levels (1787 ± 507 mg/kg), while soy sauces showed the lowest (15.3 ± 11.1 mg/kg). FS displayed a wide range of isoflavone concentrations (0.05–71.0 mg/dose unit), with deviations from labeled values often exceeding acceptable limits. Isoflavone intake was estimated using national food consumption data, revealing substantially higher intake among vegetarians in Serbia (119–156 mg/day) compared to the general population (1.4 mg/day). Regional comparison showed significantly lower intake in the Republic of Srpska (0.23 mg/day). Health benefits were expected only in the case of the vegetarian consumers in Serbia, as this population group primarily met recommended intake levels for menopausal symptom relief (≥70 mg/day) and cardioprotective effects and osteoporosis prevention (≥90 mg/day). Interestingly, FS contributed modestly to the recommended intake, with only one FS fully meeting the dose required for menopausal symptom relief. Risk assessment highlighted potential health concerns, including BAs in fermented soy foods and toxic metal(loid)s in FS. Histamine and tyramine levels posed minimal risk for healthy consumers but exceeded safety thresholds in some cases for individuals on MAOI therapy. Elemental analysis of FS revealed low additional intake of Pb, Cd, and Hg but raised concerns over As, which increased dietary exposure by up to 10% on average and 23% in case of high-consumption.

CONCLUSIONS
This research advances understanding of the health impact of soy-based diet, identifying both benefits and risks. While soy isoflavones offer significant health benefits, depending on intake levels, risks related to the exposure to BAs and toxic metal(loid)s need careful consideration, particularly in vulnerable population groups.

BACKGROUND AND OBJECTIVES
Obesity is a chronic pathology for which curative and preventive measures are constantly sought. One of these measures is the use of apple cider vinegar.
The aim of our study was to evaluate the effect of apple cider vinegar on anthropometric parameters in obese individuals.

METHODS
We conducted a comparative longitudinal study at the obesity unit over a period of one month. The study involved 50 obese patients, divided into two groups: RHV+ and RHV-. We defined T0 as the day of recruitment and T1 as the time of the check carried out one month after T0.

RESULTS
The average age of the study population was 41.4 ± 13.74 years, divided into 28% men and 72% women. The mean body mass index of both groups at T0 was 39.34 ± 7.16. The average duration of obesity in patients was 16.38 ± 8.7 years. The average weight loss was 3.83 ± 1.97 kg in the RHV+ group and 1.16 ± 1.33 kg in the RHV- control group, with a maximum weight loss of 10.5 kg and 3. 8 kg respectively in the RHV+ and RHV- groups. Univariate analysis revealed statistically significant associations between anthropometric parameters measured at T0 and those measured at T1.

CONCLUSIONS
It appears from our study that nutritional support, based on a hypocaloric diet with apple cider vinegar supplementation, demonstrated notable effects on the anthropometric parameters of obese individuals.

ADHERENCE OF TUNISIAN DIABETIC WOMEN TO THE MEDITERRANEAN DIET

Ramla Mizouri[1]; rym ben othman[1]; Faten Mahjoub[2]; Nadia Ben Amor[1]; Rim Rachdi[1]; Amel Gamoudi[1]; Awatef Kacem[1]; Olfa Berriche[1]; Henda Jamoussi[2]
[1]A, institut national de nutrition et de technologie alimentaire de tunis, tunis, Tunisia; [2]Service "A" of Nutritional Diseases, National Institute of Nutrition & Food Technology of Tunis, Tunis, Tunisia

BACKGROUND AND OBJECTIVES
The Mediterranean diet, characterized by a high consumption of fruits and vegetables, a low consumption of meat and dairy products, is considered one of the healthiest dietary models. However, the current way of life weakens the transmission of family food values and contributes to the loss of traditional references.
The objective of this study is to know the degree of adherence of a sample of diabetic women to the Mediterranean diet (DietMed).

METHODS
The study is carried out on 105 diabetic women followed at our consultation. Eating behavior was assessed using the 14-Item Mediterranean Diet questionnaire. The total score ranged from 0 to 14 and was categorized into three adherence groups: low (0 to 5), medium (6 to 9), and high (≥10).

RESULTS
The average age of the patients was 52.11±14.25 years. Diabetes has been evolving on average for 12.38 ± 8.2 years. The average body mass index (BMI) was 30.45 ± 6.23 kg/m2, the average waist circumference = 108.2 ± 14 cm. The majority of our patients (81%) had average adherence to DietMed, 8 had low adherence and 12 had maximum adherence. There was no significant correlation between DietMed adherence score and: age, education level, marital status, place of residence, waist circumference, BMI, type and duration of diabetes.

CONCLUSIONS
Adherence to the Mediterranean diet is far from optimal despite its benefits demonstrated in the general population and in diabetics. Dietary education for diabetics must always take into account eating habits and encourage them to re-adopt our traditional healthy lifestyle.

CONFLICTS OF INTERESTS

SPRAY CHILLING PRODUCTION OF SOLID LIPID MICROPARTICLES ENCAPSULATING CAROTENOIDS FROM ANNATTO (BIXA ORELLANA): EFFECTS OF EXTRACTION METHODS AND WALL MATERIALS ON PHYSICOCHEMICAL STABILITY

Carlos Ramon Silva[1]; Paula Giarolla Silveira[1]; Karoline Ferreira E Silva[1]; Pedro Henrique Campelo,[2]; Diego Alvarenga Botrel,[3]; Soraia Vilela Borges[4]
[1]Department of Food Science, Federal University of Lavras, Lavras, Brazil; [2]Food Science, UFV, viçosa, Brazil; [3]Food Science, UFLA, lavras, Brazil; [4]Food Science, Federal University of Lavras, Lavras, Brazil

BACKGROUND AND OBJECTIVES
Carotenoids are bioactive compounds valued for their antioxidant properties and natural pigmentation but are sensitive to light, heat, and oxidation, limiting their stability. Annatto (*Bixa orellana*) is a key source of bixina, a lipophilic carotenoid widely used in food. This study aimed to develop solid lipid microparticles (SLM) using spray chilling to enhance the stability of bixina, preserving its bioactivity and functionality during storage. The influence of two wall materials, GRINDSTED and DIMODAN, combined with two extraction methods (mechanical stirring and ultrasonication) on the physicochemical stability of the encapsulated compounds was evaluated.

METHODS
Four treatments were evaluated: GRINDSTED as the wall material with mechanical stirring for extraction (GT); GRINDSTED with ultrasonication (GU); DIMODAN with mechanical stirring (DT), and DIMODAN with ultrasonication (DU). Carotenoids were extracted by heating the wall materials to 70 °C to ensure the fusion of fatty acids, followed by mixing with powdered annatto seeds for 30 minutes. For ultrasonication, a digital sonifier (200 W, 20 kHz) was used. SLM were produced in a spray chiller under controlled conditions (10 mL/min feed rate, 1 °C cooling air). Samples were stored at 35 °C with and without light for 60 days. Analyses were conducted at five time points (days 0, 15, 30, 45, and 60) to assess bixina content (mg/g), antioxidant activity (ABTS, TEAC μmol/g), total phenolic content (mg GAE/g), and color variation (ΔE).

RESULTS
Initial bixina content ranged from 26.156 ± 0.003 mg/g (DU) to 26.527 ± 0.003 mg/g (GT). Antioxidant activity was highest in DT (3.386 ± 0.011 μmol/g) and lowest in GU (2.792 ± 0.009 μmol/g). During storage, bixina degradation was more pronounced under light exposure. At day 60, DT exhibited the highest bixina retention (13.629 ± 0.001 mg/g), while DU showed the lowest (7.596 ± 0.005 mg/g). ΔE values indicated significant color variation, particularly in DT (33.060 ± 0.046) under light. Phenolic content remained stable across treatments and storage conditions.

CONCLUSIONS
The combination of DIMODAN and mechanical stirring produced SLM with high bixina retention and antioxidant activity, showcasing its potential as a carotenoid encapsulation matrix. Ultrasonication was less effective in preserving bixina. This study highlights spray chilling as a scalable, cost-effective method for stabilizing bioactives.

NUTRITIONAL COMPOSITION AND FIBER CONTENT IN CHAÑAR FRUIT

Ethel Coscarello[1]; Castro, María Laura Gómez[2]; Claudia Larregain[2]; Micaela Veliz,[2]; Alicia Ciace[2]; Renee Fortunato,[2]; Roberto Aguerre,[2]
[1]Moron Provincia de Buenos Aires , Universidad de Morón, Morón, Argentina; [2]Moron Provincia de Buenos Aires, Universidad de Morón, Morón, Argentina

BACKGROUND AND OBJECTIVES

The Chañar is an Argentinian native tree, *Geoffroea Decorticans, Leguminosae, Fabaceae*, which grows from the south of Perú to the north of Río Negro. Its fruit is incorporated into the diet by indigenous peoples. The objective of this work was to determine the nutritional composition and fiber content of two varieties *Decorticans y Subtropicalis,* grown in the Arturo Ragonese Botanical Garden in the National Institute of Agricultural-livestock Technology (INTA), located in Hurlingham. Buenos Aires. Argentina.

METHODS

Total, insoluble and soluble dietary fiber: AOAC (2002) Official Method of Analysis 991.43. Proteins: AOAC (2002) Official Method of Analysis 2001.11 (with modifications). Ashes: Kirk et al. (1996). Fats: Soxhlet Method. Statistics: Anova and Tukey analysis. Software: Infostat 2011.

RESULTS

Fiber composition

	Geoffroea decorticans Var. Decorticans	***Geoffroea decorticans Var. Subtropicalis***
Total Fiber	**36 + 1.0b**	**46 ± 2.4a**
Insoluble Fiber	**2.8 ±0.3b**	**43 ± 0.6a**
High molecular mass soluble Fiber	**8.0 ± 1.0b**	**2 ± 1.8b**

Numbers with different letters in the same determination indicate significant differences ($p>0.05$)

In *Subtropicalis* variety a higher percentage of fibers was obtained; however, a higher ratio of potentially prebiotic soluble fibers was obtained in *Decorticans* variety A bread was made in which it is planned to determine its composition and carry out a sensory analysis.

CONCLUSIONS

In this field, its production is controlled by qualified staff. A plan has been designed in which it is foreseen to determine its composition and analyse its fiber composition. It is possible to add new natural raw materials with nutraceutical substances to food; nevertheless, it is necessary to control its agricultural production, to know its toxicity and its composition according to the place it grows, and the product has to be accepted by consumers

ENHANCING LIFE QUALITY THROUGH FOOD SCIENCE: THE DEVELOPMENT OF A NUTRITIOUS, FERMENTED SORGHUM AND PEARL MILLET PORRIDGE FOR SCHOOL LEARNERS

Nqobile Ngcobo[1]; Ashika Naicker[2]
[1]Food and Nutrition, Durban University of Technology, Durban, South Africa; [2]Food and Nutrition , Durban University of Technology, Durban, South Africa

BACKGROUND AND OBJECTIVES
The South African government established the National School Nutrition Programme (NSNP) to eliminate hunger and malnutrition barriers that prevent underprivileged children from learning. Many NSNP schools benefit from sponsored breakfast initiatives funded by large corporations; however, these programmes frequently compromise the nutritional content of breakfast foods. A nutritious breakfast porridge using indigenous grains could lead to progress in achieving SDGs, addressing hunger, and providing sustained energy for learners.

METHODS
The findings from the breakfast needs and preference survey conducted among school learners (n=405) informed the product development of a chocolate-flavoured sorghum and pearl millet instant porridge. The product development process involved controlled fermentation of sorghum, and consumer sensory assessment was conducted to inform changes for subsequent trials.

RESULTS
The nutritional analysis reflected that the developed instant porridge was rich in protein, dietary fibre, manganese, iron, zinc, vitamins B1, and B3. The nutritional composition of the instant porridge far exceeds the current NSNP breakfast offerings, making it a superior breakfast choice to fulfil the Recommended Daily Intake (RDI) deficiencies within the NSNP, while enhancing academic RESULTS, overall health, and welfare. Therefore, the developed porridge is a healthier and more sustainable choice for the NSNP.

CONCLUSIONS
The developed porridge addresses nutritional gaps within the NSNP and can enable improvement of school performance while simultaneously raising student attendance and cognitive function. Using indigenous grains strengthens regional farming operations and reduces farmers' reliance on imported grains while establishing greater biodiversity across agricultural lands. Its nutritional profile is improved by fermentation procedures, which increase nutrient absorption and sensory acceptability.

EFFECTS OF POSTHARVEST PROCESSING ON THE NUTRITIONAL QUALITY AND PHYTOCHEMICAL INTEGRITY OF FRUITS AND VEGETABLES: A COMPREHENSIVE REVIEW

Sandra Kwakye[1]; Justina Owusu[1]
[1]Nutrition and Food Science, University of Ghana, Accra, Ghana

BACKGROUND AND OBJECTIVES
Fruits and vegetables are a great source of vital nutrients and bioactive substances that improve human health. Postharvest losses brought on by improper handling, storage, and processing, however, continue to be a serious issue, particularly in developing nations. The effects of postharvest processing on the physical, nutritional, and phytochemical qualities of fruits and vegetables are crucial for reducing waste and improving food security. The aim of this review is to investigate how postharvest processing methods, such as mechanical processing, drying, and blanching, affect the nutritional value, physical characteristics, and phytochemical makeup of fruits and vegetables. It aims to assess how various processing techniques affect the stability of bioactive compounds and nutrient retention.

METHODS
A comprehensive review of existing literature from various studies was conducted, focusing on the effects of different postharvest processing methods on the quality and nutritional value of fruits and vegetables. Sources included research articles, reviews, and scientific reports from databases such as Google Scholar and PubMed.

RESULTS
Postharvest processing methods such as blanching, drying, and mechanical processing have significant effects on the antioxidant and phytochemical content of fruits and vegetables. Thermal methods like blanching and freezing can degrade sensitive vitamins and phenolic compounds. Nonthermal and mechanical techniques can reduce nutrient losses but also result in diminished bioactive compounds, especially in the peel and seeds.

CONCLUSIONS
Maintaining the nutritional and phytochemical integrity of fruits and vegetables requires optimizing postharvest processing methods. To decrease losses and improve the health benefits of these foods, more research on non-thermal processing and creative storage options is required.

NUTRITIONAL RISK AND QUALITY OF LIFE IN PATIENTS WITH ADVANCED OR TERMINAL CANCER AND PALLIATIVE CARE

Alejandra Barahona[1]
[1]Nutrición, UMG, Antigua Guatemala, Guatemala

BACKGROUND AND OBJECTIVES
Define quality of life according to the nutritional risk presented by patients with advanced or terminal cancer.

METHODS
To prepare this systematic review, different databases were consulted such as: PubMed, Scielo, Google Scholar and EBSCO, in the which the search for scientific articles was carried out, with different designs such as such as systematic literature reviews, randomized clinical trials, meta-analysis, cohort studies, case-control studies in order to obtain high-quality scientific evidence. 50 studies were included for analysis. English and Spanish language, managing to analyze information from the collection matrices, nutritional risk quality of life, determining factors, palliative care and nutritional support at the end of life.

RESULTS
50 scientific articles were included that were reviewed, and they demonstrated that, in cancer patients, the deterioration of the quality of life and the state nutritional status is frequent, evidencing that the severity of malnutrition in these patients is associated with worse health outcomes, poorer prognosis, and lower quality life. According to the RESULTS obtained, a nutritional evaluation is important to assess the state in which patients are found according to the nutritional risk they have, studies evaluate the severity of malnutrition and cachexia since these are the biggest nutritional problems in this population that affect the health and quality of life of patients.

CONCLUSIONS
It is essential to know the determining factors that affect the nutritional risk of patients to use techniques that minimize side effects, as well as nutritional support measures that reduce interruptions of treatment. treatment and increase quality of life. Interventions should be considered, including physical activity, dietary counseling, supplemental nutrition, and enteral or parenteral feeding. to improve function, nutritional status and possibly quality of life, guided by a multidisciplinary team that includes nutritionists, other health professionals and caregivers or family members.

ALTERNATIVE PROTEINS FROM SEAWEEDS: PROTEIN DIGESTIBILITY AND ADVANCED STRUCTURAL CHARACTERIZATION

Yubexi Correa[1]; Natalia S. Fanelli,[2]; Hans H. Stein,[2]; Marta Martínez-Sanz[1]
[1]Department of Bioactivity and Food Analysis, Institute of Food Science Research, CIAL (CSIC-UAM), Madrid, Spain; [2]Department of Animal Sciences, University of Illinois, Urbana, United States of America

BACKGROUND AND OBJECTIVES
Seaweeds have recently gained attention for their nutritional and functional potential as sustainable food sources. Seaweeds are rich in bioactive compounds, including polysaccharides, proteins, vitamins, and minerals. However, the digestibility and bioavailability of nutrients are affected by structural changes that take place during digestion. Understanding the impact of the multi-scale structure on the digestion mechanism and nutrient release will help maximize their nutritional potential for human consumption.

METHODS
Our study examines the relationship between the protein digestibility of three types of seaweeds, including *Ulva* (green), *Porphyra* (red) and *Saccharina* (brown), which was evaluated through *in vivo* experiments using growing pigs with T-cannulas inserted in the distal ileum, and the structural transformations taking place through the digestion process, which were characterized by Confocal Microscopy and Small Angle X-ray Scattering techniques.

RESULTS
Our RESULTS demonstrated that the intrinsic structural properties of seaweeds, such as cell wall composition and integrity, are critical to protein digestibility. The more intricate cell wall structures in *Saccharina* remain almost intact during digestion, hindering the accessibility of digestive enzymes and therefore, reducing protein digestibility. In contrast, cell wall structures in *Porphyra* and *Ulva* underwent significant changes, allowing protein release upon digestion.

CONCLUSIONS
These RESULTS will be key to optimize the nutritional benefits of seaweed-based foods on the basis of structure-digestibility relationship.

CONFLICTS OF INTERESTS
The authors have no conflict of interest.

IN VITRO BIO ACCESSIBILITY OF YELLOW FLESH CASSAVA GROWN IN GHANA

Elizabeth Afriyie Duah[1]; Aseidu Matilda Steiner-[1]
[1]department of nutrition and food science, University of Ghana, Accra, Ghana

BACKGROUND AND OBJECTIVES

Consuming yellow cassava has been shown in a study to have small but significant improvements in vitamin A status of children..This study sought to determine effect of processing on the in-vitro bio accessibility of carotenoids in yellow flesh cassava roots and leaves.

METHODS

Determination of in vitro bio-accessibility of carotenoids in yellow flesh cassava

The method was adapted from Hedre´n, *et al.*, (2002) with some modifications. Three grams (3g) of the cassava sample was weighed and ground in a mortar. For the oral phase of the digestion, 0.003grams alpha amylase was added to 0.005M saline solution. About 7.5 ml of the saline solution was added to sample and sonicated in a water bath at a temperature of 37ºC and pH of 6.8. After 10 minutes, the sample solution was acidified to pH of 3 using 0.01M HCl to stimulate the gastric phase. 1ml of porcine pepsin (40mg/ml) was added to the sample solution at pH 3 and incubated for an hour at 37ºC after which pH was brought up to 7 to stimulate the intestinal phase of the digestion. About 4.5 ml of a mixture of porcine pancreatin (4mg/ml) and porcine bile extract (24mg/ml) was added to the stimulated gastric fluid and 1% (w/v) alpha tocopherol. The final volume was adjusted to 25ml with physiological saline solution and incubated for two hours in a shaking water bath (100rpm at 37ºC). It was then centrifuged at 5000g for 45minutes at 4ºC.The supernatant was collected with a plastic pipette into a seperatory funnel containing 20ml of 25% (w/v) NaCl. 20ml of 95% ethanol and 15ml of petroleum ether were added and allowed to separate. The solution was washed with water and the organic phase collected and the absorbance read with an atomic spectrophotometer.

RESULTS

Processing had an effect on carotenoid bio-accessibility with carotenoids in the roots being more accessible than those in the leaves. Boiled roots contributed between 4 and 21% of the RDA for children less than 5 years and the boiled leaves contributed between 2.6 to 386% of the RDA for every 100 grams of food consumed which showed more potential to meeting the RDA.

CONCLUSIONS

Yellow cassava would serve as a promising source of provitamin A and the carotenoids in yellow cassava roots are more bio-accessible than cassava leaves. Processing also has an effect on the bio accessibility on total carotenoids in yellow cassava.

CONFLICTS OF INTERESTS

The authors have no conflict of interest.

QUALITY OF LIFE AND APPETITIVE TRAITS IN OLDER ADULTS: EXPLORING FOOD AND SATIETY RESPONSIVENESS DIMENSIONS

Macarena Valladares-Vega[1, 2]; Carolina Roldan[2]; Kathia Lagos[2]; Carolina Pino[3]
[1]Núcleo de Investigación en Nutrición y Ciencias Alimentarias (NINCAL)Escuela de Nutrición, University of the Americas, Santiago, Chile; [2]Escuela de Nutrición y Dietética, University of the Americas, Santiago, Chile; [3]Escuela de Nutrición y Dietética, Bernardo O'Higgins University, Santiago, Chile

BACKGROUND AND OBJECTIVES

The aging of the global population presents significant challenges in promoting optimal well-being among older adults (1). Quality of life (QoL) is associated in older adults with better physical and mental health, greater functional capacity, and a lower risk of depression and reduced mortality risk. QoL is associated with nutrition and appetite, which tend to decrease in older adults (2). There are two important aspects of appetite: Food Responsiveness (FR pro-intake), which is considered the main driver of food initiation, while the Satiety Responsiveness (SR anti-intake) is the primary driver of food cessation (3). High levels of FR and low levels of SR are associated with high BMI in both children and adults (4). There are no studies that address quality of life related to appetite traits in older adults. Objective: To explore the relationship between quality of life and appetite traits in older adults.

METHODS

A cross-sectional study was conducted on functionally independent older adults without diagnosed cognitive impairments (N=104; 62% women; mean age of 70.3 years, SD=6.44). QoL was measured using the WHOQOL-BREF questionnaire (physical health, psychological health, social relationships, and environment assessed domains), and eating behavior was assessed using the AEBQ questionnaire (pro-intake and anti-intake dimensions).

RESULTS

Mean scores for WHOQOL-BREF domains were 53.3 (SD 11.20). Higher levels in QoL aspects such as emotional well-being, cognitive function, and mental health (psychological health domains) are associated with a lower inclination to initiate food intake in response to external food cues (FR) ($p=0.03$). Additionally, high levels of support and social integration within the community (social relationships domains) are associated with lower levels of the feeling of satiety when eating or even afterward (SR) ($p=0.01$). No differences were observed associated with the sex or age of the participants.

CONCLUSIONS

: In older adults with a good perception of their mental health and integration in society (better QoL) there is less inclination to initiate eating and to stop eating. This is paradoxical compared to what has been reported in children and adults. This could be because, in older adults, the social aspect is highly relevant; if they are sharing food with others, the social environment may make them feel more comfortable and motivated to continue eating, which contrasts with their difficulty in initiating the eating process.

CONFLICTS OF INTERESTS

EFFICACY AND SAFETY OF VIRGIN MORINGA LEAF HARVESTED ONLY FIRST YEAR IN JAPAN

Chuang Li[1]; Hase Shizuka[2]; Nakanouchi Yutaka[2]; Moriyama Ryo-Ichi[2]; Iura Kota[2]; Fukuda Nobuhiro[3]; Shoko Nishizono[1]
[1]Department of Biotechnology and Life Sciences, Sojo University Ikeda Campus, Kumamoto, Japan; [2]Department of Engineering, Fukuoka Institute of Technology, Fukuoka, Japan; [3]Emeritus Professor, University of Miyazaki, Miyazaki, Japan

BACKGROUND AND OBJECTIVES
Moringa (*Moringa oleifera*) is a nutritious plant that grows in tropical regions. In Japan, moringa seeds are sown every year due to the cold temperatures in winter. Therefore, we developed Japanese moringa leaf (JML), which is harvested only in the first year after sowing the moringa seeds and air-dried at 40°C on the same day. We also developed virgin moringa leaf (VML), which has a limited growing period of 108 days. In this study, we evaluated the antioxidative activity and antioxidant content of VML and JML compared with moringa leaves cultivated in India (IML) and Brazil (BML), which are typically harvested and sun-dried from moringa trees that are several years old. Additionally, we investigated the effects of dietary JML on pregnancy, birth rates, and lipid metabolism in rats.

METHODS
VML, JML, IML, and BML were extracted with hot water, and their antioxidant activity was measured using the DPPH radical scavenging activity method. Polyphenols in each sample were analyzed by HPLC at 280 nm, and antioxidant components were detected by reacting with DPPH post-column using the on-line HPLC-DPPH method. In the animal experiment, 12-week-old male and female SD rats were divided into two groups and fed either a control diet based on the AIN-76 composition (CO group) or a diet supplemented with 10% JML dried powder (MO group). One pair of male and female rats were housed together for 4 weeks, after which the male rats were sacrificed. The female rats were monitored for pregnancy, abortion, and birth outcomes. Three weeks after birth, the female rats and pups were sacrificed, and tissue weights, as well as serum and liver lipid levels, were measured.

RESULTS
VML exhibited higher antioxidant activity than JML, IML, and BML. In all samples, four antioxidants were detected, and two of them were identified as 3-*O*-caffeoylquinic acid (3CQA) and 4CQA. Dietary JML did not affect pregnancy, abortion, birth numbers, or the sex ratio of offspring in rats. While dietary JML did not affect the body weight of the parents or offspring, it increased the weights of the liver, spleen, kidney, cecum, and testes in the offspring. Serum triglyceride and cholesterol levels in parental males and offspring were decreased by dietary JML. Additionally, hepatic triglyceride and cholesterol levels in parental females and offspring were decreased by dietary JML.

CONCLUSIONS
It was revealed that the major antioxidant of JML is 3CQA. While 10% dietary JML did not affect pregnancy, abortion, or birth numbers in rats, it might influence the development and nutrient metabolism of the offspring's organs through breast milk.

IMPROVING THE SENSORY QUALITY OF COMPLEMENTARY FOODS: IMPACT OF ROASTING ON SENSORY ATTRIBUTES AND ACCEPTABILITY

Ndeye Fatou Ndiaye[1]; Assane Niang[2]; Maurice Jean François Sylvestre Lopy[3]
[1]ITA, ITA Food Technology Institute, Dakar, Senegal; [2]Nutrition, ITA Food Technology Institute, Dakar, Senegal; [3]Cereals, ITA Food Technology Institute, Dakar, Senegal

BACKGROUND AND OBJECTIVES
Acceptability in complementary foods is a key factor for their uses in households (1,2,3). This study assessed the impact of the roasting stage during production on the sensory attributes and acceptability of complementary foods based on local roasted products (cereal whole grain/vegetables and legumes and cereals/vegetables and legumes processed into flours).

METHODS
Sensory analyses such as discriminative tests and sensory characterization tests by Check-All-That-Apply (CATA) were used to assess the difference between the roasting stages and to characterize the sensory attributes of the two complementary foods (4).

RESULTS
RESULTS showed that roasting cereals, vegetables and legumes flours brought perceptible organoleptic changes to the complementary foods. Complementary foods from roasted flours were considered to have an “attractive” color, “thin” viscosity, “pleasant” smell, and “pleasant” taste compared to those from roasted whole grains with attributes such as “unpleasant” color, “thick” viscosity, and “unpleasant” taste.

CONCLUSIONS
Complementary foods from roasted flours were considered more acceptable (acceptability index>70%) than complementary foods from roasted grains (acceptability index=66%).

CONFLICTS OF INTERESTS
The authors have no conflict of interest.

GOAT VS. COW DAIRY PRODUCTS DIGESTION AND INTESTINAL HEALTH IMPACT: IN VITRO STUDY USING DYNAMIC DIGESTION AND QUADRICELLULAR INTESTINAL EPITHELIUM MODELS

Tanguy Saviard[1, 2]; Olivia Ménard[1]; Marie-Françoise Cochet[1]; Mégane Bostoën[3]; Claire Gaudichon[4]; Sophie Blat[3]; Didier Dupont[1]
[1]STLO, INRAE, Rennes, France; [2]., EURIAL, Jouy, France; [3]Institut NUMECAN, INRAE, INSERM, Rennes University, Rennes, France; [4]UMR914 PNCA, AgroParisTech - INRAE - Campus Agro Paris-Saclay, place de l'Agronomie, Palaiseau, France, Palaiseau, France, France

BACKGROUND AND OBJECTIVES

Some consumers perceive goat dairy products as being easier to digest than cow dairy products. Several hypotheses have been suggested to explain this difference. Among these, it is believed that in goat milk, the higher content of short- and medium-chain fatty acids could promote lipolysis [1] and the lower alpha S1-casein content could facilitate proteolysis [2]. It is also suggested that goat milk could have positive impacts on inflammation [3]. The objective of this study is to unravel differences in the behaviour of both milks during digestion by comparing the dynamic *in vitro* digestion of goat and cow milks and yogurts, and the effects of their digesta on a quadricellular model of intestinal epithelium.

METHODS

Goat and cow milks and yogurts were formulated to be iso-proteic and iso-lipidic. They were digested using the DIDGI® dynamic *in vitro* gastrointestinal system. The kinetics of lipolysis and proteolysis were respectively measured by gas chromatography coupled with mass spectrometry and by o-phthalaldehyde method (n=3). A quadricellular model of intestinal epithelium (Caco-2, HT29-MTX, NCI-h716 and Raji-B) was stimulated with the intestinal digesta, and the gut barrier integrity was evaluated by trans-epithelial electrical resistance (TEER) for 24 hours (n=10-12). Expression of genes characteristic of different intestinal functions was quantified by RT-qPCR using a SmartChip device at 4h and 24h.

RESULTS

Lipolysis kinetics revealed a significantly greater release of fatty acids ($p<0.05$) during the gastric phase with goat dairy products compared to cow dairy products. However, no major difference was observed in the intestinal phase. Proteolysis kinetics were similar between species. TEER values were significantly higher ($p<0.05$) from 4 to 16 hours of stimulation with goat dairy products compared to cow dairy products, suggesting better intestinal barrier function with goat dairy products. Furthermore, goat dairy products increased TEER from 3 to 7 hours of stimulation as compared to control (i.e. culture medium alone) ($p<0.05$), whereas TEER values with cow dairy products did not. The analysis of gene expressions is underway to better characterize the underlying mechanisms.

CONCLUSIONS

The kinetics of lipid and protein hydrolysis did not appear to be a major factor distinguishing goat and cow dairy products. However, intestinal cells stimulation seemed to indicate a more favourable effect of goat dairy products on the intestinal epithelium barrier function compared to cow dairy products. Gene expression RESULTS will be used to characterize the other intestinal functions and to clarify the mechanisms.

EFFECTS OF DIFFERENT PROPORTIONS OF DHA AND ARA ON COGNITIVE DEVELOPMENT IN INFANTS: A META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

Lirong Xu[1]; Ailing Tian[1]; DUO LI[2, 1]
[1]School of Public Health, Institute of Nutrition & Health, qingdao, China; [2]Institute of Nutrition & Health, Qingdao University, Qing Dao Shi, China

BACKGROUND AND OBJECTIVES
The previous studies assessed the effect of docosahexaenoic acid (DHA, 22:6n-3) and arachidonic acid (ARA, 20:4n-6) supplemented infant formula on brain development and cognitive function in infants. However, the RESULTS were inconsistent. The aim of this systematic review and meta-analysis was to assess the effect of DHA and ARA supplementation on cognitive function in infants from randomized controlled trials (RCTs).

METHODS
We systematically searched and identified relevant literature from the PubMed, Web of Science, and Embase databases up to July 2024. Standard methods were applied to assess publication bias, sensitivity analysis, and heterogeneity among included studies.

RESULTS
A total of 9 RCTs were included in the study, which comprised 1,039 subjects. Meta-analysis showed significantly positive effects of DHA and ARA supplementation on cognitive development in infants (Standardized Mean Difference (SMD): 0.21; 95% CI: 0.03, 0.38). No significant difference was found on Mental Development Index (MDI) score (Weighted Mean Difference (WMD): 0.20; 95% CI: -0.03, 0.43) and Psychomotor Development Index (PDI) score (WMD: 0.12; 95% CI: -0.11, 0.35) in Bayley Scales of Infant and Toddler Development compared with control group. In subgroup analysis, when DHA/ARA was 0.5-1, PDI had a significant difference (WMD: 0.48; 95% CI: 0.03, 0.93) compared with the control group, with no significant between heterogeneity (I2=46.4%, *P*=0.155). In comparison to the control group, significant differences were observed in MDI when DHA/ARA levels were between 0.5 and 1 (WMD: 0.55; 95% CI: 0.07, 1.02), with no significant between heterogeneity (I2=51.6%, *P*=0.127).

CONCLUSIONS
In conclusion, when the DHA /ARA was 0.5-1 can significantly improve the cognitive function in infants.

CONFLICTS OF INTERESTS

METABOLOMICS ANALYSIS REVEALED THE AMELIORATING EFFECTS OF POMEGRANATE SEED OIL ON RENAL OXIDATIVE STRESS AND INFLAMMATION IN DIABETIC NEPHROPATHY MICE

Lirong Xu[1]; Meifan Pan[1]; DUO LI[2, 1]
[1]School of Public Health, Institute of Nutrition & Health, qingdao, China; [2]Institute of Nutrition & Health, Qingdao University, Qing Dao Shi, China

BACKGROUND AND OBJECTIVES
Studies have shown that pomegranate seed oil has anti-inflammatory and anti-oxidative effects. However, whether this effect can alleviate renal inflammation and oxidative stress in diabetic nephropathy mice by improving metabolic pathways is still unclear. The aim of this study was to investigate the effects of pomegranate seed oil on renal oxidative stress and inflammation related metabolic pathways in mice with diabetic nephropathy.

METHODS
Pomegranate seed oil was given to establish a diabetic mouse model by combination of high fat and STZ. HE staining, PAS staining and metabolomics were used to analyze the kidney tissue of the mice.

RESULTS
Biochemical analysis and histology showed that pomegranate seed oil ameliorated diabetic kidney injury, and significantly reduced blood glucose, serum uric acid, creatinine and urine creatinine/urine protein ratio ($p<0.05$ compared with diabetic model group). Moreover, pomegranate seed oil intervention significantly increased anti-oxidative stress indicators in the kidney of diabetic mice, such as T-SOD, GSH and CAT ($p<0.05$). At the same time, it also significantly inhibited the expression of inflammatory factors TNF-α, IL-6, IL-1β ($p<0.05$). Metabolomics analysis revealed that 25 metabolites were down-regulated and 9 metabolites were up-regulated by pomegranate seed oil intervention compared with diabetic model mice. Pathway analysis revealed that the intervention of pomegranate seed oil primarily operated through pathways involving Beta-Alanine Metabolism, Phenylalanine and Tyrosine Metabolism, Alpha-Linolenic Acid and Linoleic Acid Metabolism, as well as Glutathione Metabolism, thereby reducing oxidative stress and inflammation in diabetic nephropathy.

CONCLUSIONS
Therefore, pomegranate seed oil is expected to be a natural functional oil with anti-oxidative stress and anti-inflammation.

PREPARATION AND EVALUATION OF THE ANTIOXIDANT ACTIVITY OF LACTO-FERMENTED VEGETABLES BASED ON CARROTS AND PURPLE CABBAGE

Fatima Zahra Ghanemi; Kaddour Hicham Benariba[1]; Chaima Mamoun[1]; Asmaa Rahmoun[1]; Zineb Medjdoub[2]; Hicham Ferh[2]
[1]Biologie, Université de Tlemcen, tlemcen, Algeria; [2]Département d'Agronomie et sciences alimentaires, université de Tlemcen, Algérie, Tlemcen, Algeria

BACKGROUND AND OBJECTIVES
The current study investigates the effects of lactofermentation on vegetables using carrots and red cabbage as samples. Lacto-fermentation is a traditional preservation method that uses lactic acid bacteria to convert sugars in vegetables into lactic acid.

METHODS
The aim of this work was to assess the benefits of lacto-fermentation by evaluating antioxidant properties and some primary metabolites (fibres, ash) of carrots and cabbage. The vegetables were prepared according to a specific recipe and then immersed in a saline solution with dill and garlic. The fermentation was carried out at room temperature under anaerobic conditions for more than 4 weeks.

RESULTS
The RESULTS showed that fermented cabbage had a more remarkable antioxidant power (EC 50 = 0.16 µg/mL). fermented cabbage contains more polyphenols than carrots, with respective values of 0.45g /100g ; 0.28g /100g. Primary metabolic RESULTS showed that fermented cabbage is richer in fibre than carrots (8.01%; 2.55%).Ash values show that both fermented cabbages and carrots are rich in minerals (18.12%; 17.85%).Carrots have a much higher moisture content than cabbages (23.20%; 5.20). The RESULTS showed that the pH of the fermented vegetables was constant at pH 3.

CONCLUSIONS
In the light of these RESULTS, lacto-fermentation proved to be an effective method for the preservation of vegetables carrots and cabbage by improving their shelf life, antioxidant properties and metabolic profile. The RESULTS cover the way for future research on lacto-fermentation of other vegetables and its impact on human health.

BLACK-GRAINED WHEAT INTERVENTION AFFECTS METABOLITES RELATED TO AMINO ACIDS AND GLYCOLIPIDS METABOLIC PATHWAY IN FEMALE DIABETIC PATIENCE

Zhu Wang; Chao Gao[1]; Yuping Zhang[2]; Pin Gao[1]; Yang Liu[1]; Rui Li[2]; Yanping Liu[2]
[1]Dept. Food Nutrition and Assessment, National Institute for Nutrition and Health, China CDC, Beijing, China;
[2]Department of Nutrition, Peking Union Medical College Hospital, Beijing, China

BACKGROUND AND OBJECTIVES
Changes of amino acid, glycolipids and other metabolism has been found in type 2 diabetes mellitus (T2DM). Whole grains is convincingly associated with reduced incidence of diet-related diseases, but whether it's helpful to correct the changes of metabolism in T2DM has not well been clarified. Black-grained wheat (BGW) is a new wheat variety and considered as a value-added product, this paper tries to provide a reliable evidence to identify the effects of BGW on glycemic control through adjusting metabolites related to amino acid and glycolipid metabolic pathway.

METHODS
Forty T2DM females from Beijing, China were randomly assigned to consume either the usual diet (n=20) or replaced part cereals by BGW diet (n=20) for 5 weeks. Fasting blood samples collected at baseline and the end of the trial, and metabolites were tested by UPLC-QE-MS. The separating metabolites were identified between the BGW and Ctrl. Groups with orthogonal partial least squares discriminant analysis (OPLS-DA) .

RESULTS
Average daily BGW intake in BGW group were 68.8±14.7 g. The changes in the levels of TG, insulin, HOMA-IR, and TNF-a were significantly lower in BGW group compared with Ctrl. group (1.35±0.71 mmol/L vs. 1.90±0.89 mmol/L, -1.14±2.79 mU/L vs. 4.32±12.48 mU/L, -0.57±1.01 vs. 2.40±7.41, 2.44±0.52 pg/mL vs. 1.94±0.38 pg/mL, $P<0.05$, respectively). Metabolic profiles showed there were 39 differential metabolites between BGW and Ctrl. groups, including 35 analytic metabolites decreased and 4 metabolites increased, which may have potentially been related with metabolic pathway of phenylalanine, tyrosine and tryptophan biosynthesis, and glycerophospholipid metabolism. Alterations of several lipids and lipid-like molecules, organic acids and derivatives, organic oxygen compounds, benzenoids, phenylpropanoids and polyketides, and organoheterocyclic compounds were found to be associated with the development of T2MD.

CONCLUSIONS

Partial replacement of refined cereals by whole BGW may improve the metabolic markers in T2DM via regulating the amino acid and glycolipid metabolisms.

ANTIHYPERTENSIVE AND ANTIOXIDANT POTENTIALS OF PEPTIDE EXTRACTS FROM INDIGENOUS FERMENTED FOODS

Amster Fei Baquiran[1, 2]; Maricar Albao[1]; Alex Palomo[1]; Rodolfo Sumayao[2]
[1]Department of Science and Technology, Food and Nutrition Research Institute, Taguig, Philippines;
[2]Department of Chemistry, De La Salle Universtiy, Manila, Philippines

BACKGROUND AND OBJECTIVES

Fermentation-derived peptides have been shown to modulate various physiological processes such as antihypertensive and antioxidant effects. Despite the extensive variety of raw materials and food sources used in fermentation, bioactive peptides derived from indigenous fermented foods remain underexplored. The bioavailability and functional activities of these peptides are influenced by different factors such as enzymatic digestion that may alter their structure, concentration, and efficacy. This study investigated the antihypertensive and antioxidant potentials of peptide extracts from locally produced fermented food products.

METHODS

Peptides were extracted from 12 milk- and fish-based fermented food products by phosphate buffer extraction (crude extract) and simulated gastrointestinal digestion (GI digest). Ultrafiltration was performed to isolate bioactive peptide fractions (<3000 Da). Peptide concentration was quantified in both extracts while GI digests were further analyzed for angiotensin-converting enzyme (ACE) inhibition and for antioxidant activities using 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical scavenging and ferric reducing antioxidant power (FRAP) assays.

RESULTS

GI digests exhibited higher peptide concentrations (16.0 to 108.3 mg/g) compared to their crude extract counterparts (0.2 to 46.1 mg/g), indicating enhanced release of peptides during digestion. ACE-inhibition assays revealed relatively higher inhibiting rates in milk-based fermented food digests (21.2 to 44.2%) than in fish-based fermented foods (3.9 to 22.8%). The digest also showed variability in antioxidant activities as measured by DPPH (2.1 to 12.4%) and FRAP (1.3 to 51.9 mg ferrous equivalent per g) assays.

CONCLUSIONS

Simulated GI digestion significantly improved peptide yield while preserving their bioactivities, demonstrating its potential as an effective method for producing bioactive peptides with health-promoting properties. The findings emphasize the value of indigenous fermented foods in functional food development, warranting further exploration of their health benefits, optimize production processes, and investigate their potential applications in preventing and managing chronic diseases.

SAFETY ASSESSMENT OF EUCALYPTUS LEAF EXTRACT AS A FUNCTIONAL FOOD MATERIAL

Keiichiro Sugimoto[1]; Kazuya Nakagawa[1]
[1]Research and Development Center, Nagaoka Co., Ltd., Osaka, Japan

BACKGROUND AND OBJECTIVES

Eucalyptus (*Eucalyptus globulus*) leaf extract (ELE) with oenothein B as the active ingredient is marketed in Japan as a material for Foods with Functional Claims (FFC) to prevent obesity. On the other hand, eucalyptus essential oil is generally considered to be toxic because of reports of poisoning attributable to accidental ingestion and the presence of cyanogenic glycosides in some varieties. We evaluated the safety of ELE distributed as a commercial product.

METHODS

We investigated a commercially available ELE (product name: Eucagrandin) that is used in FFC and made by extracting with aqueous ethanol and then spray-drying to produce a powder. The ingredients were analyzed, and 1,8-cineole was quantified as an indicator of essential oil components using GC and GC/MS. A micronucleus test was conducted using ICR mice (male and female) by orally administering 2,000 mg/kg. A safety confirmation study was conducted in healthy Japanese adult men and women consuming ELE orally at the dose of 3,240 mg/day (oenthein B, 26 mg/day) for 4 consecutive weeks (UMIN000028377). Examinations were conducted at 0, 2, and 4 weeks after the beginning of the intervention and then again 2 weeks later.

RESULTS

No cyanide or cyanide glycosides (detection limit <0.1 ppm) or 1,8-cineole (<0.01%) was detected in ELE. The total polyphenol content was 24% (Folin–Ciocalteu's method; gallic acid equivalent), and the main components were gallic acid, oenothein B, ellagic acid, quercetin 3-*O*-β-D-glucuronide, and kaempferol 3-*O*-β-D-glucuronide. The micronucleus test yielded negative RESULTS. In the 9 male and 10 female subjects (51 ± 5 years old) who satisfied the test food intake rate criteria, the following parameters exhibited significant changes compared to their measurement at the start of the intervention: a decrease in diastolic blood pressure, ALB, and Hb in both men and women, and RBC in women; an increase in Na, T-Cho, WBC, Ht, PLT, and UA in both men and women, and UA in women. These changes were diagnosed as not being a clinical problem because they were within the reference range or were slight changes, and the values for each individual were also within the range of physiological variation.

CONCLUSIONS

Our RESULTS indicate safety of eucalyptus leaf extract.

OMICS INSIGHTS INTO GERMINATION EFFECTS ON THAI RICE

Worakrit Saiyasombat[1]; Jaruwan Chimasangkanan[1]; Wimonphan Chathiran[1]; Pattaraporn Morasin[1]; Warangkana Srichamnong[1]
[1]Institute of Nutrition, Mahidol University, Nakhon Pathom, Thailand

BACKGROUND AND OBJECTIVES
Rice is a staple food for over half of the global population and an important source of nutrition, particularly in developing countries. Its adaptability to diverse environments makes it vital for global food security. Studying the ion, metabolite, and protein profiles in rice can enhance its nutritional value, optimize its utilization, and inform healthier food choices.

METHODS
This study investigates the ionomic, metabolomic, and proteomic profiles of eight Thai rice varieties, comprising four white and four colored rice types, including the effects of germination on these parameters. High-performance liquid chromatography-mass spectrometry was employed for metabolomic and proteomic analyses, while inductively coupled plasma-mass spectrometry was used for ionomic analysis. In addition, antioxidant activity was measured to study the antioxidant properties of each rice and the impact of germination on the antioxidant profile.

RESULTS
The integration of these datasets revealed significant changes in the omics profiles due to germination. The RESULTS indicate that Tubtim Chumphae rice exhibits the highest antioxidant activity, which increases almost twofold upon germination. Furthermore, the increase in protein content is observed in germinated rice.

CONCLUSIONS
This study highlights the potential of germinated rice for developing plant-based protein products and personalized food development.

CONFLICTS OF INTERESTS

HIBISCUS SABDARIFFA SHOT BEVERAGE: A NUTRITIONAL APPROACH FOR ENHANCING BIOCHEMICAL PARAMETERS IN OVERWEIGHT AND OBESITY

Edgar J. Mendivil[1]; Selene I. Puebla-García[1]; Ingrid Rivera-Iniguez[2]; Laura Arellano[3]; Erika Martínez-López[4]; Sonia G. Sáyago-Ayerdi[5]

[1]Health Department, Universidad Iberoamericana Ciudad de México, Ciudad de México, Mexico; [2]UCSD Center for Healthy Eating and Activity Research (CHEAR), University of California, San Diego, San Diego, CA, USA, United States of America; [3]Department of Psychology, Education, and Health, ITESO, Universidad Jesuita de Guadalajara, Guadalajara, Mexico; [4]Instituto de Nutrigenética y Nutrigenómica Traslacional, Departamento de Biología Molecular y Ge, Centro Universitario de Ciencias de la Salud, Universidad de Guadalajara, Guadalajara, Mexico; [5]Laboratorio Integral de Investigación en Alimentos, Tecnológico Nacional de México/Instituto Tecnológico de Tepic, Tepic, Nayarit, Mexico

BACKGROUND AND OBJECTIVES

Obesity is a critical global health issue that significantly increases the risk of developing severe metabolic diseases such as type 2 diabetes, cardiovascular diseases, and dyslipidemias. Functional ingredients, such as *Hibiscus sabdariffa* (hibiscus flower), have received increased attention for their bioactive compounds, including anthocyanins and polyphenols. These compounds exhibit antioxidant and anti-inflammatory properties that may help regulate lipid and glucose metabolism. This study aimed to evaluate the effect of a hibiscus-based shot beverage on the lipid profile of adults with overweight and obesity.

METHODS

A randomized, double-blind, controlled clinical trial was conducted. We included 60 participants in a control group (placebo shot) and an intervention group (Hibiscus shot). Both groups consumed their respective beverages daily for 8 weeks without altering their diet or lifestyle. Anthropometric, biochemical, and dietary parameters were assessed at baseline and the end of the intervention. Data were analyzed using Wilcoxon and Mann-Whitney U tests for statistical significance.

RESULTS

A significant reduction in both the percentage (%) and amount (kg) of body fat mass was observed exclusively in the group consuming the hibiscus shot when comparing baseline to final data (delta $\Delta = -1.34 \pm 11.50$, $p = 0.027$; $\Delta = -1.61 \pm 2.65$, $p = 0.041$, respectively). This finding occurred despite a significant increase in sugar intake ($\Delta = +39.87 \pm 70.03$, $p = 0.009$) and Body Mass Index ($\Delta = 0.42 \pm 0.77$, $p = 0.047$). Interestingly, a significant decrease in final concentrations of total cholesterol ($\Delta = -22.5 \pm 38.5$, $p = 0.019$) and glucose ($\Delta = -1.4 \pm 10.79$, $p = 0.016$) was detected in participants treated with the hibiscus shot, contrasting with the placebo group, where a significant increase in final glucose concentration ($\Delta = +9.17 \pm 12.01$, $p = 0.045$) was observed. No changes in triglycerides or LDL-c levels were noted in either group during the intervention.

CONCLUSIONS

Consumption of *Hibiscus sabdariffa* shot beverage improved lipid profiles, glucose levels, and body composition in adults with obesity, showing significant reductions compared to a placebo. These findings underscore its potential as a functional food for managing metabolic alteration associated with obesity.

INDUCTION OF PHOSPHATIDYLCHOLINE SYNTHESIS AS A POTENTIAL MECHANISM UNDERLYING COGNITIVE ENHANCEMENT INDUCED BY ORAL INGESTION OF YEAST-DERIVED RNA

Fuyu Hayashi[1, 2, 3]; Yusuke Masuo[1]; Takahiro Ishimoto[1]; Mica Fujita[2, 3]; Riho Fujihara[1]; Keita Sutoh[2, 3]; Yukio Kato[1]
[1]Faculty of Pharmacy, Institute of Medical, Pharmaceutical and Health Sciences, Kanazawa University, Kanazawa, Japan; [2]Nutritional Development and Research Lab FD, Fordays Co., Ltd., Tokyo, Japan; [3]Fordays Nutritional Research Center, Tokyo University of Agriculture and Technology Koganei Campus, Koganei, Japan

BACKGROUND AND OBJECTIVES
Oral ingestion of nucleic acids exhibits various biological functions, but those in the brain are largely unknown. We have recently reported that the ingestion of DNA hydrolysate derived from salmon milt showed cognitive enhancement in normal mice, while the effect of ingestion of RNA on cognitive function remains unclear. The purpose of the present study was to elucidate the effect of torula yeast-derived RNA (tyRNA), which contains ~70% of RNA consisting of 20-200 bases of oligoribonucleotides, on learning and memory, and its underlying mechanisms in normal mice.

METHODS
Seven-week-old ICR mice were fed a low-nucleic acid diet (AIN-93M) and that containing 2.5% tyRNA. Fourteen days later, the spatial recognition test (SRT) was performed to evaluate cognitive function. The brain concentration of various nucleic acids-derived components was comprehensively measured after 17 days of the tyRNA feeding by LC-MS/MS. The effect of certain nucleic acids-derived components on the expression of synapsin 1 (Syn1), a presynaptic marker was evaluated in primary cultured mouse cortical neurons (PCNs) by Western blotting. Since certain nucleosides including uridine and cytidine contribute to the synthesis of phosphatidylcholine (PC), which is a component of the neuronal membranes, via the Kennedy pathway, and the synthesis of brain PC may promote neurite outgrowth, the targeted lipidomics using LC-MS/MS was performed in the PCNs incubated with uridine, cytidine, deoxycytidine (dC), and tyRNA and the brain samples obtained after 4 weeks of the tyRNA feeding.

RESULTS
In SRT, the discrimination index, an indicator of learning and memory, in tyRNA group was significantly higher than control diet group. In the brain after the tyRNA feeding, concentrations of uridine, cytidine, dC, UMP, and dCMP were significantly higher than control group. Among those five nucleic acids-derived components, incubation with only cytidine significantly increased protein expression of Syn1 in PCNs, suggesting that cytidine may promote synaptogenesis. Also, in cytidine and tyRNA group, peak intensities of PCs were significantly higher than in vehicle group in PCNs. Moreover, certain PCs level in the brain in tyRNA group was significantly higher than the control group, suggesting that tyRNA may increase PC synthesis in the neurons possibly via the Kennedy pathway.

CONCLUSIONS
Taken together, ingestion of tyRNA may increase nucleic acids-related metabolites in the brain and improve cognitive function by the increase in PCs in normal mice.

CONFLICTS OF INTERESTS

UTILIZATION AND ACCEPTABILITY OF ALTERNATIVE MEAT PRODUCTS: FOCUSING ON FEMALE UNIVERSITY STUDENTS

Yuyu Ishibashi[1]; Miwako Koizumi[1]
[1]Department of Food Safety and Management, Showa Women's University, Tokyo, Japan

BACKGROUND AND OBJECTIVES
Global issues such as food shortages and climate change become more serious. Since consumers' perception on sustainable food supply is increasing, alternative protein products are attracting attention. However, there are educational and generational differences in awareness and willingness to purchase alternative meat products. This study aimed to examine how plant-based meat is accepted among the young female generation in Japan.

METHODS
We conducted a questionnaire survey about plant-based meat utilization and acceptability, particularly focusing on female university students. One hundred with aged of 10s-60s including eighty-five female university students participated. The questionnaire covered topics such as awareness of plant-based meat substitutes, image, eating experience, reasons for choosing or not choosing, and so on.

RESULTS
Awareness of plant-based food as alternative meat was generally high (about 80% of respondents). However, only 50% had actually tried them. The reasons given for choosing plant-based meat substitutes were positive factors such as health consciousness and low environmental burden. With regards to negative attitudes, the most common negative response was 'they don't taste good'. By age, young university students were more interested in trying it out, but middle-aged and older people were more concerned about reproducible quality of taste and texture of conventional meat. Even among those who were highly conscious of environmental issues, the high price was a major barrier to their choosing plant-based meat.

CONCLUSIONS
This study revealed that female university students had highly health conscious about plant-based meat. While, many participants answered that they wouldn't choose plant-based meat because it didn't look tasty. The RESULTS provide that the most meat-like taste and the added value of healthier eating significantly impact on acceptance of plant-based meat in Japanese young female consumers. Given the importance of promoting sustainable future for food, it is important to emphasize the benefit for a global food shortage and update new knowledge based on scientific and social research in dissemination raising among young generation.

PREBIOTIC GALACTOOLIGOSACCHARIDES AND THEIR PERSPECTIVE ROLE AGAINST COLON CANCER PREVENTION

Naureen Naeem[1]; Bisma Naeem[2]; Wasey Kareem[3]; Roha Naeem[4]
[1]Criminology and Forensic Sciences, Lahore Garrison University, Lahore, Pakistan; [2]Computer Science, IMT School for Advanced Studies Lucca, Lucca, Italy; [3]Economics, Information Technology University (ITU), Lahore, Pakistan; [4]Mass Communication, Lahore Garrison University., Lahore, Pakistan

BACKGROUND AND OBJECTIVES
Colon cancer is the third leading reason of cancer-related deaths in whole world and is fourth most common cancer type. In the present study the role of galacto-oligosaccharides (GOS) was evaluated against projection of colon cancer.

METHODS
Rats were randomly divided into six groups (9 rats in each group), one positive control group (G0), one negative control group (G1), three treatment groups (G2, G3, G4) and one control group (G5). Research was carried out in two phases, production of prebiotic galacto-oligosaccharide and assessment of their protective role against colon cancer.

RESULTS
Animals belonging to prebiotic galactooligosaccharides groups (G2, G3 and G4) and inulin (Go) had significantly decreased aberrant crypt foci (ACF) counts per colon as compared to controlled animals (G1 and G5). The body mass of animals belonging to galacto-oligosaccharides(Group G2, G3 and G4) increased significantly higher as compared to control group (G1).

CONCLUSIONS
Effect of pre-biotic treatment had significant effects on organ weights; liver, heart, spleen as well as small intestine length. It was concluded in our findings that galacto-oligosaccharides (GOS) were defensive against colon cancer. However further research is needed at molecular level to find out the transformations at gene levels.

EPO3_094

RESEARCH ON THE FLAVOR COMPONENTS AND ANTIOXIDANT PROPERTIES OF GRILLED EDAMAME

Tomoko Yamaguchi[1, 2]; Wakako Shiobara[1]; Kazuki Katsumi[3]
[1]Faculty of Agriculture, Niigata University, Niigata, Japan; [2]Faculty of Education, Niigata University, Niigata, Japan; [3]Institute for Social Innovation and Cooperation, Niigata University, Niigata, Japan

BACKGROUND AND OBJECTIVES
Vegetable soybeans, also known as edamame, are renowned for their abundant nutrients and favorable sensory characteristics. They are gaining popularity as a plant-based meat on a global scale. A significant quantity of edamame is cultivated and consumed in Niigata, Japan. Kurosaki chamame is the most renowned and branded edamame, and it was the first edamame to be registered under the Geographical Indication (GI) protection system. While edamame is typically consumed in its boiled state, the focus of this study was exploring alternative cooking methods. The objective of this study was to evaluate the flavor components and antioxidant properties of grilled edamame.

METHODS
The Kurosaki chamame harvested in September 2024 were used on the day of harvest. Two hundred grams of edamame, with or without salt, were wrapped in aluminum foil and placed on a wire net. The aluminum foil-covered edamame was then placed over an open flame and grilled for 10 minutes. For the purposes of comparison, edamame, with or without salt, were boiled in water. After cooling, the samples were subjected to the measurement of color, moisture, total sugar, free amino acid, total polyphenol content, and antioxidant activity. The taste was evaluated using a taste sensor.

RESULTS
The findings of the study indicated that the color of grilled edamame exhibited lower L* and b* values, and higher a* value in comparison to boiled edamame. The moisture content of grilled edamame was found to be lower than that of boiled edamame. However, no significant differences in total sugar, total polyphenol content, or antioxidant activity were observed between grilled edamame and boiled edamame. The investigation further revealed that the addition of salt did not affect these parameters of grilled edamame. The major free amino acids detected in the edamame samples included asparagine, glutamic acid, and alanine, with arginine, histidine, and GABA were also present in relatively high concentrations. The total amino acid level in grilled edamame was found to be approximately twice as high as that of boiled edamame. Furthermore, the RESULTS of the taste sensor evaluation indicated that grilled edamame exhibited a rich umami taste, with salt enhancing the aftertaste umami, particularly in grilled edamame.

CONCLUSIONS
It was suggested that the increase in amino acid content was responsible for the enhanced umami taste observed in grilled edamame. The study concluded that grill is an effective cooking method for improving the edamame's flavor profile.

NUTRITION LABELING AND CONSUMER PERCEPTION ANALYSIS OF FOOD PRODUCTS

Federica Quintiero[1]; Luisa Torri[2]; Nazarena Cela[2]; Cinzia Ferraris[1]
[1]Dipartimento di Sanità Pubblica Medicina Sperimentale e Forense, Università Degli Studi di Pavia, Pavia, Italy; [2]Sensory Laboratory, Università di Scienze Gastronomiche - Pollenzo Food Lab, Pollenzo, Italy

BACKGROUND AND OBJECTIVES

The World Health Organization (WHO) has promoted Front Of Pack (FOP) labels to guide consumer choices, but the lack of global regulation has sparked debates about the best system. In Europe, discussions focus on two options: Nutri-Score (NS) and NutrInform Battery (NIB). We conducted a study to identify which FOP better communicates food nutritional quality. Additionally, given the Mediterranean Diet's (MD) link to reduced cardiovascular risk, we evaluated whether MD adherence influences FOP understanding and consumer choices.

METHODS

Six food products were evaluated: low-fat yogurt, white whole yogurt, stracciatella yogurt, and jams of apricots, blueberries, and plums. For each product, an image was presented, accompanied by the two different FOP labels. Participants rated each product on a 7-point Likert scale for its buyability ("would not buy at all" to "sure I would buy"), healthiness ("not healthy" to "healthy"), and nutritional value ("not at all" to "extremely"). Adherence to the MD was assessed using the Medi-Lite questionnaire.

RESULTS

The sample consisted of 457 participants aged 18-77 years (mean age: 38.9±14.8), with 70.9% being women. Preliminary RESULTS revealed that 44.8% of participants were responsible for household food purchases, though only 37.8% reported paying attention to nutrition labels. Additionally, 68.2% of the participants were adherent to the MD. Regarding the NS system, low-fat yogurt was rated the most purchasable (4.95±1.96) and healthy (5.60±1.53), while white yogurt was considered the most nutritious (5.00±1.36). Among jams, apricot jam was rated as the most purchasable (4.70±1.95), healthiest (4.97±1.63), and most nutritious (4.62±1.62). For the NIB system, the yogurt RESULTS were consistent, albeit with slightly different scores for purchasability (4.74±1.96), healthiness (5.29±1.58), and nutritional value (4.86±1.44). For jams, the RESULTS mirrored those of the NS system, indeed apricot jam was rated as the most purchasable (4.55±1.96), healthiest (4.86±1.58), and most nutritious (4.19±1.61). Statistical analysis indicated no significant difference in nutrition label comprehension between MD adherents and non-adherents.

CONCLUSIONS

According to the preliminary RESULTS, despite slight differences, the two FOP labeling systems NS and NIB are comparable in terms of the three parameters considered (purchasability, healthiness, and nutritional value). Furthermore, adherence to the MD does not appear to influence consumer choices.

VALIDATION OF STRUCTURE OF HOME COOKING SKILLS QUESTIONNAIRE: AN ITALIAN VERSION (HCSQ-ITA)

Federica Quintiero[1]; Lenycia De Cassya Lopes Neri[1]; Daniele Nucci[2]; Aline Rissatto Teixeira[3]; Betzabeth Slater Villar,[4]; Anna Tagliabue[1]; Cinzia Ferraris[1]
[1]Dipartimento di Sanità Pubblica Medicina Sperimentale e Forense, Università Degli Studi di Pavia, Pavia, Italy; [2]Struttura Semplice Dipartimentale di Igiene Alimenti e Nutrizione, ATS Brescia, Province of Brescia, Italy, Brescia, Province of Brescia, Italy, Italy; [3]NUTRITION, University of Sao Paulo, School of Public Health, SÃO PAULO, Brazil; [4]Nutrition, Faculdade de Saúde, São Paulo, Brazil

BACKGROUND AND OBJECTIVES

The Mediterranean Diet, widely recognized for its association with a lower risk of chronic non-communicable diseases, is experiencing a decline in adherence within Italy. This nutritional transition is partly attributed to a loss of culinary skills, including the ability to select, combine, and prepare foods using traditional culinary techniques for home-cooked meals. The increasing access to ready-to-use foods contributes to higher calorie intake and reduced consumption of vegetables, fruits, and whole grains. Nutrition professionals (NP) play a crucial role in addressing this issue by promoting food and nutritional education initiatives aimed at improving eating habits. To assess the culinary skills of NP, the "Primary Health Care Home Cooking Skills Scale" was developed and validated in Brazil. This study aims to validate the scale's Italian version.

METHODS

For the validation of the structure, the original Brazilian questionnaire underwent several stages, including translation, cultural adaptation, synthesis, and reverse translation into Italian. A panel of nutrition experts (n=10) reviewed the translated version electronically using the Delphi technique, with rounds continuing until consensus was reached on the clarity and relevance of each question. A pilot test was conducted with a sample of 30 students and NP, who completed the questionnaire twice at a 15-day interval to evaluate its reproducibility. A minimum Content Validity Index (CVI) value of 0.9 was established as the threshold for agreement for all items. The Pearson coefficient was calculated for reproducibility analysis.

RESULTS

After translation and cultural adaptation, the pilot application of the HCSQ-ITA to the sample suggested modifications to include the vegetarian group. The final version of the HCSQ-ITA consists of 28 questions with Likert scale options to assess the frequency that best represents the respondent's routine (never = 0 points, nearly never = 1, sometimes = 2, almost always = 3, always = 4). The total score is calculated as a sum, categorized as follows: ≤28 (low home culinary skills), 29–56 (moderately low), 57–84 (moderately high), and ≥85 (high). By the end of the second Delphi round, the Content Validity Index (CVI) exceeded 0.9 for all items, and the Pearson coefficient for reproducibility analysis was 0.87.

CONCLUSIONS

The structure of the Italian version is considered adequate. Future analyses will be conducted in a larger sample to assess the internal consistency of the questionnaire through factorial analysis.

THE COMPARATIVE STUDY OF PHENOLIC COMPOUND OF THE ARTICHOKE (CYNARA SCOLYMUS L.), ACCLIMATIZED IN MONGOLIA

Mejeenov Purevjav[1]; Tseepil Tugsuu[2]; Matsumoto Terugi[3]
[1]Boarding member, Mongolian Nutrition Society, Ulaanbaatar, Mongolia; [2]Director, Gazar Shim Office, Ulaanbaatar, Mongolia; [3]Home, Home, Tokyo, Japan

BACKGROUND AND OBJECTIVES
The artichoke, ancient plant leaves are used as an herbal medicine and have been recognized since ancient times for their beneficial and therapeutic effects, including promotion of blood circulation, mobilization of energy reserves, induction of choleresis, inhibition of cholesterol biosynthesis and low-density lipoprotein oxidation and significant antibacterial, antifungal and antioxidant as well as strong hepato protective effects. This study evaluates the amount of phenolic compound of the Artichoke which has been acclimatized in Mongolia.

METHODS
: We selected the Artichoke dried leaves and three kind of artichoke drink from the market. The artichoke leaf sample which grown in the typical major area for the cultivation in Selenge prefecture located in north side of Mongolia. Qualitative analyses of polyphenols were carried out using a series LC-20A HPLC system equipped with a system controller, two chromatographic pumps, degasser, an autosampler with a 100 μL sample loop, a UV detector, a column oven and an MS detector with an ESI source (Shimadzu, Japan).

RESULTS
The Artichoke (*Cynara scolymus L.*) which has been acclimatized in Mongolia is major source of phenolic compound as cynarin, chlorogenic acid. In particular, dried artichoke leaves contain chlorogenic acid 5228.3 μg/g and total cynarin (1,3 and 1,4–di-0-caffeoylquinic acid) 4160.8 μg/g, which are phenolic compounds that are beneficial to health. The caffeic acid not detected. The amount of apigenin (7-0-rutinoside) was 97.25 μg/g.

CONCLUSIONS
The comparison of phenolic compound of artichokes acclimatized in Mongolia is with other related research RESULTS, the chlorogenic acid content being similar, but cynarine content being higher.

CONFLICTS OF INTERESTS

EPO3_102

FOOD SUPPLEMENT SAFETY: INSIGHTS FROM RASFF DATA ON ADULTERATION AND OVERDOSAGE

Maja Amidžić[1]; Ljilja Torović[1]
[1]Department of Pharmacy, Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia

BACKGROUND AND OBJECTIVES
The increasing popularity and accessibility of food supplements (FS) has been accompanied by growing health risks. A significant concern is the adulteration of FS with unauthorized synthetic pharmaceuticals, as some manufacturers prioritize consumer wishes (market demands) over safety. Even vitamins and minerals can pose a health risk for supplements consumers when present in excessive levels. This study aimed to provide insights in unauthorized presence of prescription drugs and excessive doses of vitamins and minerals in FS, based on the European Union Rapid Alert System for Feed and Food (RASFF) data.

METHODS
Notifications related to the food category "dietetic food, food supplements, fortified foods" and the hazard categories "composition" and "novel food" (year 2022-2024) were taken from the RASFF portal. Data on FS adulteration with prescription drugs and non-compliance with vitamin and mineral regulations were manually extracted and assessed.

RESULTS
The RASFF records revealed 89 notifications involving prescription drugs, with the most commonly identified adulterants in FS being: phosphodiesterase-5 inhibitors (PDE-5; 64 notifications), including sildenafil, tadalafil, vardenafil, and their synthetic analogues; anorexics (8), such as sibutramine; stimulants, including natural phenethylamines (synephrine; 4 notifications) and synthetic stimulants (notably 1,3-dimethylamylamine (DMAA) and 1,3-dimethylbutylamine (nor-DMAA); 4 notifications in total); anabolic agents (2); other drugs (8) and cannabinoid cannabidiol (CBD), pending authorization as a novel food ingredient (19). Notably, many FS contained multiple unauthorized prescription drugs simultaneously, highlighting their regulatory non-compliance. Additionally, 22 notifications were related to vitamin and mineral composition non-compliance, including excessive intake or overdosage (16 notifications). Violations predominantly involved vitamins (76.5%), with the most frequent being vitamin D (5 cases) and vitamin B6 (4), while mineral-related violations (4 cases) included zinc and iodine. Overall, 64.9% of a total of 111 notifications were classified as a serious risk, with 66.7% issued as alerts. Products originating from Turkey accounted for the highest proportion of hazardous FS (15.3%), particularly those adulterated with PDE-5 inhibitors (70.6%).

CONCLUSIONS
To mitigate health risks and ensure FS safety, advanced analytical methods, stricter regulatory frameworks, improved quality control, and multidisciplinary collaboration are essential.

CONFLICTS OF INTERESTS
The authors have no conflict of interest.

UNDERSTANDING CONSUMER ACCEPTANCE OF CALCIUM-FORTIFIED JUICES AND NOVEL FOODS WHILE PROMOTING IMPROVED NUTRITION AND SUSTAINABLE DIETS

Marija Knez[1, 2]; Cihat Günden[3]; Pelin Atakan[4]; Murat Yercan[3]; Jelena Milesevic[1, 2]; Marija Ranic[1, 2]; Mirjana Gurinovic[2]; Konstadinos Mattas[5]; Marija Takic[1]
[1]Centre of Research Excellence in Nutrition and Metabolism, Institute for Medical Research, University of Belgrade, Belgrade, Serbia; [2]Capnutra, Capacity Development in Nutrition, Belgrade, Serbia; [3]Department of Agricultural Economics, Ege University, İzmir, Türkiye; [4]Department of Agricultural Economics and Agribusiness, Yasar University, İzmir, Türkiye; [5]Department of Agricultural Economics, Aristotle University of Thessaloniki, Thessaloniki, Greece

BACKGROUND AND OBJECTIVES
The growing demand for sustainable diets and improved nutrition has sparked innovation in the food supply chain, including eggshell calcium for fortifying fruit juices.

METHODS
The Web of Science and Scopus databases were used to screen articles published between 2013 and 2023 using the predetermined query, resulting in 129 articles.

RESULTS
This approach offers a more sustainable and efficient option for enhancing dietary calcium intake and reducing waste while providing a convenient and accessible solution for individuals who are lactose intolerant or prefer plant-based diets. Calcium-enriched juice concentrates and ready-to-drink 'shots' cater to diverse consumer preferences, ensuring ease of integration into daily diets. This approach, alongside developing fortified foods like cereals and snack bars, aims to improve calcium intake and bone health globally. Complementary strategies include promoting calcium-rich foods, educational campaigns on eggshell calcium benefits, nanotechnology advancements, and partnerships with food manufacturers to improve accessibility and affordability of calcium-fortified products. However, the acceptance of such innovations remains a challenge. Behavioral factors, including personality traits and social context, play a crucial role in consumer responses to novel foods. These factors have been less studied than sensory aspects. Perceiving dietary changes as a loss, along with resistance to unfamiliar foods, can hinder the adoption of products like eggshell calcium-fortified juices. Consumers may face challenges in purchasing and consuming these juices due to concerns about taste, price, the effectiveness of eggshell calcium, and the presence of added ingredients, despite its more sustainable and resource-efficient benefits. Additionally, lack of awareness, dietary preferences, packaging convenience, and sustainability considerations can further impact their acceptance of these products. Strategies like framing, pro-diversity labeling, and highlighting the biodiversity and health benefits of eggshell calcium-fortified products could help overcome these barriers, making consumers more receptive to these sustainable and nutritious options.

CONCLUSIONS
The success of calcium-enriched juices and novel foods depends on aligning product development with consumer expectations and addressing behavioral barriers to foster greater acceptance. By prioritizing these factors, the food industry can better support the transition toward sustainable diets while meeting consumer needs for improved nutrition and health.

VIABILITY AND ANTIOXIDANT POTENTIAL OF LACTICASEIBACILLUS CASEI IN BLUEBERRY JUICE FORMULATIONS

Guerra Maria[1]; Fabiola Cerda,[2]; Guillermo Petzold,[3]; Patricio Orellana-Palma[4]; Carla Guzman[5]
[1]Facultad de Ciencias para el Cuidado de la Salud, Universidad San Sebastian, Concepción, Chile; [2]Ingeniería de Alimentos, Biobio University Campus Fernando May, Chillán, Chile; [3]Ingeniería en Alimentos, Biobio University Campus Fernando May, Chillán, Chile; [4]Departamento de Ingeniería en Alimentos, Universidad de La Serena, La Serena, Chile; [5]Facultad de Ciencias para el Cuidado de la Salud, Universidad San Sebastián, Concepción, Chile

BACKGROUND AND OBJECTIVES

In the last decade, there has been an expansion and consumption of foods with functional properties, using ingredients such as dietary fiber, probiotics, prebiotics, and polyphenols due to their beneficial health properties. Therefore, a growing interest is developing functional beverages from fruit and vegetable juices. This research aims to evaluate the viability of *Lacticaseibacillus casei* in blueberry juice and its physicochemical characteristics.

METHODS

Four formulations were prepared: sucrose solution with probiotic (SP), sucrose and gallic acid solution with probiotic (SGAP), blueberry juice with probiotic (BP), and blueberry juice adjusting the pH (BpH); and fifth, a control sample of blueberry juice (B); samples were stored at 4 °C for 28 days. Viable counts of *L. casei* were determined during storage at 4 °C during day 0 (just after homogenization), 3, 5, 7, 14, 21, 28. An aliquot of 1 mL of each sample was diluted (10-1-10-6) using a saline solution and a micro drop inoculation technique for 48 h at 37 °C.

RESULTS

L. casei viability decreased over time, mainly in SGAP samples; however, SP and BJP samples performed better throughout the storage period. This indicated that sucrose solution and fruit juice conditions were more suitable for maintaining the probiotics' viability. Antioxidant capacity was determined using FRAP and DPPH methods during storage at 4°C for 28 days (about 4 weeks). RESULTS exhibited that SGAP samples had better antioxidant capacity than juice samples during storage, possibly due to gallic acid's bactericidal effect. As for the juice samples, the BJ samples showed a more significant loss of antioxidant capacity from day 7 to 14, which was more pronounced in the FRAP method; regarding the BJP samples, the behavior was like the BJ samples.

CONCLUSIONS

The pH is a detrimental factor in the viability of L. *casei* since, after day 7, the viability decreases notably under refrigerated conditions. The prebiotic effect of polyphenols also affects the anthocyanins since they are used as a substrate, which is reflected in the loss of anthocyanins in the sample of blueberry juice containing *L. casei*.

SODIUM IN DIFFERENT PROCESSED SOUPS IN 2013

PATRICIA MOGROVEJO[1, 2]; Nicole Jimenez[2]; Pablo Jimenez[2]
[1]Maestría Nutrición y Dietética , Universidad de las Américas, Quito, Ecuador; [2]Research, Savinmed, Quito, Ecuador

BACKGROUND AND OBJECTIVES

Excessive sodium (Na) consumption can lead to hypertension, Cardiovascular Diseases (CVD) and renal disease. In Ecuador, CVD is a leading causes of death in adults. Objective: To determine sodium content according on package in processed soups.

METHODS

In 2013, twenty-two processed soups sold in supermarket in Quito – Ecuador were collected. The Na content was collected from Nutrition Facts label on package. Soups were divided in the following categories: creams, soups, Ecuadorian Commercial Brands (ECB), Supermarket Private Brands (SPB), and International Commercial Brand (ICB). Statistical analysis: the data were analyzed for the different processed soups categories for mean sodium content comparison using paired T test using statistical software SPSS 12.0.

RESULTS

The mean sodium and salt content was higher in ICB than ECB and SPB. ICB had 43,75% (277,65 mg/100g) more Na content than ECB and 45,91% (291.37 mg/100g) more sodium content than SPB. In addition, ICB had more salt content 44,03% (0,69 mg/100g) that ECB, and 45,91% (0,72g/100g) more salt content that SPB. Also, creams had more salt content 89% (49,14mg/100g) than soups.

Table 1. The mean sodium content (mg/100g) and mean salt (g/100g) from International Commercial Brand (ICB), Ecuadorian Commercial Brands (ECB) and Supermarket Private Brands (SPB) in 2013

Brands	**Mean sodium (mg/100g) ± DE**			**Mean salt (g/100g) ± DE**		
ICB	634,70	±	124,97	1,59	±	0,31
ECB	357,05	±	45,70	0,89	±	0,11
SPB	343,33	±	52,41	0,86	±	0,13
Total	429,03	±	148,05	1,07	±	0,37

CONCLUSIONS

Ecuadorian government play a key role in implementing food policies and regulations for the food industry to regulate sodium. As well as, it is important to implement food reformulation policies aimed at reducing the risk of diet-related non-communicable diseases such as CVD. Finally, educating the population about nutritional labeling and the risks of excess sodium consumption is crucial.

FATTY ACID COMPOSITION AND LIPID HEALTH INDICES OF GLUTEN FREE CEREAL FOOD

Mina Janković[1]; Radmila Velicki[2, 3]; Ljilja Torović[4]
[1]Department of General Education Subjects, Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia; [2]Department of Hygiene, Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia; [3]Center for Hygiene and Human Ecology, Institute of Public Health of Vojvodina, Novi Sad, Serbia; [4]Department of Pharmacy, Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia

BACKGROUND AND OBJECTIVES
Until recently, there was a scarcity of gluten free food on the market. However, raised awareness of its nutritional importance for people with gluten intolerance/celiac disease, resulted with great increase of variability and availability of such foods. Produced from cereals with low gluten content such as corn, rice, buckwheat and millet, as opposed to wheat, barley, rye and oat, gluten free foods differ in their composition from common foods, including lipid profiles. The study addresses fat content, fatty acid (FA) composition and corresponding lipid quality indices of gluten free food, reflecting its health profile.

METHODS
Fat content of 62 prepacked 'gluten free' cereal foods (flour, bread, breakfast cereals, pasta, biscuits and snacks) collected on the Serbian market was determined using Soxhlet method. Extracted fat was further subjected to GC-FID profiling of 37 FA. FA composition was used for grouping of characteristic FAs, i.e., saturated (SFA), mono- (MUFA) and poly-unsaturated (PUFA), omega-3 (ω-3-FA) and omega-6 (ω-6-FA) as well as for calculation of atherogenicity (IA) and thrombogenicity (IT) indices, and hypo-/hyper-cholesterolemic (HH) and ω-6/ω-3 ratios.

RESULTS
The mean fat content (%) of food groups was as follows: bread 6.1±2.5, breakfast cereals 5.7±2.8, flour 1.6±1.2, pasta 3.5±5.3, snack 11.0±9.5, of which SFA contributed from 1.5±1.1 in bread to 2.8±2.3 in breakfast cereals, MUFA from 1.3±0.9 in breakfast cereals to 5.0±4.3 in snacks and PUFA from 1.3±0.9 in breakfast cereals to 0.8±0.8 in flours. ω-3-FAs, represented by ALA, without EPA and DHA presence, were the highest in bread group (0.5%), while ω-6-FAs reached maximum share of fat in snack group (2.4%). With regard to lipid quality indices, in case of IA and IT, the group mean values were in the same order: pasta (0.3±0.1 and 0.6±0.3) < bread ≈ snack < flour < breakfast cereals (2.8±4.4 and 1.9±2.2). According to the mean HH ratio, food groups were positioned in a little bit different order: bread (7.8±5.5) > snack > pasta > flour > breakfast cereals (3.2±1.9), while ω-6/ω-3 ratio caused major disturbances: breakfast cereals (13.5±4.2) < bread < snack < pasta < flour (32.0±5.4).

CONCLUSIONS
Taking into account all considered lipid quality indices together, gluten free pasta and bread show more favorable characteristics in comparison with snack, flour and especially breafast cereals. However, differences in the amount of foods consumed significantly affect dietary FA intake amounts and consequent health effects.

CONFLICTS OF INTERESTS

EPO3_108

FAT AND FATTY ACID INTAKE FROM GLUTEN FREE CEREAL FOOD

Ljilja Torović[1]; Mina Janković[2]; Milka Popović[3, 4]
[1]Department of Pharmacy, Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia; [2]Department of General Education Subjects, Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia; [3]Department of Hygiene, Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia; [4]Center for Hygiene and Human Ecology, Institute of Public Health of Vojvodina, Novi Sad, Serbia

BACKGROUND AND OBJECTIVES
A variety of gluten free foods, nutritional therapy for people with gluten intolerance/celiac disease, is increasingly available on the market. Gluten free cereal foods are produced from corn, rice, buckwheat and millet, as substitutes for gluten-rich cereals such as wheat, barley, rye and oat. As it is known that difference in cereal source causes difference in fat content and composition, the current study assess fat and essential fatty acid (FA) (linoleic acid, LA; alpha-linolenic acid, ALA) intake from cereal food in people on gluten free diet.

METHODS
A total of 62 prepacked cereal foods labelled as 'gluten free' (8 bread, 4 breakfast cereal, 12 flour, 15 pasta, 23 snacks) was collected on the Serbian market. FA composition was determined in extracted fat (Soxhlet method), using GC-FID. Amounts of essential FAs were combined with national chronic food consumption data and resulting dietary intake estimates were evaluated in relation to the dietary reference values (DRVs), expressed based on energy (E) intake: total fat (35-40)% (toddlers) and (20-35)% (all other population groups), LA 4% and ALA 0.5%.

RESULTS
Taken all groups of cereal food together, in case of toddlers mean contribution of total fat to E requirements was (22-26)% for males and (24-27%) for females. Regarding other age groups, the contribution levels ranged from (16-28)% to (20-35)% in case of males, and from (19-33)% to (22-40)% in case of females, with the lowest levels recorded for adolescents of both sexes and the highest for other children-males and elderly-females. Regarding specific populations, pregnant women obtain (18-31)% of their E requirements through fat intake, while vegetarians reach (22-39)% and (28-48)%, for males and females, respectively. According to the contribution to the intake of essential FAs, the order of age groups (males/females) was: toddlers (60/64% LA, 85/91% ALA) > other children > elderly > adults > adolescents (38/44% LA, 56/65% ALA). For pregnant women, the intake of LA and ALA reached 42 and 61%, respectively, while vegetarians again positioned very high, with 52/64% of LA and 69/85% of ALA provided from gluten free cereal food. For all population groups, bread was the richest source of fat, LA and ALA intake.

CONCLUSIONS
The consumption of cereal food provides fats supplying from around one quarter to around one third of E requirements, depending on the age and sex of population on gluten free diet, with somewhat higher levels in case of vegetarians. For a comprehensive evaluation of fat and essential FAs intake, other dietary sources of lipids need to be taken into account.

EPO3_109

MINERAL COMPOSITION OF GLUTEN FREE CEREAL FOOD

Mina Janković[1]; Danijela Lukić[2]; Ljilja Torović[3]
[1]Department of General Education Subjects, Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia;
[2]Center for Hygiene and Human Ecology, Institute of Public Health of Vojvodina, Novi Sad, Serbia;
[3]Department of Pharmacy, Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia

BACKGROUND AND OBJECTIVES
Individuals with gluten intolerance/celiac disease must avoid cereals which are rich sources of gluten such as wheat, barley, rye and oat, and products thereof. The substitutes used for production of gluten free foods are corn, rice, buckwheat and millet, which can be significant dietary source of essential minerals. The objective of the current study was to explore the mineral composition of gluten free cereal food, which is essential for the assessment of its nutritional value in terms of capacity to fulfil dietary reference requirements.

METHODS
A total of 88 samples, including flour, bread, breakfast cereals, pasta, biscuits, snacks and cereal bars, all marked with 'gluten free' wording and/or a crossed grain symbol, was obtained on the Serbian market. Mineral content was determined in samples prepared using microwave digestion, by inductively coupled plasma coupled with either optical emission (ICP-OES) (Na, K, Ca, Mg) or mass spectrometry (ICP-MS) (Mn, Fe, Cu, Zn, Se, Mo).

RESULTS
The mean macroelement contents (mg/kg) of food groups were ordered as follows: Ca - cereal bars (1122±1076) >> biscuits > snacks > breakfast cereals ≈ pasta > bread > flour (80±57); Mg – cereal bars (903±506) > breakfast cereals ≈ snacks > pasta > bread > biscuits > flour (376±425); K – snacks (6772±13397) ≈ cereal bars > pasta > breakfast cereals > biscuits > bread > flour (1688±1157). Although Na is an essential mineral, lower content is preferable: pasta (252±462) << flour < cereal bar < biscuits < bread ≈ snacks (10882±8615). With regard to microelements, the food group mean contents (mg/kg) ranged as follows: Fe – from 2.2±1.0 to 46±22, Zn from 3.1±3.2 to 17±7.6, Cu from 6.2±3.7 to 0.6±0.4, in all cases with the lowest level recorded in breakfast cereals and the highest in cereal bars; Mn content reached maximum in snacks (8.8±9.0), Mo in cereal bar (0.43±0.27) and Se in pasta (0.13±0.25).

CONCLUSIONS
Knowing the mineral composition of food makes it possible to make informed food choices and combine various food groups in the most favorable way. Furthermore, it allows for the assessment of population dietary intake of these important nutrients. In case of food intended for population groups with limited food choices, such as individuals obliged to adhere to a gluten free diet, this becomes especially important.

EPO3_110

INTAKE OF MINERALS FROM GLUTEN FREE CEREAL FOOD

Ljilja Torović[1]; Mina Janković[2]; Sanja Bijelovic[3]
[1]Department of Pharmacy, Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia; [2]Department of General Education Subjects, Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia; [3]Department of Hygiene and Human Ecology, University of Novi Sad, Faculty of Medicine, Public Health Institute, Novi Sad, Serbia, Novi Sad, Serbia

BACKGROUND AND OBJECTIVES
Gluten free foods, intended for people with gluten intolerance/celiac disease, are increasingly present on the market. Such food is considered nutritional therapy, making it possible to avoid gluten-rich cereals (wheat, barley, rye and oat) by their substitution with corn, rice, buckwheat and millet. These cereals and products thereof thus become important dietary sources of essential minerals. The current study assesses the intake of minerals from cereal food in people on gluten free diet.

METHODS
Sample collection comprised 88 prepacked cereal foods with 'gluten free' labelling (12 flour, 10 bread, 15 pasta, 16 biscuits, 26 snacks, 4 breakfast cereals, 5 bars), purchased on the market of Serbia. Content of minerals, determined using ICP-OES and ICP-MS, was combined with national chronic food consumption data and resulting mineral intakes were evaluated in relation to the dietary reference values (DRVs).

RESULTS
Taken all groups of cereal food together, mean contribution to mineral DRV (Average Range (AR) or Adequate Intake (AI), what applicable) within one age group descended in the following order (%, males/females, where applicable, or age classes, when applicable): toddlers – Mo (400) > Mn > Na > K > Se (94) > Mg > Cu > Fe > Zn > Ca (18); other children – Mo (296) > Na > Mn > Mg (68) > K > Se > Cu > Zn > Fe > Ca (12); adolescents – Mo (182) > Na > Mg (67/80) > Cu > Fe > K > Mn > Se > Zn > Ca (11); adults – Mo (163) > Fe (74/64) > Mg > Na > Mn > Cu > Zn > K > Se > Ca (13/15); elderly – Mo (144) > Mg > Na (65) > Fe > Mn > Cu > Zn > K > Se > Ca (14). With regard to specific population groups, the order of intake of minerals by pregnant women was as follows: Mo (150) > Mg and Na (66) > Fe and Mn > Cu > Zn > K > Se > Ca (12/14), while in case of vegetarians, it was Mo (224) > Mg (85/99) > Na > Cu > Zn > K > Fe > Mn > Se > Ca (19/22). It is easily observable that all orders begin with Mo, the only element with intake exceeding 100% of DRV for all population groups, and ends with Ca, fulfiling from 11% of DRV for adolescents to 18% for toddlers. For all population groups, bread and breakfast cereals were the richest sources of minerals, in latter case with exception of Fe, Cu and Zn.

CONCLUSIONS
The study underscores the importance of monitoring the intake of essential nutrients, especially in case of population with restricted food choice due to specific health conditions. High-quality and safe gluten free food making it possible to reach DRVs should be the ultimate goal of all interested parties - producers, public health authorities and consumers.

COMPARATIVE STUDY OF TRADITIONAL AND VACUUM PROCESSING OF MONGOLIAN DAIRY “EEZGII"

Narangerel Chimedregzen[1]
[1]School of Food, Light Industry and Design, Mongolian University of Science and Technology, Ulaanbaatar, Mongolia

BACKGROUND AND OBJECTIVES

Mongolians have a wealth of experience and methods of making dairy products adapted to the climate and home conditions of their homeland, and have been using milk to make many types of puddings unknown to many regions of the world. One of them is the owner. “Eezgii” is a very unique food that is spread only among the Mongolian people. All the components of milk are gathered together and the water is evaporated immediately. By combining the traditional methods of processing “eezgii” with modern advanced technology, we can not only meet our own demands and needs, but also take a leading position in the world with our precious products with unique taste and characteristics.

METHODS

“Eezgii” is usually made in spring and autumn, and freshly milked milk is heated until it rises, fermented whey, fermented milk, and yogurt are added to it, and then the eedima is gently boiled in whey. Importance of food and nutrition. “Eezgii” is a very nutritious food and can be used to treat chronic liver and biliary diseases. The composition of Eezig contains a certain amount of biologically active substances such as lactulose, lactulosolin, calcium lactate, which are of special importance to the human body.

RESULTS

The drying process was carried out by vacuum and traditional methods. 500 ml of cow's milk with 6.4% fat, 3.87% protein and 84.08% moisture was used in the experiment. Heat the milk to 81oC, add yogurt equal to 10% of it, stir it gently (about 11 minutes for edum formation), separate the edum from the yellow milk and divide it into two equal parts.

Boiling started at 60oC in the vacuum apparatus, and drying was carried out at a constant temperature of 65oC. The sweep lasted a total of 25 minutes.

When the whey was dried by the traditional method, boiling started at 88oC, and when drying was carried out at a constant temperature of 93oC, the whey was completely dried in about 33 minutes.

CONCLUSIONS

From this, it can be seen that the drying and processing of rind in a vacuum device is more beneficial in terms of time and productivity than the traditional method.

It can be seen from the oil and protein content and the unsaturated acid ratio of the oil that the temperature at which the rice is dried in the vacuum device is 65oC.

EPO3_115

EFFECT ON THE ANTIOXIDANT PROPERTIES AND PALATABILITY OF DIFFERENT EXTRACTION OF LINDERA PRAECOX LEAF TEA

Tomoko Yamaguchi[1, 2]; Mei Hoshino[1]
[1]Faculty of Agriculture, Niigata University, Niigata, Japan; [2]Faculty of Education, Niigata University, Niigata, Japan

BACKGROUND AND OBJECTIVES
The former firewood and coal forests owned by Japanese mountain communities in areas with heavy snowfall grow abundant hardwood trees. The concept of sustainable forest management is addressed within the framework of the Sustainable Development Goals (SDGs). In light of the necessity to utilize local resources in a sustainable manner, the focus of our research is on the health benefits of hardwood tree leaves. These leaves are rich in polyphenols and possess antioxidant properties. In the previous study, the leaves of *Lindera praecox* (Lp) were founded to have the highest polyphenol content and antioxidant activity among 20 kinds of leaves. The objective of this study was to examine the preparation method for a tea made with Lp leaves that is both high in health functionality and palatability.

METHODS
The leaves of Lp were collected in Tadami-machi, Fukushima Prefecture, Japan. The dried leaves were extracted with hot water for 3 or 10 min (hot-water extract tea). A boiling-water extract tea was also prepared by extracting the dried leaves while heating for 3 or 10 min. The total phenol and catechin contents, antioxidant activity, color, and sensory attributes of hot-water and boiling-water extract tea were determined.

RESULTS
The boiling-water extract tea of Lp leaves exhibited significantly higher total phenol content and antioxidant activity compared to the hot-water extract tea. However, differences in extraction time were only significant for total polyphenols, which were higher at 10 min than at 3 min. The presence of gallic acid and catechin was detected in both hot-water and boiling-water extract tea. Epicatechin gallate was found in only boiling-water extract tea, and the highest content of total catechin was observed in boiling-water extract tea of 10min heating. The color of boiling-water extract tea exhibited lower L* values, and higher a*, b*, and chrome values in comparison to hot-water extract tea. Boiling-water extract tea of 3 min was preferred at sensory evaluation with good smell and bitterness compared to hot-water extract tea of 3 min. However, boiling-water extract tea of 10 min was not preferred with strong bitterness compared to boiling-water extract tea of 3 min.

CONCLUSIONS
These RESULTS indicate that boiling-water extraction with heating is a superior tea preparation method that elicits higher antioxidant properties. It was observed that an increase in heating time resulted in a corresponding increase in health benefits; however, the optimal duration for palatability was found to be shorter heating times.

CONFLICTS OF INTERESTS
The authors have no conflict of interest.

PREPARATION OF FERMENTED SOY BEVERAGE WITH ACEROLA JAM AND USE OF OKARA IN GLUTEN FREE DESSERT MIX TO REDUCE WASTE AND ADD NUTRITIONAL VALUE

Ana Lucía Fernández[1]; Amarís Víquez,[1]; Alexandra Yanis,[1]; Dagny Magallón,[1]; Rosa Quintero,[1]
[1]Science And Technology Faculty, Technological University of Panama, Panamá, Panama

BACKGROUND AND OBJECTIVES

Soybeans were chosen as raw material for their nutritional properties and low cost, to create an affordable yogurt-like product of high nutritional quality due its probiotic, antioxidant and protein content. The acerola was added to enhance flavor of the beverage and add antioxidants. Acerola is a tropical fruit that is not widely comercialized.
Okara is obtained as a soy by-product, which is often wasted. Okara is a potential source of fiber and protein. Therefore, it was used in the development and fortification of a gluten-free brownie flour.

METHODS

The fermented soy yogurt-type product was prepared by making the soy beverage and fermenting it with sugar and probiotics capsules. The acerola jam was formulated from frozen acerola, with the addition of cane sugar and pectin. The okara was dehydrated and ground. The properties of the products were measured using a vibrational viscometer, Kjeldahl methods, titratable acidity, Bligh Dyer, total polyphenols and DPPH. Sensory analysis was also performed for the okara gluten free dessert mix.

RESULTS

The soy ferment has a viscosity of 300.83 mPa·s at 20°C, and 79.90 mPa·s for the ferment with acerola. Proteint content was 6.11±0.56% for soy ferment and 3.95±0.98% with the acerola jam added. Lipids were 3.06±0.00% for soy ferment. Total solids for the soybean ferment were 1.51°Brix and 5.03°Brix for the acerola ferment. When testing the antioxidant capacity of acerola jam, it was determined that the inhibition of the DPPH reagent was 92.3%. Adding jam to the product can contribute to its antioxidant capacity since the DPPH inhibition of soy yogurt was 14.9%. Okara resulted in 25.4±1.41% of protein, which contributed to the protein of the GF mix (6.25±6.09%).

CONCLUSIONS

The yogurt-like product provides a protein content of approximately 6.11%. The fat content was 3.06%. These values are comparable with similar products of animal origin. The addition of acerola jam reduces the protein content of the final product, since jam mainly provides carbohydrates. However, it does significantly provide antioxidant compounds, improving the nutritional quality of the product.
From a compositional perspective, okara increased protein content by 58.88%, thus suggesting a significant potential source of plant protein. Additionally, the use of okara reduced the waste of the soy ferment production to almost zero.

A SCOPING REVIEW OF STUDIES ON NUTRITIONAL AND ENVIRONMENTAL EVALUATION OF CANTEEN MENUS IN INSTITUTIONAL CATERING SYSTEMS

Lara Chehade[1]; Daniela Martini[1]; Massimiliano Tucci[1]; Cristian Del Bo'[1]; Patrizia Riso[1]
[1]Department of Food, Environmental and Nutritional Sciences (DeFENS), University of Milan, Milano, Italy

BACKGROUND AND OBJECTIVES
There is a growing increase in the number of meals consumed outside, such as in public canteens and in fast-food chains. These meals may deeply influence the nutritional quality as well as the environmental impact of the total dietary pattern. Currently, there is a limited knowledge about the nutritional and environmental impact of menus/meals offered within the catering system. Thus, within the SUM_LIFE project (www.onfoods.it), a scoping review was performed to analyze existing evidence on the nutritional quality (NQ) and environmental impact (EI) of institutional canteen menus and meals.

METHODS
The search was conducted using PubMed and Scopus databases. Articles published between 2013 and 2023 were included if they were quantitative articles that included the NQ and/or EI of menus or meals served in institutional canteens.

RESULTS
Out of a total of 10762 studies initially retrieved from PubMed and Scopus, seventy-six studies were included in the final evaluation. RESULTS revealed that most articles were conducted in developed high-income countries and in early education centers like schools and nurseries. Most studies evaluated meals and menus for NQ in comparison to EI, with only a limited number measuring both. Moreover, our RESULTS noted that interest in EF increased in recent years, with greenhouse gas emission being the most common indicator.

CONCLUSIONS
The work performed identifies the scarce number of studies assessing NQ and even more EI of institutional canteen menus. By considering the importance of such catering service, findings from this study should promote further initiatives aimed at better comprehend the nutritional, environmental impact of the catering sector as a basis to develop future strategies to improve its overall sustainability.

PHENOLIC CONTENT AND ANTIOXIDANT ACTIVITY OF DANDELION VS. NETTLE

Ivana Djuricic[1]; Tijana Ilic[1]; Jelena Kukic-Markovic[2]; Milica Zrnic-Ciric[1]; Nevena Ivanović[1]
[1]Department of Bromatology, Faculty of Pharmacy, University of Belgrade, Belgrade, Serbia; [2]Department of Pharmacognosy, Faculty of Pharmacy, University of Belgrade, Belgrade, Serbia

BACKGROUND AND OBJECTIVES
Dandelion (*Taraxacum officinale* L.) and nettle (*Urtica dioica* L.) have been consumed in various forms as a valuable source of nutrients and are often hailed as superfoods due to their dense nutritional profiles and health benefits. The main bioactive compounds found in these plants are carotenoids, flavonoids (e.g., quercetin), phenolic acids, polysaccharides (e.g., inulin), sterols (e.g., β-sitosterol, stigmasterol), chlorophylls, etc. The aim of this study was to compare the total phenolic content (TPC) and antioxidant activity of lyophilized dandelion (whole plant including roots) and nettle (aerial parts).

METHODS
Total phenolic content was analyzed by the spectrophotometric method with FC reagent at a wavelength of 630 nm. Samples were extracted with 80% ethanol to measure antioxidant activity by *in vitro* assays (DPPH, FRAP and CUPRAC). The composite antioxidant index (ACI) was then calculated to estimate the total antioxidant capacity.

RESULTS
The TPC was found to be 13.25 mg GAE/g in dandelion, while 3.16 mg GAE/ g was found in nettle. All the *in vitro* tests showed higher antioxidant activity for dandelion than nettle, with ACI values ~96% and ~17%, respectively.

CONCLUSIONS
This study highlights the superior phenolic content and antioxidant capacity of lyophilized dandelion compared to nettle. These findings also underscore the dandelion as a more potent natural source of antioxidants, offering promising applications in functional foods and nutraceuticals. Further research could explore additional bioactive properties and their health implications.

EPO3_123

STREET FOOD OFFERINGS AT METRO STATIONS, BY SOCIOECONOMIC LEVEL

Michelle Lozada-Urbano; Reyna Andrea Mija[1]; Abigail Farfan Marchan[2]; Giuseppe Yupanqui Cisneros; José Flores Briceño; Hans Contreras Pulache
[1]Nutrición y Dietética, Universidad Privada Norbert Wiener - Sede 7820, Jesús María, Peru; [2]Nutrición y Dietética, Universidad Privada Norbert Wiener - Sede 7820, Lima, Peru

BACKGROUND AND OBJECTIVES

Street food is part of Peruvian culture. Although nutritious foods can be found, less healthy options are becoming increasingly popular and frequent in these food vending areas. However, the nutritional composition of street food in urban environments is unknown. The aim of this study was to describe the gastronomic offer of street food vending in the Metro 1 stations of Lima, the composition of the dishes offered, their hygiene characteristics, and their nutritional value according to the socioeconomic level of the district.

METHODS

Line 1 of the Lima Metro is divided into two main sections: the North Section: Connects Villa El Salvador with the center of Lima and the South Section: Connects the Bayóvar station with the center of Lima. In total, 25 stations were evaluated.Work was done on both the North and South sections and on all stations. Student pairs were created to visit each of the stations and observe all the food stalls within 100 meters of the station, filling out a form for each stall that was selling on the street.

RESULTS

The sample was obtained between the months of September and October 2024. The stations with the most stalls and variety of dishes were the stations (n-%), Gamarra (48-27.3%), María Auxiliadora (22-12.5%), Grau (17-9.7%), Bayovar (14-8%), the stations with the least sales were Cabitos, Ayacucho and Jorge Chávez with 1 stall each. The stalls where there is no street vending are La Cultura, San Borja Sur and Angamos. 93.8% (166) of the stalls that sell food do so on the sidewalk around the station. 75.6% (133) of street vendors sell a single dish. The most common food sold (number of stalls) was Ceviche (20), quail egg (huevo de codorniz) (19) mote broth and pork cracklings (sopa de mote y chicharron de cerdo (14 each), Chanfainita (12), green broth and red noodles (sopa verde y tallarines rojos) (11 each). There are other products such as quinoa drinks, chuño (potato), potato with egg, corn with cheese, boiled beans, stuffed potatoes, cancha popcorn, chifles, churros, among others.

CONCLUSIONS

The gastronomic offer in the metro is wide, ranging from elaborate preparations to boiled products, fried foods, salty products, sweets and drinks. Sales are higher in areas with high traffic, however, at the station. The culture is not street vending by municipal order, sales are in restaurants in the surroundings. Numerous street vending is more frequent in areas where the socioeconomic level is low.

NUTRITIONAL STUDY OF A BREAD MADE WITH CASSAVA STARCH MODIFIED WITH ALPHA AMYLASE FOR PEOPLE WITH CELIAC DISEASE AND DIABETES

Vanessa Abad-Quevedo[1]; Cornejo Fabiola[2]; Pedro Maldonado-Alvarado[1]
[1]Department of Food Science and Biotechnology, National Polytechnic School, Quito, Ecuador; [2]Faculty of Mechanical Engineering and Production Sciences, Escuela Superior Politecnica del Litoral, Guayaquil, Ecuador

BACKGROUND AND OBJECTIVES
Recent studies are showing that cassava starch modified with alpha amylase maximize breadmaking properties without the need to add a leavening agent. However, its nutritional properties have not been studied, in particular to know if the finished product can be used for people with celiac disease and diabetes. The aim of this contribution was to evaluate the nutritional properties of a bread made with cassava starch modified with alpha amylase.

METHODS
Cassava starch of the variety INIAP 651 from Ecuador was modified with alpha-amylase (0, 2, 4, 6, 8, 9 enzyme units/g substrate during 20 min). The following nutritional properties of the bread were evaluated from a dough with this modified starch: non-resistant starch (NRS), total starch (TS), resistant starch (RS), rapid digested starch (RDS), slow digested starch (SDS) (1) and glycemic index (GI) (2).

RESULTS
The RESULTS are in line with litterature and showed the following values for the studied treatments in NRS: 39.63 – 45.14 g/100 g, TS: 40.00 – 45.72 g/100 g, RS 0.37 – 0.58 g/100 g, RDS: 15.85 – 27.52 g/100 g, SDS: 15.33 – 27.52 g/100g and GI: 51.25 – 60.99 (3). Best RESULTS were obtained with 9 alpha-amylase U/g that had lower values in NRS, RDS and GI as wells as higher values in SDS.

CONCLUSIONS
Cassava starch hydrolyzed with low levels of alpha amylase allows to obtain bread without gluten with suitable nutritional properties for people with celiac disease and diabetes.

FATTY ACID COMPOSITION IN SACHA INCHI OIL AND MICROCAPSULES

Nataly Bernuy Osorio[1]; Eduardo Guevara Guevara[1]; Sheyla Gutierrez Asencios[1]; Ivonne Gutierrez Zorrilla[1]
[1]Department of Nutrition, National Agrarian University, La Molina, Peru

BACKGROUND AND OBJECTIVES
Sacha inchi oil is known for its omega 6 and 3 content, and its inclusion in the diet is widely recommended; however, the consumption of these polyunsaturated fatty acids (PUFA) can be affected during their passage through the gastrointestinal tract. To protect these components, it is possible to use environmentally friendly technologies such as microencapsulation by atomization. The objective was to evaluate the fatty acid composition in sacha inchi oil (SIO) and in its microcapsules (MSIO).

METHODS
To do this, the fatty acid profile analysis was performed in the SIO (Amazonas, Peru) using gas-liquid chromatography, and later in the MSIO, to determine the omega-6/omega-3, SFA/UFA and SFA:MUFA:PUFA ratios.

RESULTS
The RESULTS show that the ratios obtained from SIO and MSIO were not significant (omega-6/omega-3 was 5.37 and 5.57, SFA/UFA was 0.24 and 0.27, SFA:MUFA:PUFA was 1:1.3:2.8 and 1.1:1.4:2.7; respectively); however, the use of atomization favors the protection of the fatty acid content in sacha inchi oil.

CONCLUSIONS
In conclusion, the fatty acid composition in sacha inchi oil was not affected by the processing to obtain microcapsules.

PHENOLIC COMPOUNDS FROM TOMATO REDUCE STARCH DIGESTIBILITY: POTENTIAL FOR DEVELOPING LOW-GLYCAEMIC STARCH MEALS

Marina Corrado[1, 2]; Guillermo D. Manrique[3]; Camilla Mesirca Prevedello[1]; Anna Vallverdú-Queralt[1, 2]; Maria Pérez[1, 2]; Rosa M- Lamuela-Raventós[1, 2]
[1]Polyphenol Research Group, Department of Nutrition, Food Science and Gastronomy, INSA-UB, University de Barcelona, Barcelona, Spain; [2]CIBER Physiopathology of Obesity and Nutrition (CIBEROBN), Institute of Health Carlos III, Madrid, Spain; [3]Faculty of Engineering, Universidad Nacional del Centro de la Provincia de Buenos Aires, Olavarría, Buenos Aires, Argentina

BACKGROUND AND OBJECTIVES
Synergistic nutrient combinations may lower postprandial glycaemia and reduce the risk of non-communicable diseases like type 2 diabetes. This study focuses on interactions between starch, the main carbohydrate in Western diets, and phenolic compounds from tomatoes. Given that starch-based foods are frequently consumed with tomatoes or tomato products, this combination may represent an opportunity to develop meals with reduced glycaemic potency. The objective of this study was to assess the effects of tomato polyphenols on starch digestibility, considering different doses, tomato varieties, and processing methods.

METHODS
Phenolics were extracted using a green extraction method (1) from raw tomatoes peels (two varieties) and a commercial tomato paste. Total phenolic content was determined by Folin-Ciocalteu colorimetric method and untargeted metabolomics analysis is used to characterise phenolic compounds in each type of tomato (2). Starch digestibility was evaluated using a single enzyme digestion model, where the endpoint of the reaction is known to correlate with *in vivo* glycaemic index (3). Gelatinised starch was incubated with (poly)phenol extracts at two doses: equal to starch content and half the starch content. The reducing sugars released over 60 minutes were quantified using a DNS colorimetric method (4).

RESULTS
A dose-dependent effect was observed, with greater inhibition of starch digestibility at the higher (poly)phenol extract concentration, where starch digestibility was 7.1% lower compared to the control with no extract, (mixed-model, $p = 0.018$ at 60 minutes). The use of different varieties or the use of processed tomato paste vs raw did not affect this outcome.

CONCLUSIONS
Tomato phenolic compounds can significantly reduce starch digestibility *in vitro*, although high concentrations of (poly)phenols are needed to achieve a significant effect. The lack of variation between tomato varieties and processing methods suggests that even processed tomato products like tomato paste can serve as effective source of bioactive compounds to modulate glycaemic responses. These findings support the feasibility of consuming tomatoes alongside starch-based meals as a practical strategy to lower glycaemic potency, which is now being explored.

POLYPHENOL PROFILE OF SELECTED SEEDS FROM THE SERBIAN MARKET

Margarita Dodevska[1]; Jelena Kukic-Markovic[2]; Sanja Djurović[3]; Nevena Ivanović[4]
[1]., Institute for Public Health "Dr. Milan Jovanović Batut", Belgrade, Serbia; [2]Department of Pharmacognosy, Faculty of Pharmacy, University of Belgrade, Belgrade, Serbia; [3]Department of Phytopharmacy and Environmental Protection, Institute for Plant Protection and Environment, Belgrade, Serbia; [4]Department of Bromatology, University of Belgrade Faculty of Pharmacy, Beograd, Serbia

BACKGROUND AND OBJECTIVES
Edible seeds are rich in various macro and micronutrients, as well as in some biologically active compounds with a positive health effects. The aim of this work is to identify and determine main phenolic compounds and total phenolics content (TPC) in selected commercial seeds samples (sesame and black sesame, raw and roasted sunflower, raw and roasted pumpkin, chia and linseed) from the Serbian market.

METHODS
The samples were extracted with dichloromethane (in Soxhlet apparatus) and then with 80% methanol. Obtained hydromethanol extracts were dried and analysed. The identification and quantification of phenolics (hydroxybenzoic derivatives (HBAs), hydroxycinnamic derivatives (HCAs), flavonoids and coumarins) was performed using HPLC. Total phenolics content (TPC) was determined spectrophotometrically with FC reagent. The analyzed parameters were used to generate the PCA model.

RESULTS
The highest TPC, especially chlorogenic acid, was determined in raw and roasted sunflower seeds, followed by chia and linseeds. These RESULTS are confirmed by PCA that showed 49.8% (PC1) and 34.1% (PC2) of the total variance of the dataset. According to the PCA for seeds, raw and roasted sunflower seed were the most significant source of total polyphenols and HCAs (first axis: 0.924 and 0.942, respectively); while chia was the most significant sources of flavonoids and coumarin (first axis: -0.696 and -0.531, respectively). Nevertheless, pumpkin seed raw and pumpkin seed roasted were the most significant sources of HBAs (second axes: 0.868).

CONCLUSIONS
This work showed that defatted seeds are valuable sources of various phenolics, mainly phenolic acids. Obtained RESULTS implicate further investigations on this matter in order to clarify their composition and potential as a functional foods components.

CONFLICTS OF INTERESTS
The authors have no conflict of interest.

TOXIC ELEMENTS (METAL(LOID)S) PROFILING IN GLUTEN FREE CEREAL FOOD

Ljilja Torović[1]; Mina Janković[2]; Danijela Lukić[3]; Milka Popović[4, 3]
[1]Department of Pharmacy, Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia; [2]Department of General Education Subjects, Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia; [3]Center for Hygiene and Human Ecology, Institute of Public Health of Vojvodina, Novi Sad, Serbia; [4]Department of Hygiene, Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia

BACKGROUND AND OBJECTIVES
Not only wheat, barley, rye and oat but also their substitutes used for production of gluten free foods, such as corn, rice, buckwheat and millet, could be contaminated with toxic elements (metal(loid)s), of which only a few are regulated by the law. The objective of the current study was to explore the elemental profiles of gluten free cereal food and provide data for the assessment of dietary exposure and health risk.

METHODS
A total of 88 samples, including flour, bread, breakfast cereals, pasta, biscuits, snacks and cereal bars, all marked with 'gluten free' wording and/or a crossed grain symbol, was obtained on the Serbian market. Concentrations of 23 elements (Be, B, Al, V, Cr, Mn, Fe, Co, Ni, Cu, Zn, As, Se, Sr, Mo, Cd, Sn, Sb, Te, B, Hg, Tl, Pb) were determined using inductively coupled plasma mass spectrometry technique, after microwave digestion of the samples.

RESULTS
The overall occurrence rates of the elements of primary toxicological concern were 70.0% (Cd) > 44.4% (Pb) > 35.6% (As) > 15.6% (Hg). The proportion of the samples containing these elements varied greatly among food groups, within the following ranges (%): Cd 50.0-81.3 (breakfast cereals - biscuits); Pb 0-66.7 (breakfast cereals - flour); As 16.7-50.0 (flour - bread, biscuits); Hg 0-40.0 (breakfast cereals - bars). The ranges of their mean concentrations were the following (μg/kg): Cd 2.5-21.3 (breakfast cereals - bread); Pb not detected-19.3 (breakfast cereals - flour); As 7.6-30.5 (bars - biscuits); Hg not detected-7.1 (breakfast cereals - snacks). The maximum concentration of Pb, determined in one pasta sample, was 76.7 μg/kg, well below the regulatory allowance. However, in case of Cd, maximum concentration (165 μg/kg, in pasta made of rice) was on the verge of the excess. On the other hand, Fe, Cu, Zn and Mn were present in all the samples – besides the possibility of exhibiting toxic effects in case of excessive intake, they are important as essential elements.

CONCLUSIONS
The study underlines the significance of elemental composition of food and provides data for risk assessment. The availability of safe food is of great importance for all consumers, especially those on a specific diet, which limits their food choices.

CONFLICTS OF INTERESTS
The authors have no conflict of interest.

THE ALIMCARE PROJECT - EMPOWERING EDUCATION TO INTEGRATE FOOD AS A PREVENTION TOOL FOR HEALTH AND IN THE CONTINUITY OF CARE WITHOUT GIVING UP THE PLEASURE OF EATING

Claire Duga[1]; Lucie Lebrun[1]; Emilie Afonso[2, 3]; Stéphanie Guerin-Marichez[2]; Véronique Plichon[3]; Géraldine Carlu[2]; Carine Delayre-Orthez[1]
[1]IDEALISS,URL 7519, Institut Polytechnique UniLaSalle, Beauvais, France; [2]Campus des Métiers et des Qualifications d'Excellence Tourisme et Innovation, Touquet, France, CMQ, Lille, France; [3]Campus des Métiers et des Qualifications d'Excellence Autonomie Longévité Santé, Lille, France, CMQ, Lille, France

BACKGROUND AND OBJECTIVES
As changes in lifestyles and eating habits are responsible for a massive increase in chronic diseases related to diet, there is a need to develop innovative awareness-raising and training programs on the challenges of a healthy, sustainable diet and a diet adapted to the needs of vulnerable people. The 5 year AlimCare project aims to contribute to increase the skills of professionals and educators in the field of catering, health and personal care, whether at home or in a care facility, empowering them to contribute to improving the health of populations.

METHODS
The methdology is based on the development of evidence-based education and training programs (initial and lifelong), practical workshops, particularly culinary workshops, interactive digital workshops and videos. 7 action areas have been determined. In addition, demonstration and experimentation sites will be constructed such as the HealthLab as innovative center for translational studies with transdisciplinary and participatory interventions. All activities targt two topics: 1) healthy and sustainable food to prevent chronic diseases in the general population and 2) food adapted to the needs of frail people (living at home or in care facilities) for better care of people suffering from chronic diseases, while preserving flavours and pleasure of eating. The demonstrations are specially designed for the local food culture and highlighting emblematic products from French regions.

RESULTS
The project ALIMCARE, which will be presented during the event, is a unique initiative both in terms of its topics and its targets. No other similar program has been identified internationally.

CONCLUSIONS
The AlimCare projet propose a new device for the creation and enrichment of initial and continuing health training through food for catering, support for people, home support and care pathways, with a potential for international dissemination.

CONFLICTS OF INTERESTS
The authors have no conflict of interest.

1. The project ALIMCARE is funded by the French government as part of the “Compétences et Métiers d’Avenir” call for expressions of interest under the France 2030 program operated by the Caisse des Dépôts. There will be no need to raise additional funds.

ORGANOLEPTIC PROPERTIES, NUTRITIONAL CONTENT AND LACTAGOGAL ACTIVITY OF CHICKEN-HERB ESSENCE

Ahmad Sulaeman[1]; Erma Puspasari,[1]
[1]Human Ecology, IPB University, Bogor, Indonesia

BACKGROUND AND OBJECTIVES
Breastfeeding is one of the important stages in the First 1,000 Days of Life, therefore the sufficient production of breast milk is very substantial. Chicken-herb essence, rich in protein and amino acids, has noticeable benefits, one them is stimulate breast milk production. However, research on its efficacy is still limited. Moreover, the commercially available chicken essence was less preferred. This study aims to formulate a functional drink of chicken essence combined with herbs in order to improve the sensory quality

METHODS
The stages of the research were reformulation of the chicken-herb essence, sensory evaluation and nutritional content analysis

RESULTS
Chemical content showed that 100 g of selected chicken-herb essence contained 121.75 kcal energy, 4.05 g protein, 0.73 g ash, 68.84 g moisture, 26.39 g carbohydrates, and <0.02 g fat. It was detected dipeptide 353,52 ng/mL, 0.31mg Iron/100 g, 14 mg calcium/100 g. Essential and non-essential amino acids were detected with SAA (methionine and cystin) as the limiting amino acid (AAS = 6.66).

CONCLUSIONS
The developed formula (F1-F4) was more preferably and acceptable (aroma, viscosity, taste, mouth-feel, and overall) compared to the commercial one. Lactagogue test in this research (using animal model) showed an increase milk production with difference in baby rat weight is 0.68 units. Therefore Chicken-herb Essence has an effect for improving milk production.

MICRONUTRIENT % DAILY VALUES IN FOCUS: SHIFTING FROM DAIRY TO PLANT-BASED MILK ALTERNATIVES

Gerieka Anapi[1]; Airisse Rae Basinang[1]; Jin Mark Pagulayan[1]; Casiana Blanca Villarino,[1]
[1]Department of Food Science and Nutrition, University of the Philippines Diliman, Quezon City, Philippines

BACKGROUND AND OBJECTIVES
As the demand for plant-based milk alternatives (PBMiA) grows, assessing their impact on micronutrient % daily value (%DV) is essential. This study measured the effect on the micronutrient %DV of Filipinos with the substitution of dairy milk (DM) with PBMiA.

METHODS
Micronutrient data from PBMiAs and DM nutrition labels sold in Metro Manila were collected. The % DV was calculated based on age categories in the Philippine Dietary Reference Intakes (PDRI).

RESULTS
Calcium %DV will decrease ($p<0.05$) by 6.54–14.65% when all groups shift to coconut-based (COB) and legume-based (LEB) alternatives but not with cereal-based (CEB) or nut-based (NUB). CEB and LEB will increase potassium %DV ($p<0.05$) of adults by 0.07–4.35% while COB and NUB will decrease it (2.23–5.97%). In children, CEB will increase potassium %DV ($p<0.05$) by 5.70%, while NUB will decrease it (7.60%). As expected, sodium %DV will increase ($p<0.05$) by 0.52–5.00% in adults with no effect ($p>0.05$) on the % DV for children. In contrast, zinc %DV and vitamin B1 % DV of all groups will decrease ($p<0.05$) by 105.20–167.00% and 11.70-26.40%, respectively, in all groups. Vitamin B12 %DV will increase with CEB and NUB but will decrease with COB and LEB in adults and with COB in children.

CONCLUSIONS
These RESULTS suggest that shifting from DM to PBMiAs has varied impacts on Filipino consumers' %DV of key micronutrients, highlighting the importance of these factors in informed decision-making.

EFFECTS OF SMALL-QUANTITY LIPID-BASED NUTRIENT SUPPLEMENTS ON MARKERS OF MICRONUTRIENT STATUS, INTESTINAL HEALTH, INFLAMMATION, GROWTH, AND NEURAL FUNCTION AMONG YOUNG ZAMBIAN CHILDREN: A SECONDARY ANALYSIS OF A RANDOMIZED CONTROLLED TRIAL

Jacqueline Lauer[1]; Juha Pyykkö[2]; Mpela Chembe[3]; Tamara Bilima-Mulenga[3]; Dorothy Sikazwe[4]; Bertha Chibwe[5]; Savanna Henderson[6]; Doug Parkerson[6]; Jukka Leppänen[7]; Günther Fink[8]; Peter Rockers[2]; Lindsey Locks[1]

[1]Department of Health Sciences, Boston University, Boston, United States of America; [2]Department of Global Health, Boston University School of Public Health, Boston, United States of America; [3]Zambia Country Office, Innovations for Poverty Action Zambia, Lusaka, Zambia; [4]Zambian Ministry of Health, Government of Zambia, Lusaka, Zambia; [5]CIDRZ Central Laboratory, Centre for Infectious Disease Research in Zambia, Lusaka, Zambia; [6]Washington DC Office, Innovations for Poverty Action, Washington DC, United States of America; [7]Department of Psychology and Speech-Language Pathology, University of Turku, Turku, Finland; [8]Epidemiology and Household Economics, University of Basel, Basel, Switzerland

BACKGROUND AND OBJECTIVES

Research suggests that provision of small-quantity lipid-based nutrient supplements (SQ-LNS) benefits growth, development, and survival outcomes among infants and young children in low-resource settings. However, the mechanisms underlying the positive impact of SQ-LNS on these outcomes are not fully understood. To help elucidate these mechanisms, we sought to examine the effects of SQ-LNS on markers of micronutrient status, intestinal health, inflammation, growth, and neural function among young Zambian children.

METHODS

We conducted intention-to-treat, subgroup analyses of 318 children from Zambia enrolled in a 2x2 cluster-randomized trial assessing the effects of SQ-LNS, as well as home-installed growth charts, on linear growth after 18 months of intervention. At endline, hemoglobin was assessed in children's homes using HemoCue devices. At a local hospital, an eye-tracking assessment (n=314) was performed along with a blood draw (n=240). Additional markers of micronutrient status (soluble transferrin receptor, ferritin, retinol binding protein 4, and thyroglobulin) as well as intestinal health (soluble CD14 and intestinal fatty acid binding protein), inflammation (alpha-1-acid glycoprotein and C-reactive protein), and growth (insulin-like growth factor 1 and fibroblast growth factor 21) were assessed via the Multiple-Micronutrient and Environmental Enteric Dysfunction Assessment Tool (MEEDAT). Neural function was assessed via saccadic reaction time. Comparisons by receipt of SQ-LNS vs. not were performed using both unadjusted and adjusted ordinary least squared regression models.

RESULTS

Children in our sample were ~31 months of age and ~54% were female. Just over half (~52%), were stunted at endline. We found no statistically significant differences in markers of micronutrient status, intestinal health, inflammation, growth, or neural function in children who received SQ-LNS vs. not.

CONCLUSIONS

Overall, 18 months of SQ-LNS provision with high rates of adherence had little to no impact on select markers of micronutrient status, intestinal health, inflammation, growth, or neural function in young children in Zambia. These RESULTS indicate that the demonstrated benefits of SQ-LNS for infants and young children are likely through alternative pathways, which should be explored in future research studies.

ARE PLANT-BASED DIETS THE WAY FOR MEAT LOVING SOUTH AFRICANS? A QUALITATIVE APPROACH

Vhushavhelo Nedzingahe[1]; Mthokozisi Kwazi Zuma[2]; Nelene Koen[3]; Xikombiso Mbhenyane[4]
[1]Human Nutrition, Stellenbosch University, Stellenbosch, South Africa; [2]Research, Agricultural Research Council , Pretoria, South Africa; [3]Department of Global Health, Division of Human Nutrition, Faculty of Medicine and Health Sciences, Stellenbosch University, Cape Town, South Africa; [4]Human Nutrition, Faculty of Medicine and Health Sciences, Stellenbosch university,, Cape Town, South Africa, South Africa

BACKGROUND AND OBJECTIVES
Plant-based diets focus on eating more foods derived from plants, such as fruits, vegetables, grains, nuts, and seeds, while reducing the consumption of animal products like meat and dairy (Satija & Hu, 2018). This dietary approach can lead to various health benefits, including better heart health, improved weight management, and a lower risk of chronic diseases. Shifting the focus to plant-based food sources can lower body weight, high blood pressure and risk of heart disease, cancer and diabetes - and can contribute to the environmental impact sustainability (FAO et al, 2019). The South African population has increasingly been facing multiple burdens of malnutrition that includes undernutrition and overweight, obesity, and nutrition-related non-communicable diseases (WHO, 2017). Poor diet is one of the factors that contribute to the increasing rates of overweight, obesity and non-communicable diseases. This study explored the knowledge, attitudes, perceptions and health benefits of plant-based diets amongst South Africans.

METHODS
The study design was a Participatory Action Research, using qualitative approach. A total of 8 focus group discussions were conducted in four provinces. ATLAS.ti 24 computer software was used for analysis.

RESULTS
Participants were knowledgeable about plant-based diets and had a positive outlook on the healthfulness of plant-based diets. The primary reason for not adopting plant-based diets was their cost. A lack of information from health professionals regarding plant-based nutrition facts was expressed. Multiple layers of contextual factors influenced the consumption of plant-based foods and these have been categorised into themes: 1. Knowledge, attitudes and perceptions on plant-based foods; 2. Evolution of dietary patterns and the food system: past, present and influencing factors; 3. Benefits and relationship between plant-based foods and non-communicable diseases; 4. Healthy food environment through home gardening; 5. Actions that can be used to promote the consumption of plant-based diets; 6. Health and nutrition advice for better wellbeing; 7. Animal rights and traditional/cultural beliefs.

CONCLUSIONS
While participants agreed on the health benefits that are associated with the plant-based diets, there are barriers that cannot be overlooked in the South African context. This includes the perceived affordability of the diet and the meat-eating culture that has taken over the country.

BARRIERS AND ENABLERS TO MULTIPLE MICRONUTRIENT SUPPLEMENTATION ADHERENCE IN CAMBODIA: PERSPECTIVES FROM PREGNANT WOMEN, FAMILIES, AND HEALTH PROFESSIONALS

Jocelyne Labonté[1]; Mai-Anh Hoang,[2]; Aishwarya Panicker[3]; Kroeun Hou[4]; Sokchea Meng[4]; Sambo Sreang[4]; Sokhal Vin[3]; Cassandra Sauer[5]; Mary Chea[6]; Crystal Karakochuk[5]

BACKGROUND AND OBJECTIVES
In Cambodia, iron-folic acid (IFA) supplements have long been provided to pregnant women through antenatal care services at government-run health centers. While IFA supplements can reduce health risks for pregnant women and their offspring, growing evidence suggests that multiple micronutrient supplements (MMS) are a superior prenatal supplement (1-3). The Cambodian Ministry of Health is currently assessing the possibility of transitioning from IFA supplements to MMS as part of the country's standard antenatal care package. The identification of factors that may affect MMS adherence is a critical component of that assessment, as low adherence can compromise supplementation effectiveness. The objective of this study was to explore the potential barriers and enablers to MMS adherence, based on the insights of pregnant women, their family members, and health professionals in Cambodia.

METHODS
Data were collected in the semi-rural province of Kampong Thom in April 2023. Three focus group discussions were held with each of the following groups: pregnant women (n = 19 total participants), family members (n = 18), and midwives (n = 18). Additionally, three in-depth interviews were conducted with maternal and child health chiefs (n = 3), who oversee antenatal care in health centers. Data were analyzed via content analysis through the lens of the social ecological model, using NVivo 14.

RESULTS
Participants highlighted the roles pregnant women, family members, the health system, and community norms may play in influencing MMS adherence. Identified barriers included concerns among pregnant women and their family members about the supplement's quality, side effects, and safety. Additional challenges, such as limited access to antenatal care services and disruptions in prenatal supplement supply chains, were also noted as potential barriers. Conversely, supplementation enablers included the willingness of pregnant women and their families to learn more about MMS, and their openness to a supplement that is safe, effective, and endorsed by the Ministry of Health or health professionals. Moreover, midwives' strong prenatal education and counseling skills, alongside the established norms of prenatal supplementation in Cambodia, may also promote MMS adherence.

CONCLUSIONS
This study provides valuable insights into the factors that could impact MMS adherence among pregnant women in Cambodia. These findings will inform strategies to support the country's transition from IFA supplements to MMS.

NUTRIENT COMPOSITION AND IRON BIO-ACCESSIBILITY OF SOME INDIGENOUS GREEN LEAFY VEGETABLES AND LEGUMES IN GHANA

Patience Atitsogbey[1]; Matilda Steiner-Asiedu[1]; Emmanuel Kyereh[2]; Alan Smalley[3]; Robert Akparibo[4]; Viren Ranawana[4]; Menon Manoj[5]
[1]Nutrition and Food Science, University of Ghana, Accra, Ghana; [2]Food Research Institute, Center for Scientific and Industrial Research, Accra, Ghana; [3]School of Mechanical, Aerospace and Civil Engineering, The University of Sheffield, Sheffield, United Kingdom; [4]School of Medicine and Population Health, The University of Sheffield, Sheffield, United Kingdom; [5]School of Geography and Planning, The University of Sheffield, Sheffield, United Kingdom

BACKGROUND AND OBJECTIVES
Background: Indigenous leafy green vegetables and legumes are nutritious, affordable, and readily available sources of essential micronutrients. Promoting their consumption can improve health, especially in low-income communities. **Objective:** To determine the chemical composition and iron bioaccessibility of indigenous green leafy vegetables and legumes commonly consumed in Ghanaian households

METHODS
Methods:: Five green leafy vegetables and three legumes were purchased, steamed/cooked, cooled, and freeze-dried for analysis. β-carotene content was quantified using modified ISO BS EN 12823:1-2014, and vitamin A equivalents were estimated. Vitamin C was determined using the 2,6-dichlorophenolindophenol method. Iron was determined using acid digest and ICP-MS, and iron bioaccessibility was assessed using a static in vitro gastric digestion method and ICP-MS. Phytate was determined using a titration method. Data were analyzed using one-way ANOVA and presented on a dry matter basis

RESULTS
RESULTS: The green leafy vegetables had significantly higher amounts of all examined nutrients compared to the legumes, though phytate levels varied. RESULTS are presented in the Table. All values in mg/100g except Vit A which is in µg RAE/100g; RAE=Retinol Activity

	β-Carotene	**Vit A**	**Vit C**	**Iron**	**Iron BA**	**Phytate**
Xanthosoma s.	10.39a	1732.84a	47.44d	9.60ab	2.31b	0.09bc
Corchorus olitorius	5.86d	977.74d	70.81b	17.52ab	5.77ab	0.14ab
Spinacia olerace	1.59e	264.50e	40.60e	36.45ab	8.05a	0.19a
Talinum triangulare	8.79b	1466.00b	79.07a	39.80a	4.99ab	0.11bc
Taraxacum officinale	7.99c	1334.18c	35.44f	22.57ab	3.54b	0.05c
Phaseolus vulgaris	0.04a	4.50c		4.33ab	0.75a	0.11a
Vigna angularis	0.05a	8.33a		7.19a	2.11a	0.13ab
Arachis hypogaea	0.04a	5.59b		2.79b	2.03a	0.08b

CONCLUSIONS
CONCLUSIONS: Green leafy vegetables generally contain higher quantities of β-carotene, vitamin C, iron content, and iron bioaccessibility. Among legumes, red beans and peanuts had more bioaccessible iron and less vitamin A precursor, and low phytate levels in both foods. These foods have the potential to alleviate micronutrient deficiencies when consumed daily and could be promoted through nutrition education and advocacy.

AUTOMATIC MENU CREATION FOR SCHOOL LUNCH BASED ON ESTIMATION OF DISH GENRES CONSIDERING THE FUSION OF MULTIPLE GENRES

Mayu Takiguchi[1]; Yuki Mekata[1]; Hideki Katagiri[1]
[1]Department of Industrial Engineering and Management, Kanagawa University, Kanagawa, Japan

BACKGROUND AND OBJECTIVES

In Japan, it has become common to include multiple dish genres in a menu. For example, multiple genres, such as Japanese, Western, and Chinese are included in one menu. Many elementary and junior high schools in Japan provide school lunch, which are important in passing on food culture such as the fusion of multiple genres. Creating a school lunch menu takes a lot of time and effort because it requires consideration of various factors, such as nutritional intake, ingredient costs, and dish genres.

In previous studies on automatic menu creation for school lunch, models based on combinatorial optimization that consider nutritional intake and ingredient costs were proposed. However, menus were created by combining dishes from the same genre, so the models were not able to create menus that combined multiple genres. In this study, we propose an algorithm that automatically estimates the dish genres to assign multiple genres to a menu. We aim to automatically create school lunch menus that consider the fusion of multiple genres based on genre estimation.

METHODS

To estimate the dish genres, we focused on the name of the dish. If the name of the dish contained words related to a genre, we assigned the genre to the dish. Next, we focused on the combination of dishes in a menu. The genre assigned to the staple food or main dish was also assigned to the other dishes in a menu. We constructed an algorithm that performs these procedures automatically.

We formulated a menu optimization problem based on a model proposed in a previous study. We constructed a model that creates menus that include multiple genres by setting one genre for each menu and selecting dishes that include the genre within the assigned genres.

RESULTS

We applied the proposed genre estimation algorithm to dishes contained in school lunch menu data. We confirmed that it is possible to assign multiple genres to one dish. Furthermore, from the RESULTS of menu creation using the model, it was possible to create a menu that combined multiple genres. By using the model based on genre estimation, it was possible to realize combinations of dishes that were not possible in previous studies.

CONCLUSIONS

In this study, we proposed an algorithm to automatically estimate the dish genres. We also automatically created a menu that combined multiple genres. As a result, it became possible to create a menu similar to the one actually served at school lunch in Japan.

MAPPING AND CHARACTERIZATION OF SOLIDARITY KITCHENS IN BRAZILIAN REGIONS

Mariana Iamamoto[1]; Semíramis Martins Álvares Domene[2]; Aline Rissatto Teixeira[1]
[1]Nutrition, University of Sao Paulo, School of Public Health, São Paulo, Brazil; [2]Health and Society Institute, Federal University of São Paulo, Santos, Brazil

BACKGROUND AND OBJECTIVES
The COVID-19 pandemic exacerbated the issue of food insecurity in Brazil, worsened by the lack of government action during that period. In response, social movements mobilized to mitigate the hunger crisis across various Brazilian states. Brazilian Law No. 14,628 of 2023 marks the creation of the Solidarity Kitchen Program, highlighting the political commitment to ensure the Human Right to Adequate Food (HRAF), as established in the Federal Constitution. The Program aims to recognize Solidarity Kitchens (SKs) that are committed to providing free, quality meals to the population, prioritizing vulnerable groups, including people experiencing homelessness. This context emphasizes the importance of developing and implementing concrete actions to maintain and improve the operation and infrastructure of these spaces. This research aims to describe and characterize the SKs, considering social vulnerability indicators in territories across Brazilian regions.

METHODS
Data were collected using the Registration Form for Solidarity, Popular, and Community Kitchens, developed by the Ministry of Social Development and Assistance, Family, and Fight Against Hunger. The form received 2,466 responses between May and November 2023, and the database was shared on March 22, 2024. After excluding 811 non-operational kitchens, 1,655 fully functional kitchens remained. These data were cross-referenced with Social Vulnerability Indicators from the Institute for Applied Economic Research.

RESULTS
The mapping revealed that many municipalities with high or very high vulnerability do not have any SKs available, with most of these units being concentrated in capital cities or nearby areas. Over 50% of SKs in all Brazilian regions reported a lack of IT infrastructure (computer with internet access), with the worst situations observed in the South (66.4%), Northeast (65.2%), and North (60.9%) regions, followed by the Center-West (56.5%) and Southeast (54%). This scenario hinders communication with government agencies and affects the evaluation of public policies that support or invest in SKs. Additionally, 18.8% and 20% of SKs in the North and Northeast regions (the hottest areas in the country), respectively, reported not having refrigerators (compared to 5.8% in the Southeast, 9% in the South, and 9.8% in the Center-West), negatively impacting the productivity of these spaces and the quality of meals, thus compromising services to the population.

CONCLUSIONS
These RESULTS may support the formulation of public policies to guarantee HRAF in vulnerable territories and to create a network-based, intersectoral model to support SKs.

IMPACT OF A CARBOHYDRATE EDUCATIONAL TOOL WITH FIBER CONTENT ON DIABETES SELF-MANAGEMENT

KuanChing Lai[1]; Yuan Xin[2]
[1]Nutrition Division and Inter-professional integrated care service, Hsinchu Cathay General Hospital, Hsinchu city, Taiwan; [2]Nutrition Division, Hsinchu Cathay General Hospital, Hsinchu city, Taiwan

BACKGROUND AND OBJECTIVES
This study evaluates the effectiveness of a carbohydrate educational tool designed to improve self-care in diabetic patients. The tool is a color-coded system (green, yellow, red) based with dietary fiber content to improve patient in making healthier food choices.

METHODS
Over six months, 67 participants (mean age 57.1 ± 14.4 years) were enrolled. The intervention's impact was assessed using paired sample t tests and Pearson's correlation coefficients.

RESULTS
Significant improvements in HbA1C levels were observed, decreasing from 8.6 ± 2.5% to 7.4 ± 1.5% ($t = 4.007$, $p = 0.001$). Correlations between Self-Care score and HbA1C(after), and dietary attitude were medium correlation ($r=0.323,0.442$, respectively). Self-Care score and dietary fiber intake, dietary cognition were low correlation ($r=0.259, 0.244$, respectively). Participants who frequently chose green-labeled foods had higher dietary fiber intake and better scores in self-efficacy, dietary cognition, and dietary attitude. The tool effectively enhanced patients' ability to make informed food choices, supporting better blood sugar management.

CONCLUSIONS
The carbohydrate educational tool with fiber content significantly improved diabetic self-effective, self-management, dietary cognition, attitude, and better to blood sugar control.

FOOD-BASED INDICES FOR THE ASSESSMENT OF NUTRITIVE VALUE AND ENVIRONMENTAL IMPACT OF MEALS AND DIETS: A SYSTEMATIC REVIEW

Eva-Leanne Thomas[1]; David Livingstone[1]; Anne P. Nugent[1, 2]; Jayne Woodside[3]; Leona Lindberg[1]; Paul Brereton[1]

[1]Institute for Global Food Security, Queen's University Belfast, Belfast, United Kingdom; [2]School of Agriculture and Food Science, University College Dublin, Dublin, Ireland; [3]School of Medicine, Dentistry and Biomedical Sciences, Queen's University Belfast, Belfast, United Kingdom

BACKGROUND AND OBJECTIVES

Food consumption practices are impacting both human and planetary health [1, 2]. Food-based labelling is a commonly used strategy intended to influence consumption practices. To date most food-based labelling focuses on the nutritive value of foods, however, there is a growing need to include information on the environmental impact of foods and meals [3]. This complex information may make it difficult for consumers to improve food choices with respect to human and planetary health. A simplified approach is needed that expresses a foods health *and* environmental value. This systematic review aimed to identify existing food-based indices that classify or rank meals and diets in terms of nutritive value and environmental impact – termed Nutritive and Environmental Combined Indices (NECIs). The review examined the key characteristics of NECIs and identified their intended public health purpose.

METHODS

Following the PRISMA 2020 standardised reporting guidelines, six bibliographic databases were searched using keywords related to ‘nutrition’, ‘environment’, ‘health’, ‘index’, ‘meal’ and ‘diet’. Records of retrieved studies were screened independently using Ryyan software by two reviewers.

RESULTS

21 studies were included for analysis in the review. Within these studies 21 NECIs were identified, with 5 specifically designed for use in meals, 8 for diets, and 8 offering scope to be applied to meals or diets. 48% of indices (n=10) incorporated an additional sustainability dimension, most commonly economic (n=8). Most indices, 71%, presented nutritive and environmental scoring as a single metric (n=15), 19% of indices presented scores in parallel (n=4), and two studies presented their respective indices as both a single metric and in parallel. The 21 NECIs varied widely in their nutritional and environmental scoring methods, functional units, system boundaries, and ranking approaches. The most common approach to scoring the nutritional and the environmental dimensions of NECIs was the Nutrient Rich Diet (NRD) score (n=6) and Life Cycle Assessment (n=14), respectively, and among single-metric NECIs, 47% applied equal weighting to included dimensions (n=8).

CONCLUSIONS

This systematic review highlights the number, and methodological variety, of existing food-based labelling indices that assess nutritive value and environmental impact of meals or diets. These findings can be used to assist public health actors in the future development of a standardised index to support healthy and sustainable meal and diet choices.

THE EFFECT OF QUINTUPLY-FORTIFIED SALT ON THE GUT MICROBIOME OF NON-PREGNANT WOMEN OF REPRODUCTIVE AGE IN PUNJAB, INDIA; A SUBSTUDY OF A RANDOMIZED, COMMUNITY-BASED TRIAL

Lauren Thompson[1]; Yvonne E Goh[2]; Manu Jamwal[3]; Gurjinder Brar[3]; Bidhi Singh[3]; Charles D. Arnold,[1]; Angela Zivkivic,[1]; Nancy Krebs[4]; Reena Das[3]; Mona Duggal[5]; Christine Mcdonald[6]

BACKGROUND AND OBJECTIVES
Women of reproductive age (WRA) in resource-limited settings are vulnerable to multiple micronutrient deficiencies including iron, zinc, folate, and vitamin B12. Large-scale food fortification (LSFF) of staple foods and condiments offers a cost-effective approach to improving micronutrient intake. However, the impact of LSFF on the gut microbiome remains poorly understood. This analysis aimed to determine whether quintuply-fortified salt (i.e. salt fortified with iron, zinc, vitamin B12, folic acid, and iodine) alters the gut microbiome in non-pregnant WRA (NPWRA) after 12 months.

METHODS
A double-blind, randomized, controlled community-based trial was conducted among 998 NPWRA (18-49 years) in Punjab, India. Eligible participants were randomized to receive: 1) quintuply-fortified salt with 1.3 mg iron in the form of encapsulated ferrous fumarate, 1.4 mg zinc, 0.6 µg vitamin B12, 52 µg folic acid, and 30 µg iodine (eFF-Q5S); 2) quintuply-fortified salt with the same micronutrients, but with iron in the form of encapsulated ferric pyrophosphate plus EDTA (FePP-Q5S); or 3) standard iodized salt (IS). Stool samples were collected from a subsample of NPWRA representing all three study groups at baseline and 12 months and subjected to 16S rRNA gene sequencing. Linear mixed models were used to estimate intervention effects on alpha diversity (Shannon index and the abundance-based estimator (ACE) index). Permutational MANOVA (PERMANOVA) was used to test Bray-Curtis dissimilarity between groups (beta diversity). Zero-inflated negative binomial mixed models were used to evaluate intervention effects on the relative abundance of individual taxa.

RESULTS
Among the 129 NPWRA who provided both a baseline and 12-month stool sample, 86 had sufficient read depth following sequencing (eFF-Q5S, n = 33; FePP-Q5S, n = 26; IS, n= 27). Mean ± SD household salt intake across the intervention period ranged from 6.24 ± 1.31 g/adult female equivalent (AFE) per day in the FePP-Q5S subgroup to 5.68 ± 1.13 g/AFE per day in the IS subgroup. The most abundant genus groups at baseline were *Prevotella* (24.9%) and *Bifidobacterium* (10.6%). Neither alpha diversity nor beta diversity differed significantly at baseline or at the end of the 12-month intervention. There was no difference in the relative abundance of *Enterobacteriaceae*, *Lactobacillus*, and *Bifidobacterium*, *Prevotella or Streptococcus* across groups following the 12-month intervention period.

CONCLUSIONS
Quintuply-fortified salt did not appear to alter the gut microbiome of NPWRA in Punjab, India.

ESTIMATING THE HEALTH IMPACTS OF LOW-SODIUM PEA PROTEIN ISOLATE-BASED MEALS

Marta Bianchi[1]; Edoardo Desiderio,[2]; Susanne Bryngelsson,[2]; Jun Niimi,[1]; Joshua Mayers,[1]; Tim Nielsen,[2]
[1]Food and Agriculture, Rise Research Institutes Of Sweden, Gothenburg, Sweden; [2]Food and Agriculture, RISE Research Institutes of Sweden, Lund, Sweden

BACKGROUND AND OBJECTIVES

The development and consumption of plant-based meat alternatives is on the rise in Sweden as elsewhere in Europe. Many of these products have high sodium content [1]. Efforts are therefore needed to improve their nutritional profile. In this project, the process to obtain pea protein isolate (PPI), a major ingredient in many plant-based products, is optimized to achieve a reduced sodium content. Objective of this work is to estimate the health impact of meals based on reduced sodium pea protein versus current sodium pea protein as well as against meat-based meals.

METHODS

A diet scenario is modelled based on consumption of a pasta meal containing either mince from an extruded low sodium PPI, standard sodium PPI or meat mince (mixed beef and pork). The recipe is based on one widely used in public school meals in Sweden. The nutritional and protein profile of meals are estimated with the Nutrient Rich Food index (NRF) 11.3 [2] and the quality-corrected (q-c) protein score [3]. The health impact of reduced sodium intake is estimated according to the HENI index by obtaining characterization factors specific for Sweden from the Global Burden of Disease study [4].

RESULTS

RESULTS are preliminary, as the project is still on-going. The process optimization to obtain a low sodium PPI is described elsewhere [5]. The optimized PPI contains ≤ 0,1 g/100 g sodium, and the derived texturized product has at least a 4 times lower sodium than commercial products. Nutritional analytical data are not yet available for the low sodium texturized mince, therefore NRF11.3 and the q-c protein score are estimated from food composition tables [6]. Nutrient density according to NRF11.3 of the low sodium PPI pasta meal is more than double that of a meat pasta meal (40 vs. 18 NRF score) but only slightly higher than a regular salt PPI pasta meal (38 NRF score). However, the q-c protein is 34% higher in the meat mince than in both the pea-based minces. For the assessment of the HENI index, the calculation of dietary risks factors specific for Sweden is on-going. Using the best available data from a Dutch study [7], and accounting only for the sodium content, a portion of the low sodium PPI pasta meal contributes to 48% and 17% less minutes of healthy life lost compared to a meat or regular salt plant-based pasta meals, respectively.

CONCLUSIONS

This study preliminarily indicates that a low sodium plant-based meal could provide higher nutrient density and less minutes of life lost compared to a meat-based meal, and only marginally compared to a regular salt plant-based meal.

A GLANCE OF TRADITIONAL FOOD SYSTEMS AMONG KAZAKH AND KYRGYZ PEOPLES IN THE EURASIAN STEPPE IN TEKES, XINJIANG, CHINA

Zeyuan Wang[1, 2]; Mengyao Ma[3]; Yatong Carris Jiang[4]; Xiaohui Liu[5]; Li Yihong[3]
[1]Social and Behavirol Health Sciences, University of Toronto, Toronto, Canada; [2]Culinaria Research Center, University of Toronto Scarborough, Toronto, Canada; [3]Good Food Fund China, Good Food Fund China, Beijing, China; [4]Department of Nutrition, University of Alberta, Edmonton, Canada; [5]School of Ethnology and Sociology, Minzu University of China, Beijing, China

BACKGROUND AND OBJECTIVES

Eurasia's steppe, the world's largest contiguous rangeland, has supported nomadic pastoralism for over 5,000 years. The Kazakh and Kyrgyz, cross-border ethnic groups primarily residing in Kazakhstan, Kyrgyzstan, and China, face high rates of non-communicable diseases (e.g., hypertension) and micronutrient deficiencies (e.g., iron). However, their traditional food systems remain understudied. Existing literature and policies focus on meat and milk, disregarding the historical use of diverse fruits, nuts, and herbs by Kazakh nomads documented by Russian anthropologists in the 17th Century.

METHODS

To address inconsistencies between current knowledge and historical records, a questionnaire based on Xinjiang Agricultural University's research into wild edibles was used. Elders with pastoral experience were invited via chain sampling to identify ingredients, describe preparation methods, and discuss medicinal uses. Interviews continued until data saturation, involving 30 participants from Tekes, Xinjiang—a settlement for Kazakh and Kyrgyz peoples with nomadic traditions.

RESULTS

A total of 98 food ingredients were identified, including 11 types of animal meat, 7 types of animal milk, 73 wild plants, 2 types of honey, and 5 edible soils. There is a rich tradition of gathering wild plants during grazing and consumed as fruits, jams, or tea. Consuming like tea was the most common way to consume plant-based foods, and almost half of plant-based foods can be consumed like tea. Reducing blood was the most common medicinal function, and approximately 20% of the wild plants were believed to have such a property. Barriers to accessing and using traditional foods included over-grazing, the use of fertilizers, tourism development, resettlement, lifestyle changes, pasture loss, environmental regulations, and climate change. Interaction with Han and Hui groups introduced more knowledge and use of wild plant-based foods and fish.

CONCLUSIONS

This study demonstrates that traditional nomadic food systems include a diverse range of food ingredients that are underutilized and often forgotten in daily life and academic studies. These underutilized foods have huge potential to alleviate non-communicable diseases and micronutrient deficiency and improve plant-based food availability of nomadic people in the Eurasian steppe. To develop sustainable nomadic food systems and promote planetary health on the Eurasian steppe, it is crucial to further study and value the traditional knowledge and food ingredients of nomadic food systems.

BULGARIAN DIETARY TRADITIONS IN THE PAST AND RECENT TIMES AND A LINK TO PLANETARY NUTRITION

Ludmila Ivanova[1]
[1]Faculty of Medicine, Sofia University St. Kliment Ohridski, Sofia, Bulgaria

BACKGROUND AND OBJECTIVES

Bulgarian food patterns have evolved significantly from traditional practices to modern dietary trends, reflecting historical, cultural, and socio-economic changes. Historically the Bulgarian diet centered on locally sourced, seasonal foods, emphasizing plant-based foods such as grains, vegetables, legumes, and less dairy products with low meat, poultry, fish, and egg consumption. In recent decades urbanization and globalization have shifted the dietary habits of Bulgarians to more animal foods, processed and convenience foods, raising concerns about health and sustainability.
However, there is an elevating interest in rediscovering some traditional dietary models and promoting Bulgaria's gastronomic heritage which is in line with the recently promoted planetary nutrition.
The aim is to compare the average dietary intake of some selected foods/food groups by the Bulgarian population at the beginning of the 20th century (1906-1911) and the average intake in the period 2019-2023, as well as with the healthy planetary trends.

METHODS

The sources for food intake data were the available published papers on nutrition and food intake of the Bulgarian population from the beginning of the last century and the recent data from the National Statistics Institute of Bulgaria. The data are presented in g/per person per day. The RESULTS are discussed in line with the directions of the planetary nutrition recommended as a healthier option for human health and the planet

RESULTS

The Bulgarian past times dietary model compared to recent food intake is characterized by low intake of animal foods in g/person/day (red meat- 50.5/101.9; poultry - 3.58/26.7; fish - 4.3/ 16.1, milk and dairy products - 67.6/128.65, eggs – 49/158 pcs per year). The diet is mainly plant foods, rich in wholegrain bread and cereals (665.7/ 255.4 g/person/day), little variety of vegetables, mainly cabbage and beans, and low in fresh fruits (42.05/147.7 g/person/day). The diet from the beginning of the 20th century covers limited consumption of animal protein, and less variety of vegetables and fruits. Some positive trends of the past are the low intake of added sugar (6.3/17.6 g/person/day) and salt.

CONCLUSIONS

The current Bulgarian diet reflects the convergence and adaptation influenced by globalization. Integrating some Bulgarian traditional food patterns from the past with current healthy dietary guidelines can successfully align the diet to the planetary nutrition concept.

NUTRITIONAL STATUS, EATING HABITS, AND NUTRITIONAL EDUCATION IN ADOLESCENT STUDENTS FROM MARGINALIZED COMMUNITIES IN GUANAJUATO: A CALL FOR SUSTAINABLE ACTION

Urquieta Luz[1]
[1]Nutrición, Universidad Abierta y a Distancia de México, Ciudad de México, Mexico

BACKGROUND AND OBJECTIVES
The promotion of sustainable food systems and global health is essential to achieving the United Nations' 2030 Agenda for Sustainable Development. Understanding the nutritional status of vulnerable populations provides critical insights for addressing malnutrition and promoting equity in health and education. This study aimed to evaluate the nutritional status, eating habits, and level of nutritional education among high school students from marginalized communities in Guanajuato, Mexico. Additionally, it highlights the urgent need to improve school meal programs, which currently offer low-nutritional-value foods, by incorporating the expertise of nutritionists and advocating for policy adjustments to combat malnutrition.

METHODS
This cross-sectional study analyzed data from the researcher's teaching activities in natural sciences and physical education with 76 high school students (14–18 years) in Guanajuato. Data collection included questionnaires, dietary recalls, fitness tests, and anthropometric measurements, conducted during routine classes. The data were gathered during routine class activities and anonymized to ensure confidentiality, adhering to principles of respect and confidentiality without requiring formal ethical approval or authorizations.

RESULTS
The study revealed that 49% of participants had a normal weight, 33% were underweight, 13% were overweight, and 5% were obese. Only 15% of students ate breakfast before school, while 71% consumed three to four meals per day. Alarmingly, 80% of the participants regularly consumed foods of low nutritional value, and only 5% included vegetables in their daily diet. A significant protein deficit was also identified, with most students failing to meet recommended dietary intakes, contributing to poor muscle development and physical performance. Moreover, 85% lacked basic knowledge of nutrition, and over 50% exhibited poor physical fitness and muscle strength. Notably, several students relied on school meal programs promoted by the government, which provided meals with inadequate nutritional content, exacerbating poor health outcomes.

CONCLUSIONS
More than 80% of students displayed malnutrition and poor physical performance. Urgent policy adjustments are needed to restructure school meal programs under the guidance of nutritionists to promote sustainable, healthy diets. These changes will empower adolescents to adopt better habits, improving their quality of life and supporting the 2030 Agenda for Sustainable Development.

EXAMINING THE EFFECT OF EGGS IN PREGNANCY ON CHILD GROWTH AND DEVELOPMENT: STUDY DESIGN, STUDY POPULATION, AND ADHERENCE IN A RANDOMIZED CONTROLLED TRIAL IN RURAL RWANDA

Chhavi Tiwari[1]; Apolline Kampire[2]; Eric Matsiko[3]; Aloys Nsabimana[4]; Heather Stark[5]; Juan Andrade[6]; Yang Yang[7]; Etienne Nsereko[2]; Miles Kirby[8]; Sarah Mckune[1]
[1]Department of Environmental and Global Health, University of Florida, Gainesville, United States of America; [2]College of Medicine and Health Sciences, University of Rwanda, Kigali, Rwanda; [3]Department of Human Nutrition and Dietetics, University of Rwanda, Kigali, Rwanda; [4]Health and Nutrition, World Vision Rwanda, Kigali, Rwanda; [5]Epidemiology, University of Florida, Gainesville, United States of America; [6]Department of Food Science and Human Nutrition, University of Florida, Gainesville, United States of America; [7]Department of Statistics, Franklin College of Arts and Sciences, University of Georgia, Atlanta, United States of America; [8]Research, Learning, and Analytics Unit | Evidence and Learning Team, World Vision International, Maine, United States of America

BACKGROUND AND OBJECTIVES
Adequate nutrition during pregnancy is essential for maternal and child health. Animal-source foods (ASF), such as eggs, have been shown to positively impact child growth and development in some settings, but less is known about benefits if consumed consistently during pregnancy. The *Deux Oeufs* study is a randomized controlled trial designed to assess the effects of egg supplementation on maternal health and child growth outcomes in rural *Nyagatare* District, Rwanda. This paper describes the study design, baseline characteristics of the study population, and preliminary adherence findings.

METHODS
We will enroll 956 pregnant women and randomize into two groups: a treatment group provided two eggs daily (directly observed) from enrollment in the first trimester until childbirth, and a control group maintaining their typical diet. All participants will receive standard prenatal care, a fortified flour, health insurance, mobile phones, and modest compensation. The primary outcome is child length-for-age z-score at birth. Secondary outcomes include maternal health metrics and child growth and neurodevelopment measures during pregnancy, at birth, and at six weeks and six months postpartum.

RESULTS
As of December 01, 2024, 386 women have been enrolled and enrollment is expected to be completed by August 2025. Initial RESULTS show that 89.7% of intervention women have attended at least 90% of possible egg consumption days, and intervention women have consumed the dose of two eggs on 99.8% attended consumption days. Additional RESULTS will include a full description of the study design, baseline characteristics of study participants, including nutritional status, prevalence of ASF consumption, dietary diversity, food security, demographic and socioeconomic status, and intervention adherence data.

CONCLUSIONS
To our knowledge, this is the first trial to examine the effects of providing two eggs during pregnancy in sub-Saharan Africa. Findings will help inform whether the consumption of a locally available and scalable ASF can provide maternal and child health gains that could potentially translate into longer-term benefits.

A MULTI-NUTRIENT PACK IS BENEFICIAL FOR IMPROVING THE NUTRITIONAL AND IMMUNE STATUS OF PATIENTS WITH PULMONARY TUBERCULOSIS: A DOUBLE-BLIND RANDOMIZED CONTROL TRIAL WITH A 6-MONTH FOLLOW-UP

Yang Yang[1]; Aiguo Ma[1]
[1]Department of Nutrition and Food Hygiene, School of Public Health, Qingdao University, Qingdao, China

BACKGROUND AND OBJECTIVES
Nutrition is critical for anti-tuberculosis treatment. The aim of this study is to investigate the effect of a multi-nutrient pack on patients with pulmonary tuberculosis.

METHODS
We conducted a double-blinded, randomized controlled trial in 840 adult patients with pulmonary tuberculosis in China, who were randomly divided into the multi-nutrient pack (containing protein, vitamins A, B1, B2, niacin, B6, folic acid, B12, C, D, E, calcium, iron, zinc, and selenium) intervention group or the placebo (a cereal matrix with no micronutrients) group. The intervention lasted for six months. The nutritional status, clinical symptoms, sputum smear RESULTS, and immune function were recorded during the intervention.

RESULTS
Compared with the placebo group, the multi-nutrient pack intervention significantly improved the patients' body weight, hemoglobin, and total lymphocyte count of patients by 6.3%, 11.1%, and 7.5% respectively at the end of the trial (P=0.044, P=0.044, and P=0.052, respectively). The consumption of multi-nutrient pack improved the differential white blood cell (WBC) count and the lymphocyte subpopulation count. The sputum smear conversion was shorter in multi-nutrient pack group than placebo group (P=0.006). Patients with hypoproteinemia or anemia at baseline benefited more from multi-nutrient pack than those with normal levels.

CONCLUSIONS
In conclusion, the multi-nutrient pack is beneficial for improving the nutritional status, immune function and clinical symptoms especially in hypoproteinemia or anemia patients with pulmonary tuberculosis; which may be related to its optimal compliance, convenience, and low cost during the trial.

DEVELOPING AND VALIDATING AN EXPERIENCE-BASED FOOD-SAFETY SCALE USING QUALITATIVE INSIGHTS FROM BANGLADESH, ETHIOPIA, AND VIETNAM

Sejla Isanovic[1]; Jef Leroy[2]; Silvia Alonso[3]; Edward A Frongillo[1]; Phuong Nguyen[2]; Lina Mego[3]; Aklima Parvin[4]
[1]Health Promotion, Education, and Behavior, University of South Carolina, Arnold School of Public Health, Columbia, United States of America; [2]Nutrition, Diets, and Health Unit, International Food Policy Research Institute, Washington DC, United States of America; [3]Health Program, International Livestock Research Institute, Addis Ababa, Ethiopia; [4]Nutrition, Diets, and Health Unit, International Food Policy Research Institute, Dhaka, Bangladesh

BACKGROUND AND OBJECTIVES
Unsafe foods constitute a major global health challenge with an estimated 600 million episodes of foodborne illness and 420,000 deaths annually. Food safety and nutrition are closely linked: foodborne illness contributes to undernutrition (e.g., through reduced nutrient bioavailability); the most nutrient-dense foods carry the largest food safety risks. Concerns about food safety are important determinants of dietary choice, but current methods to assess food safety overlook consumers' experiences. Our objective was to develop a cross-culturally appropriate and user-friendly scale to assess food safety experiences in LMICs. Developing this scale requires identifying the important constructs that constitute the experiences of food safety that the scale should reflect.

METHODS
A scoping review was conducted to identify existing constructs related to consumers' experiences of food safety from 213 studies. Qualitative interviews were conducted with consumers from Dhaka, Bangladesh (n=51), Addis Ababa, Ethiopia (n=50), and Hanoi, Vietnam (n=41) to provide an in-depth understanding of the cognitive, emotional, social, and contextual constructs that influence food-choice behaviors related to food safety. A constant comparative method was used for coding and analysis.

RESULTS
Food safety was conceptualized as dynamic and multifaceted. Eleven constructs emerged: sensory attributes, attitudes, affect, awareness, knowledge, previous incidents, preferences, risk perceptions, trust, intentions, and behaviors. From interviews, trust, attitudes, risk perceptions, and previous incidents were central in shaping mental representations of food safety and subsequent behaviors. Constructs related to affect were not uniform: concern about chemicals differed from that about cleanliness, environmental hygiene differed from vendor honesty, and worry about a child's reaction to foods differed from family dietary patterns. Trust was linked to specific, repeated interactions and vendor responsiveness. Emotions were salient, making constructs like trust and concern nuanced and tailored to experience. Consumers employed routine strategies and specific, observable indicators to reduce food safety risks.

CONCLUSIONS
Food-choice behaviors related to food safety are complex and necessitate the development of a scale that assesses experiences related to food safety. Insights from the review and interviews informed the development of questionnaire items, which are under review by experts in preparation for cognitive interviewing.

LEVERAGING LOCAL PLANT-BASED INGREDIENTS AND ONLINE PLATFORMS TO MINIMIZE CROWDS AND PREVENT VIRUS TRANSMISSION DURING THE PANDEMIC

Jiyuen Tieng Chen[1]; SHU CHI LIN[2]; Meng Han Hong[2]; Yu-Hsien Chao[2]; Chia Lun Tsai[2]
[1]Department of Nutrition, Taiwan Adventist Hospital, Taipei, Taiwan, Taiwan; [2]Department of Nutrition, Taiwan Adventist Hospital, Taipei, Taiwan

BACKGROUND AND OBJECTIVES
The pandemic underscored the increased risk of cluster infections in traditional markets and supermarkets. To address this, a team of nutritionists launched a non-face-to-face online platform offering "local vegetables and fruits" and "anti-epidemic bentos," with online payment options, to minimize the infection risk for employees.

METHODS
The services, "local vegetables and fruits" and "anti-epidemic bentos," were available from April 2021 to June 2022. Google Forms was used for employees to place orders and select pick-up times. An online survey was conducted to gather employee feedback on their experiences.

RESULTS
A total of 202 responses were received. Of these, 97% of employees believed that a balanced, plant-based meal could help prevent viral infections. Additionally, 91% (183 individuals) felt that purchasing fresh food from external sources increased infection risk. Notably, 97% agreed that the "anti-epidemic bento" effectively reduced the risk of infection and provided a sense of security.

CONCLUSIONS
Most employees indicated that purchasing "local vegetables and fruits" and "anti-epidemic bentos" significantly reduced the risk of cluster infections while providing balanced nutrition to boost immunity. Therefore, the provision of non-face-to-face meal services has proven to be an effective strategy to enhance employee safety, prevent infection, and improve overall quality of life.

GLOBAL POLICY CHANGES ON HOMOLOGOUS SUBSTANCES OF FOOD AND MEDICINE

Xiaoyu Sun[1]; Guiju Sun[1]
[1]School of Public Health, Southeast University, Nanjing, China

BACKGROUND AND OBJECTIVES
Homologous substances of food and medicine (HSFM) are substances that are both food and traditional Chinese medicine (TCM), implementing the TCM concept of "food and medicine homology". Due to the improvement of people's standard of living and the high demand for improving the quality of life, the usage of HSFM is becoming more and more common, and the legislative issue of HSFM is becoming more and more urgent. HSFM now have a clearer definition and related management policies, which are constantly being improved and updated. However, there is little research to sort out and analysis the current status of management in each country. Therefore,we aims to collect the relevant policies that are publicly available in several country and, in particular, elucidates explicitly the historical traceability of HSFM in China, the evolution of the relevant policies, and the catalogue of HSFM that has been updated to date.

METHODS
Sort out the changes in China's dual-use material policy for food and medicine, and analyze the list of HSFM of China. Simultaneously collect and analyze policies similar to HSFM in China of other countries such as the United States, the European Union, South Korea, Japan, and Canada.

RESULTS
The data show that the management of HSFM is similar but not identical among different countries, and that there are areas that can be learnt from each other as well as areas that need to be improved. By analysing the policies of different countries, this paper finds that South Korea, Singapore and China have adopted a catalogue for the management of HSFM, which has avoided the current situation of market scrutiny through a clearer catalogue management.It also points out that there is no country that makes health claims on HSFM in terms of policy, which also limits the development of the HSFM industry to a certain extent . A comparison of policies in different countries shows that policymakers can optimise policies to meet consumer demand and stimulate product development in the market by accelerating the addition of substances to the catalogue of HSFM and attempting to make health claims, among other measures.

CONCLUSIONS
HSFM play a certain role in residents' health, and the national government needs to formulate corresponding policies for effective management.

SLUDGES ON THE WAY OF HEALTHY NUTRITION: UNDERSTANDING BARRIERS TO HEALTHY FOOD CHOICES, INSIGHTS FROM AN EXPERT PANEL

Ana Ines Estevez Magnasco[1]; Christina Vogel[2]; Dominic Lemken[1]
[1]Socioeconomics of Sustainable Nutrition, Bonn University, Bonn, Germany Germany; [2]Centre for Food Policy, City University of London, Northampton Square, London, UK, United Kingdom

BACKGROUND AND OBJECTIVES
Nudge theory has promoted healthier food choices, yet the concept of "sludge" — frictional elements that obstruct beneficial decisions — remains underexplored in food systems. Sludges can manifest in various forms, such as poor product placement in supermarkets, complex labeling in canteens, or insufficient support for informed choices in hospital settings. These hurdles complicate decision-making processes, steering consumers away from healthier options. Despite its potential significance, the operationalization of sludges in the food system and their role in shaping consumer behavior remains unclear.
This study aims to establish a clear and comprehensive definition of sludges as applied to food systems, identify the mechanisms through which they operate, and assess their impact on consumer behavior and policy frameworks. The ultimate goal is to build foundational evidence to inform strategies that mitigate sludges and facilitate healthier food choices.

METHODS
To informed the design of our Delphi study, we conducted a systematic literature review and semi-structured interviews with experts in behavioral economics and nutrition . Ninety experts from fields such as public health nutrition and food policy are participating in two iterative survey rounds. The study aims to achieve consensus on the types, mechanisms, and impacts of sludges in out-of-home food environments.

RESULTS
We aim to develop an operational definition of sludges, identify key mechanisms hindering healthy choices, and assess their severity. Findings will inform actionable policy recommendations to mitigate sludges and guide future behavioral experiments to improve consumer food environments.

CONCLUSIONS
This research will clarify the concept of sludges and their implications for food systems, contributing to healthier and more equitable environments by supporting interventions that facilitate informed consumer decisions.

DESIGNS OF NUTRITION INTERVENTIONS IN FRAGILE SAHELIAN COUNTRIES COULD BE IMPROVED BY BETTER PROCESS AND IMPACT EVALUATIONS

Paula Dominguez-Salas[1]; Aurélie Bechoff[2]; Kendra Byrd[3]; Lydia O'Meara[4]
[1]Natural Resources Institute, University of Greenwich (Medway Campus), Gillingham, United Kingdom; [2]Food and Markets Department, Natural Resources Institute, University of Greenwich, Chatham Maritime, United Kingdom; [3]Food and Market, Natural Resources Institute, University of Greenwich, Chatham Maritime, United Kingdom; [4]Natural Resources Institute, University of green, London, United Kingdom

BACKGROUND AND OBJECTIVES

Despite investments to improve nutrition, progress has stalled in the West African Sahel where malnutrition remains high, with child stunting at 47% in Niger and anemia in pregnant women at 59% in Mali. We aimed to 1) understand what intervention designs in these fragile states addressed key malnutrition drivers, 2) assess the evidence on designs that improve malnutrition, 3) elucidate design strengths and weaknesses, and 4) determine what lessons can be learned to improve designs. Findings will inform design improvements of nutrition initiatives in fragile states to enhance nutrition and health.

METHODS

We assessed designs and outcomes of nutrition initiatives over the last 10 years in Burkina Faso, Chad, Mali, Mauritania, Niger and Senegal, triangulating: 1) a review of peer-reviewed, grey literature, and impact and process evaluations of multisectoral interventions, in English and French; and 2) semi-structured key informant virtual interviews in French and English with funders, project designers and implementers in the region. Country case studies focused on Senegal and Chad and a thematic analysis used a six-step reflexive approach. A design gap analysis was undertaken by mapping RESULTS against two conceptual frameworks.

RESULTS

We conducted 29 interviews and assessed 64 documents from 41 studies. Initiatives targeted immediate (81%), underlying (73%), and systemic (70%) drivers of malnutrition. Less than 35% conducted robust impact evaluations and no clear pattern emerged, but several multisectoral interventions achieved positive impacts. Four themes converged: 1) situational analysis and targeting, 2) theory of change (ToC) and formative research, 3) monitoring and evaluation, and 4) stakeholder engagement to foster sustainable, long-term change. Strengths included in-depth early-on contextualization, (e.g participatory approaches rooted in self-identified community needs), integration within existing structures, adequate monitoring and evaluation, robust ToCs and flexibility to adapt to changing contexts. Weaknesses included choice of inappropriate indicators, lack of mechanisms for accountability, uncoordinated role of different partners, and lack of policymaker engagement.

CONCLUSIONS

Our RESULTS highlight the importance of investing in robust ToCs; co-design / co-monitoring with local governments and communities for strong governance, contextualization and sustainability; and robust process and impact evaluations. The paucity of impact evaluations limits our understanding of optimal designs, and development/humanitarian interventions should be coupled with research to build the evidence base.

FOODWAL: PROMOTING SUSTAINABLE FOOD SYSTEMS IN WALLONIA : INNOVATIONS BASED ON COLLABORATIVE INTER-DISCIPLINARY NETWORK

Hélène Schraverus[1]; Aline Ferain[1]; Guillaume Bayon-Vicente[2]; Laetitia Lengele[3]; Ana I. Fernandez Salina[4]; Leroy Baptiste[5]; Nathalie Gillard[4]; Gauthier Eppe[6]; Nathalie M. Delzenne[3]; Yvan Larondelle[1]
[1]FoodWal, UCLouvain, Louvain-la-Neuve, Belgium; [2]Proteomics and microbiology, University of Mons, UMons, Belgium; [3]Metabolism and Nutrition Research Group, Louvain Drug Research Institute, UCLouvain, Brussels, Belgium; [4]Analytical laboratory, CER Groupe, Marche-en-Famenne, Belgium; [5]Proteomics and microbiology, UMons, Mons, Belgium; [6]Mass Spectrometry laboratory, ULiège, Liège, Belgium

BACKGROUND AND OBJECTIVES

FoodWal, a pioneer initiative based in Wallonia, fosters collaboration among research stakeholders in the food system to drive innovation, sustainability and regional economic development. By addressing the key challenge of feeding future generations in a healthy and sustainable way, FoodWal proposes a systemic approach to achieving sustainable food for global health.

METHODS

FoodWal operates through a multi-stakeholder consortium that includes academia, research centres and industry partners and is supported by policymakers. By leveraging cutting-edge collaborative research and local knowledge, the initiative develops and implements three projects.

RESULTS

FoodWal's projects showcase impactful innovation in sustainable food systems:

1. MICROBoost develops sustainable innovations using microbiome to enhance food quality, including the development of advanced microbiotics and digital tools for personalised nutrition. It also evaluates microbiotic impacts on health.
2. PEPTIBoost develops innovative methods to produce and characterise bioactive peptides from protein-rich by-products and other alternative protein sources. It evaluates the health benefits of these peptides and develops AI tools to predict their properties and accelerate their discovery.
3. PROTEBoost aims at producing microbial proteins from food by-products and optimises processes to make them scalable while preserving nutritional quality of the biomass. It also formulates attractive, healthy and sustainable food products and develops digital tools for process optimisation and life cycle analysis.

CONCLUSIONS

FoodWal contributes to the broader goal of sustainable food systems by aligning regional priorities with global targets. Its replicable model of collaborative research offers valuable insights for other regions aiming at enhancing the sustainability and the resilience of their food systems.

EAT-LANCET DIET IMPLEMENTATION AND THE IMPORTANCE OF BUILT-ENVIRONMENT IN THE CONTEXT OF JAPAN: PRACTICE AT THE SCHOOL CAFETERIA

Kanako Masuno[1, 2]; Momoka Saito[1]; Mutsumi Kitagawa[1]; Mao Fujie[1]; Fumiko Shimizu[1]; Masako Yokotsuka[1, 3]
[1]Department of Nutrition Science, Showa Women's University, Tokyo, Japan; [2]Interfaculty Initiative in Planetary Health, Nagasaki University, Nagasaki, Japan; [3]Institute of Women's Health Sciences, Showa Women's University, Tokyo, Japan

BACKGROUND AND OBJECTIVES
EAT-Lancet diet had introduced as a healthy and sustainable diet both for human and planet. The evidence of its positive effect has been accumulating and the concept of EAT-Lancet diet is becoming more valuable and spreading mainly in Western countries. However, it is still novel concept in Japan and the adherence is remaining unclear because there is almost no research published about this topic in Japan as of 2022. So, we aimed at detecting the adherence to EAT-Lancet diet and exploring the motivator and bottleneck so as to spread the EAT-Lancet diet in Japan.

METHODS
This research was designed as the school-based participatory research and conducted consistently during February 2023 to the end of July 2024. It consists of 1)EAT-Lancet diet offering project at school cafeteria operated by registered dietitian, and 2)cross-sectional study using semi-structured questionnaire. Independent variables were basic demographic data, dietary habits, and the perception toward health and environment issues. Dependent variable was the adherence toward EAT-Lancet Diet. Focus group interviews was also adopted to explore the challenges from the providers' perspective.

RESULTS
We could collect both of the quantitative data and qualitative data from semi-structured questionnaire regarding to adherence to EAT-Lancet diet, motivator and bottleneck to spread EAT-Lancet diet in Japan. Overall, the concept of EAT-Lancet diet was positively precepted and the higher proportion of plant-based protein was positively accepted because of Japanese traditional food culture. On the other hand, it was shown that not a few participants were expecting not so much the benefits for the environment or health, but rather the effects of weight loss. From the focus group interview, potential driver and bottlenecks to expand EAT-Lancet diet outside the school cafeteria were suggested from the perspective of human and financial resource.

CONCLUSIONS
It was shown that the arrangement of built-environment with the appropriate nutrition education is inevitable together with introducing the concept of EAT-Lancet diet in Japan. Japan is known to be the country which has relatively higher proportion of thinness among young women due to the social pressure and desire for thinness. So, it seems to be inevitable to offer the proper occasion to educate them about ideal nutrition intake balance as well as EAT-Lancet diet. By doing so, we can move forward both of the human health and environmental health.

IRONING OUT THE FUTURE: HOW WILL SUSTAINABLE DIETS IMPACT IRON BIOAVAILABILITY?

Grace Bennett[1]; Pedro Cardenas-Canto[1]; Liangzi Zhang[1]; Paul Kroon[2]; Marion Buso[3]; Cristina Gonzalez[3]; Maria Traka[1, 3]
[1]Food and Nutrition National Bioscience Research Infrastructure, Quadram Institute, Norwich, United Kingdom; [2]Food, Microbiome and Health, Quadram Institute, Norwich, United Kingdom; [3]EuroFIR AISBL, EuroFIR AISBL, Brusse, Belgium

BACKGROUND AND OBJECTIVES
Iron is crucial for many metabolic processes, including oxygen transport via binding to haemoglobin. Deficiency is common (two billion people globally), previously described as “a major public health concern”. Haem iron from animal sources is the most bioavailable form of iron from the diet, however, is not environmentally sustainable. The bioavailability of non-haem iron from plant-based foods is complex and can be inhibited by the presence of bioactive compounds in the foods consumed. The aim of this research is to determine the bioavailability of non-haem iron from current and future sustainable UK diets. To do this we are integrating compositional information on modifiers of iron bioavailability within national dietary intakes.

METHODS
Levels of dietary bioactive compounds known to influence iron bioavailability, namely phytate and polyphenols (in tannin equivalents), were identified and mapped to the “electronic Bioactive Substances in Food Information System” (eBASIS/FoodBioactivesDB), which contains compositional information on plant-derived bioactives. Foods commonly reported in the National Diet and Nutrition Survey (NDNS) yrs 9-11 containing key iron bioavailability modifiers are being targeted for additional data input. NDNS (yrs 9-11) data was analysed to identify current iron status and key iron sources. In time, bioactive compound data alongside bioactive and nutrient data will be used to accurately examine iron bioavailability from current UK diets using a validated algorithm.

RESULTS
Phytate and polyphenols are major bioactive compounds inhibiting iron absorption, however availability of compositional data is limited. Foods containing tannin equivalents such as tea and coffee were widely consumed by the NDNS cohort (7% of total reported food items consumed). High phytate foods like legumes, unprocessed grains, nuts and seeds were less commonly reported (4%). Fortified breads and cereals were the largest contributor to total iron intake across all age groups in NDNS (38-53%), followed by meat and meat products (12-19%). Adolescent girls were most at risk for iron deficiency; 49% reported intake below the LRNI and 17% were below the threshold for serum ferritin (<10ng/mL). Young girls (aged 4-10 years) and women of reproductive age (19-49 years) were also at risk.

CONCLUSIONS
As transition to sustainable diets is inevitable, it is vital to predict bioavailability of non-haem iron intake. Future work will determine bioavailability of iron in the UK and apply diet modelling to inform plant-based food strategies which maintain adequate iron stores.

DISHI FITI ISHI FITI (EAT WELL, LIVE WELL): PRIORITIZING FOOD SYSTEMS INTERVENTIONS TO REDUCE ADOLESCENTS' NUTRITION INSECURITY AND MALNUTRITION IN LOW-INCOME KENYAN NEIGHBORHOODS

Gwenyth Lee,[1]; Gershim Asiki,[2]; Elizabeth Fox,[3]; Simon Kimenju,[4]; Benjamin Mccormick,[5]; Vincent Mutuku,[6]; Wiktoria Staromiejska,[7]; Shauna Downs[8]
[1]Department of Biostatistics and Epidemiology, Rutgers Global Health Institute, New Brunswick, United States of America; [2]Non-communicable Diseases Research Unit, African Population & Health Research Centre, Nairobi, Kenya; [3]Department of Public & Ecosystem Health, Cornell University College of Veterinary Medicine, Ithaca, United States of America; [4]Kula Vyema Centre of Food Economics, Kula Vyema Centre of Food Economics, Ruiru, Kenya; [5]The Rowett Institute, The Rowett Institute, Aberdeen, United Kingdom; [6]G-thamini Foundation, G-thamini Foundation, Nairobi, Kenya; [7]Department of Health Behavior, Society and Policy, Rutgers School of, Newark, United States of America; [8]Department of Health Behavior, Society and Policy, Rutgers School of Public Health, Newark, United States of America

BACKGROUND AND OBJECTIVES
Nutrition insecurity in low- and middle-income countries (LMICs) contributes to undernutrition, micronutrient deficiencies and obesity, creating "multiple burdens" of malnutrition that increase risk of diet-related non-communicable diseases. Adolescence is an optimal period for intervention before negative life-long patterns are established, yet few programs target this age group or consider the broader systems influencing adolescent food choices. Our mixed-methods study aims to address nutrition insecurity among adolescents in Nairobi, Kenya by investigating factors influencing their food choices and capturing the interplay between nutrition insecurity, food environments, and health outcomes using participatory systems thinking and modeling.

METHODS
To better understand perceived systems drivers of adolescent diets across formal and informal settlements in Embakasi South, Nairobi, our participatory systems approach engages with adolescents, parents, educators, and food systems stakeholders, through cognitive mapping and group-based modeling. The RESULTS of this work will inform the second stage of our study, a longitudinal cohort to link the neighborhood and household food environments to adolescent food choices and dietary and nutritional outcomes through discrete choice experiments, adolescent dietary assessments, anthropometric measurements, and Bayesian network modeling.

RESULTS
Free-listing activities with adolescents, parents/educators, and food systems stakeholders identified key factors that influence food choices among adolescents, including vendor hygiene and appearance, affordability, and taste. Decision-making is also influenced by the different settings in which they acquire food (e.g., at home, from street vendors, etc.). The relative salience of these factors differentially varied across the gradient of formality according to different stakeholder groups.

CONCLUSIONS
These findings, along with the RESULTS from our other study activities, will be used in modeling exercises to understand how modifiable characteristics of the informal versus formal environment affect adolescent food choices. They will also inform the ranking and prioritization of food systems interventions to reduce malnutrition and promoting better long-term health of adolescents into adulthood.

CONFLICTS OF INTERESTS

DETERMINANTS OF IRON STATUS IN VEGANS LIVING IN NEW ZEALAND

Kathryn Beck[1]; Amelia Dunnett[1]; Claire Badenhorst[1]; Rebecca Paul[1]; Hajar Mazahery[2]; Cathryn Conlon[1]; Pamela Von Hurst[1]
[1]School of Sport, Exercise and Nutrition, Massey University, Auckland, New Zealand; [2]Curtin School of Population Health, Curtin University, Bentley, Australia

BACKGROUND AND OBJECTIVES
A vegan diet has many health benefits; however, nutrients such as iron are less bioavailable in plant food, presenting a risk for iron deficiency (ID). Research on iron intake and status in vegans is limited and has not been explored in New Zealand (NZ). This study aimed to investigate iron status in a NZ vegan population and explore risk factors for ID.

METHODS
Males (n=52) and females (n=143) over 18 years of age who had been vegan for at least two years were recruited. Nutrient intake was gathered through four-day food records. Biomarkers of iron status were measured including serum ferritin (SF), haemoglobin, serum iron, total iron-binding capacity and transferrin saturation. Health, demographic and lifestyle factors were assessed using questionnaires. Participants were grouped as ID (SF<30µg/L) and iron sufficient (SF≥30µg/L) and the differences between these groups were assessed using independent t-tests (for parametric data) or chi square test (for categorical data).

RESULTS
The prevalence of ID was 47.3% overall. Significantly higher rates of ID were found in females (58.7%) compared to males (15.4%) ($p \leq 0.001$). Mean±SD iron intake was above the estimated average requirement (EAR) for both females (17.2±5.2mg) and males (22.3±6.4mg). In females, ID was more likely in those who were younger ($p \leq 0.001$), those who had donated blood in the last six months ($p=0.025$), and in those who were still menstruating ($p=0.010$). No significant differences in nutrient intake were observed between ID and iron sufficient females. In males, energy ($p \leq 0.001$), protein ($p=0.004$), dietary fibre ($p \leq 0.001$), iron ($p=0.001$), calcium ($p=0.003$) and vitamin C ($p=0.006$) intake was higher in ID compared with iron sufficient males.

CONCLUSIONS
Nearly half of the vegan sample was ID, and over half of vegan females were ID. In females, being younger, donating blood in the past six months and still menstruating were more likely in those with ID. Dietary intake was associated with ID in males, however the sample size was small. This study has provided novel insights on the risk of ID for vegans living in New Zealand. Further research is needed to confirm these findings and to explore other aspects of dietary intake beyond just nutrient intake.

VALIDATION OF THE CARBON ISOTOPIC RATIO AS A BIOMARKER OF ADDED SUGAR AND CORN INTAKE IN MEXICAN ADULTS

Monica L Castro-Acosta; Luz Muñoz-Aispuro[1]; Itzel Nieto-Marin[1]; Perla Gamez-Valdez[1]; Aricel Bojorquez-Uribe,; Veronica Lopez-Teros[2]; Diane O'brien[3]; Johanna Lampe,[4]; Cornelia Loechl[5]; Tinku Thomas[6]
[1]Facultad de Ciencias de la Nutrición y Gastronomia, Universidad Autonoma de Sinaloa, Culiacán Rosales, Mexico; [2]Departamento de Ciencias Quimico Biologicas, Universidad de Sonora, Her, Mexico; [3]Biology and Wildlife, University of Alaska, Fairbanks, United States of America; [4]Division of Public Health Sciences, Fred Hutch Cancer Center, Sea, United States of America; [5]NAHU/NAHRES, IAEA, Vienna, Austria; [6]Biostatistics, St. John's Medical College, Bengaluru, India

BACKGROUND AND OBJECTIVES
Dietary assessment methods are susceptible to bias due to innate errors, so validating a biomarker of added sugar and corn intake may provide useful information in dietary analysis. The carbon isotopic ratio (13C/12C; CIR) has great potential as an added sugar and corn intake biomarker due to sugarcane and corn's natural abundance of 13C. Sugar-sweetened beverage (SSB) intake in Mexico is among the highest worldwide (163 L/per capita), while corn is the primary staple food (346 kg/per capita). Because of the high carbohydrate content in SSB and refined corn, there is concern about their relationship with obesity, CVD, and T2D. **Objective:** To evaluate the utility of CIR as a biomarker of added sugar and corn intake in Mexican adults.

METHODS
This one-month study includes 72 healthy, diet and weight-stable adults (37 women and 35 men, BMI ≥ 18.5 kg/m2, aged 18 - 50 y). At enrollment, information on lifestyle variables was collected through a questionnaire. Anthropometric measurements were performed weekly, and dietary intake was reported by four non-consecutive 24 four dietary recalls, three on different weekdays and one on weekends. Added sugar was estimated based on the 10-step methodology of Louie et al. (2015), and food variables were coded using the method described by O'Brien et al. (2022). Blood samples were collected at the end of the study period for biomarker analysis. Serum CIR was analyzed by coupled elemental analysis/isotope ratio mass spectrometry (EA-IRMS) at the Alaska Stable Isotope Facility at the University of Alaska Fairbanks.

RESULTS
The median (IQR) intake of added sugar, corn, and SSB was 55 g/d (30, 75 g/d), 111 g/d (77, 166 g/d), and 333 ml/d (113, 665 ml/d), respectively. Corn, animal protein, red meat, fish, SSB, and added sugar in SSB were significantly correlated with CIR ($p<0.05$). Multivariate regression analysis further confirmed the predictive value of corn and red meat, significantly impacting CIR ($R2= 0.187$).

CONCLUSIONS
These findings will provide valuable data to better understand the relationship between diet and cardiometabolic disease in Mexican adults.

IMPACT OF SOYBEAN ENRICHED UGALI ON HEALTH MARKERS OF CHILDREN ATTENDING PRIMARY SCHOOLS RURAL TANZANIA

Neeta Singh[1]
[1]Nutrition , University of the Incarnate Word, San Antonio, United States of America

BACKGROUND AND OBJECTIVES
Childhood Malnutrition, as well as micronutrition deficiencies, remains a public health issue in Tanzania, especially in rural areas. Stunting, wasting, or underweight are classified as malnutrition in respect to height or weight compared with age or to each other. Further, dietary insufficiency from reliance on a predominantly starch based diet as rural communities increasingly depend on staples such as tubers or cereals. Ugali refers to starchy porridge cooked by boiling raw casava or mixing casava flour to form viscous porridge, often served with sides or served as such depending on socio economic status of the population. The objective of the research was to measure the impact of feeding program in the form of soybean enriched Ugali on health markers, subjective markers and educational outcomes on first grade, ages 6 to 7 years old in rural Tanzania

METHODS
Six months Observational cross-sectional study was designed to measure the impact of feeding soybean enriched Ugali on objective/growth data (height, weight, BMI), subjective health markers (presence of diarrhea, symptoms of respiratory illness and health care access) and educational outcomes (attendance, attention, student engagement) among selected primary schools in rural areas. A baseline questionnaire to assess proxy variables of socioeconomic and health status preceded a six-month for first grade, n=114, 6- 7 year old children in rural Tanzania. Weight and height measures were obtained at regular intervals: baseline, midpoint, and final. Growth was the primary outcome to assess impact of the feeding period.

RESULTS
Multiple linear regression modeling for weight velocity, when controlling for age and gender, shows coughing and flu symptoms as the variable that best explains variance in weight velocity at a significance of $p = 0.009$. Further research is needed to assess a longer period of time, with a causal or experimental design including a control group, in order to investigate stronger evidence.

CONCLUSIONS
A typical school day in this region is approximately a twelve-hour day at school where meals are not served until the child returns home for an evening meal. The feeding program such as soybean enriched Ugali will increase educational outcomes, bring positive health outcomes, towards reduction in chronic malnutrition among children attending in rural areas lacking access to government school feeding programs.

SOCIO-DEMOGRAPHIC, SOCIO-POLITICAL AND ENVIRONMENTAL FACTORS ASSOCIATED WITH FOOD INSECURITY OF HOUSEHOLDS WITH CHILDREN UNDER 3 YEARS OF AGE IN HIGH ANDEAN AREAS IN THE CONTEXT OF A SOCIAL AND POLITICAL CRISIS

Sissy Espinoza-Bernardo[1, 2]; Violeta Rojas[1, 2]; Hally Huillca[1, 2]; Bill Estrada[2]; Mercedes Maravi Castro[2, 1]; Margot Quintana[1, 2]; Rocio Galvez[2]; Juan Pablo Aparco[1, 2]
[1]Nutrition Department, National Major University of San Marcos, Lima, Peru; [2]Food and Public Nutrition Research Nucleus - NIANP, National Major University of San Marcos, Lima, Peru

BACKGROUND AND OBJECTIVES
The high Andean areas of the LMICs have a high prevalence of childhood anemia in children aged 6 to 35 months, and food insecurity. Added to this are environmental factors such as climate change that affect their productive potential for access to food. The objective was to evaluate the demographic, sociopolitical and environmental factors associated with food insecurity in households with children under 3 years of age in high Andean areas in the context of a social and political crisis in a low-income country

METHODS
Cross-sectional correlational study that involved 330 households of children under 3 years of age attending health facilities in Andean area. Food security at the household level was measured using the FAO FIES instrument. A previously validated survey on the factors studied was applied. Univariate, bivariate, and multivariate analysis was done in R software, version 4.0.2.

RESULTS
Almost all (97%) households assessed were food insecure, with severe food insecurity prevailing. From the multivariate analysis, the socio-demographic factor related to the educational level of the head of household was a protective factor against moderate-severe food insecurity, (OR=0.16; 95% CI 0.03-0.98). Socio-political factors showed that households that experienced difficulties in accessing food due to the socio-political crisis were 1.52 times more likely (OR= 2.52; 95% CI 1.02-6.25) to experience moderate-severe food insecurity; households that lost income during the socio-political crisis were 3.1 times more likely to experience moderate-severe food insecurity (OR= 4.10; 95% CI 1.96-8.60). No environmental factors associated with moderate-severe food insecurity were identified.

CONCLUSIONS
The educational level of the household head had a protective effect against food insecurity. Also, difficulties in access and loss of income were risk factors for moderate-severe food insecurity in households with children under 3 years of age in high Andean areas in the context of a social and political crisis in Peru.

NECSCORE: A CO-CREATED NUTRITION-ENVIRONMENT-CULTURE PROFILING SYSTEM FOR PROMOTING YOUTH ENGAGEMENT ON TRADITIONAL RECIPES FROM INDIGENOUS FOODS

Flaminia Ortenzi[1]; Sophie Healy-Thow[2]; Wendy Gonzalez[1]; Joseph Skibbens[3]; Thato Noinyane[4]; Miriam Shindler[5]
[1]Knowledge Leadership, The Global Alliance for Improved Nutrition (GAIN), Geneva, Switzerland; [2]Programme Services Team, Global Alliance for Improved Nutrition, London, United Kingdom; [3]SDG2 Partnerships, Global Citizen, New York, United States of America; [4]SDG2 Campaigns, Global Citizen, Johannesburg, South Africa; [5]Programme Services Team, The Global Alliance for Improved Nutrition (GAIN), Geneva, Switzerland

BACKGROUND AND OBJECTIVES
Traditional recipes possess significant cultural value as they are deeply rooted in the geographic context, historical heritage, and identity of populations. Additionally, these dishes are often nutritious and can be produced sustainably. Despite significant potential to positively contribute to healthy and sustainable diets globally, traditional dishes are increasingly being displaced by more convenient and processed alternatives. Youth could play an important role in re-popularizing traditional recipes. Our goal was to co-develop and test a simple profiling system in collaboration with youth, called the Nutrition-Environment-Culture Score (NECScore). The NECScore is intended to help youth re-discover the value of traditional dishes and reflect on strategies to further enhance it.

METHODS
Eight youth leaders from the global ACT4FOOD movement shared examples of traditional recipes from their countries of origin, including pictures and detailed descriptions of ingredients, preparation methods, and personal and cultural significance. The research team supplemented these descriptions with online searches when necessary. Based on this information, we developed dish profiles with key messages about nutritional value (considering the list of ingredients and their proportions), environmental impacts, and socio-cultural characteristics. As a following step, we conducted a co-design session with youth leaders to create visual cues representing the three attributes outlined in dish profiles.

RESULTS
We developed profiles for 18 culturally diverse dishes from eight countries. While some of these were nutritionally balanced and relatively sustainable meals, others were primarily starch-based or meat-based, offering opportunities to enhance diversity and lower environmental footprints by incorporating other food groups. All analysed dishes were associated with values of connectedness, family/community, and belonging, as they are often prepared for special occasions and tied to shared memories. The visual cues co-designed with youth featured a three-star rating system for each of the attributes. Overall, youth leaders demonstrated enthusiasm and active engagement throughout the process.

CONCLUSIONS
CONCLUSIONS:
The profiling system holds promise as a tool for engaging and collaborating with youth around traditional recipes. As next step, we will test and refine the NECScore with youth.

CONFLICTS OF INTERESTS

TRANSFORMING FOOD SYSTEMS FOR IMPROVED NUTRITION: WHAT DRIVES THE CONTAMINATION OF NUTRIENT-RICH FRUIT AND VEGETABLES IN EAST AND WEST AFRICA AND HOW CAN THIS BE ADDRESSED?

Paula Dominguez-Salas[1]; Srinivasa Sudharshan Kondapalli Sai[1]; Abayomi Louise[1]; Alarcon Pablo[2]; Duvenage Stacey[3]; Grace Delia[4]; Nicolaides Linda[1]; Pal Himadri[1]; Walls Helen[5]
[1]Natural Resources Institute, University of Greenwich (Medway Campus), Gillingham, United Kingdom; [2]Pathobiology and Population Sciences, Royal Veterinary College, Hawkeshead Lane, Hatfield, UK, Hatfield, United Kingdom; [3]Natural Resources Institute, Universi, Chatham, United Kingdom; [4]Natural Resources Institute, University of Greenwich (Medway Campus), Central Avenue, Gillingham, Chatham, UK, Chatham, United Kingdom; [5]Faculty of Public Health and Policy, London School of Hygiene & Tropical Medicine, Keppel Street, London, UK, London, United Kingdom

BACKGROUND AND OBJECTIVES

Demand for nutrient-rich fruits and vegetables (F&V) is increasing, due to demographic growth and health awareness. As a result, F&V supply chains are becoming longer and more complex, adding food safety challenges in sometimes fragile production and monitoring systems. Foodborne illnesses caused by contaminated F&V can reduce the positive impact of F&V. This research aims to understand better the levels and drivers of F&V contamination to propose strategies for food systems transformation to provide healthier diets.

METHODS

We reviewed existing frameworks to develop a bespoke F&V framework bringing together contaminant entry points and influencing factors, and the informal nature of African markets. This was completed through an iterative process with the evidence from a scoping review, and validated by expert panel advice. We also conducted an umbrella review to examine regional trends in East and West Africa and evidence gaps, and a zoom in scoping review at each region. We conducted a short survey among authors of eligible publications to compile additional information on the protocols followed, and accreditation processes of the laboratories, and assess the quality of the available evidence and some of the challenges.

RESULTS

Our comprehensive framework will allow implementers/policymakers gain a better understanding of F&V food safety, and how it links with nutrition. Geographical representativity of the 23 reviews was limited. Informal markets supplying the most nutritionally vulnerable households, are under-researched. Factors driving the contamination were not often mentioned but included climatic and environmental conditions, farming systems, processing and storage techniques, and socio-political factors. Significant evidence gaps include environmental hygiene, infrastructure, or services in outdoor food markets. Regulation, control and enforcement remain inadequate, particularly in relation to smallholders and informal chains. The contamination of various hazards such as pesticides and heavy metals along F&V supply chains often exceeds accepted levels. More systematic assessment is needed to understand which supply chains are more prone to contamination and the influencing factors.

CONCLUSIONS

While F&V are very nutritious, there are significant trade-offs with their susceptibility to contamination. Our findings underscore the need for evidence to address critical issues to transform East and West Africa F&V value chains, especially within the informal sector, and make them suitable to supply healthy and sustainable diets.

ASSOCIATION BETWEEN DIETARY IRON INTAKE AND VITAMIN D STATUS: POST-HOC ANALYSIS OF THE D2-D3 STUDY

Emily Brown[1]; Darling Andrea[1]; Elliott Ruan[1]; Julie Lovegrove[2]; Givens Ian[2]; Hunt Julie[1]; Lanham-New Susan[1]; Hart Kathryn[1]
[1]Discipline of Nutrition, Exercise, Chronobiology & Sleep, University Of Surrey, Guildford, United Kingdom; [2]Institute for Food Nutrition and Health, University of Reading, Reading, United Kingdom

BACKGROUND AND OBJECTIVES

Vitamin D and iron deficiencies are global public health concerns; improving micronutrient sufficiency could help to reduce incidences of preventable diseases symptomatic of deficiency, such as, osteomalacia or anaemia. However, the extent to which these micronutrients interact is little understood. The aim of this research was to determine whether (baseline) dietary iron intake is related to dietary vitamin D intake and/or serum vitamin D concentrations.

METHODS

Post-hoc analysis of the D2-D3 Study dataset (a 12-week randomised, placebo-controlled food-fortification trial) was conducted using IBM SPSS Statistics (2024) [1,2]. Dietary intakes were compared to UK RNI data and bivariate correlations were performed to investigate associations between dietary iron intake and vitamin D intake/status at baseline.

RESULTS

Descriptive analysis showed that the median dietary intake of vitamin D was 1.99 [1.21-3.57] µg/day for all participants, well below the RNI of 10µg. The median [IQR] dietary intake of iron across all participants aged >50 years was 11.34 [9.38-13.62] mg/day, which is above the UK RNI of 8.7mg. However, for participants aged 19-50 years, the median intake was 3.86mg, well below the RNI of 14.8mg, at 10.94 [8.73-13.71] mg/day. Baseline dietary iron (mg) and vitamin D (µg) intakes were significantly positively correlated across all participants ($rs(260) = 0.399$, $p = <0.001$). No significant correlation between pre-intervention serum vitamin D concentrations (nmol/L) and baseline dietary iron intake (mg) was found for the sample as a whole.

CONCLUSIONS

Whilst data analyses found a significant positive association between dietary iron and vitamin D intakes, there were no apparent associations between dietary iron intake and vitamin D status. To ascertain cross-sectional/longitudinal associations between baseline, 6- week, and 12-week serum iron and vitamin D concentrations, we aim to continue post-hoc analysis of the D2-D3 dataset to investigate whether there are positive increases in iron biomarkers following vitamin D supplementation, compared to control.

CONFLICTS OF INTERESTS

STRENGTHENING AND RESTORING TRADITIONAL INDIGENOUS FOODWAYS FOR HUMAN AND PLANETARY HEALTH: CASE STUDIES FROM THE CENTER FOR INDIGENOUS INNOVATION AND HEALTH EQUITY

Valarie Blue Bird Jernigan[1]
[1]Center for Indigenous Health Research and Policy, Oklahoma State University Center for Health Sciences, Tulsa, United States of America

BACKGROUND AND OBJECTIVES

Food sovereignty, the rights of Indigenous peoples to determine their own food systems, is a culturally centered movement rooted in traditional Indigenous knowledge. While food sovereignty initiatives can be found within many Indigenous communities, the conceptual linkages between food sovereignty and health have not been well documented within the public health literature. We present case studies of food sovereignty initiatives developed as part of the Center for Indigenous Innovation and Health Equity (CIIHE) initiative, a community–academic partnership with the goal of strengthening Indigenous food systems and practices to promote health and well-being.

METHODS

The CIIHE is a community–academic initiative between Oklahoma State University, the University of Hawai‘i, and American Indian, Alaska Native, Native Hawaiian, and Pacific Islander communities. Participatory Indigenous research and evaluation strategies are used to uplift and implement food sovereignty interventions and assess the impact of these interventions on community health. The efforts are driven by supporting the transmission of intergenerational knowledge and strengthening and restoring relational responsibilities among Indigenous peoples, food, and land. Ten communities across the US are implementing and evaluating food sovereignty interventions in rural, reservation, and urban communities. Process and findings will be shared as part of this presentation.

RESULTS

Innovative food sovereignty initaitives developed include a cultural foods and healing camp for elders in Fairbanks, Alaska, as well as a traditional Indigenous foods gathering in Anchorage, Alaska; a community supported agriculture initiative and mobile market in Osage Nation reservation in Oklahoma, as well as an Indigenous food hub in Quapaw Nation, Oklahoma; and a restoration of traditional heirloom seeds from the Trail of Tears forced removal of Choctaw tribal members in the Choctaw Nation of Oklahoma. The Yurok Tribe in Northern California is restoring their traditional food villages. These and other examples will be shared.

CONCLUSIONS

Settler colonialism disrupted traditional Indigenous foodways and practices and created high rates of diet-related disease among Indigenous peoples. This approach directly intervenes upon systems-level barriers to health, making it an important strategy for health equity.

FOOD ENVIRONMENTS AND GLOBAL SYNDEMIC: A BIBLIOMETRIC ANALYSIS OF CURRENT LITERATURE

Fernanda Severo; GIOVANNA GARRIDO; Laís Ferreira Dias; Henrique Melo[1]; Aline Carvalho[1]; Ana Luiza Gomes Domingos[2]
[1]Nutrition, Faculdade de Saúde Pública USP, São Paulo, Brazil; [2]Post-doctorate, Escola de arte, São Paulo, Brazil

BACKGROUND AND OBJECTIVES
We are currently facing a global syndemic, consisting of the interconnected pandemics of obesity, undernutrition, and climate change, which both affect and are driven by food systems. Within this context, food environments serve as the interface where consumers interact with the food system, shaping individual food choices and nutritional status. However, there are still gaps in understanding the interaction between food environments and this syndemic. This study aims to investigate how the literature has explored the relationship between food environments and the global syndemic.

METHODS
This work involves a bibliometric analysis of original articles published between 2018 and 2024 with a search strategy that combines terms related to food environments, and undernutrition, obesity, or climate change in titles, abstracts, and keywords. Publications specifically focused on pregnant women or associated with diseases were excluded.

RESULTS
The search resulted in 4,068 findings, of which, after removing duplicates and non-original articles, 1,607 were analyzed by title. Only 283 studies were deemed suitable for analysis based on the abstract. Of these, 221 were considered eligible for inclusion in this research.
Regarding the syndemic variables, approximately 72% of the papers (160 articles) focused exclusively on the connection between food environments and obesity, while 17% (37 articles) addressed the relationship between food environments and undernutrition, and only 2% (4 articles) explored links with aspects related to climate change. Additionally, some works examined more than one component of the global syndemic: 18 discussed obesity and undernutrition, 1 explored malnutrition and climate change, 1 obesity and climate change and none addressed all three synergistic pandemics.

CONCLUSIONS
There is a predominance of studies linking food environments to obesity, reflecting greater scientific interest in these interactions. However, few articles explore associations between more than one pandemic, and even fewer address climate change. Therefore, this work highlights a significant gap in the literature regarding the impacts of food environments on the global syndemic and highlights the need for integrated approaches that include these components to mitigate such critical challenges affecting many parts of the world.

REPRESENTATION OF THE DEGREE OF FOOD PROCESSING IN DIETARY QUALITY INDICES

Zaray Rojas Conzuelo[1, 2]; Anita Frehner,[1]; Sander Biesbroek[2]; Edith Feskens[2]; Christian Schader[1]
[1]Department of Food System Sciences, FiBL - Research Institute of Organic Agriculture, Frick, Switzerland;
[2]Division of Human Nutrition and Health, Wageningen University & Research, Wageningen, Netherlands

BACKGROUND AND OBJECTIVES
Recent meta-analytical evidence suggests that a higher degree of food processing is linked to adverse health outcomes 1–4. While dietary quality indices (DQI) are widely used to assess diets, it remains unclear to what extent they capture food processing. This study aims to qualitatively analyse how DQIs consider variations in food processing within and across food groups and how these variations are scored.

METHODS
The current state of knowledge about the influence of the degree of food processing on health was identified from synthesis of systematic reviews and meta-analyses (i.e. umbrella reviews). Based on this, four criteria were developed to evaluate the extent to which DQIs consider this knowledge for scoring diets. The Global Diet Quality Score (GDQS)5, the Alternate Healthy Eating Index 2010 (AHEI 2010)6, Probability of Adequate Nutrient Intake (PANDiet)7, Plant-based Dietary Index (PDI), Healthful PDI (hPDI), and Unhealthful PDI (uPDI)8 were selected for the analysis. The NOVA classification 9 was used to categorise the degree of food processing in which the foods included in a DQI could theoretically fall.

RESULTS
In the GDQS, AHEI-2010 and PDI, the food groups that score negatively fall almost exclusively into the processed and ultra-processed categories. The exceptions are potatoes/white roots and tubers, juices; and animal-based foods in the PDI. In contrast, food groups that score positively can span multiple processing categories and thus receive the same number of points regardless of their processing level (e.g. legumes and whole grains). Notably, in the GDQS and AHEI-2010, fruits scored positively only when consumed as whole food. The GDQS captured the most nuances of processing variation, partly due to its larger number of food groups; while the PANDiet captured the least (as it is based on nutrients). Changes in the food matrix were only considered in the GDQS for the fruit group, while changes in nutrients were not directly considered in any, but are reflected, for instance, by differentiating refined from whole grains.

CONCLUSIONS
Although the indices do not explicitly include food processing as a factor, they still reflect some of the current knowledge about the association between food processing and health, especially for food groups considered as unhealthy. Next to the coverage of unhealthy food groups, the indices could need refinement to distinguish the food processing within all food groups. If food processing is to be evaluated, it is recommended to use a processing classification system in addition to the DQIs.

FOOD SUPPLY AND SUSTAINABILITY: TÜRKIYE'S COMPLIANCE WITH THE PLANETARY HEALTH DIET

Mustafa Volkan Yılmaz[1]; Esma Asil[1]; Aslı Uçar[1]; Funda Pınar Cakıroğlu[1]
[1]Nutrition and Dietetics, Ankara University, Faculty of Health Sciences, Ankara, Türkiye

BACKGROUND AND OBJECTIVES
The world's growing population, climate change, depletion of natural resources, and emerging nutritional challenges have increasingly underscored the importance of sustainable and healthy dietary approaches. Within this context, global recommendations such as the "Planetary Health Diet" (PHD) address both ecological and human requirements holistically. This study aims to determine and evaluate the extent to which the food supply available for human consumption in Türkiye meets the components of the PHD.

METHODS
To determine the per capita food supply, the number of stakeholders benefiting from the country's food availability—including residents, those under refugee status, and tourists—was calculated. Utilizing official governmental reports and food balance sheets, the per capita food supply for human consumption was established. Subsequently, the alignment of this per capita food supply with the PHD recommendations was assessed by examining how well the recommended components are met, thereby evaluating the current food supply's capacity to fulfill sustainable dietary guidelines.

RESULTS
The findings indicated that the food supply for whole grains, tubers or starchy vegetables, all vegetables, all fruits, red meat, poultry, and eggs meets the PHD recommendations. However, the supply of dairy foods, fish, legumes, and nuts was found to be insufficient. Additionally, the availability of added sugars significantly exceeded the levels recommended by the PHD.

CONCLUSIONS
The RESULTS suggest that achieving a sustainable and healthy dietary pattern aligned with PHD recommendations in Türkiye requires a comprehensive re-evaluation of policies related to production, distribution, consumption, and waste management. In particular, to ensure sustainable food security and to compensate for the current reliance on animal-based protein sources, there is a need for policies that increase the supply of dairy foods, fish, legumes, and nuts.

LEGUMES IN THE DIET: ASSESSING THE GAP BETWEEN CURRENT CONSUMPTION AND 2050 SUSTAINABILITY SCENARIOS – THE FRENCH CASE

Isabelle Savary-Auzeloux[1]; Christelle Guillet[2]; On Behalf The Legumic French Consortium[3]
[1]Human Nutrition Unit, Inrae - Center Clermont-Auvergne-Rhône-Alpes, Saint-Genès-Champanelle, France; [2]Clermont Auvergne University, Clermont-Ferrand, France; [3]INRAe, INSTITUT NATIONAL DE LA RECHERCHE AGRONOMIQUE, Paris, France

BACKGROUND AND OBJECTIVES

The transition of food systems towards higher share of plant-based products is considered one of the most important strategies to achieve carbon neutrality and reduce the overall environmental pressures of agriculture by 2050. These diets must also meet human nutritional requirements and promote health. Several international and French scenarios predict an increase in the proportion of plant-based foods in diets, especially legumes. However, legume consumption remains low in France, highlighting the need for research to overcome barriers and increase interest in their consumption, particularly in some western countries. The goal of the consortium is to assess how much the proportion of legumes in the French diet can increase and what the potential impact on the entire legume supply chain (from production to consumption) might be expected at the agronomic and nutritional levels. This began with a critical evaluation of the current legumes consumption (in various forms) in the french diet.

METHODS

The Legumic consortium, established in 2023 and funded by INRAe metaprograms, brings together academic and interprofessional partners with complementary expertise in agronomy, ecology, ecophysiology of legumes, nutrition, sensory analysis and consumer behavior. An analysis of the consumption and purchase of legumes by the French population was conducted using French surveys (INCA3, Esteban, Nutrinet). These data were compared with the projections for 2050 proposed by French and European scenarios (TYFA, Afterres, SISAE) aimed to promote a healthy and sustainable diet.

RESULTS

The analysis of legume consumption data shows variations across different categories (e.g. diet type, age, gender). However, overall legume consumption in France remains very low. Furthermore, there are important differences between low and high legume consumers (with a factor 10 or more). All scenarios for 2050 predict an increase in the share of legumes in the diets. The analysis of the current French legume consumer panel, along its variability may provide insights into new approaches to increase share of legumes in the French diet.

CONCLUSIONS

Data from various dietary surveys show a high diversity in the profiles of legume consumers. The substantial increases in legume consumption recommended by the scenarios raise the question of potential levers to make legumes more attractive in the French diet. Currently, working groups within the Legumic consortium are exploring strategies to increase the share of legumes in the French diet, considering agronomic, ecological and nutritional constraints.

PROBIOTIC BIOPOLYMER-BASED CAPSULES: NEW PERSPECTIVES IN DIETARY SUPPLEMENT DEVELOPMENT

Roxana Gheorghita[1]; Cristina Radu[1]; Iavorschi Monica[1]; Lobiuc Andrei[1]
[1]Faculty of Medicine and Biological Sciences, Stefan cel Mare University of Suceava, Romania, Suceava, Romania

BACKGROUND AND OBJECTIVES

Due to its exceptional encapsulation capabilities, biopolymers have found extensive applications in the development of pharmaceuticals and biomedical systems. Studies have shown that encapsulation in natural polymers is an excellent method for preserving the stability and viability of various compounds, such as probiotics [1], vitamins [2], polyphenols [3], and drugs [4]. This study aims to assess the feasibility of encapsulating probiotic strains of Lactobacillus clausii within biopolymeric matrices composed of sodium alginate and starch. The proven drug encapsulation efficiency of alginate, combined with starch's role in capsule production, its swelling and solubilization properties, affordability, and versatility, offers a robust basis for creating formulations designed for the targeted and controlled release of active substances.

METHODS

Capsules developed through the extrusion method, containing Lactobacillus clausii and the control samples (non-encapsulated lyophilized probiotics), were tested to determine cell viability, encapsulation efficiency, and production yield. The physical evaluation of the capsules included microstructure, diameter, and color evaluation. The in vitro digestion behavior in simulated gastrointestinal fluids was assessed to determine the survival rate of the probiotic strains.

RESULTS

The encapsulation of Lactobacillus clausii in biopolymeric matrices enhanced the viability and stability of probiotic cells compared to the strains used as control samples. The capsules presented spherical shape, free of pores or fissures in the matrix, but with an irregular surface. The color showed slight variations. The probiotic strains were protected in gastric fluids and released into intestinal fluids at 0.5 hour after immersion. The highest swelling index was observed in the formulation with the highest starch content, while the lowest swelling index was found in the formulation with a higher sodium alginate content.

CONCLUSIONS

Encapsulation enhanced the stability and viability of probiotic strains during exposure to simulated gastrointestinal juices. The addition of starch in the matrix enhanced the swelling of the capsules and aided in their disintegration. Future studies involve adding the capsules to natural yogurt and checking the parameters (cell viability, acidity, syneresis, water holding capacity) over a 2-week storage period.

EPO4_053

EVALUATING THE NATURALNESS OF 'NATURAL' LABELED PRODUCTS AND THEIR ALIGNMENT WITH CONSUMER EXPECTATIONS IN TERM OF NATURALNESS AND HEALTHINESS

Dalila Radaelli[1]; Alenica Hässig[1]; Román Sergio[2]; Sanchez-Siles Luisma[3]; Michael Siegrist[1]
[1]D-HEST, ETH Zürich, Zürich, Switzerland; [2]Facultad de Economía y Empresa, Universidad de Murcia, Murcia, Spain; [3]Institute for Research and Nutrition, Hero Group, Lenzburg, Switzerland

BACKGROUND AND OBJECTIVES
Natural claims are increasingly prevalent in the Swiss and global markets. However, the term ‘natural’ lacks a clear definition in the food industry, leading to potential consumer misinterpretation due to positive associations with health. The term is only regulated by a global standard, which is not binding. Food companies overuse the term ‘natural’ because of its positive association. However, are foods labeled as ‘natural’ more natural? Are they perceived as more natural and thus due to the heuristic effect healthier?

METHODS
This study aimed to assess these two questions in two parts. Firstly, this study looked at food items from the most popular food categories (“Desserts & Ice Cream”, “Meals & Meal Centers”, “Sauces & Seasonings”, “Snacks” and “Soups”) with a ‘natural’ claim available on the Swiss food market from 2019 to 2023. The Food Natural Index (FNI), developed by Sanchez-Siles et al. (2019), was calculated for these foods through ingredient analysis and then compared to foods that did not have a "natural" label.
In a second phase of the study, an online questionnaire was used to assess perceptions of naturalness and healthiness associated with foods with and without a 'natural' label.

RESULTS
The RESULTS of the first study indicate that products labeled "natural" had a significantly higher FNI than their unlabeled counterparts. RESULTS of the second study revealed that consumers perceive products labeled as “natural” to be more natural and healthier, and the perceived naturalness of two food items (i.e., natural labeled or unlabeled) had a full mediation effect on participants' perceived of healthiness.

CONCLUSIONS
The study found that the unregulated use of the "natural" label does not directly mislead consumers. However, since perceived naturalness fully mediates the relationship between labeling and perceived healthiness, it may cause consumers to rely on heuristics rather than objective information, such as ingredient lists or nutritional content, leading to biased judgments and decisions regarding food healthiness.

LONG-TERM IMPACT ASSESSMENT OF A NUTRITION-SENSITIVE AGRICULTURAL INTERVENTION AMONG ADULTS IN RURAL SRI LANKA

Caroline A. Joyce[1]; Bess L. Caswell[2]; Christine P. Stewart,[3]; Charles D. Arnold,[4]; Xiuping (Jenny) Tan[4]; Hasara Sitisekara[5]; Renuka Jayatissa[6]; Dilka Peiris[7]; Renuka Silva[5]; Deanna Olney[8]
[1]Institute for Global Nutrition, University of California, Davis, West Sacramento, United States of America; [2]Agricultural Research Service, Western Human Nutrition Research Center, Davis, United States of America; [3]Institute for Global Nutrition, University of California, Davis, Davis, United States of America; [4]Institute for Global Nutrition, University of California Davis, Davis, CA, United States of America; [5]Department of Nutrition and Dietetics, Wayamba University of Sri Lanka Makandura Premises, Makandura, Sri Lanka; [6]Nutrition, Medical International Institute of Health Sciences, Wattala, Sri Lanka; [7]Nutrition, World Food Programme, Colombo, Sri Lanka; [8]Nutrition, Diets, and Health, International Food Policy Research Institute, Washington, United States of America

BACKGROUND AND OBJECTIVES
In 2020, a WFP Food Assistance for Assets (FFA) program (R5N) was implemented in rural Sri Lanka to address the vulnerability of smallholder farmers to climate shocks and nutrient insecurity. Over 12 months, R5N provided cash for work on community assets or productive assets to vulnerable households to support livelihood development and associated training. Some of the targeted communities were randomly selected to also receive a health promotion process (HPP) to support diet, nutrition, and health practices. Our aims were to compare the long-term impact on usual micronutrient intakes and diet quality among adults in the 1) R5N-only, 2) R5N+HPP), and 3) control groups.

METHODS
We analyzed the intervention's impact 2 and 3 years after baseline. Sociodemographic and dietary data were collected using household surveys and phone-based 24-hour recalls (N=1283 at baseline). We collected repeat recalls from 44-92% of participants. The National Cancer Institute method with bootstrap standard errors was used to estimate mean usual intakes and the prevalence of inadequate micronutrient intake, and to compare between groups. The Global Diet Quality Score (GDQS) was used as an indicator of diet quality.

RESULTS
The control group included older, more educated, and more male participants than the intervention groups ($p<0.01$). In the propensity score-matched analyses, energy intake was significantly lower in the control, R5N-only, and combined R5N groups at 3 years compared to baseline ($p<0.01$), while the R5N+HPP group reported no change. For 9 of the 11 micronutrients analyzed, the prevalence of inadequacy was ≥50% at all time points in all study arms. In the full sample and among women, there were no significant differences in differences (DIDs) in usual nutrient intakes or the prevalences of inadequacy at 2 or 3 years. Among men, the R5N+HPP group experienced small but significant protective effects on energy, carbohydrate, calcium, niacin, and zinc intakes relative to the control and R5N-only groups. The only significant DID in GDQS was among women in the combined R5N group vs. control comparison (all-R5N: -0.6 points, control: -0.4 points [$p=0.04$]).

CONCLUSIONS
A 12-mo. nutrition-sensitive FFA program had limited long-term impacts on dietary intake. The findings indicate the potential for nutrition-sensitive FFA programs to have positive impacts on diets; however, program design and/or implementation must be strengthened to confer greater benefits across both men and women, especially considering the compounding negative impacts of multiple shocks experienced during the study period.

CONFLICTS OF INTERESTS

EXPLORING THE BENEFITS AND TRADE-OFFS OF ALTERNATIVE PROTEIN SOLUTIONS

Eva Jermendi[1]; Michiel Balvers[1]; Gerben De Gier[1]; Pol Grootswagers[1]; Jacintha Domić[1]; Ric De Vos[2]; Twan America[2]; Robert Hall[2]; Edith Feskens[1]
[1]Human Nutrition and Health, Wageningen University and Research, Wageningen, Netherlands; [2]Plant Sciences Group, Wageningen University and Research, Wageningen, Netherlands

BACKGROUND AND OBJECTIVES
Plant-based diets are becoming increasingly popular. However, there is still much to uncover about their nutritional value and molecular composition compared to omnivorous diets. This also applies to the metabolic health effects of plant-based diets, where differences may be associated with different molecular diversities between plant-based and omnivorous diets. The present study aims to evaluate the molecular composition and metabolic effects of the two diets through untargeted metabolomics and proteomics analyses of food and human plasma samples.

METHODS
In this project, samples from two human randomized cross-over intervention trials are used. In the first trial, 34 older adults followed an isonitrogenous and isocaloric vegan and omnivorous diet for 10 days each, and blood samples were taken at 3 time points (0, 10 and 20 days). The second trial focused on the post-prandial metabolic response to an isonitrogenous and isocaloric vegan and an omnivorous meal in 16 participants, where blood samples were collected across 15 time points (t= −180, −120, −60, 0, 15, 30, 45, 60, 90, 120, 150, 180, 240, 300, and 360 min). Food and blood samples were analysed using untargeted metabolomics and proteomics tools.

RESULTS
This project will reveal distinct signatures in vegan meals and diets by metabolomic and proteomic profiling, including unique nutrient and anti-nutrient profiles. By comparing the metabolomic profiles of the meals and plasma samples, we hope to identify novel biomarkers of nutritional exposure to plant-based proteins and understand the health benefits or challenges associated with plant-based foods. Ultimately the food and plasma profiles will be linked to health effects. The RESULTS will be available by the time of the conference.

CONCLUSIONS
With this project we aim to demonstrate the health impacts of vegan meals and diets by applying advanced metabolomics and proteomics platforms. By using omics techniques we will generate impactful findings that support the optimization of plant-based diets for better health outcomes. The integration of food and plasma analysis will help to understand the health effects of diverse plant-based foods, contributing to the development of evidence-based dietary recommendations.

LEVEL OF ACCURATE INFORMATION OF LARGE LANGUAGE MODELS ON ENTERAL NUTRITIONAL SUPPORT

Gulce Unal Yildiz[1]; Gunay Yildiz[2]
[1]Neurology, Kepez State Hospital, Antalya, Türkiye; [2]Department of Emergency Medicine, Antalya Education and Research Hospital, Antalya, Türkiye

BACKGROUND AND OBJECTIVES
Large language models (LLMs) present a novel approach to information retrieval. In this study, we sought to evaluate the accuracy of two open-source LLMs, namely Gemini and ChatGPT, in the context of enteral nutritional support.

METHODS
The present study was conducted using a test consisting of 10 questions derived from the ESPEN Enteral Nutrition Guidelines. The subjects of the study were the Gemini 1.5 and ChatGPT 4.0 models, which had been trained with the aforementioned guide. The subjects were presented with the questions in a random order, and their cookies had been cleared. Each correct answer was assigned a value of 1 point, while each incorrect answer received a value of 0 points. The collected data were then subjected to statistical analysis using the SPSS software.

RESULTS
The two models under consideration both demonstrated an accuracy rate of 80%. A subsequent analysis revealed that there was no statistically significant difference in the meansuccess rates (p>0.05). The models demonstrated comparable performance, particularly in the domain of clinical nutrition.

CONCLUSIONS
While Gemini and ChatGPT have demonstrated proficiency in providing reliable information on enteral nutrition, existing open-source systems require enhancement. These findings underscore the promise of LLMs as clinical decision support tools.

ASSOCIATION OF HEALTHFUL DIET PATTERN ADHERENCE WITH RISK OF INSOMNIA AMONG ADULTS: A LARGE-SCALE LONGITUDINAL STUDY USING GUANGZHOU BIOBANK COHORT STUDY

Jiao WANG[1]; Lin Xu[1]
[1]School of public health, Sun Yat-sen University, Guang Zhou Shi, China

BACKGROUND AND OBJECTIVES
Adherence to healthful diet patterns, such as the Dietary Approach to Stop Hypertension (DASH), the Mediterranean-dietary (MIND), and the planetary-health diets (PHD), has been widely recognized as being associated with a multitude of health-related outcomes. However, the existing body of research, particularly longitudinal analyses, is limited in reporting whether these diets serve as significant behavioral determinants of insomnia. Against this backdrop, the current study was designed with the aim of delving into the intricate relationship between adherence to these three diet patterns and the risk of insomnia among Chinese adults.

METHODS
This prospective cohort study harnessed data from the Guangzhou Biobank Cohort Study (GBCS). A total of 30,518 participants were initially recruited between 2003 and 2008, and subsequently, 18,104 participants had their sleep information re-assessed via self-reported questionnaires from 2008 to 2012. The DASH, MIND, and PHD scores were meticulously derived using a comprehensive food frequency questionnaire (FFQ), with higher scores signifying a greater degree of adherence to these dietary patterns. Participants were then stratified into three distinct groups based on the tertiles of their dietary scores. To evaluate the association between the DASH, MIND, and PHD dietary patterns and insomnia, we employed logistic regression analysis, utilizing both crude and adjusted models.

RESULTS
Initially, a total of 5,168 participants reported experiencing insomnia at baseline. After a follow-up period of 4.1 years, an additional 5,285 cases of insomnia were identified. Upon adjusting for common confounders such as sex, age, education, occupation, income, body mass index (BMI), systolic blood pressure (SBP), diastolic blood pressure (DBP), glucose levels, physical activity, smoking habits, and alcohol consumption, we found, compared to the lowest PHD tertile group, participants in the highest tertile exhibited a significantly lower risk of insomnia, with an odds ratio (OR) of 0.83 and a 95% confidence interval (CI) ranging from 0.76 to 0.91 (P value< 0.001). Similarly, the middle tertile group also demonstrated a reduced risk, with an OR of 0.93 and a 95% CI of 0.85 to 1.00 (P value=0.05). However, in contrast, the DASH and MIND scores did not exhibit any significant association with the risk of insomnia (all P value> 0.05).

CONCLUSIONS
There is a significant inverse longitudinal association between adherence to PHD dietary patterns and insomnia. Further studies are required to reveal the mechanisms.

PROTEOMICS INSIGHT INTO NUTRIENT RETENTION OF UNDERUTILIZED LEGUME: “A CASE STUDY OF BAMBARA GROUNDNUT (VIGNA SUBTERRANEA)”

Florence Adetutu Udofia[1]; Lizex Husselmann[2]; Gadija Mohamed[3]; Michael Abberton[4]; David Tabb[5]
[1]Bioscience Center, International Institute of Tropical Agriculture, Oyo State, Nigeria, Federal Republic of; [2]Department of Biotechnology, faculty of Natural Science, UWC, Bellville, South Africa; [3]Post-Harvest and Agro-Processing Technologies, ARC Infritec-Nietvoorbij, Stellenbosch,, South Africa; [4]Genetic Resources Center, International Institute of Tropical Agriculture, Oyo, Nigeria, Federal Republic of; [5]Department of Bioinformatics, University of Groningen, Groningen, Netherlands

BACKGROUND AND OBJECTIVES
Malnutrition, including protein and micronutrient deficiencies, remains a significant public health challenge in developing countries due to food insecurity, poverty, and dependence on staple crops. Research has shown that promoting underutilized legumes within food systems can enhance access to nutritious foods and foster healthier and more sustainable diets. Bambara groundnut (BGN) is a Drought-tolerant, underutilized legume rich in antioxidants and considered a complete food due to its diverse nutrient profile. However, one challenge is its hard-to-cook phenomenon, which limits its utilization and consumption. Therefore, this study investigated proteins and biochemical pathways associated with cooking in Bambara groundnut to enhance its nutritional benefits.

METHODS
Bambara groundnut accessions were boiled for 60 minutes and then pulverized into a fine powder using standard Laboratory techniques. Protein was extracted from the selected accession's uncooked and cooked Bambara groundnut. Protein profiling was done using a combination of Bradford assay, SDS-PAGE, and liquid chromatography-tandem mass spectrometry methods.

RESULTS
The SDS-PAGE analysis RESULTS show that cooking did not degrade all the proteins, while the spectrometry analysis revealed 1,970 proteins, with 251 proteins showing differential expression for the cooked samples. Additionally, 1,376 proteins were consistently quantified, with 153 exhibiting significant differences between boiled and uncooked samples. Principal Component Analysis (PCA) confirmed distinct clustering of boiled samples, with a clear separation between the Cooked and Uncooked groups forming a separate cluster.

CONCLUSIONS
These findings show that although nutrient degradation occurs, significant nutrient retention occurs. This provides insights into optimizing cooking methods to preserve the nutritional integrity of Bambara groundnut.

THE NUTRITIONAL VALUES OF A TRADITIONAL SOURDOUGH BREAD

Serena Pavoni[1]; Cyril Chupiet[1]; Adriano Farano[1]; Gaëtan Boléa[2]; Guillaume Walther[3, 4]
[1]R&D, Pane Vivo - Bac, Paris, France; [2]R&D, Biophysium, Avignon, France; [3]IGBalance, Avignon Université: Campus Hannah Arendt, Avignon, France; [4]LaPEC UPR4278, Avignon Université: Campus Hannah Arendt, Avignon, France

BACKGROUND AND OBJECTIVES

Carbohydrates, of which bread is a major source, account for 50-55% of daily energy intake. Their impact on health depends on the quantity ingested and their quality, assessed using indicators such as the glycaemic index (GI), glycaemic load, fibre (type and content) and minerals. To ensure a high-quality carbohydrate intake, recommendations limit high-GI breads (>70), such as standard white bread, made from refined flour and industrial yeast. Moreover, this type of bread has a low fibre and mineral content. However, using wholemeal flour and an increase in fiber are not enough to reduce the GI. In fact, it depends on factors that cannot be considered separately. These include the variety of wheat, the type of milling, and consequently the type of flour, as well as the fermentation method. The aim of this study was to assess the carbohydrate quality of a bread made from wholemeal flour of old durum wheat, fermented with natural sourdough, by measuring its fibre and mineral content and quantifying its GI.

METHODS

Analyses of total fibre composition (enzymatic method MI MUNO85) and minerals (phosphorus, calcium, iron, copper, zinc, magnesium, manganese and potassium, method MI MUNO05-ICP-OES) were performed by Capinov laboratory (Landerneau, France). The GI of bread was measured (1) *in vitro*, through the quantity of glucose released following a digestion simulation including the oral, gastric and intestinal phases (adapted from COST INFO GEST 2019) and (2) in a clinical study, by monitoring the blood glucose levels of 11 healthy individuals for 2 hours after consumption of the bread (ISO standard). The level of resistant starches was measured and compared with that of an industrial-type white bread.

RESULTS

Our RESULTS show that this bread contains more total fibres than an industrial-type white bread (5.9 vs. 3.8 g/100g) and is also richer in minerals, particularly iron (24.7 vs. 12.5 mg/kg), zinc (31 vs. 7.5 mg/kg), manganese (17.1 vs. 6.7 mg/kg) and magnesium (2530 vs. 277 mg/kg). Our RESULTS also show that the GIs of this experimental bread are 47.2 and 48.6 respectively for the in vitro and in vivo studies, and that the level of resistant starch is 5 times higher than that of a traditional bread fermented with sourdough.

CONCLUSIONS

In conclusion, this type of bread could form part of the diet of individuals who need to control their diet, as in the case of diabetes for example, or in the context of a preventive diet.

THE INCREASE OF THE LEVEL OF SOME VITAMINS AND TRACE MINERALS IN THE LAYER FEED ENABLES TO ENRICH THE CONTENT OF THE EGGS IN THESE NUTRIMENTS AND TO PRODUCE MULTI-ENRICHED EGG

Clarisse Palacios[1]; Jacques Delarue[2]; Anne-Yvonne Prigent[3]; Michel Colin[4]
[1]Human Nutrition, COPRI SAS, Ploudalmézeau, France; [2]ER7479 SPURBO, Faculty of Medicine/University of Brest, Brest, France; [3]Finistère, EARL 3L, Ploudalmézeau, France; [4]Finistère, COPRI SAS, Ploudalmézeau, France

BACKGROUND AND OBJECTIVES

Some publications have demonstrated that the egg content in vitamins and trace minerals is influenced by the content in the layer feed (1). Following our work on the DHA enrichment of eggs (2), we have studied experimentally the possibility of increasing the levels of vitamins D3, E, B9, B12 of iodine and selenium. The data's for vitamin A (3) and iron comes from the literature (4). Partial RESULTS of the experimentation have already been published (5).

METHODS

The content of standard eggs in vitamins A, D3, E, B9, B12 and in iodine, iron and selenium have been studied summarizing the data's of 8 nutritional tables, including the French (6,7), the Japanese (8) and the US ones (9). The value retained is the average of the data's from these different tables after elimination of the values separated by 2 times the standard deviation of the raw mean. The values concerning the vitamins D3, E, B9, B12, the iodine and the selenium for the multi-enriched eggs were established during 8 trials comparing 2 treatments, one consisting in distributing a standard diet to hens for 4 weeks, the other a diet enriched with one or more nutriments.

RESULTS

The level in eggs of the vitamins and trace minerals can be increased by distributing layer feeds with higher nutriments contents (Table 1). The vitamin E and iodine have particularly high possibilities of enrichment (Respectively x 14 and 8). The increase is between 2.5 and 3 times for the vitamins D and B12 and between 20 and 70 % for the other nutriments.

Table 1: Levels of vitamins and trace minerals for standard (SE) and multi-enriched eggs (MEE) (/100 grams)

Nutrients	SE	MEE	Rate of increase	% coverage of MEE
Vitamin A (µg)	175	289	x 1,7	41,3
Vitamin D (µg)	2,12	5,85	x 2,8	117,0
Vitamin E (mg)	2,05	28,65	x 14,0	286,5
Vitamin B9 (µg)	65	81	x 1,2	40,4
Vitamin B12 (µg)	1,31	3,54	x 2,7	252,6
Iodine (µg)	30,3	247,8	x 8,2	190,6
Iron (mg)	1,65	2,94	x 1,8	18,4
Selenium (µg)	27,9	45,3	x 1,6	82,4

CONCLUSIONS

The eggs contents in some vitamins and trace minerals can be increased through the feeding of the layers, enabling to develop a multi-enriched egg able to improve health population.

EFFECT OF DRYING TECHNIQUES ON NUTRITIONAL COMPOSITION, ANTI-NUTRITIONAL FACTORS AND ANTIOXIDANT POTENTIAL OF LEAF AND STEM PARTS OF PORTULACA QUADRIFIDA (KIMMA)

Dandi Mitiku[1, 2]; Endale Amare[1]; Eskedar Getachew[2]; Anbissa Muleta[1]; Abebe Ayelign[3]
[1]Nutrition, Environmental Health and Non-communicable disease, Ethiopian public health institute, Addis Ababa, Ethiopia; [2]Food science and applied nutrition, Bioprocessing and Biotechnology center of excellence, Addis Ababa Science and Technology University, Addis Ababa, Ethiopia; [3]Center for Food Science and Nutrition, Addis Ababa University, Addis Ababa, Ethiopia

BACKGROUND AND OBJECTIVES
Food and nutrition continue to pose a global challenge in public health and environmental sustainability issues. At the core lies a problem of food and nutrition burden which encompasses a range of issues in malnutrition, food insecurity, and the rise in diet- related diseases. Ethiopia faces higher rate of malnutrition due to food insecurity and nutrient-poor staple diets. *Portulaca quadrifida* (locally known as Kimma) an underutilized plant, has potential to contribute in tackling the challenges of malnutrition and promote health. This study examined the nutritional composition, anti-nutritional factors and antioxidant activity of *Portulaca quadrifida* focusing on its potential for improving diets and supporting sustainable food systems.

METHODS
Samples of fresh whole plant material of *Portulaca quadrifida* was collected from Benishangul Gumuz region Bullen district using systematic sampling technique. Both leaf and stem parts were collected, dried separately using air and freeze drying for further analysis.

RESULTS
The finding showed that greater ash, fat, as well as tannins and oxalates at concentrations of **13.62-16.91%, 3.05-3.27%, 2.85-3.42%** and **0.04-0.05%** respectively across both drying methods on the leaves. Whereas stems were superior in protein **10.16-15.07%** and had lower tannin and oxalate content **0.93-1.38%** and**0.0269-0.0293%** respectively. Significant ($P<0.05$) differences in both plant parts were observed between drying methods. In terms of antioxidant activity freeze drying demonstrated a higher total phenolic **1130.6-2876.4mgGAE/100g** and total flavonoid **216.9-3390mgQE/100g** than air drying. It also exhibited stronger antioxidant activities with radical-scavenging effects using DPPH **38.93-58.25mgAAE/100g.**

CONCLUSIONS
The study emphasizes the potential of utilizing both plant parts due to the varying nutritional and antioxidant properties suggesting further research on its sustainability, economic potential and functional food applications.

EPO4_065

THE IMPACT OF ILLEGAL SMALL-SCALE MINING ON NUTRITION, FOOD SECURITY, AND SUSTAINABLE DEVELOPMENT IN AFRICA

Angelica Essandoh[1]; Justina Owusu,[1]
[1]Nutrition, University of ghana, Legon, Accra, ghana, Ghana

BACKGROUND AND OBJECTIVES
Illegal small-scale mining has become a significant challenge across Africa, providing economic opportunities while contributing to socio-economic, environmental, and public health concerns. In Ghana, this practice is referred to as "galamsey," while similar informal mining practices, such as "zama zamas" in South Africa and "makorokoza" in Zimbabwe, underscore common challenges of unregulated mining in resource-rich regions. This review examines the historical context, drivers, impacts, and policy responses to "galamsey" in Africa, with a focus on its implications for nutrition, food security, and sustainable development

METHODS
A comprehensive review of peer-reviewed articles, government reports, and case studies was conducted. A systematic search was made in databases such as PubMed, ScienceDirect, Google Scholar, and JSTOR using search terms like "galamsey," "illegal small-scale mining," "food security and mining," and "nutrition and mining." Comparative analyses of illegal mining practices in Ghana, Zimbabwe, South Africa, and Nigeria were included to broaden the contextual understanding.

RESULTS
Illegal small-scale mining is linked to colonial histories and economic policies that relaxed regulations. Economic hardship, unemployment, and weak regulatory frameworks drive the practice. Environmental degradation, including deforestation, water contamination, and soil erosion, severely affects agricultural productivity and food security. Health risks from exposure to toxic substances including mercury release into water bodies exacerbate malnutrition by contaminating food and water sources, impairing nutrient absorption and weakening immunity. While illegal small-scale mining supports local economies, its unregulated nature worsens income inequality and food insecurity. Limited enforcement, corruption, and lack of community engagement hinder regulation efforts.

CONCLUSIONS
Illegal small-scale mining poses a significant threat to food security, nutrition, and sustainable development in Africa. Policy recommendations include strengthening legal frameworks, improving enforcement mechanisms, promoting sustainable livelihoods, and engaging local communities in monitoring efforts. Future research should assess the long-term impacts of illegal small-scale mining on food systems and evaluate the effectiveness of policy interventions in supporting food security and global health goals.

EPO4_066

IODINE NUTRITION AFTER DRINKING COW'S MILK COMPARED TO OAT DRINK – A RANDOMISED CONTROLLED STUDY

Sarah Louise Rung[1]; Inger Aakre[2]; Eline Olsen Gravrok[1]; Jutta Dierkes; Hanne Rosendahl-Riise,[3]
[1]Department of Clinical Medicine, University of Bergen, Bergen, Norway; [2]Food Security and Nutrition, Norwegian Institue of Marine Research, Bergen, Norway; [3]Centre for Nutrition, Department of Clinical Medicine, University of Bergen, Bergen, Norway

BACKGROUND AND OBJECTIVES
A recent dietary trend involves replacing cow's milk with plant-based alternatives, motivated by the perception that plant-based options are healthier and more sustainable. This trend is especially popular among young women, of whom iodine nutrition is also of concern. Some of the plant-based alternatives are fortified with iodine, but the bioavailability and whether it is feasible to consume enough to provide an adequate iodine intake is unknown. Thus, the main objective of the present study was to compare the iodine nutrition in those drinking iodine-fortified oat drinks compared to cow's milk.

METHODS
A randomised study was initiated, in which participants were randomly assigned to either drink 6 dl of cow's milk or oat drink for 4 weeks. Healthy women between 18 and 40 years of age who were habitual milk drinkers were recruited during the fall of 2024 in Bergen, Norway. 24-hour urine was collected, and urinary iodine excretion (UIE) was calculated at baseline and end of the study. 24-hour dietary recall was used to assess habitual diet and dietary iodine intake at both time points.

RESULTS
32 healthy women (oat drink=15, cow´s milk=17) aged 19-28 years participated in the study. The median (p25-p75) UIE (p25-p75) was 123 (97-143) µg/24h at baseline and 147 (133-179) µg/24h at end of study for the oat drink group and 137 (112-174) µg/24h at baseline and 180 (136-207) µg/24h at end of study in the cow´s milk group, aligning with the epidemiological criteria for sufficient iodine nutrition. A significant increase in UIE and estimated iodine intake (from 24-hour urine and 24-hour dietary recall) was noted in the cow's milk group but not in the oat drink group. However, no significant differences between the two groups were found following the intervention for UIE, which may indicate that both drink alternatives contribute to increased iodine intake.

CONCLUSIONS
Compliance was high and comparable between both groups (oat drink and cow's milk), indicating that both drink alternatives were equally feasible for participants. Furthermore, it appears that iodine-fortified oat drink may be associated with increased iodine intake and could thus serve as a comparable source of iodine to cow´s milk.

CONFLICTS OF INTERESTS
The authors have no conflict of interest.

THE STATE OF FOOD COMPOSITION DATABASES: DATA ATTRIBUTES AND FAIR DATA HARMONIZATION

Sarah Brinkley[1]; Jenny Gallo[2]; Natalia Vazquez Manjarrez[3]; Juliana Chaura Cortés[4]; Quartey Naa K-A[5]; Sahar Toulabi[6]; Melanie Odenkirk[7]; Eva Jermendi[8]; Laporte Marie-Angélique[9]; Maya Rajasekharan,[2]; John De La Parra[10]; Selena Ahmed[11]

[1]Biodiversity for Food & Agriculture, Bioversity International, Rome, Italy; [2]Food for Nutrition and Health, International Center for Tropical Agriculture (CIAT), Palmira, Valle del Cauca, Colombia; [3]FISIOLOGIA DE LA NUTRICIÓN, Salvador Zubirán National Institute of Health Sciences and Nutrition, Ciudad de México, Mexico; [4]Pontificia Universidad Javeriana, IÓMICAS Research Institute, Cali, Colombia; [5]Food Science and Technology, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana; [6]Food Science, Colorado State University, Fort Collins, United States of America; [7]Department of Horticulture and Landscape Architecture, Colorado State University, Fort Collins, United States of America; [8]Division of Nutrition and Health, Wageningen University & Research, Wageningen, Netherlands; [9]Digital Inclusion, Alliance Bioversity and CIAT, Montpellier, France; [10]Global Food Portfolio, The Rockefeller Foundation, New York, United States of America; [11]Periodic Table of Food Initiative, American Heart Association, Inc, Dallas, United States of America

BACKGROUND AND OBJECTIVES

Food composition databases (FCDBs) are essential tools for characterizing and advancing scientific understanding of the molecular composition of food across the spectrum of edible biodiversity. This knowledge supports applications across food systems from agriculture to human health. To unlock the full potential of food data, FCDBs must adhere to criteria such as validated analytical methods, high-resolution metadata, and FAIR Data Principles (Findable, Accessible, Interoperable, and Reusable). However, the complexity and variability of these databases pose significant challenges to meet these standards

METHODS

In this study, we conducted a systematic review of 35 data attributes across 101 FCDBs from 110 countries to evaluate their current state. Data attributes were categorized into three groups: general database information, food samples and components, and alignment with FAIR principles

RESULTS

Our findings reveal that many countries lack the resources to produce or maintain a national FCDB covering locally consumed foods. Existing databases show substantial variability in scope and content, with the number of foods and components ranging from a few to thousands. Databases with large numbers of foods often rely on secondary data from scientific articles or other FCDBs, while those with fewer food and components mainly include primary analytical data generated by database entities. Update frequencies also vary, with web-based databases being updated more frequently than static tables. When assessed for FAIR compliance, all FCDBs met the Findable criteria. However, challenges such as inadequate metadata, inconsistent scientific naming, and unclear data reuse policies hinder the comparability and usability of these databases. Features of FCDBs also correlate with economic classification, as high-income countries tend to produce databases with primary data, web interfaces, and more regular updates. This highlights the need for increased support and guidelines to ensure consistent and accurate global comparisons

CONCLUSIONS

This landscape assessment provides a detailed snapshot of the current state of FCDBs and identifies opportunities for improvement. We recommend expanding food and component coverage, unifying analytical methods, and enhancing metadata and FAIR compliance to improve global harmonization. By fostering a comprehensive understanding of food composition, FCDBs can better support stakeholders in addressing societal challenges, leveraging data-driven solutions to promote human and planetary health

TITLE: LEVERAGING THE ROLE OF UNDERUTILIZED FOODS TOWARDS A SUSTAINABLE FOOD SYSTEM: THE CASE OF ANCHOTE (COCCINIA ABYSSINICA)

Esayas Abrha[1, 2]; Alganesh Tola[2]; Paulos Getachew[3]; Endale Amare[1]
[1]Nutrition, Environmental Health and Non-communicable disease, Ethiopia Public Health Institute, Addis Ababa, Ethiopia; [2]Food Sciences and Nutrition, Ethiopian Institute of Agricultural Research, Addis Ababa, Ethiopia; [3]Food Sciences and Nutrition, Addis Ababa University, Center for Food Sciences and Nutrition, Addis Ababa, Ethiopia

BACKGROUND AND OBJECTIVES
Introduction: The study will investigate the potential of underutilized foods (UFs) to improve food security and sustainability. UFs, which are sometimes overlooked in contemporary diets, have a variety of nutritional properties and can be quite advantageous. In order to advance sustainable food systems and broaden culinary horizons, consideration of underutilized crops is essential. Anchote are frequently overlooked despite their high nutritional values and potential to improve food security and decrease malnutrition. The reasons include social taboos, labor-intensive processing, environmental factors, and traditional management methods. A wide variety of UFs should be incorporated into agriculture and food systems in order to accomplish goals including the elimination of hidden hunger, encouragement of food diversity, and environmental sustainability.

METHODS
Methodology: A cross-sectional study was conducted among farmers producing Anchote. A total of 40 farmers from four districts were e involved in this research. Anchote cultivars tuber part and the indigenous knowledge data collections were conducted by focus group discussion and key informants' data collection methods. Five kilograms of Anchote variety samples were taken from each of these four districts, for a total of forty kilograms. Following collection, the samples will be analyzed utilizing cutting-edge OMIC technologies, such as proteomics, lipideomics, ionomics, and metabolomics.

RESULTS
Expected RESULTS: The underutilized plant Anchote from the tuber crop was investigated for its nutritional and biochemical composition using omics techniques to determine how they might be affected by the growing agro-ecology and variety effect. The nutritional and biochemical chomposition of the Anchote will be well understood by this study, which could provide important information on its quality and affordability.

CONCLUSIONS
Conclusion: underutilized plants, anchote can mitigate food and nutrition insecurity by providing vitamins, minerals, dietary fibers, and bioactive compounds. This research will provide valuable insights for policymakers, food producers, and consumers to leverage the potential of anchote in creating a more sustainable and equitable future of food.

UNLOCKING THE POTENTIAL OF UNDERUTILIZED CROPS FOR SUSTAINABLE FOOD SYSTEMS AND IMPROVED NUTRITION IN EUROPE

Marija Knez[1, 2]; Marija Ranic[1, 2]; Jelena Milesevic[1, 2]; Mirjana Gurinovic[2]; Marija Takic[1]; Amil Orahovac[3]; Sonia Negrao[4]; Bálint Balázs[5]; George Bourakis[6]; Athanasios Koukounaras[7]; Andreas Katsiotis[8]; Konstadinos Mattas[9]
[1]Centre of Research Excellence in Nutrition and Metabolism, Institute for Medical Research, University of Belgrade, Belgrade, Serbia; [2]Capnutra, Capacity Development in Nutrition, Belgrade, Serbia; [3]Faculty of Food Safety, Food Technology and Ecology, University of Donja Gorica, Podgorica, Montenegro; [4]School of Biology and Environmental Science, University College Dublin, Dublin, Ireland; [5]Environmental Social Science Research Group, Environmental Social Science Research Group, Budapest, Hungary; [6]Department of Economic and Management Sciences, Mediterranean Agronomic Institute of Chania, Chania, Greece; [7]Laboratory of Vegetable Crops, School of Agriculture, Aristotle University of Thessaloniki, School of Agriculture, Aristotle University of Thessaloniki, Thessaloniki, Greece; [8]Department of Agricultural Sciences, Biotechnology and Food Science, Cyprus University of Technology, Limassol, Cyprus; [9]Department of Agricultural Economics, Aristotle University of Thessaloniki, Thessaloniki, Greece

BACKGROUND AND OBJECTIVES

The BioValue and Diversicrop projects share a common goal of enhancing food security, agricultural sustainability, and human nutrition by focusing on underutilized, genetically diverse crops. These initiatives address critical challenges in the European agri-food system, such as climate resilience, nutritional quality, and sustainable land use, aligning with the European Green Deal's Farm to Fork and Biodiversity strategies and contributing to the UN Sustainable Development Goals.

METHODS

BioValue and Diversicrop used agent-based modeling, participatory breeding, consumer surveys, literature reviews, case studies, and database analysis.

RESULTS

BioValue emphasizes the reintegration of underutilized crops into the European agri-food value chain through advanced methodologies, including agent-based modeling to optimize production, quality control, and delivery systems. Its participatory breeding programs identify high-yield, market-viable cultivars across diverse climatic regions, while novel food development engages nutritionists, food scientists, and chefs to create innovative, consumer-accepted products. By promoting seven underutilized crops in twelve countries, BioValue supports sustainable agriculture, healthier diets, and resilience to environmental and political challenges.
Similarly, Diversicrop explores the historical, genetic, and adaptive potential of resilient crops such as rye and legumes to inform sustainable cultivation practices and dietary recommendations. The project employs a multidisciplinary approach, with the nutrition working group assessing the nutritional value, health benefits, and consumption patterns of these crops through literature reviews, case studies, and analysis of databases like FAO food balance sheets and EFSA resources. By integrating historical insights, modern agricultural techniques, and policy data, Diversicrop aims to overcome barriers to the utilization of these crops, enhancing crop diversity, improving nutritional outcomes, and strengthening the resilience of European food systems.

CONCLUSIONS

These projects highlight the value of collaboration and innovation in tackling agricultural and nutritional challenges. By revitalizing underutilized crops and advancing sustainable food systems, BioValue and Diversicrop support resilient, nutritious food for future generations.

FIBER-ENRICHED KOMBUCHA TEA MODULATES TRIGLYCERIDES AND THE GUT MICROBIOTA IN HEALTH POPULATION: A RANDOMIZED CONTROLLED TRIAL

Guadalupe X. Bazán[1]; Beatriz Arce-López[1]; Susana Molina[1]; Maria Carmen Crespo[1]; Maria García-Beccaria[1]; Cristina M. Fernandez-Diaz[1]; Silvia Cruz-Gil[2]; Ana Calvo Madueño[2]; Andrea Ochaita Aguado[2]; Ana Ramirez De Molina[2]; Ricardo Ramos-Ruíz[1]; María Isabel Espinosa-Salinas[1]
[1]GENYAL Platform, IMDEA Food, CEI UAM+CSIC. Carretera de Cantoblanco, 8. 28049, Madrid, Spain; [2]Molecular Oncology Group, IMDEA Food, CEI UAM+CSIC. Carretera de Cantoblanco, 8. 28049, Madrid, Spain

BACKGROUND AND OBJECTIVES
The development of functional foods with health-promoting properties is a priority in addressing chronic diseases. Studying the effect of these foods on gut microbiota provides critical insights into the interplay between microorganisms, health, and disease. This study aimed to evaluate the effects of fiber-enriched kombucha tea on biochemical parameters and gut microbiota composition in a healthy population.

METHODS
A randomized, double-blind, parallel nutritional intervention trial was conducted with 60 participants (58 completed: 42 women and 16 men; mean ± SD age: 39.7 ± 14.5 years). Participants were randomized into two groups consuming either 250 mL/day of a control beverage or the fiber-enriched kombucha tea for six weeks. Lifestyle and biochemical data were collected, and gut microbiota composition and diversity were assessed using 16S rDNA sequencing.

RESULTS
Significant biochemical and microbiota-related improvements were observed in the study group compared to the control. The study group exhibited a statistically significant reduction in triglyceride levels (baseline mean ± SEM: 69.6 ± 7.0 mg/dL; post-intervention: 62.8 ± 5.1 mg/dL), while the control group experienced a slight increase (baseline: 77.2 ± 8.6 mg/dL; post-intervention: 82.7 ± 8.8 mg/dL; $p = 0.031$). Additionally, fiber-enriched kombucha consumption led to a notable increase in *Bifidobacterium* abundance, recognized for its intestinal health benefits and immunomodulatory effects. A reduction in *Ruminococcus torques*, linked to inflammatory bowel diseases, was also observed.

CONCLUSIONS
Fiber-enriched kombucha tea demonstrates potential health benefits, including triglyceride modulation and positive alterations in gut microbiota composition. These findings suggest its promise as a functional beverage for improving metabolic and gut health in healthy individuals. Further randomized controlled trials are warranted to confirm these benefits.

THE INTERSECTION BETWEEN FOOD PRODUCTION AND THE GLOBAL SYNDEMIC: A SCOPING REVIEW

Laís Dias[1]; Fernanda Severo[2]; Anderson Alves[3]; Aline Carvalho[4]
[1]Department of Nutrition, School of Public Health of University of São Paulo, São Paulo, Brazil; [2]Departamento de Nutrição, Faculdade de Saúde Pública USP, São Paulo, Brazil; [3]Department of Nutrition, Federal University of Sergipe, Lagarto, Brazil; [4]Nutrition, University of São Paulo, School of Public Health, São Paulo, Brazil

BACKGROUND AND OBJECTIVES
Food systems are key drivers of the global syndemic, which involves undernutrition, obesity, and climate change. However, few studies explore how specific components of the food system influence this syndemic. This study aimed to identify the relationships between food production and the components of the global syndemic.

METHODS
A scoping review was conducted between January and September 2024. The search strategy utilized keywords related to food production and each component of the syndemic (obesity, undernutrition, and climate change), filtered by title and abstract, and limited to the last five years. The main inclusion criterion was that the study addressed food production and at least two components of the global syndemic.

RESULTS
The initial search identified 6,567 articles, of which 4,080 remained after removing duplicates. Following the title screening, 951 articles were selected, and 28 were included after abstract and full-text review. Among these, 27 studies addressed climate change and undernutrition, while one study explored all three components of the syndemic within the scope of food production.
An in-depth analysis revealed that food production significantly contributes to the worsening of the global syndemic. Studies showed that climate change negatively impacts soil fertility, reducing agricultural productivity. This, in turn, affects physical and economic access to food, influencing dietary intake and population nutritional status. Furthermore, the adverse effects of climate change drive some farmers to shift to livestock farming as an immediate solution to declining soil fertility and reduced crop yields. In addition, the increase in extreme weather events caused by climate change disproportionately affects rural populations, leading to higher migration rates. This migration disrupts access to healthy foods and further deteriorates the nutritional status of affected populations. While the relationship among food production, climate change and undernutrition is well-documented, there are significant gaps in understanding the link among food production, undernutrition and obesity, as few studies address obesity in this context of food production.

CONCLUSIONS
The findings emphasize the central role of food production in worsening the global syndemic, particularly through climate change and undernutrition, while highlighting the need for further research on obesity. This review lays the groundwork for developing sustainable strategies to tackle these interconnected challenges.

EXAMINING THE EFFECTS OF HAEMOGLOBIN AND IRON STATUS ON CHILD NEURODEVELOPMENT IN UGANDA

Margaret Nampijja[1, 2]; Agnes Mutua[3]; Alison Elliott[2, 4]; John Muriuki[3]; Amina Abubakar[5, 6, 7]; Emily Webb[8]; Sarah Atkinson[3, 9, 10]

[1]Maternal and Child Wellbeing Unit, African Population & Health Research Centre, Nairobi, Kenya; [2]Medical Research Council, Uganda Virus Research Institute, Entebbe, Uganda; [3]Epidemiology and Demography, KEMRI-Wellcome Trust Research Programme, Kilifi, Kenya; [4]Department of Clinical Research, London School of Hygiene & Tropical Medicine, London, United Kingdom; [5]Institute for Human Development, Aga Khan University, Nairobi, Kenya; [6]Neuroscience Unit, KEMRI-Wellcome Trust Research Programme, Kilifi, Kenya; [7]Department of Psychiatry, University of Oxford, Oxford, United Kingdom; [8]Faculty of Epidemiology and Population Health, London School of Hygiene & Tropical Medicine, London, United Kingdom; [9]Centre for Tropical Medicine and Global Health, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom; [10]Department of Paediatrics, University of Oxford, Oxford, United Kingdom

BACKGROUND AND OBJECTIVES

Children in Sub-Saharan Africa (SSA) are highly vulnerable to impaired development, especially in the critical first five years of life, due to multiple exposures such as infections and nutritional deficiencies. Anaemia and iron deficiency (ID), which are prevalent among pregnant women and young children in SSA, have been linked to abnormal brain development. However, evidence on the association between ID, anaemia, and child neurodevelopment in SSA remains limited. This study aimed to examine the effects of maternal and child haemoglobin (Hb) levels and child iron status on neurodevelopmental outcomes in preschool-aged Ugandan children.

METHODS

We utilized data from the Entebbe Mother and Baby Study, a prospective birth cohort, to assess the effect of maternal and child Hb levels, and child iron status, on developmental scores in 933 and 530 pre-school Ugandan children, respectively. Neurodevelopmental outcomes were measured at 15 months and 5 years. We used regression analyses to examine associations between maternal and child Hb levels, child iron status, and neurodevelopmental scores, adjusting for potential confounders.

RESULTS

Lower Hb levels in infancy were associated with reduced psychomotor and language scores at 15 months (β:0.07, 95% CI: 0.02-0.12, p=0.003). Lower maternal Hb levels were also independently associated with reduced psychomotor scores in children at 15 months (β: 0.05, 95% CI: 0.0002-0.09, p=0.05). We found an interaction between maternal and infant anaemia such that anaemia at both time points resulted in a much larger reduction in psychomotor scores at 15 months (β: −0.35, 95% CI: −0.52-−0.19, p<0.0001). However, no associations were observed between anaemia or ID and cognitive or motor scores at five years of age.

CONCLUSIONS

These findings highlight the importance of addressing anaemia during pregnancy and early childhood to improve child development. While no long-term effects on neurodevelopmental outcomes at five years were observed, more research is necessary to fully understand the impacts of anaemia and ID on child neurodevelopment in SSA. We plan to further investigate the effects of anaemia and iron status on neurodevelopmental outcomes in young African children applying the Mendelian Randomization approach to infer causality.

EXAMINING SEX DIFFERENCES IN UNDERNUTRITION AMONG CHILDREN UNDER FIVE: FINDINGS FROM A META-ANALYSIS OF 93 CROSS-SECTIONAL SURVEYS IN SEVEN EMERGENCY CONTEXTS

Kaitlyn Samson[1]; Jenna Hickey[2]; Pai-Shan Cheng[3]; Aseel Masri[3]; Alyssa Vets[3]; Victoria Sauveplane-Stirling[2]; Megan Brown Wollenberg[1]; Jana Daher[1]; Hassan Ali Ahmed[4]; Daniel Sellen[2]
[1]Technical Department, Action Against Hunger, Toronto, Canada; [2]Anthropology, University of Toronto, Toronto, Canada; [3]Dalla Lana School of Public Health, University of Toronto, Toronto, Canada; [4]Nutrition and Child Development Programme Group, UNICEF, New York, United States of America

BACKGROUND AND OBJECTIVES
There is growing evidence that gender inequality is associated with malnutrition. Recent literature suggests that undernutrition may differ across sexes and by assessment tools. The objective of this research was to determine if the status of undernutrition differed between sexes among children under five years of age in seven humanitarian contexts.

METHODS
Data were obtained from n=93 representative, sub-national SMART surveys (2018-2022). Bayesian random-effects meta-analysis was used to determine the log odds ratios for undernutrition outcomes among boys versus girls. Undernutrition outcomes assessed included global acute malnutrition (GAM), severe acute malnutrition (SAM), and stunting. GAM and SAM were assessed by both weight-for-height z-scores (WHZ), mid-upper-arm circumference (MUAC), and edema. Stunting was assessed through height-for-age z-score (HAZ). An index combining all children classified as acutely malnourished was also explored.

RESULTS
Overall, data from n=29,323 boys and n=28,772 girls were included in the WHZ analysis while data from n=29,763 boys and n=29,129 girls were included in the MUAC analysis. Data from n=28,010 boys and n=27,367 girls were available for HAZ analysis. Significant differences were found for all undernutrition indicators across sexes, but the odds differed depending on the indicator analyzed. Based on WHZ, boys had significantly higher odds of GAM (OR: 1.30; 95% CrI: 1.23, 1.38) and SAM (OR: 1.47; 95% CrI: 1.33, 1.63) as compared with girls. However, when using MUAC, boys were observed to have significantly lower odds of GAM (OR: 0.82, 95% CrI: 0.77, 0.87) and SAM (OR: 0.87; 95% CrI: 0.78, 0.97) as compared with girls. Looking at a combined index of acute malnutrition, that considered both MUAC and WHZ, boys had slightly higher odds of both cGAM (OR: 1.06, 95% CrI: 1.01, 1.12) and cSAM (OR: 1.10; 95% CrI: 1.01, 1.20) than girls. The odds of stunting (OR: 1.45 95% CrI: 1.37, 1.53) were also higher among boys than girls.

CONCLUSIONS
Our findings show that, based on WHZ and HAZ, boys have significantly higher odds of undernutrition than girls. However, when children were assessed using MUAC, girls had significantly higher odds of both GAM and SAM. Altogether, these data affirm the complementarity and additive nature of the two measurement methods and emphasize the need to use both for acute malnutrition assessments. Further research is needed to understand how and why sex and gender differences in undernutrition occur so that preventative, gender-transformative programming can be implemented.

ADDRESSING VACCINE HESITANCY IN ADULTS: A CBPR STUDY THROUGH THE LENS OF THE EXPANDED FOOD AND NUTRITION EDUCATION PROGRAM

Virginie Zoumenou[1]; Verona Mulgrave[2]; Dionne Ray[3]; Kritika Gupta[4]
[1]Extension/Human Ecology, University of Maryland Eastern Shore, Princess Anne, United States of America; [2]Extension, Delaware State University, Dover, United States of America; [3]Extension, University of Maryland Eastern Shore, Princess Anne, United States of America; [4]Institutional Research & Evaluation, University of California R, Riverside, United States of America

BACKGROUND AND OBJECTIVES
Adults in Black Indigenous People of Color (BIPOC) communities face disproportionate risks from vaccine-preventable diseases. Vaccine hesitancy, driven by mistrust, misinformation, and systemic barriers, poses a significant public health challenge. This study aimed to assess vaccination perceptions, develop culturally relevant interventions, and evaluate changes in attitudes following an educational initiative linked to the Expanded Food and Nutrition Education Program (EFNEP) in rural Delaware and Maryland.

METHODS
A mixed-methods Community-Based Participatory Research (CBPR) approach was employed, combining quantitative surveys with qualitative focus groups and interviews.The study included 124 participants pre-intervention and 89 post-intervention, primarily adults from BIPOC communities engaged in EFNEP in Sussex County (Delaware) and Somerset and Wicomico Counties (Maryland).Quantitative data were analyzed using logistic regression, while qualitative data were thematically coded. Pre- and post-intervention data comparisons identified shifts in barriers, facilitators, perceptions, and trust.

RESULTS
Pre-Intervention Barriers: Lack of accurate information (57.4%) and mistrust in public health agencies (36.8%).
Facilitators: Nutrition education program, family networks, and healthcare provider recommendations were critical in encouraging vaccination.
Post-Intervention Outcomes: Barriers to vaccination decreased by 93%, and trust in healthcare providers rose by 90%. Participants reported improved understanding of vaccine safety and efficacy, though lingering skepticism was noted

CONCLUSIONS
Community-focused educational interventions integrated with EFNEP effectively reduced vaccine hesitancy and enhanced trust among rural BIPOC adults. Community Engagement: Leveraging trusted community leaders and networks to disseminate vaccine information can enhance credibility and acceptance. These findings emphasize the importance of culturally sensitive strategies and the synergy between nutrition education and vaccine confidence-building efforts. Future research should explore the scalability and long-term impact of such integrated interventions across diverse populations.

HEALTHY EATING INTENTIONS OF CHINESE ADULTS ARE MODIFIED BY FOOD LITERACY: THE THEORY OF PLANNED BEHAVIOR

Ji-Yun Hwang,; Baicai Xu,[1]
[1]Department of Foodservice Management and Nutrition, Sangmyung University - Seoul Campus, Seoul, Korea, Republic of

BACKGROUND AND OBJECTIVES
With rapid economic growth in China, unhealthy dietary patterns have become a significant contributor to the rising prevalence of chronic diseases. Food literacy—encompassing the knowledge, skills, and capacity to select, prepare, and consume food—plays a crucial role in shaping dietary behaviors. This study investigates the impact of food literacy on healthy eating intentions based on the theory of planned behavior (TPB).

METHODS
A cross-sectional survey was conducted with 492 adults in Shandong Province, China. Data were analyzed using multiple regression analysis and structural equation modeling (SEM). The TPB framework, consisting of attitudes, subjective norms, and perceived behavioral control (PBC), was employed to explore the relationship between food literacy and healthy eating intentions.

RESULTS
Higher food literacy levels were associated with increased scores for TPB constructs and stronger behavioral intentions. Regression analysis revealed that all three core components of TPB—attitudes, subjective norms, and PBC—were positively correlated with healthy eating intentions, with PBC showing the strongest association. Notably, food literacy enhanced PBC, leading to greater behavioral intentions. Among participants with the lowest and highest food literacy levels, subjective norms and attitudes, respectively, were the primary drivers of behavioral intentions. SEM analysis demonstrated that food literacy directly influenced TPB components, while subjective norms and PBC significantly predicted healthy eating intentions. However, attitudes did not significantly predict behavioral intentions.

CONCLUSIONS
This study highlights the pivotal role of food literacy in fostering healthier eating behaviors through its influence on TPB constructs. Enhanced food literacy not only strengthens PBC and subjective norms but also promotes intentions to adopt healthier diets. These findings suggest that policymakers and educators should prioritize initiatives aimed at improving food literacy among adults to promote public health. This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (MSIT) (RS-2023-00280503)

SEVERE ANAEMIA AND BACTERAEMIA AMONG KENYAN CHILDREN: A RETROSPECTIVE ANALYSIS OF 26 YEARS HOSPITAL SURVEILLANCE DATA

Kelvin Mokaya Abuga[1]; John Muriuki[1]; Agnes Mutua[1]; Ken Mwai[1]; Neema Mturi[1]; Calman Maclennan[2]; Manfred Nairz[3]; Philip Bejon[1, 4]; Anthony Scott[1, 5]; Thomas Williams[1, 6, 4]; Sarah Atkinson[1]
[1]Epidemiology and Demography, KEMRI-Wellcome Trust Research Programme, Kilifi, Kenya; [2]Jenner Institute, University of Oxford, Oxford, United Kingdom; [3]Internal Medicine II, Medical University Innsbruck, Innsbruck, Astria, Austria; [4]Nuffield Department of Clinical Medicine, University of Oxford, Oxford, United Kingdom; [5]Department of Infectious Disease Epidemiology, London School of Hygiene and Tropical Medicine, London, United Kingdom; [6]Department of Infectious Disease and Institute of Global Health and Innovation, Imperial College, London, United Kingdom

BACKGROUND AND OBJECTIVES
Severe anaemia is an important cause of hospital admission and death among children living in sub-Saharan Africa, yet epidemiologic data on the causes and outcomes of severe anaemia in this population remains scarce.

METHODS
We conducted a retrospective analysis of systematically collected admissions data of children under 14 years admitted between August 1998 and June 2024. World Health Organization age-specific definitions of severe anaemia were used. We examined temporal trends, underlying causes, and the association between severe anaemia and bacteraemia.

RESULTS
Of 106,544 admissions, 16.6% (n=17,659) had severe anaemia and 36.5% (n=38,902) had moderate anaemia. The median age of severely anaemic children increased over time. Sickle cell disease (adjusted odds ratio (aOR) 9.7 [95% confidence interval 9.1, 10.4]), malaria (aOR 3.4 [3.2, 3.5]), human immunodeficiency virus infection (aOR 1.8 [1.6, 2.0]), wasting (aOR 1.7 [1.6, 1.7]), and stunting (aOR 1.6 [1.5, 1.6) were independently associated with severe anaemia. Severe anaemia was associated with a 72% increased risk of all-cause bacteraemia (aOR 1.7 [1.6, 1.9]), specifically with non-typhoidal *Salmonella*, *Escherichia coli*, *Streptococcus pneumoniae* and *Haemophilus influenzae*. The risk of bacteraemia increased along a spectrum of anaemia severity. The case fatality rate of children with severe anaemia and bacteraemia was 29.5% and varied by underlying bacterial pathogen.

CONCLUSIONS
Severe anaemia has multifactorial and age-specific causes, and remains a largely unrecognised and understudied risk factor for bacteraemia in Kenyan children. Addressing severe anaemia could reduce both anaemia-related morbidity and bacteraemia incidence.

EXPLORING THE GENDERED NATURE OF MALNUTRITION: AN ANALYSIS OF DATA AVAILABILITY AND GENDER DIFFERENCES IN SEVEN HUMANITARIAN CONTEXTS

Jenna Hickey[1]; Aseel Masri[2]; Alyssa Vets[2]; Victoria Sauveplane-Stirling[1]; Pai-Shan Cheng[2]; Megan Brown Wollenberg[3]; Kaitlyn Samson[3]; Jana Daher[3]; Hassan Ali Ahmed[4]; Alison Riddle[5]; Daniel Sellen[1]
[1]Anthropology, University of Toronto, Toronto, Canada; [2]Dalla Lana School of Public Health, University of Toronto, Toronto, Canada; [3]Technical Department, Action Against Hunger, Toronto, Canada; [4]Nutrition and Child Development Programme Group, UNICEF, New York, United States of America; [5]Global Health, Bruyère Health, Ottawa, Canada

BACKGROUND AND OBJECTIVES
There is growing evidence that gender inequality is associated with malnutrition. To provide effective programming, humanitarian actors require data on nutrition needs and contributing factors. The purpose of this research was to utilize a gender transformative framework to understand 1) data availability for sex and age-disaggregated data (SADD) and existing gender metrics and 2) the differences in undernutrition between sexes.

METHODS
Mixed-methods analyses were conducted, underpinned by the Gender Transformative Framework for Nutrition (GTFN) as the main analytical framework. A landscaping exercise was conducted to develop a clear understanding of gender data availability, determining which gender indicators and metrics may contextualize the differences in undernutrition between sexes. Key informant interviews were held to further explore the potential differences in undernutrition across sexes. Key insights were collected from gender and nutrition specialists (n=17). Responses were analyzed using deductive thematic content analysis and NVivo statistical software. Quantitative analyses are described elsewhere.

RESULTS
An analysis of program data revealed significant gaps in SADD within current nutrition monitoring frameworks and inconsistencies within collected gender metrics and gender indicators used across programs and global dashboards. Unreliable gender data presented challenges and provided limited information for use of an analytical framework to guide a thorough gender analysis (e.g., GTFN). Concurrently, inconsistencies in how metrics are collected, collated, and shared across regions presented a barrier to accuracy and the ability to compare data and provide insight into gender differences associated with undernutrition. Respondents, however, cited potential reasons why gender differences in undernutrition may occur, including biological differences between sexes, boys having increased exposure to infection, differential care practices by gender, and gendered societal norms.

CONCLUSIONS
There was a striking absence of both quantitative and qualitative program data for sex and gender, alongside an absence of standardization in gender indicators and data collection methods. To ensure that nutrition programs are truly equitable, it is essential to address the gendered nature of nutritional needs. By prioritizing technical development for standardisation in gender indicators, and sex and gender-disaggregated data collection methods, the global humanitarian community can take a significant step toward achieving transformative action in gender equality for nutrition programming.

REFINING THE NEXT GEN(D)ERATION LEADERSHIP COLLECTIVE'S THEORY OF CHANGE: A SCOPING REVIEW TO GUIDE INTERVENTIONS THAT IMPACT POWER STRUCTURES IN FOOD AND NUTRITION SYSTEMS

Juliana Miraldi[1]; Júlia Alves,[1]; Beatriz Nunes,[1]; Suha Zreik,[2]; Rajji, Lea Al[2]; Hala Ghattas,[2, 3]; Ana Clara Duran[1]
[1]Center for Food Studies and Research, UNICAMP Universidade Estadual de Campinas, Campinas, Brazil; [2]Faculty of Health Sciences, American University of Beirut, Beirut, Lebanon; [3]Arnold School of Public Health, University of South Carolina, Columbia, SC, USA, United States of America

BACKGROUND AND OBJECTIVES
The Next Gen(d)eration Leadership Collective's (NGLC) was founded in 2020 by women working globally in food and nutrition systems, with the aim of contributing to reducing power imbalances in food systems. To this end, the NGLC has developed a theory of change (TofC) focused on the support of collective action that guides its activities . This theory, informed by literature reviews and internal discussions among the collective's members - currently has six interconnected nodes: “Collective support,” “Collective efficacy,” “Collective agency,” “Mobilizing a coalition,” “Collective action,” and “Redressing power imbalances in leadership.” The aim of this review is to: (i) systematically identify the commonly used definitions for each of the NGLC TofC nodes and compare these with current definitions used by the Collective, and (ii) identify the satellite terms correlated to these central nodes.

METHODS
For this purpose, a theoretical scoping review was carried out in February to July 2024 following the 2020 Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. The keywords were defined by consulting Decs/Mesh ('Collective agency' OR 'Collective efficacy' AND 'Theory of change') and the search used five databases (PubMed/Medline, Embase, Web of Science, Scopus, and JSTOR). Papers were extracted and assessed using Covidence. Three reviewers independently screened titles and abstracts, followed by full-text screening for eligibility and data extraction. Conflicts were resolved by an independent reviewer. The eligibility criteria included: language (English, French, Spanish, Portuguese and Italian), have undergone a peer-review process, and include conceptual definitions of the nodes of the NGLC TofC.

RESULTS
After eliminating duplicates, 761 papers were identified, of which 77 were included for this study. Papers came from different disciplines and a great variety of journals. The literature was aligned with the definitions of nodes used in the NGLC TofC, but the satellite terms broadened and refined these definitions, and indicated homologies between other terms that can be used by the collective.

CONCLUSIONS
The concatenation and definition of the nodes of the current NGLC TofC largely corresponds to what was found in the literature; however, the literature allowed us to identify terms connected to the nodes that enrich the conceptual definition used by the NGLC.

“WE ARE WOMEN, AND OUR VOICES SHOULD BE LOW”: UNDERSTANDING THE INFLUENCE OF HOUSEHOLD GENDER DYNAMICS AND INTIMATE PARTNER VIOLENCE ON HOUSEHOLD DECISION-MAKING AND FOOD CHOICE IN RURAL TANZANIA

Ibukun Owoputi[1]; Rachel Bezner Kerr[2]; John Hoddinott[1]; Rosemary Kayanda[3]; Katherine Dickin,[4]
[1]Division of Nutritional Sciences, Cornell University, Ithaca, NY, United States of America; [2]Department of Global Development, Cornell University, Ithaca, United States of America; [3]DMI-TZ, Development Media International Associates C.I.C., Mwanza, Tanzania, United Republic of; [4]Department of Public and Ecosystem Health, Cornell University, Ithaca, United States of America

BACKGROUND AND OBJECTIVES
Behavior change interventions to improve nutrition must account for household gender dynamics and the impact of intimate partner violence (IPV). IPV can undermine women’s autonomy and decision-making, limiting their ability to adopt and sustain recommended health and nutrition practices. This study examined how IPV and its threat influence women’s agency in decision-making on food production, purchasing, and preparation.

METHODS
This mixed-methods study explored barriers to improved nutrition and health among 58 couples in rural Tanzania through Demographic and Health Survey items, in-depth interviews, and pile-sorting exercises using artificial money. Decision-making and IPV were assessed separately among men and women. Quantitative and qualitative analyses were triangulated to identify patterns and implications.

RESULTS
Men and women often reported that household decisions were made jointly, as assessed with standardized questionnaires used globally, yet interviews revealed that women were often only informed of decisions or that husbands had the final say. Pile-sorts revealed distinct patterns in resource allocation: men prioritized investments in business and savings, reflecting their role as primary providers, while women allocated resources to clothing and food, aligning with their caregiving responsibilities. Women were usually tasked with and had agency over meal preparation, but lack of decision-making power over what food was grown, sold, or purchased constrained their ability to access the necessary food. IPV or the threat of IPV further constrained women’s ability to influence agricultural activities and food purchasing decisions.

CONCLUSIONS
Lack of agency among the primary preparers of household meals limits uptake of nutrition recommendations. Addressing cultural norms and the impact of IPV on household dynamics is critical to the success of nutrition and health interventions. In-depth assessment of decision-making patterns can help identify how to overcome constraints on women’s agency. Community-based strategies to empower women and mitigate IPV-related barriers are essential for fostering sustainable behavior change and improving health outcomes.

ADHERENCE TO THE PLANETARY HEALTH DIET AND ITS RELATIONSHIP WITH THE NUTRITIONAL STATUS OF ADOLESCENTS

Ana Cecilia Pereira Dantas,[1]; Ashley Brito Valentim,[2]; Mayara Lopes Estevão,[2]; Ana Victória Varela Da Silva,[1]; Antonia Mariza Herculino Da Silva,[1]; Antonio Ciro De Holanda Neto,[1]; Juliana Raissa Oliveira Ricarte,[3]; João Pedro Soares Rocha,[1]; Raniel Martam Araujo De Castro,[1]; Lara Pereira Saraiva Leão Borges,[2]; Soraia Pinheiro Machado,[2]; Carla Soraya Costa Maia[2]

BACKGROUND AND OBJECTIVES

The Planetary Health Diet Index (PHDI) was developed to verify adherence to a healthy and sustainable diet proposed by EAT-Lancet Comission. Evidence indicates that greater adherence to this diet can help promote remission of obesity in children and adolescents. Given the scarcity of studies evaluating adherence to this diet among adolescents in Brazil, the objective was to assess it and its relationship with nutritional status.

METHODS

This was an observational, cross-sectional study carried out in public schools with adolescents aged between 10 and 18. A sub-sample of 100 adolescents who took part in a larger study entitled “Dyslipidemia and dietary practices in adolescents in Fortaleza” was used. Weight and height were measured to assess nutritional status using the Body Mass Index (BMI) for age and a 24-hour food recall was applied. To assess adherence to the planetary health diet, the PHDI was used, which divides foods into 16 components, categorized into four groups: adequacy, optimum, ratio and moderation. The total score of the index ranges from 0 to 150 points, where the higher the score, the greater the adherence to the diet. RESULTS were presented by mean and standard deviation (SD). The PHDI was compared between the groups with and without excess weight using the Student's t-test for independent samples or the Mann-Whitney test, depending on the normality of the data. The significance value considered was $p<0.05$.

RESULTS

The adolescents had a mean age of 13 (SD 1.22) years and were mostly female (54%), with a mean BMI of 20.15 kg/m2 (SD 4.15). The total PHDI score for the sample was 38 points (SD 11.63) and there was no difference between the groups. Adolescents who had excess weight had a lower prevalence of consumption of Dairy products ($p=0.030$) and Vegetable oils ($p=0.005$), scoring lower in the Optimum Group ($p=0.027$). In the Moderation Group, the consumption of Red meat was more frequent ($p=0.029$) in the group with excess weight, while Chicken and sausages were more consumed ($p=0.042$) in the group without excess weight.

CONCLUSIONS

The adolescents showed low adherence to the planetary health diet, reaching only 25% of the maximum PHDI score. No relationship was found between adherence to the diet and nutritional status, but adolescents with excess weight reported more frequent consumption of red meat and less frequent consumption of dairy products, vegetable oils and chicken and sausages, compared to those who did not have excess weight.

THE LOW GLOBAL DIET QUALITY SCORE IS ASSOCIATED WITH HIGH RISK OF OVERWEIGHT IN PEOPLE WITH MULTIPLE SCLEROSIS

MARIA LUISA PEREIRA DE MELO[1]; Linka Richellis Nascimento De Freitas[1]; Sousa De Queiroz Campos Ana Clara[2]; Costa D'almeida José Artur[3]; Pereira Saraiva Leão Borges Lara[1]
[1]PROGRAMA DE PÓS-GRADUAÇÃO EM NUTRIÇÃO E SAÚDE, Universidade Estadual do Ceará - Campus do Itaperi, Fortaleza, Brazil; [2]Nutrição, Universidade Estadual do Ceará - Campus do Itaperi, Fortaleza, Brazil; [3]Neurologia, Fortaleza General Hospital, Fortaleza, Brazil

BACKGROUND AND OBJECTIVES
Obesity, and diet quality contributes to the progression and symptomatology in people with Multiple Sclerosis [pMS]. The Global Diet Quality Score [GDQS] was developed to be a simple, timely and cost-effective is reflective of both nutrient adequacies. Therefore, this study seeks to investigate the relation between anthropometric indexes and body adiposity with the GDQS in pMS.

METHODS
This is a cross-sectional, analytical study that included pMS. The nutritional state was evaluated based on body mass index [BMI], waist circumference [WC], and body fat percentage [% BF]. The GDQS was used for qualitative dietary assessment and was calculated according to a validated methodology.

RESULTS
The study included 106 participants, the majority of whom were female (80.2%) and had the relapsing-remitting clinical form [RRMS] (89.6%). The group presented a nutritional diagnosis of overweight according to BMI (n = 61, 57.5%), and 53.8% had an elevated WC (n = 57), 60.4% and 44.3% had elevated %BF, according to BIA and US, respectively. GDQS classification, 98% of the sample (n = 104) had low dietary quality and a high risk of developing non-communicable chronic diseases. Patients with higher BMI (p = 0.012), and WC (p = 0.018) had lower GDQS scores.

CONCLUSIONS
It is concluded that in pMS, a low GDQS score appears to be associated with overweight, and higher WC. Further longitudinal research on this topic is necessary for the development of targeted treatments.

IMPACT OF COMMUNITY- FOCUSSED INTERVENTIONS, POLICIES AND PROGRAMMES ON GROWTH AND ANAEMIA IN CHILDREN UNDER FIVE IN LMICS: A SYSTEMATIC REVIEW OF SYSTEMATIC REVIEWS

Usha Ghimire[1]; Aravinda Guntupalli[1]; Janet Kyle[1]; Santosh Gaihre[1]
[1]Institute of Applied Health Sciences, School of Medicine, Medical Sciences and Nutrition, University of Aberdeen, Aberdeen, United Kingdom

BACKGROUND AND OBJECTIVES
Child undernutrition is a major global health concern, with children in low- and middle-income countries (LMIC) at the highest risk (1-3). Several LMICs have implemented various interventions, policies, or programmes on a local, regional, or national level to address this issue. Systematic reviews have synthesised the effectiveness of those initiatives, with some focusing on a single specific outcome, such as child growth, while others examine multiple factors and outcomes in multiple settings (4-6). However, very little is known about the effectiveness of community-focussed interventions, policies or programmes, on child growth and anaemia together (key indicators of child undernutrition) in LMICs. Therefore, this systematic review of systematic reviews was conducted to address this research gap.

METHODS
The major electronic databases; MEDLINE, Embase, CINAHL, Scopus, Cochrane and Web of Science were searched from 2000 to 2024 April. The articles were reviewed by four authors. The methodological quality of identified reviews was assessed using AMSTAR-2 tool (7).

RESULTS
In total 63 systematic reviews of variable quality (low-high) assessing the impact of the interventions, policies and programmes on child growth and/or anaemia in under-5 children were identified. Of the 20 studies reporting on both child growth and anaemia, community-focussed interventions with positive effects were animal source food consumption, fortification, supplementation, educational programmes, cash transfers, and nutritional support programmes (n=5). Among 41 studies reporting on stunting, wasting, and underweight, a combination of nutrition-specific (n=3) and nutrition-sensitive interventions (n=8) such as agricultural intervention, cash transfers, WASH (water, sanitation, and hygiene), micronutrient supplementation, education, group platforms, and fortification proved highly effective. Interventions that contributed to reduction of anaemia (n=17) were fish consumption, cooking in an iron pot, iron fortification, micronutrients and zinc supplementation. Programmes such as Mexico Oportunidades, Progresa effectively improved child growth and/or anaemia status. Furthermore, multisectoral policies focusing on scaling up community-based nutrition programmes were effective in improving child growth.

CONCLUSIONS
This study identified several community-focussed interventions that effectively improved child growth or reduced anaemia. Among these, five interventions and one programme had the greatest positive impact on both outcomes. These findings can guide the design of interventions, policies, and programs to address multi-forms of child undernutrition in LMICs.

DIETARY IRON BIOAVAILABILITY IN PREMENOPAUSAL AUSTRALIAN WOMEN

Ewa Szymlek-Gay[1]; Honni Rooney[1]; Jayden Ordner[1]; Linda Atkins[1]
[1]Institute for Physical Activity and Nutrition (IPAN), School of Exercise and Nutrition Sciences, Deakin University, Melbourne, Australia

BACKGROUND AND OBJECTIVES
Premenopausal women are at risk of iron deficiency due to increased requirements for iron. To prevent iron deficiency, recommended intakes have been developed based on physiological requirements for absorbed iron and iron bioavailability. However, iron bioavailability is difficult to estimate as it depends on the composition of the diet and an individual's absorptive efficiency. Several algorithms have been proposed to estimate iron bioavailability from diets. These algorithms can be complex and often underestimate bioavailability. Recently, a new approach was developed by Dainty et al.,(1) which is based on calculated iron requirements, total dietary iron intakes, and the distribution of serum ferritin concentration values in the population. This model has been used by the European Food Safety Authority to set recommended iron intakes for adults.(2) In contrast, the recommended iron intakes for Australian adults are based on iron bioavailability estimates from the US Institute of Medicine, which were primarily derived from 15 free living US adults.(3) Therefore, the aim of this study was to predict dietary iron absorption in a representative sample of premenopausal Australian women using the model developed by Dainty et al.(1)
METHODS
Dietary iron intake and serum ferritin data from the 2011-13 Australian National Nutrition and Physical Activity Survey and National Health Measures Survey were analyzed in 503 premenopausal women aged 18-49 years. Women were excluded if they were pregnant or lactating, had elevated C-reactive protein, consumed iron-containing supplements, or misreported energy intake. Dietary iron intake was assessed via two non-consecutive 24-hour recalls. Usual daily iron intake was determined by the Multiple Source Method. Dietary iron absorption was estimated using the predictive model developed by Dainty et al.(1) and the Institute of Medicine's distribution of individual dietary iron requirements.(3)
RESULTS
Mean (SD) usual dietary iron intake was 10.4 (2.6) mg/d. The prevalence of serum ferritin < 15 µg/L was 14.1% (95% CI: 10.2%, 19.3%), and < 30 µg/L was 37.0% (95% CI: 31.8%, 42.5%). Predicted dietary iron absorption at serum ferritin concentrations of < 15 µg/L was 29.5%, and at serum ferritin concentrations of < 30 µg/L it was 19%.
CONCLUSIONS
Our findings do not support the bioavailability assumption of 18% used to develop the Australian recommended iron intakes for premenopausal women based on the need to maintain serum ferritin concentrations of 15 µg/L.

IRON DEFICIENCY ANAEMIA AND OBESITY: INVESTIGATING THE LINK BETWEEN INFLAMMATION AND IRON BIOMARKERS IN WOMEN

Qonita Rachmah[1]; Phung Hai[1]; Ahmed Faruk[1]
[1]Public Health, School of Medicine and Dentistry, Griffith University, Gold Coast, Australia

BACKGROUND AND OBJECTIVES
Research indicates that obesity-related inflammation may disrupt iron metabolism, potentially increasing the risk of iron deficiency anaemia (IDA). However, only a limited number of studies have explored this, particularly among women in developing countries. This case-control study aimed to examine the association between iron biomarkers, inflammation status, and obesity in young adult women.
METHODS
Six hundred young women (aged 19–29 years) were initially screened and matched for the case and control groups. After matching for socio-demographic criteria, 174 cases (overweight/obese women) and 167 controls (normal-weight women) were included in the analysis. Iron status markers, inflammation markers, and hepcidin levels were measured. Biochemical data were presented as means (standard deviation) or medians (interquartile range), and bivariate and multivariate analyses were performed.
RESULTS
Iron deficiency (serum ferritin <150 µg/l) and anaemia (haemoglobin <12 g/dl) were prevalent in 5.0% and 25.8% of participants, respectively, with no significant differences observed between groups. Serum ferritin levels were significantly higher in overweight/obese women (mean ± SD = 44.26; p = 0.014). Similarly, levels of haemoglobin, Alpha-1-acid Glycoprotein (AGP), C-reactive protein (CRP), and hepcidin were higher in the case group, although these differences were not statistically significant (p > 0.001). Multivariate modelling identified BMI as a significant predictor of serum ferritin (coefficient = 0.136; standard error = 0.006; p = 0.014), AGP (coefficient = 0.200; standard error = 0.013; p < 0.001), and CRP (coefficient = -0.123; standard error = 0.029; p = 0.028).
CONCLUSIONS
This study indicated that, whereas iron deficiency and anaemia were common in young adult women, there were no significant differences between overweight/obese and normal-weight groups. However, women who were overweight or obese had higher serum ferritin levels, and BMI was found to be a significant predictor of serum ferritin, AGP, and CRP levels. These RESULTS imply that inflammation linked to obesity may affect iron metabolism, which requires more investigation.

CONSUMPTION OF ORGANIC FOODS DURING PREGNANCY AND INFANCY AND BMI Z-SCORE UP TO 7.5 YEARS

Manel Ghozal[1]; Manik Kadawathagedara[2]; Julia Baudry[3]; Sandrine Lioret[4]; Barbara Heude[1]; Marie-Aline Charles[5]; Emmanuelle Kesse-Guyot[6]; Blandine De Lauzon-Guillain[1]

[1]Centre for Research in Epidemiology and StatisticS (CRESS), Université Paris Cité, Université Sorbonne Paris Nord, Inserm, INRAE, Paris, France; [2]CRESS/EAROH, Inrae Ile-De-France, Paris, France; [3]Université Sorbonne Paris Nord, Inserm, CNAM, INRAE, Equipe de Recherche en Epidémiologie Nutritionnelle (EREN), Bobigny, France; [4]CRESS, Inserm, Villejuif, France; [5]Université Paris Cité and Université Sorbonne Paris Nord, Inserm, INRAE, Centre for Research in Epidemiology and StatisticS (CRESS), F-75004, Paris, France; [6]Centre of Research in Epidemiology and Statistics, Nutritional Epidemiology Research Team (EREN), Université Sorbonne Paris Nord and Université Paris Cité, INSERM, INRAE, CNAM, Bobigny, France

BACKGROUND AND OBJECTIVES

Consumption of organic foods has been associated in adults with a lower risk of overweight, regardless of possible confounding factors (in particular dietary patterns and socioeconomic position). However, no studies have investigated these associations with consumption during the perinatal period. The objective of this work was to analyze the link between the consumption of organic foods during pregnancy and infancy and BMI of children up to 7.5 years of age.

METHODS

Data from 9,946 children of a nationwide birth cohort were analyzed. Consumption of organic foods was assessed using a single item in mothers at the delivery for the whole pregnancy and in infants monthly during the complementary feeding period. Anthropometric data were collected from the child's health booklet up to 7.5 years. At the 7.5-year follow-up, parents were also asked to weigh and measure their child according to an established protocol. Child's BMI z-scores were calculated at 1, 2, 3, 5 and 7.5 years. The associations between organic food consumption and BMI z-score and overweight were evaluated, at each age, using multivariable linear or logistic regressions, adjusted for main confounders, including socioeconomic position, diet quality during pregnancy and both parents' BMI.

RESULTS

Almost half of women never consumed organic foods during pregnancy, whereas 8% consumed them daily. Similarly, almost half of children never consumed organic foods during the complementary feeding period, while one of tenth consumed them almost always. A frequent consumption of organic foods at both periods was associated with a lower BMI z-score at 1 year and a lower risk of overweight at 5 years (OR [95%CI] = 0.64 [0.45; 0.90]). All associations remained consistent after accounting for any breastfeeding duration or other infant feeding practices.

CONCLUSIONS

These RESULTS suggest that frequent consumption of organic foods during the perinatal period might be associated with lower risk of overweight up in early childhood, independently of other feeding practices. However, these findings need to be confirmed at older ages as well as in other studies using more detailed exposure.

DIETARY INTAKE AND FOOD HABITS AMONG MIGRANTS IN EUROPE: A SCOPING REVIEW

Maria Somaraki[1]; Meriem Makhloufi,[1]; Caroline Méjean[1]
[1]MoISA, Univ Montpellier, CIHEAM-IAMM, CIRAD, INRAE, Institut Agro, IRD, Montpellier, France

BACKGROUND AND OBJECTIVES
Significant demographic changes are underway globally and in Europe–9% of the EU inhabitants are foreign-born. Migration reflects nutrition transitions, which relate to health outcomes and broader sustainability dimensions. Such transitions may present direct and indirect links with the changing food environment and the individual characteristics describing the evolving socio-economic and cultural position of migrants. We conducted a scoping review in order to map the studies describing diet and food habits among migrant groups in Europe.
METHODS
Two bibliographic databases, i.e. Web Of Science (WoS) and PubMed, were used to retrieve relevant literature. We included studies published from 2000 onwards, which were conducted in Northern and Western Europe, and they were based on quantitative assessments of food intake. Studies involving children and/or families along with parental practices were excluded. Search keywords described behaviours related to food, diet and nutrition, along with terms related to acculturation and (im)migration. Terms that pertained to ethnic and minority groups were omitted. Last, we included keywords related to each European country that defines the context of interest. Finally, 47 articles were retained after the consecutive steps of detecting duplicates, title/abstract screening and full-text screening.
RESULTS
About 9% of the articles described findings from a single multi-site cross-sectional study, and 13% referred to interventions focusing on nutrition-related conditions. About one third of articles provided comparisons with host population, while 25% described nutrition transitions from the birth country. Only 1 study compared migrants with populations in both host and birth countries. While immigrants globally adopt a Western diet, especially meat and sweets, they retain some elements of traditional diets such as high intake of fruits, legumes or tubers. The role of acculturation, primarily assessed through length of residence in host country, has been highlighted in such processes. The role of the food environment in host country has been explicitly addressed in one study only.
CONCLUSIONS
While population-wide shifts in food behaviour have implications for public and planetary health, migrant research than can inform adapted interventions in Europe is scarce. Further research should comprehensively explore the role of acculturation and socio-economic position. In addition, multi-site studies across diverse European settings can clarify the role of the food environment along with characterising differences compared to birth country.

HUMAN MILK METABOLITES MODULATE INFANT INTESTINAL IMMUNE AND BARRIER FUNCTIONS AS WELL AS INTESTINAL MICROBIOTA: IN VIVO STUDY IN YUCATAN PIGLETS

Sarah Blanchet[1]; Johanna Morel[1]; Gwénaëlle Randuineau[1]; Armelle Cahu[1]; Sylvie Guérin[1]; Véronique Romé[1]; Régis Janvier[1]; Patrice Dahirel[1]; Marina Giblaine; Isabelle Le Huërou-Luron[1]; Sergine Even[2]; Sophie Blat[1]
[1]Institut NUMECAN, INRAE, INSERM, Rennes University, Rennes, France; [2]UMR STLO, INRAE, Institut Agro Rennes Angers, Rennes, France

BACKGROUND AND OBJECTIVES
Human milk (HM) is a complex food that meets the nutritional needs of newborns. It also contains numerous bioactive compounds such as metabolites, present in low concentrations and including short-chain fatty acids (butyrate, acetate, propionate), polyamines (putrescine, spermine, spermidine), gamma-aminobutyric acid and lactate. These metabolites are also known to be produced by the intestinal microbiota and to contribute to the maintenance of intestinal homeostasis. However, their role in HM has been little studied. The aim of this study was to evaluate their bioactive properties on the infant intestinal functions and microbiota, in an *in vivo* model of Yucatan minipigs.
METHODS
Piglets aged 2 days (n=9-10 per group) were fed for 23 days with: (i) a standard infant formula (IF) (CTRL group), or (ii) an IF supplemented with metabolites at HM concentrations (MTB group), or (iii) an IF supplemented with fermented milk fractions (FF group) in order to evaluate the relevance of IF fermentation to provide metabolites. The impact of the diets on intestinal physiology was characterized using *ex vivo* (Ussing chambers), molecular biology (RT-qPCR, ELISA) and histology approaches, and the intestinal microbiota was studied by 16S rRNA gene sequencing.
RESULTS
A principal component analysis of all the variables could separate the MTB and FF groups from the CTRL group. The metabolite-supplemented IF, either MTB or FF, significantly impacted the intestinal immune function, particularly in ileal Peyer's patches: they reduced the expression of both pro-inflammatory (*TNFa)* and anti-inflammatory (*TGFB1* and *IL10Ra)* markers, and the expressions of *FOXP3*, a T cell marker, and *TLR4*. Both the IF resulted in increased secretion of immunoglobulin A (IgA) in the ileum compared with CTRL IF. In the colon, MTB and FF IF increased paracellular permeability, decreased tight junction gene expressions (*CLDN2* and *OCLN*) and increased the depth of crypts. Finally, FF IF decreased microbiota alpha diversity in the caecum and feces of piglets.
CONCLUSIONS
Our study demonstrated that HM metabolites are bioactive and are able to modulate the infant intestinal immune and barrier functions *in vivo*, as well as its intestinal microbiota.

TRENDS IN LOW-CALORIE SWEETENED PRODUCT CONSUMPTION AND ITS ASSOCIATION WITH DIETARY CONSUMPTION OF MINIMALLY PROCESSED FOODS IN UK CHILDREN: A NATIONAL STUDY FROM 2008 TO 2019

Mathuramat Seesen[1]; Kiara Chang[1]; Jennie C Parnham[1]; Anthony A. Laverty[1]; Christopher Millett[1]; Fernanda Rauber[2]; Renata Bertazzi Levy[3]; Martin White[4]; Edward W Gregg[5]; Eszter P Vamos[1]
[1]Public Health Policy Evaluation Unit, Imperial College London, London, United Kingdom; [2]Center for Epidemiological Research in Nutrition and Health, Universidade de São Paulo, São Paulo, Brazil; [3]Preventive Medicine, Faculdade de Medicina da Universidade de São Paulo (FMUSP), São Paulo, Brazil; [4]Medical Research Council Epidemiology Unit, University of Cambridge, Cambridge, United Kingdom; [5]Department of Epidemiology and Biostatistics, Imperial College London, London, United Kingdom

BACKGROUND AND OBJECTIVES
Little is known about the association between low- and no-calorie sweetened (LCS) product consumption and children's diet quality, despite the promotion of these products as sugar alternatives. This study examines the trends and associations between LCS product consumption and intakes of minimally processed foods and beverages (MPFB) and ultra-processed foods and beverages (UPFB) among UK children.
METHODS
Repeated annual cross-sectional data from the National Diet and Nutrition Survey (2008/09-2018/19) for children aged 4-18 years (N=5,922) were analysed. Children were categorized into No-LCS (0%g/day), Low-LCS (≤6.8%g/day), Mid-LCS (6.9-17.4%g/day), and High-LCS (≥17.4%g/day) groups based on a four-day food diary. The trends in consumption of MPFB and UPFB by LCS groups were assessed using multivariable linear regression models, adjusted for sociodemographic factors.
RESULTS
In 2008/09, the percentages of children in the Low-LCS, Mid-LCS, and High-LCS groups were 20.4%, 24.9%, and 25.1%, respectively. The population breakdown of LCS consumption remained largely unchanged throughout study period. In 2008/09, all LCS consumers had a lower intake of MPFB but a higher intake of UPFB compared to the No-LCS group. Consumption of MPFB (0.9%g/day per year; 95%CI: 0.6, 1.1) and water (2.7%g/day per year; 95%CI: 2.2, 3.1) increased in the No-LCS group over 11 years. Similar changes were observed in other LCS groups but were less pronounced in the High-LCS group (vs No-LCS). Moreover, over 11 years, the trend in UPFB intake in the No-LCS group decreased significantly (-0.8%gtotal/day per year; 95%CI: -1.1, -0.6). In comparison, the High-LCS group (vs No-LCS) showed a smaller decline in UPFB intake (0.7%g/day per year; 95%CI: 0.3, 1.1).
CONCLUSIONS
Over 70% of UK children consumed LCS products between 2008 and 2019. LCS product consumption was associated with a smaller increase in the consumption of minimally processed foods and beverages, and water, while it was also associated with a smaller decrease in ultra-processed foods and beverages in children's diets during the study period. These findings highlight the need for a more comprehensive consideration of less processed dietary patterns in UK's healthy eating guidelines, beyond promoting LCS in children's diet.

THE RELATION BETWEEN ANC COUNSELING AND ADHERENCE TO MULTIPLE MICRONUTRIENT SUPPLEMENTS (MMS) IN INDONESIA

Tika Rianty[1]; Akhir Riyanti[1]; Nancy Kosasih[1]; Trisari Anggondowati[2, 1]; Fitri Nandiaty[1]; Monica Fox[3, 4]; Budi Utomo[5]; Otte Santika[6]; Endang Achadi[1]; Kristen Hurley[3, 7]

[1]Center for Family Welfare, Faculty of Public Health, Universitas Indonesia, Depok, Indonesia; [2]Department of Epidemiology, Faculty of Public Health, Universitas Indonesia, Depok, Indonesia; [3]International Health, Johns Hopkins University, Bloomberg School of Public Health, Baltimore, United States of America; [4]Program Quality and Impact (PQI) Team, Vitamin Angel Alliance, Goleta, United States of America; [5]Department of Population Studies and Biostatistics, Faculty of Public Health, Universitas Indonesia, Depok, Indonesia; [6]Senior Country Program Advisor for Indonesia, Vitamin Angel Alliance, Bogor, Indonesia; [7]Chief Nutrition Officer, Vitamin Angel Alliance, Goleta, United States of America

BACKGROUND AND OBJECTIVES

Despite the decades-long Iron and Folic Acid (IFA) supplementation program, anemia remains a significant public health problem. One significant challenge faced by the IFA program in various countries, including Indonesia, is low adherence. In 2020, WHO recommended Multiple Micronutrient Supplementation (MMS) for pregnant women (PW) as a substitute for IFA, in the context of rigorous research. Implementation research is being conducted in Indonesia to provide recommendation to the government in scaling up MMS. As part of the implementation research, healthcare providers (HCPs) received orientation about anemia and MMS, and in some of the study sites were trained with enhanced communication strategy to provide counseling. We conducted an analysis to evaluate the association between MMS counseling and adherence of PW in taking MMS.

METHODS

A survey of PW was carried out in eight districts. Data from PW were collected through home visits that took place on two occasions: (1) at the time of recruitment and (2) three months following recruitment. Data from a total of 1856 PW were analyzed. Adherence was measured by bottle-weighing and PW's consumption control card. Adherence is defined as taking at least 70% of the number of MMS they need to take within 3 months. A counselling index score was generated based on list of items that midwives explained during ANC.

RESULTS

About half of PW (51.3%; n=952) took at least 70% of the eligible 90 MMS tablets (considered as adherent). During their first ANC visit, PW received counseling about 'to take 1 tablet of MMS every day' (81%), 'how to open the bottle' (82.1%), 'how to close the bottle' (62.6%), 'how to fill in the consumption control card' (62.9%), 'MMS ingredients' (55.6%), and 'MMS benefits' (53.2%). Furthermore, the counseling index analysis shows that PW who were counseled on six or more topics during their first ANC were more likely to adhere (take more than 70% MMS tablets) within three months (OR=1.236; 95%CI=1.028 – 1.486).

CONCLUSIONS

Findings demonstrate the importance of counseling about MMS during women's first ANC visit to improve their adherence to taking MMS. This implies that program implementers should formulate health strategies that emphasize the significance of comprehensive nutrition education and counseling in the early stages of pregnancy to enhance adherence to micronutrient supplementation.

LIFESTYLE AND DIETARY HABITS OF HUNGARIAN SEVENTH-DAY ADVENTISTS AND CONTROLS: A PILOT STUDY

Eszter Hallósy[1]; Zoltán Szabó[2]; Éva Szabó[3]
[1]Doctoral School of Health Sciences, University of Pécs Faculty of Health Sciences"D", Pécs, Hungary;
[2]Department of Food and Nutrition Sciences, University of Pécs Faculty of Health Sciences"D", Pécs, Hungary;
[3]Department of Biochemistry and Medical Chemistry, University of Pécs Medical School, Pécs, Hungary

BACKGROUND AND OBJECTIVES
Among members of the Seventh-day Adventist Church, there are several lifestyle factors (vegetarian diet, avoidance of stimulants) in their daily lives that may contribute to longer life expectancy at birth and a higher number of years of healthy life compared to other populations. The objective of this study was to assess the lifestyle and dietary habits of Adventists living in Hungary (HA) and compare them with age-matched controls.
METHODS
In this pilot study the participants completed both a general and a nutritional questionnaire in an anonymous online format. A total of 595 individuals participated in the study (HA: n=382; control: n=213).
RESULTS
The proportion of non-users of stimulants was significantly higher among HAs than in the control group (coffee: 58% vs. 16.9%; alcohol: 96.1% vs. 33.3%; tobacco: 97.9% vs. 73.7%; HA vs. controls; $p<0.001$ each). Furthermore, the HA group exhibited a significantly higher prevalence of a vegan (17.3% vs. 0.5%; $p<0.001$) or vegetarian diet (28.3% vs. 3.3%; $p<0.001$) compared to the control group. In general, individuals in the HA group demonstrated a healthier dietary pattern, characterised by significantly lower average salt, processed food, and animal food consumption. On the other hand, members of the HA group predominantly consumed plant-based foods, whole grain bread, alternative side dishes (e.g., bulgur, millet, brown rice), and alternative sweeteners (e.g., honey, date syrup). In contrast, the control group predominantly consumed white bread, traditional side dishes (white rice, egg pasta) and frequently used sugar. Additionally, low-intensity exercise (51.8% vs. 32.9%; $p<0.05$) and good sleep quality (38.7% vs. 25.4%; $p<0.001$) was more prevalent among those in the HA group.
CONCLUSIONS
Our research has confirmed that the prevalence of vegetarian or vegan diet is higher among HAs compared to the control population. Our findings indicate that Hungarian Adventists adhere to a healthier lifestyle, characterised by the low consumption of stimulants and the use of a diverse range of alternative side dishes and sweeteners.

EPO5_015

FACTORS INFLUENCING COMMERCIAL MILK FORMULA USE IN SOUTH AFRICA: A MIXED-METHODS ANALYSIS

Sphindile Mapumulo[1]; Christiane Horwood[2]; Lyn Haskins[1]; Tanya Doherty[3]; Gillian Kingston[4]; Nigel Rollins[5]
[1]Centre for Rural Health, University of KwaZulu-Natal, Durban, South Africa; [2]Centre for Rural Health, University of KwaZulu-Natal - Howard College, Durban, South Africa; [3]Health Systems Research Unit, South African Medical Research Council, Cape Town, South Africa; [4]Kings Business School, Kings College, London, United Kingdom; [5]Department of Maternal, Newborn, Child and Adolescent Health and Ageing, World Health Organization, Geneva, Switzerland

BACKGROUND AND OBJECTIVES
The consumption of commercial milk formula (CMF) continues to increase, despite substantial evidence supporting the benefits of breastfeeding. Although regulated by the International Code of marketing of breastmilk substitutes, CMF marketing often presents CMF feeding as a convenient solution to feeding challenges, influencing mothers' choices.
METHODS
This study presents South African data from a multi-country, mixed-methods study investigating women's exposure to CMF marketing and their perceptions of infant feeding. The study included a cross-sectional survey of 1,050 women (pregnant women, breastfeeding mothers of children under 18 months, and mothers using CMF) in two large South African cities. Participants were selected using convenience sampling stratified by feeding practice and the age of the child. In addition, ten focus group discussions (FGDs) were conducted with pregnant women and mothers of children aged <18 months to explore attitudes toward CMF marketing. Thematic analysis was conducted using NVivo v.12.
RESULTS
Most women planned to breastfeed and received encouragement from health workers; however, breastfeeding challenges, returning to work, and the convenience of CMF feeding were the main reasons for switching to CMF. Social media platforms like Instagram and Facebook were key information sources. Mothers highly regarded health workers' advice. The introduction of formula feeding often had negative effects on the baby's health, prompting mothers to try different brands until they found one they perceived as suitable for their child. Mothers reported that health workers played a role in helping them identify the appropriate brand to use. Family members, particularly grandmothers, played a significant role recommending initiating CMF. Survey data indicated that recommendations for CMF came mostly from family (58.8%), friends (23.3%), and health workers (18.3%). CMF Marketing and word-of-mouth strongly influenced CMF feeding decisions, with television (69.4%) and in-store ads (27.9%) as the most common channels. The majority of women (79.2%) believed that breastmilk is best for babies, and 79.9% agreed that it promotes mother-baby bonding. However, 48.9% thought that formula milk is similar to breastmilk, and 53.2% believed that breastfeeding and formula feeding offer the same benefits (Table 1).
CONCLUSIONS
The study highlights the multifaceted factors driving CMF consumption in South Africa, suggesting the need for targeted public health strategies to promote breastfeeding and provide mothers with accurate, supportive information for informed feeding choices.

MATERNAL VITAMIN B12 STATUS AND RISK OF SGA IN WOMEN WITH A HISTORY OF METABOLIC BARIATRIC SURGERY

Laura Heusschen,[1]; Inge Van Loon,[2]; Arianne Van Bon[3]; Judith Van Laar[4]; Ineke Krabbendam,[5]; Eric Hazebroek,[1]; Agnes Berendsen[2]
[1]Bariatric surgery, Vitalys | Kliniek tegen overgewicht | Locatie Elst, Elst, Netherlands; [2]Human Nutrition and Health, Wageningen University & Research, Wageningen, Netherlands; [3]Internal Medicine, Rijnstate, Arnhem, Netherlands; [4]Obstetrics and Gynecology, Máxima MC, De Run, Veldhoven, Netherlands, Veldhoven, Netherlands; [5]Obstetrics and Gynecology, Gelderse vallei, Ede, Netherlands

BACKGROUND AND OBJECTIVES
More than half of all metabolic bariatric surgeries are performed in women of childbearing age, after which there is an increased risk of small-for-gestational age infants. Low maternal vitamin B12 has been suggested as a contributing factor to this increased risk, with a potential modifying role of folate status. Therefore, we investigate the association between maternal vitamin B12 status and risk of delivering a small-for-gestational age infant in women with a history of metabolic bariatric surgery, while exploring the potential modifying role of folate status.
METHODS
Multicenter observational cohort study including 125 pregnant women with a history of metabolic bariatric surgery. Linear mixed models and Cox proportional hazard regression models were used to analyze the association between delivering a small-for-gestational age infant (n=19, 15%) and plasma vitamin B12 status over the course of pregnancy as well as per trimester. Effect modification by serum folate was tested by adding interaction terms to the respective models.
RESULTS
Mean plasma vitamin B12 levels significantly decreased over the course of pregnancy, with plasma vitamin B12 levels being lower in the small-for-gestational age group compared to the non-small-for-gestational age group (247 pmol/L (95% CI 155-338 pmol/L) vs 352 pmol/L (95% CI 303-400), p=0.02). In the first and second trimester, women with high plasma vitamin B12 levels had a 70-77% lower risk of delivering a small-for-gestational age infant compared to women with low vitamin B12 levels (RR T1 0.23 (95% CI 0.07-0.70), RR T2 0.30 (95% CI 0.10-0.92). In the third trimester high vitamin B12 was associated with a reduced risk of small-for-gestational age among women with high folate levels (RR 0.22 (95%CI 0.05-1.03). In contrast, for women with low folate levels, there was no association between maternal vitamin B12 and small-for-gestational age (RR 2.44 (95% CI 0.43-13.82).
CONCLUSIONS
This study indicates an inverse association between high maternal vitamin B12 and risk of small-for-gestational age infants in pregnant women with a history of metabolic bariatric surgery, especially in case of high folate status. Future research should further identify whether there is a sensitive window of exposure during which maternal vitamin B12 status may be more strongly related to the risk of delivering a small-for-gestational age infant while incorporating the effect of supplementation, functional markers of vitamin B12 and appropriate measures of fetal growth.

RELATIVE VALIDITY OF A QUESTIONNAIRE-BASED SIX-ITEM ASSESSMENT OF SELF-REPORTED HABITUAL MAIN MEAL FREQUENCY AND TOTAL MEAL FREQUENCY

Frida Carlsson[1]; Erika Olsson[1]; Jonas Höijer[1]; Karl Michaëlsson[1]; Eva Warensjo Lemming[1, 2]
[1]Department of Surgical Sciences - Medical Epidemiology, Uppsala University, Uppsala, Sweden; [2]Department of Food Studies, Nutrition and Dietetics, Uppsala University, Uppsala, Sweden

BACKGROUND AND OBJECTIVES
Frequency and timing of eating are suggested to have implications for health, but further investigation is needed to reach consensus (Svendsen & Forslund, 2024). Adequate and valid tools for assessing meal patterns are essential for the relevance of RESULTS from the emerging field of chrono-nutrition (O'Connor, 2024). Commonly used tools for evaluating meal frequency, such as food records (FR), are time consuming and expensive, and validated cost-effective tools are called for (Phoi, 2022). Therefore, we aimed to evaluate the relative validity of a 6-item assessment of meal frequency included in a Food Frequency Questionnaire (FFQ) used in two large prospective cohorts (Harris, 2013), compared to repeated 3-day FRs. To our knowledge, this is the first study to attempt to validate such a tool.
METHODS
The FFQ and 3-day FRs were collected (one and five times, respectively) in a previously conducted 15-week intervention study (NCT03821116) of Swedish men and women, aged 40-74 (n=74). FFQ-reported *total meals/day* and *main meals/day* (breakfast, lunch, dinner) were compared to FR-reported estimates (mean of 15 days). A Wilcoxon signed rank test was performed to determine the median difference between FFQ and FR-reported main meals/day, and a paired sample t-test was used to determine the mean difference between total meals/day.
RESULTS
No statistically significant difference was found between the FFQ and FR reported main meals/day ($p = 0.82$). The median was 3.0 (IQR = 0) for the FFQ, and 2.9 (IQR = 0.2) for FRs. The mean difference between total meals/day reported from FFQ (3.94 (SD = 1.07)) and FRs (4.39 (SD = 0.73)) was 0.44 ($p = 0.0003$).
CONCLUSIONS
Our RESULTS support the FFQ-based six-item assessment as a valid tool for estimating frequency of main meals/day. Although, the mean difference for FFQ and FR-based estimates of total meals/day was statistically significant, the absolute difference was modest. These preliminary RESULTS will be followed by further investigations into possible reasons for the differences, providing insights for further improvements in meal frequency assessment, valuable for future research on meal patterns and health implications.

SOCIO-DEMOGRAPHIC AND NUTRITIONAL PREDICTORS OF ADEQUATE IRON INTAKE IN WOMEN OF FERTILE AGE

Alina Popa[1]; Andreea-Maria Mitran[2]; Otilia Nita[3]; Lidia Iuliana Arhire[3]; Laura Mihalache[3]; Andreea Gherasim[3]
[1]Internal Medicine / Diabetes, nutrition, metabolic diseases, Grigore T Popa University of Medicine and Pharmacy Iasi, Iasi, Romania; [2]Faculty of Pharmacy, Grigo, iasi, Romania; [3]Internal medicine / Diabetes, nutrition and metabolic diseases, Universitatea de Medicină și Farmacie „Grigore T. Popa” din Iași, Iași, Romania

BACKGROUND AND OBJECTIVES
Adequate iron intake is essential for women of childbearing age; it can play a critical role in preventing anemia, supporting reproductive health, and ensuring optimal outcomes for the well-being of mother and child. Socio-demographic factors (level of education, income, and living environment) significantly influence food choices and access to iron-rich foods. Also, the quality of the diet and the awareness of the recommended dietary practices shape the food patterns.
METHODS
Our research investigated factors influencing adequate iron intake among a sample of 251 women of childbearing age. The analysis focused on socio-demographic variables (education, income, living environment), dietary patterns, diet quality index (DQI), and anthropometric indicators (pregestational BMI and weight gain during pregnancy).
RESULTS
Our RESULTS indicated that only 15.5% of participants had an adequate iron intake, with significant differences according to education level (χ^2=8.49, p=0.004, OR=2.212, CI=1.015–4.817) and the quality of the diet (χ^2=6.23, p=0.013, OR=2.251, CI=1.002–5.056). Multiparity and dietary patterns did not significantly predict iron adequacy. Logistic regression confirmed that education (OR=2.21, CI=1.015–4.817) and DQI (OR=2.25, CI=1.002–5.556)were key predictors of adequate iron intake, highlighting the importance of nutritional literacy and diet quality in addressing micronutrient deficiencies.
CONCLUSIONS
Our findings emphasize the need for targeted interventions to improve diet quality and nutrition education. These determinants highlight disparities in nutritional health and the need for tailored interventions aimed at improving iron intake among women of childbearing age, thereby reducing the prevalence of iron deficiency and associated health risks.

PARTICIPATORY INSIGHTS: UNDERSTANDING ADOLESCENT FOOD CHOICES AND ENVIRONMENTS IN ETHIOPIA AND VIETNAM

Deborah Nabuuma[1]; Brice Even,[2]; Mestawet Gebru,[3]; Hang Thi Minh Thai,[2]; Thi Thanh Thu Pham,[2]; Beatrice Ekesa[4]; Irmgard Jordan,[5]; Céline Termote[5]
[1]Research, Alliance Bioversity-CIAT, Panang, Malaysia; [2]Research, Alliance Bioversity-CIAT Vietnam Country Office, Hanoi, Vietnam; [3]Research, Alliance Bioversity-CIAT, Addis Ababa, Ethiopia; [4]Research, Alliance Bioversity-CIAT, Kampala, Uganda; [5]Food environment and consumer behaviour, Alliance of Bioversity International and CIAT, Nairobi, Kenya

BACKGROUND AND OBJECTIVES
Adolescence is marked with significant biological and psychosocial growth and development, heightened nutrient needs and increasing autonomy in diets and eating habits. Yet many are at risk of malnutrition including micronutrient deficiencies, and overnutrition. Improving adolescents' food environments and diets requires understanding their values and interactions within their (changing) food environments. This study explored and compared adolescent's food environments in Ethiopia and Vietnam and their interactions.
METHODS
The qualitative study applied a participatory video making approach conducted across multiple sites with varying levels of urbanization, 3 districts in Vietnam and 2 woredas in Ethiopia. Adolescents aged 15-17 years (52 in Vietnam and 36 in Ethiopia), identified through purposively selected secondary schools, participated in a series of activities, with girls and boys in each site producing separate videos. Qualitative data comprised of workshop transcripts and videos (7 in Vietnam and 4 in Ethiopia) were analyzed using MAXQDA software using open coding, within the food environment dimensions: availability and accessibility, outlet properties, prices and affordability, product properties, marketing and desirability and knowledge. RESULTS were compared across the two countries.
RESULTS
In addition to food at home, adolescents had access to various types of food outlets, located within and near their schools and homes, that provided a wide range of both healthy and unhealthy food options, with a wider range of processed and ultra-processed foods in Vietnam. Foods were chosen based on the available budget, often opting for the cheaper, tastier and convenient options even if less nutritious. Engagement was varied, with more distinct differences between boys and girls in Ethiopia. Participation was extensive from farming, harvesting, shopping, preparation, to serving. Adolescents showed varying nutrition knowledge including some misinformation. Eating together in social settings was common in both countries but with some differences between boys and girls. Further analysis ongoing.
CONCLUSIONS
As adolescents navigate their unique cultural and social contexts, their food choices are influenced by a complex interplay of factors, including accessibility, affordability, messaging, knowledge and peer dynamics. Significant variations in the food environments of the two countries were noted but not as much between sites. Interventions must consider these contextual factors and actively engage adolescents alongside other food system actors in strategies that enhance the food environments and diets.

PREVALENCE AND DETERMINANTS OF VITAMIN D DEFICIENCY AMONG REPRODUCTIVE-AGE WOMEN IN LEBANON

Carla El-Mallah[1]; Amirhossein Yarparvar[2]; Valeria Galetti[1]; Omar Obeid[3]; Diana Kobayter[4]; Firass Abiad[5]; Lima Working Group[6]

[1]Nutrition, GroundWork, Fläsch, Switzerland; [2]Nutrition, UNICEF, Beirut, Lebanon; [3]Nutrition and Food Sciences, American University of Beirut, Beirut, Lebanon; [4]Nutrition, Mercy-USA, Beirut, Lebanon; [5]Public Health, Ministry of Public Health, Beirut, Lebanon; [6]Nutrition, Nutrition Working Group, Beirut, Lebanon

BACKGROUND AND OBJECTIVES

Vitamin D is a prohormone and an essential nutrient for various body functions and is produced endogenously during exposure to ultraviolet light. Vitamin D deficiency is a significant global public health problem and high prevalences have been found in multiple countries in the Middle Eastern region despite abundant sunshine. In this study, we aimed at assessing the prevalence of vitamin D deficiency among reproductive-age women living in Lebanon and uncovering the most important context-specific leading factors.

METHODS

A nationally representative cross-sectional study was conducted in 2023 in Lebanon. Household- and individual-level demographic data was collected, along nutritional and metabolic blood biomarkers. Serum vitamin D was analyzed on the same day of data collection, and vitamin D deficiency was defined as serum vitamin D concentration was below 30 nmol/L (12 ng/mL). Risk factors of vitamin D deficiency were identified using bivariate analyses, and indicators with a p-value <0.2 in the bivariate analysis were subsequently included in the multi-variable Poisson regression model. Indicators with a p-value <0.05 in the regression model are reported below.

RESULTS

A total of 2803 non-pregnant women aged between 15 and 49 years old were recruited, with a median age of 33.5 years. The weighted median serum vitamin D was 37.3 nmol/L, and the prevalence of vitamin D deficiency was 37.9%. The RESULTS from the multivariable model found that veiling and vitamin D supplementation were the most prominent risk factors of vitamin D deficiency. The prevalence of vitamin D deficiency was significantly higher in veiled women (adjusted prevalence ratio (aPR) 3.8, 95%CI: 3.1, 4.6) and significantly lower in those who consumed vitamin D supplements in the past 6 months (aPR = 0.30 [0.24,0.39]). Vitamin D deficiency was significantly higher in the younger age group (15-19 years), those in lower wealth quintile households, and those with lower educational levels. The prevalence of vitamin D deficiency was 14% to 28% higher in women with darker skin color, while it was 16% lower among those with greater than one hour of sun exposure per day. The deficiency was higher in women with anemia, vitamin B12 deficiency, and low HDL cholesterol, but lower in women with elevated triglycerides.

CONCLUSIONS

In a country where the sun shines more than 300 days a year, the prevalence of vitamin D deficiency is higher than global estimates. National strategies, such as promotion and distribution of vitamin D supplements, are needed, particularly among veiled women.

INFANT FEEDING DURING THE FIRST YEAR OF LIFE IS ASSOCIATED WITH BMI IN CHILDHOOD IN A NATION-WIDE COHORT STUDY FROM PREGNANCY TO CHILDHOOD

Jenny Jonsdottir[1]; Kristin M. Matthiasdottir,[1]; Kristjana Einarsdottir,[2]; Birna Thorisdottir,[1]; Inga Thorsdottir[1]
[1]Faculty of Food Science and Nutrition, School of Health Sciences and Unit for Nutrition Research, The Icelandic Health Science Institute, Reykjavík, Iceland; [2]Centre of Public Health Sciences, University of Iceland, Reykjavik, Iceland

BACKGROUND AND OBJECTIVES
Ensuring proper nutrition during the first year of life is crucial for both short and long-term population health, including prevention of overweight and obesity. We aimed to assess associations between: (I) the status of exclusive breastfeeding (**EBF**) at 3 months, (II) a novel Infant Diet Score (**IDS**) describing overall diet 0 - 12 months, with overweight and obesity in a nation-wide cohort of children.
METHODS
Data obtained from health records on 30,623 children born 2009-2015 in a Nordic country included demographics, birth and maternal factors; infant feeding 0-12 months recorded regularly; and weight/height measurements at 2.5, 4, 6 and 9 years. The IDS was composed by duration of EBF and any breastfeeding; age of cow's milk and semisolids/solid's introduction; estimate of food variety and vitamin D supplement use, a higher score representing greater alignment with nutrition recommendations. Anthropometric data was converted to BMI-for-age z-scores by using the WHO Child Growth Standards/References and their cut-offs used for overweight/obesity. We tested associations using logistic regression and odds ratios adjusted (aORs) for birth weight, residency, pre-pregnancy BMI, maternal age, maternal employment and parental cohabitation.
RESULTS
Compared with children who were EBF at 3 months, children who were not EBF, had higher odds of obesity at 6 years (aOR:1.44; 95% CI:1.24-1.67) and 9 years (aOR:1.36; 95% CI:1.16-1.59). Compared with children who were in the highest IDS quintile 0-12 months, children in the lowest IDS quintiles (1st and 2nd) had increased odds of obesity at 6 (aOR:1.50; 95% CI:1.11-2.04), (aOR:1.55; 95% CI:1.54-2.08) and 9 years (aOR:1.41; 95% CI:1.05-1.90), (aOR:1.50; 95% CI:1.12-2.02). We found no associations between IDS quintiles and overweight/obesity at 2.5 and 4 years.
CONCLUSIONS
Children not EBF at 3 months and children with lower alignment to infant feeding guidelines were more likely to be categorized as obese at six and nine years of age. This study underlines the importance of ensuring good nutrition during the first year of life for the primary prevention of obesity.

REASONS WHY CHILDREN AREN'T SUPPLEMENTED: A LOOK AT A COUNTRY SOUTH OF THE SAHARA IN AFRICA

Mohamed Lamine Fofana[1]; Alexandre Delamou,[2]; Abiodou Moise Owoloye,[3]; Koho Zoumanigui,[1]; Abdoul Aziz Diallo[4]; Mohamed Lamine Yattara,[5]; Kadiatou SANOH[6]; Facely Camara,[7]; Aissatou Toure,[7]; Romance Disseka,[3]

[1]Vitamin A Supplementation, Helen Keller INTL, Conakry, Guinea; [2]Chair of Public Health, Ministry of Higher Education, Conakry, Guinea; [3]Vitamin A Supplementation, Helen Keller INTL, Abidjan, Ivory Coast; [4]Monitoring Evaluation, Helen Keller INTL, Conakry, Guinea; [5]Management, Helen Keller INTL, Conakry, Guinea; [6]Nutrition, Helen Keller Intl Guinea, Conakry, Guinea; [7]National Department of Family Health and Nutrition, Ministry of Health and Public Hygiene, Conakry, Guinea

BACKGROUND AND OBJECTIVES

In 2024, Helen Keller supported vitamin A supplementation (VAS) for children aged 6-59 months in Guinea, aiming for at least 80% coverage and effective implementation. It conducted a coverage survey following distribution in the first half of this year. This study aims to identify why children do not benefit from this supplementation.

METHODS

Data comes from the post-campaign coverage survey administered to caregivers of children aged 6-59 months in the six regions supported by Helen Keller International. This survey used a WHO (2015) stratified cluster design that drew 115 clusters. A total of 1,378 households and 1,527 childminders were interviewed.

RESULTS

Of the 2,007 children involved, 1,698 were supplemented, representing 84.6%; 255 were not supplemented, or 12.7% and the status of 54 children was unknown, representing 2.7%. The main reasons identified included parents' lack of information about the campaign (90.6%), refusals due to cultural beliefs and misperceptions (6.7%), and 2.7% cases of illness. In addition, shortcomings in the close follow-up of teams were noted.

CONCLUSIONS

The RESULTS suggest that it is crucial to strengthen communication and community mobilization to improve vitamin A supplementation coverage, notably by providing sufficiently early information on the campaign period and organizing awareness campaigns. It is also important to correct misperceptions about vitamin A.

CONFLICTS OF INTERESTS

MIGRANTS AND FOOD SECURITY AT SANTIAGO FROM CHILE: A STUDY OF SOCIO-URBAN BARRIERS AND FOOD DESERTS

Felipe Ulloa-León[1]; Josefina Ulloa[1]; Francisco Vergara Perucich[1]; Leslie Landaeta-Díaz[2]
[1]Núcleo Centro Producción del Espacio, University of the Americas, Providencia, Chile; [2]Núcleo de Investigación en Nutrición y Ciencias Alimentarias, University of the Americas, Providencia, Chile

BACKGROUND AND OBJECTIVES
Food security has become a growing challenge in Chile. 41.5% of migrants in Santiago do not have enough food due to lack of money, and 32.5% do not eat healthy food due to lack of food. This is a critical situation for migrants, who face greater difficulties accessing adequate food.
To explore the existence of urban access barriers to healthy food services, in terms of proximity and their impact on the food security of the migrant population in the Metropolitan area.
METHODS
A comparative spatial distribution analysis and subsequent clustering were carried out using 2017 census data and OpenStreetMap, identifying the distribution of migrants and their access to markets and supermarkets in urban areas. A food desert index was constructed, determining the distance from homes to healthy food outlets at more than 1,500 meters. A cluster analysis technique was applied and migrant density was related to access to nutritious food.
RESULTS
Four clusters were identified that combine migration density and access to healthy food stores (Figure 1). The availability of street markets and supermarkets (Figure 2) indicates that migrants tend to focus on urban areas with available services, influenced by accessibility and the relatively low cost of housing. However, the main barriers become economic since limited purchasing power restricts migrants' ability to acquire healthy foods, leaving them in food insecurity.https://drive.google.com/file/d/1nbgBe_43YwTCyQ7GQvaimTwEsELmTXBC/view?usp=sharing
CONCLUSIONS
Migrants are vulnerable from a food point of view despite being located in urban areas with greater access to services due to their economic limitations.
CONFLICTS OF INTERESTS
The authors have no conflict of interest.

WEIGHT CONTROL BEHAVIOURS AMONG SERBIAN ADOLESCENTS AND THEIR RELATIONSHIP WITH BODY IMAGE - DATA FROM HEALTH BEHAVIOUR IN SCHOOL-AGED CHILDREN SURVEY 2022

Jelena Gudelj Rakic[1]; Biljana Kilibarda[1]; Verica Jovanovic[2]
[1]Centre for Health Promotion, Institute of Public Health of Serbia "Dr Milan Jovanovic Batut", Belgrade, Serbia; [2]Cancer Screening Office, Institute of Public Health of Serbia "Dr Milan Jovanovic Batut", Belgrade, Serbia

BACKGROUND AND OBJECTIVES
Adolescence is considered risk period for weight gain due to intensive hormonal and metabolic changes, but also changes in eating behaviours. Some adolescents perceive their physical appearance to be quite different from their actual body weight and consequently start practicing different behaviours aiming at weight control. Although many adolescents seek professional help to lose weight, some use fasting, vomiting, and laxatives as ways to control their weight. The aim was to assess adolescents' weight control behaviours and their relationship with the body image.
METHODS
Secondary analysis of data obtained from the Health Behaviour in School-aged Children Survey (HBSC) in Serbia 2022 were used. Survey was conducted as a cross-sectional study on a nationally representative sample of adolescents aged 11, 13 and 15 years. In this study only data for adolescents aged 13 and 15 were analyzed. Participation was anonimous and voluntary following the methodology of the standardized international study protocol.
RESULTS
According to body mass index (BMI), 7.6% of adolescents aged 13 and 15 in Serbia were underweight, while 10.5% were overweight and 2.6% were obese. One sixth of adolescents (17.4%) were on a diet at the time of study, 10.6% of adolescent were on a diet or doing something else to control weight in the last 12 months, while 21.2% of them were different times on a diet in the last 12 months. Boys and girls who perceived themselves fat were more likely to practice different behaviours for weight control, more often unhealhty behaviours such as fasting (12.8%) or smoking more (7.5%). Only 5 % of respodents dieted under professional supervision.
CONCLUSIONS
Considering the health risks associated with the way adolescents perceive their weight, especially related to weight control behaviours, identification and monitoring of these behaviors is necessary. In order to avoid harm to health it is important to raise the awareness of doctors in primary health care and design interventions aimed at improving adolescent nutrition.

STRUCTURE AND UNSTRUCTURED FOOD INTAKE IN THE DOMESTIC ENVIRONMENT

Paula Hernandez Hirsch[1]; Maggiolo, Carolina Franch[2]; Osiac, Lorena Rodriguez[3]; Isabel Pemjean[4]
[1]PhD Student, Freie Universität Berlin, Berlin, Germany; [2]Anthropology, Universidad de Chile - Campus Juan Gómez Millas, Ñuñoa, Chile; [3]Public Health, University of Chile - North Campus, Santiago, Chile; [4]CIAPEC, Institute of Nutrition and Food Technology, University of Chile, Santiago, Chile

BACKGROUND AND OBJECTIVES
Food cycles in the domestic environment make use of structures - more or less stable - so that the multiple processes required for feeding can take place. In other words, there is an organization, relatively constant over time, involving the acquisition, preparation, consumption and disposal of food. The anthropological perspective in combination with the nutritional perspective provides an in-depth analysis of the organization, distribution and regularity of daily food consumption practices in households, in a context in which malnutrition by excess has taken on a worrying preponderance at national and global level.
Objective: To identify the structures of daily food intake in households of low socioeconomic level in the city of Santiago-Chile.

METHODS
Ethnographic, based on observations and semi-structured interviews conducted between 2020 and 2021 in 24 low-income households in Santiago, Chile.

RESULTS
Four types of daily intakes are described, categorized according to their relevance, periodicity, composition and visibility. Discrepancies were evidenced between an idealized dietary structure, on which nutritional recommendations are based, and concrete feeding practices, where schedules are shifted, certain intakes are suppressed, others are duplicated and new feeding styles, previously unidentified, emerge.

CONCLUSIONS
The findings showed 2 patterns of food consumption, one structured and visible and another unstructured, which does not have a defined location in time and space. The latter constitutes a strong obstacle to a healthy diet and may be a potentiator of overweight and obesity in the group studied

CONFLICTS OF INTERESTS

INFLUENCE OF SOCIAL AND PHYSICAL FOOD ENVIRONMENT ON THE DIETARY INTAKE OF ADOLESCENTS (10-19 YEARS) IN DELHI, INDIA

Sunaina Thakur[1]; Pulkit Mathur[1]
[1]Department of Food and Nutrition and Food Technology, Lady Irwin College, University of Delhi, New Delhi, India

BACKGROUND AND OBJECTIVES
Food choices are influenced by the food environment. This study aimed to understand the physical & social food environment of adolescents and its relationship with their consumption of fruits and vegetables, foods high in fat, salt, & sugar (HFSS), and sugar sweetened beverages (SSBs). Insights regarding the interplay of food environment with food choices can inform policymakers regarding strategies for promoting diets amongst this age group.
METHODS
This cross-sectional observational study included 632 adolescents aged 10-19 years from four private schools in Delhi, India, selected through non-probability purposive sampling. Information on home food availability, accessibility, parent modelling, family food rules and habits, involvement in cooking, and dietary intake was assessed using a pre-tested questionnaire. Data was analysed using Chi-square/Fisher's exact test and linear regression, with a level of significance set at $p<0.05$.
RESULTS
The regular (more than three times a week) availability of different unhealthy foods and SSBs at home significantly increased their consumption ($p<0.001$). Adolescents consumed more fruits and vegetables when parents regularly cut and made these accessible as snacks ($\beta=0.63$, $p<0.001$) and when parents modelled healthy eating behaviours ($\beta=0.24$, $p<0.001$). Interestingly, adolescents who regularly assisted with food preparation at home had higher consumption of fruits and vegetables ($\beta=0.37$, $p<0.001$) as well as HFSS foods and SSBs ($\beta=0.29$, $p=0.011$). Eating dinner with family regularly while watching television or using a screen was positively associated with the consumption of HFSS foods and SSBs ($\beta=0.53$, $p<0.001$) and negatively with fruit and vegetable intake ($\beta= -0.24$, $p=0.008$). Adolescents who were regularly expected to eat all vegetables served, even if they did not like them, showed a positive association with fruit and vegetable intake ($\beta=0.55$, $p<0.001$) and a negative association with HFSS food and SSB consumption ($\beta= -0.26$, $p=0.047$). Among the majority of adolescents (72.2%), the most trusted and reliable source of information about what to eat or avoid was the family.
CONCLUSIONS
Intervention strategies should aim to promote healthier food choices among adolescents by increasing the household availability and accessibility of nutritious foods while limiting unhealthy options. Encouraging adolescents to participate in healthy meal preparation with parents may foster better dietary decisions. Parents should act as role models for their children and also encourage mindful eating during family meal times.

BACKGROUND AND OBJECTIVES
Anemia during infancy is widespread in low- and middle-income countries, significantly impairing physical and cognitive development. Identifying its underlying causes is crucial for developing effective intervention strategies. This study aimed to determine factors affecting anemia, iron deficiency, hemoglobin level and serum ferritin level in infants aged 6 months.
METHODS
This study included baseline data from 287 healthy, full-term infants aged 6 months who participated in a double-blinded, randomized controlled trial. Outcomes assessed at 6 months included anemia prevalence, iron deficiency, hemoglobin levels, and serum ferritin levels. Multivariate binomial logistic regression was used to analyze the relationship between factors associated with anemia and iron deficiency. Multiple linear regression was used to analyze the relationship between factors associated with hemoglobin levels and serum ferritin levels.
RESULTS
The proportions of anemia and iron deficiency among 6-month-old infants in this study were 18.1% and 5.0%, respectively. One standard deviation (SD) higher in weight-for-age Z-scores was associated with a lower risk of anemia (adjusted odds ratio [aOR] 0.56, $p = 0.010$). An increase of 1 µmol/L in retinol-binding protein (RBP) level was associated with a lower risk of iron deficiency (aOR 0.01, $p = 0.030$). Further analysis showed that higher weight-for-age Z-scores were significantly associated with higher hemoglobin levels ($\beta = 0.14$, $p = 0.026$), while higher RBP levels were associated with higher serum ferritin levels ($\beta = 30.63$, $p = 0.011$).
CONCLUSIONS
Better growth was significantly associated with a lower risk of anemia and higher hemoglobin levels, while adequate vitamin A status was linked to reduced iron deficiency and increased iron stores. These RESULTS underscore the critical roles of good nutrition and adequate vitamin A in preventing anemia and iron deficiency in infants.

BODY COMPOSITION CHANGES IN INDONESIAN CHILDREN DURING TREATMENT OF SEVERE ACUTE MALNUTRITION WITH A LOCALLY PRODUCED READY-TO-USE THERAPEUTIC FOOD ARE MODULATED BY PRE-BIOTIC RICE BRAN: A RANDOMIZED CONTROLLED TRIAL

Silvia Barbazza[1]; Campos-Ponce Maiza[1]; Van Der Hoeven Marinka[1]; Sonia Fortin[2]; Frank T. Wieringa[2]
[1]Health Science, Vrije Universiteit Amsterdam, Amsterdam, Netherlands; [2]QualiSud, Research and Development Institute IRD Montpellier, Montpellier, France

BACKGROUND AND OBJECTIVES
Current formulations of ready-to-use therapeutic foods (RUTFs) to treat severe acute malnutrition (SAM) focus on nutrient quantity and do not give due attention to their impact on the intestinal microbiome or body composition in children treated for SAM. This study aimed to assess the efficacy of daily RUTF administration with rice bran (RUTF+) compared to RUTF without rice bran (RUTF-) on body composition indicators.
METHODS
A total of 200 children aged 6–59 months with uncomplicated SAM (weight-for-height z-scores (WHZ) <−3, and/or mid-upper arm circumference (MUAC) <115mm, and or having bilateral pitting oedema +/++), or approaching SAM (WHZ<−2.5) were enrolled in a double-blinded, randomized controlled trial. Children received either a locally produced RUTF, or the same RUTF with 5% rice bran for 8 weeks of treatment, followed by 8 weeks of monitoring. Anthropometric data, including weight, height, mid-upper arm circumference and skinfold measurements at 4 points (biceps, triceps, subscapular and supra-iliac), were collected monthly. Body composition outcomes analyzed were Body Fat Percentage (BFP), Fat Mass (FM), Fat-Free Mass (FFM), the ratio of Abdominal vs. Peripherical skinfolds, and singular skinfolds. Linear mixed models were applied across all ages and split by age group (6-23 months and 24-59 months) at weeks 0, 4, 8, 12, and 16 for per protocol analysis (PP).
RESULTS
Weight, MUAC and FFM increased significantly in both treatment arms over treatment and post-treatment follow-up, but with significant differences between age groups. During treatment, in children 6-23 months old, increases in fat-free mass were greater in the RUTF+ group (+208 g and +297 g for week 4 and 8 respectively) as compared to RUTF- at 4 and 8 weeks (+146g and +212g ; $p<0.05$). Fat mass increases rapidly in the first 4 weeks (+248g) but hardly between 4 and 8 weeks (+25g). Increases in fat mass from the start of treatment tended to be greater in the RUTF+ group at 4 and 8 weeks (+276g and 311g) than in the RUTF- group (+190g and + 198g, respectively; $p=0.06$). In older children, there were no significant differences in FFM or FM between the two groups during treatment. MUAC was greater in the RUTF+ group than in the RUTF- group at week 4 (+1.8 mm) and week 8 (+1.7 mm), but differences were not statistically significant.
CONCLUSIONS
This study suggests that rice bran, a known pre-biotic, modulates the impact of RUTF on the accumulation of fat and lean mass during SAM treatment, with a tendency towards greater effect in younger children, whose microbiome is not yet mature.

HOW AND WHY CAN A “CASH PLUS” PROGRAMME IMPACT ON FOOD INSECURITY AND WELL-BEING OF VULNERABLE HOUSEHOLDS IN FRANCE? A PROGRAMME IMPACT PATHWAYS ANALYSIS

Maria Somaraki[1]; Mathilde Savy[1]; Sabrina Eymard-Duvernay[1]; Christophe Dubois[2]; Alejandra Giraldo[1]; Camille Calandre[1]; Pierre Berri[1]; Sophie Lochet[3]; Radjaa Kebiri[3]; Nadia Berrambou[4]; Morgan Couppa[4]; Marlène Perignon[1]
[1]MoISA, Univ Montpellier, CIHEAM-IAMM, CIRAD, INRAE, Institut Agro, IRD, Montpellier, France; [2]ActAP, ActAP, Marseille, France; [3]Action Contre la Faim, Action Against Hunger, Montreuil, France; [4]Fondation de l'Armée du Salut, Fondation de l'Armée du Salut, Paris, France

BACKGROUND AND OBJECTIVES
The French “Passerelle Plus” programme seeks to reduce food insecurity of vulnerable households while avoiding some issues of the current food aid system (e.g. stigmatization, lack of choice). The programme comprises three components, i.e. households are offered unconditional cash transfers (CT) along with social orientation and a workshop on sustainable diets. While a randomized controlled trial assesses the programme’s impact as a whole, a process evaluation seeks to elucidate the “how” and “why” of the programme. The present study describes the development of the Programme Impact Pathways (PIP) that is embedded into the process evaluation of “Passerelle Plus”.
METHODS
A PIP analysis bridged the implementation and evaluation aspects by outlining the theoretical chain of causality for programme impact. In two workshops, implementers of the different programme components (n=6 NGO members/social workers; n=2 nutritionists, respectively) shared their understanding of the programme and its objectives. Using coloured papers and arrows, they visualised the programme’s processes throughout the “inputs–process–outputs–outcomes–impacts” flow, thus linking each activity to specific outcomes. Using the visual aids, participants were able to share their views on barriers and facilitators of implementing such a programme in disadvantaged settings.
RESULTS
Three impact pathways pertaining to the three programme components were identified through their synergies. For example, access to financial means may directly address the issue of food insecurity and well-being linked to poverty. During the workshops, dignity of recipients was identified as a key facilitating factor which is related to freedom of choice on what to spend the CT and the non-dependence on food aid. Moreover, social workers provide tangible support in guiding households through administrative formalities to access social rights, which can further increase financial access through housing or other benefits. Last, the nutrition workshop builds on the group sharing concrete sustainable food practices including food budgeting. Identified barriers were lack of facilities and problems with CT distribution, along with recipients’ time availability and French language skills.
CONCLUSIONS
The identified impact pathways build on the synergies across programme components, and provide insights into the ‘"black box" of a complex “Cash-Plus” programme. As such, PIP analysis is the first step that defines the key research questions and data collection methods of the process evaluation.

BARRIERS AND FACILITATORS TO ADOLESCENTS SEEKING MANAGEMENT OF SMALL AND NUTRITIONALLY AT-RISK INFANTS UNDER SIX MONTHS AND THEIR MOTHERS (MAMI) SERVICES IN SOMALILAND

Yuusuf Yuusuf[1]; Said Mohamoud[2]; Patricia Welch[3]; Meftuh Omer,[2]; Shannon Pryor,[4]; Adam Abdulkadir[2]; Mohamed Mahat[2]; Hodan Abdi,[1]; Adan Mahdi[2]

[1]Program Development and Quality, Save the children, Hargeysa, Somalia; [2]Program Development and Quality, Save the Children International, Mogadishu, Somalia; [3]Centre for Humanitarian Public Health Team, Save the Children Schweiz - Organisation für die Rechte der Kinder, Zürich, Switzerland; [4]Global Health, Save the Chil, Washington, United States of America

BACKGROUND AND OBJECTIVES

Globally, adolescent childbearing (10-19 years) poses significant health risks for mothers and their infants, including complications during pregnancy, poor birth outcomes, and increased vulnerability to malnutrition. The MAMI Care Pathway provides targeted support to nutritionally infants under six months and their mothers. We explored barriers and facilitators to adolescents access to and use of MAMI services in Somaliland, to inform program adaptations to improve service reach and responsiveness. Enrollment in MAMI often takes place in facilities, however 78.2% of adolescents don't deliver in a facility and only 29.6% attend antenatal care services.

METHODS

The qualitative study in Somaliland included in-depth interviews (pregnant adolescents and adolescent mothers), focus group discussions (adolescent mothers, male partners, older female relatives and community health workers, (CHWs)) and key informant interviews (service providers).

RESULTS

Adolescents face multiple barriers to health services access including care seeking uncommon unless the baby or mother appeared or felt sick, fears and anxieties of adolescent clients, cost of transport, distance to health facilities, beliefs and behaviors of family and poor quality of services. Facilitators include support from CHWs and physical accompaniment to services, husbands expressed desire to support their adolescent wives, adolescents perceiving CHWs and health workers as a source of information and positive experiences with MAMI staff. Vaccination services were frequently mentioned by respondents as a valuable health service. Awareness of MAMI services among adolescent mothers is low, and many rely on information from older mothers.

CONCLUSIONS

The study concludes that tailored interventions are needed to find adolescent clients to strengthen inclusion in MAMI in Somaliland. Recommendations include strengthening community outreach to improve awareness about MAMI and related health and nutrition services along the continuum of care, increasing community-level screening activities, engaging family members in discussions about the importance of health services for adolescent mothers and their <6 months infant and when to attend, and incorporating respectful care content into MAMI training. Additionally, integration of MAMI screening into vaccination services presents an opportunity to reach adolescents. These adaptations aim to improve the reach and effectiveness of the MAMI Care Pathway.

FACTORS INFLUENCING EXCEPTIONS TO A VEGAN DIET

Vanessa Vohland[1]; Eleonore Heil[2]
[1]Working Group Nutrition Ecology, University of Giessen, Gießen, Germany; [2]AG Nutrition Ecology , Justus Liebig Giessen , Giessen, Germany

BACKGROUND AND OBJECTIVES
A vegan diet excludes all animal products. Adhering to this choice can be challenging in daily life, as the consumption of animal-based foods is deeply ingrained in societal norms. This deviation from the norm often RESULTS in stigmatisation, making the choice even more difficult. Furthermore, some vegans occasionally make exceptions to their diet, particularly in situations where vegan alternatives are not available.
This prompts the research question: How frequently do vegans make exceptions, and what factors influence these exceptions?
METHODS
A standardised online questionnaire was used to collect data about the vegan diet, food consumption frequencies and various reasons and frequencies of the exceptions to the vegan diet. The study population comprised individuals affiliated with a university, including both students and faculty members, as well as individuals from vegan facebook groups. Participants were required to adhere to a vegan diet. The data was analysed univariate, bivariate and multivariate using IBM SPSS Statistics Version 28.
RESULTS
389 vegans took part in the study. Of these, 76.7 % were female, 19.0 % male and 2.3 % diverse, with an average age of 26.6 years. 51.8 % of the participants chose a vegetarian dish in a restaurant when no vegan option was available. 23.4 % of the participants ate animal-based foods at home, 68.0 % when travelling, 51.2 % on special occasions (weddings), 66.4 % when the food would otherwise be thrown away, 29.7 % to avoid uncomfortable situations and 47.0 % when others are cooking. 30.8 % of the participants deviated from the vegan diet, when eating with people who are not vegan, but only 4.1 % when eating with other vegans. 70.6 % of the participants often or always brought vegan dishes to celebrations.
CONCLUSIONS
For some vegans wasting food is worse than eating it. From an environmental perspective, food waste is a major problem, especially when it concerns animal-based products. The increased consumption of animal-based foods by eating with non-vegans could be due to social desirability and a sense of belonging. It is clear from the data that many self-reported vegans do not follow a strict vegan diet and this should be taken into account in future public health interventions. Definitions for the diet could be useful, especially for the question of the type of diet, as the diet is interpreted very individually. In addition to strict vegans, the term default veganism or flexigan could be included for vegans with exceptions.

SCREEN USE AT MEALTIME AMONG CHILEAN CHILDREN AGED 2 TO 15 YEARS

Sandra López-Arana[1]; Edson Bustos-Arriagada[1]; Oscar Castillo-Valenzuela,[1]; Angelo Liberona[2]
[1]Faculty of Medicine, Nutrition and Dietetics School, Universidad Finis Terrae, Providencia, Chile;
[2]Comunicaciones y Servicios Marketing, Chile Nestlé S.A., Las Condes, Chile

BACKGROUND AND OBJECTIVES
The World Health Organization (WHO) recommends the use of screens and electronic devices for no more than one hour per day in children aged 2 to 5 years. Screen use during meals has been associated with adverse consequences on physical, social and emotional outcomes in childhood. We described screen use at mealtime among children between 2 to 15 years.
METHODS
Six hundred parents of children aged 2 to 15 years were surveyed during May to June in 2024. Sociodemographic information was collected, and questions about screen use during meals were evaluated. We performed logistic regression analysis to determine the associations between sociodemographic variables and screen use at mealtime.
RESULTS
Most surveyed participants were mothers (65.8%; n=395), with an average age of 37.6 ± 9.2 years. Of the children, 50.3% were boys and 49.7% were girls. The age distribution was 33.5% were aged between 2 to 5 years, 43% were between 6 to 12 years, and 23.5% were between 13 to 15 years. Parents reported that almost a third (29.3%) of children used screens while eating. In the logistic regression models, younger children were more likely to use screens during meals than older children. Specifically, after adjustments for the child´s sex and socioeconomic status, the odds ratio (OR) relative to children aged 13 to 15 years was as follows: OR= 2.06; 95% CI: 1.23 to 3.46 for children aged 2 to 5 years, and OR= 2.00; 95% CI: 1.21 to 3.32 for children aged 6 to 12 years.
CONCLUSIONS
Our study highlights that younger children are more likely to use screens during meals compared to older children. This finding emphasizes the need for targeted interventions to address screen use among younger age groups, considering the potential adverse effects on their health and development.

EXPLORING HOW TO SCALE UP PROGRAMMING AROUND INFANTS AT RISK FOR POOR GROWTH AND DEVELOPMENT, ADOLESCENT NUTRITION AND CARE GROUPS IN UGANDA: NOVEL IMPLEMENTATION RESEARCH FINDINGS

Justine Kavle[1]; Alex Mokori[2]; Zakaria Fusheini[2]; Joseph Gaithuma[3]; Ruth Waithira[3]; Tim Mateeba[4]; Laura Ahumuza[4]
[1]Public Health Nutrition, Kavle Consulting, Washington, United States of America; [2]Nutrition Division, UNICEF, Kampala, Uganda; [3]Public Health Nutrition, Kavle Consulting, Nairobi, Kenya; [4]Nutrition Department, Ministry of Health, Kampala, Uganda

BACKGROUND AND OBJECTIVES
This implementation research unpacks key issues, and the way forward for operationalizing national programming for infants at risk for poor growth and development and improving upon current adolescent nutrition and Care Group programming in Uganda
METHODS
The study triangulated in-depth interviews (IDIs) with 15 government stakeholders and implementing partners, 30 health providers, 30 mothers, and 6 care group promoters, alongside 6 focus groups discussions (FGDs) with care group implementers, and 12 FGDs with adolescent boys and girls, 10-19 years of age in West Nile, Karamoja and Kampala, Uganda.
RESULTS
Our preliminary findings present challenges and opportunities for introduction of programming around infants at-risk for poor growth and development- inclusive of insights on screening and assessment, services targeting maternal mental health, the need to address breastfeeding challenges. The prevention of growth faltering for infants that have the potential for moderate and severe wasting is highlighted. For adolescent nutrition, data on how peer and parental influences, the broader school feeding environment as well as how cultural and social norms affected dietary intake and food choice will be presented. Leveraging on existing Care Groups – as an important platform for improving nutrition practices will be discussed- from a feasibility and sustainability perspective.

CONCLUSIONS
Addressing gaps pertaining to community and facility service delivery for infants at risk for poor growth and development, as well as adolescent nutrition and Care Groups are key for sustainable country programming. This should include strengthening provision of practical support for maternal and infant health, including addressing breastfeeding challenges and maternal mental health, as well as existing social, cultural and gender norms.

INCLUSION OF FOOD BIODIVERSITY THROUGH INDIGENOUS PEOPLES AND TRADITIONAL COMMUNITIES IN PUBLIC FOOD PROCUREMENT: A CASE STUDY IN EASTERN AMAZON

Bianca da Conceição Cabral; Mendonce Sharon[1]; Teresa Borelli[1]; Bernardo Tomchinsky[2]; Andrea Das Graças F. Frazão[3]; Danny Hunter[4]

[1]Food Environment and Consumer Behaviour Division, Alliance Bioversity International and CIAT, Roma, Italy; [2]Instituto de Estudos em Saúde e Biológica, UNIFESSPA - Campus I, Marabá, Brazil; [3]Faculdade de Nutrição/Instituto de Ciências da Saúde, Universidade Federal do Pará, Belém, Brazil; [4]Food Environment and Consumer Behaviour Division, Alliance for Bioversity and CIAT, Sydney, Australia

BACKGROUND AND OBJECTIVES

Food biodiversity is threatened by the homogenisation of global food systems that promote monotonous diets, and drive biodiversity loss, food insecurity and climate change. Indigenous Peoples and traditional communities play a crucial role in this context, as their biocultural diversity inherently integrates knowledge and practices that enhance nutrition, strengthen resilience, and build adaptive capacity. Incorporating this ancestral knowledge into public food procurement can transform food systems, promoting sustainability and inclusion. This study analyses the inclusion of food biodiversity and the participation of Indigenous Peoples and traditional communities in public procurement in a region of the Eastern Amazon, Brazil. This study analyses the inclusion of food biodiversity and the participation of Indigenous Peoples and traditional communities in public procurement.

METHODS

This research was carried out in six municipalities in a Region of the Brazilian Amazon, focusing on the Food Acquisition Programme (PAA) and the National School Feeding Programme (PNAE). The lists (notices) of these programs' purchases, contracts and school menus were analyzed, referring to one year of execution. The foods were classified as socio-biodiversity based on MAPA/MMA Interministerial Ordinance No. 10/2021 and the Ministry of Health's official publication of Brazilian Regional Foods.

RESULTS

In the PNAE, 146 foods were demanded, of which 25.0% to 37.5% represented socio-biodiversity among the municipalities, while in the menus this socio-biodiversity ranged from 0.0% to 21.9%. Municipalities with a higher inclusion of biodiversity had more *in natura* or minimally processed foods, while a lower percentage was associated with a higher presence of ultra-processed foods. The PAA included 292 demanded foods, with socio-biodiversity ranging from 17.6% to 32.4%. According to PNAE data analyzed, only one municipality included suppliers from traditional communities, such as babassu coconut breakers. Whereas PAA data showed that Indigenous Peoples, Quilombolas and other communities participated widely, except in one municipality. The PAA was more inclusive, owing to policies specifically designed for these groups and reflected a greater food biodiversity.

CONCLUSIONS

The RESULTS indicate that policies that prioritize Indigenous Peoples and traditional communities are fundamental to expanding the use of socio-biodiversity and fostering more sustainable food systems, demonstrating the transformative potential of these programmes.

CURRENT STATUS OF NUTRITION-RELATED HOME ECONOMICS EDUCATION IN JAPAN

Mizuho Adachi[1]
[1]Department of Physical Education, Nippon Sport Science University, Setagaya City, Japan

BACKGROUND AND OBJECTIVES
In Japan, textbooks are the primary teaching material that are reviewed for compliance with study courses. In 2017, the study courses for elementary and junior high schools were revised, followed by a revision for high schools in 2018, the first in 10 years . These novel study courses emphasize that home economics should contribute to enhancing Shokuiku [meaning Food and Nutrition Education] . However, it has been noted that home economics textbooks before the revision lacked sufficient content on nutrition education compared to those in the U.S. and U.K. This study aimed to analyze home economics textbooks based on novel study courses to understand the content of nutrition education.
METHODS
First, to organize the nutritional content in the curriculum, we assessed the learning objectives and guidelines for nutrition in the novel home economics curriculum for elementary, junior high, and high schools. Subsequently, we analyzed the nutrition-related content in the textbooks corresponding to the novel curriculum guidelines by categorizing the items and number of pages. Two elementary school textbooks, three junior high school textbooks, and 16 high school textbooks were analyzed.
RESULTS
Nutrition-related content in the novel study courses was compared across school types. In the section “The Role of Meals,” elementary school students learn why we eat and its role in health and growth. In junior high school, students focus on their relationships, enhance their eating habits and nutritional balance, and learn to play a role in preserving the food culture. In high school, students learn about the role of food in various life stages. Textbooks on nutrition were classified into eight categories—role of meals, functions of nutrients, food combinations and nutritional balance, menu planning, food culture, meal preparation, cooking, and others. Across all school types, the largest portion of content was associated with cooking. While most elementary and junior high school content was focused on food, high school content emphasized the function of nutrients.
CONCLUSIONS
Nutrition-related content in home economics textbooks varied by school type regarding the number of pages, items emphasized, and their coverage order. Even textbooks compliant with the novel study courses lacked data on physiological content, such as digestion, nutrient absorption, and the formation of healthy eating habits across the lifespan, thereby limiting the role of home economics in nutrition education.

COPING STRATEGIES AND EXPERIENCES OF WOMEN LEADERS FROM COMMON POTS IN PERI-URBAN AREAS OF A LOWER MIDDLE INCOME COUNTRIE (LMIC) FACING FOOD INSECURITY DURING THE COVID-19 PANDEMIC

Fiorella Sofia Garcia Guerrero[1]; Sissy Espinoza-Bernardo[2]
[1]School of Nutrition, National Major University of San Marcos, Lima, Peru; [2]Departamento de Nutricion, Universidad Nacional Mayor de San Marcos, Lima, Peru

BACKGROUND AND OBJECTIVES
Background: At the beginning of the COVID-19 Pandemic, the population in a vulnerable situation was not able to afford their daily diet, for this reason, the resurgence of citizen support initiatives called "common pots" was observed. However, the coping strategies carried out and their experiences with food insecurity are unknown.
Objective: Understand the coping strategies and experiences of women leaders from common pots in peri-urban areas of a lower middle income countrie (LMIC) in the face of food insecurity during the COVID-19 Pandemic.
METHODS
Qualitative approach study and phenomenological design. The study subjects were 26 women leaders from common pots in peri-urban areas of a LMIC. For data analysis, triangulation of information was carried out by technique to achieve the reliability of the study.
RESULTS
The coping strategies carried out by the leaders were the collection and rescue of food in different markets, they also gave priority to the cheapest foods as well as those received in donations, in addition, the conservation methods of food depended on the equipment available to each organization. Additionally, the positive experiences they recovered were having learned to cook for a greater number of diners and work as a team with their neighbors, and, on the contrary, the negative experience was having received negative comments from merchants and some beneficiaries.
CONCLUSIONS
Coping strategies against food insecurity were similar in the six common pot organizations. On the other hand, the experiences of the members of each common pot were understood.

DEVELOPMENT OF DIETARY LIFESTYLE ASSESSMENT TOOL FOR YOUNG ADULT POPULATION IN SOUTH KOREA

Dahye Han[1, 2]; Minjeong Jeong[1, 2]; Kim Jinhyun[1, 2]; Eunjin Jang,[1, 2]; Sohyun Park[1, 2]
[1]Food Science and Nutrition, Hallym University, Chuncheon, Korea, Republic of; [2]The Korean Institute of Nutrition, Hallym University, Chuncheon, Korea, Republic of

BACKGROUND AND OBJECTIVES
Recent epidemiological data have identified young adults in their 20s as a health and nutrition vulnerable group in urgent need of policy intervention. Therefore, this study was designed to develop a measurement tool for systematically classifying dietary lifestyle patterns in young adults. By clustering dietary lifestyle patterns of young adults and analyzing their associations with various health risk factors, this tool aims to support dietary improvement initiatives for this age group.
METHODS
This study surveyed 800 young adults in Korea aged 20–35 (300 participants in the 1st phase, 500 in the 2nd phase, and 50 participants in the 2nd phase) through three rounds of online surveys. The tool development process involved generating preliminary items through a literature review and pilot studies on the selected young adults, followed by expert consultation. The developed tool was subjected to exploratory factor analysis and principal component analysis to identify factor structures, and confirmatory factor analysis was conducted to validate the measurement model. Internal consistency was assessed using Cronbach's alpha coefficient and average inter-item covariance, with thresholds set at ≥0.7 and 0.2–0.4, respectively. Statistical analyses were performed using Stata 17.0.
RESULTS
In the first survey, dietary lifestyle patterns were classified into 56 items across eight domains: health and hygiene, convenience, affordability, trendiness, gastronomy, emotions, ecological environment, and social relationships. Through exploratory factor analysis and principal component analysis, the tool was refined to 30 items with high internal consistency. The health and hygiene domain was narrowed to include only health-related items. In the second survey, each domain demonstrated high Cronbach's alpha values: health (4 items, α = .7699), convenience (4 items, α = .7353), affordability (4 items, α = .7537), trendiness (4 items, α = .8266), gastronomy (4 items, α = .8501), emotions (4 items, α = .8266), ecological environment (3 items, α = .8432), and social relationships (3 items, α = .7659). A follow-up survey conducted one month later with 50 participants from the second phase showed high reliability.
CONCLUSIONS
The dietary lifestyle assessment tool developed in this study (comprising 30 items across six domains) demonstrated high reliability. Further confirmatory factor analysis and correlation analysis with health-related factors will validate its effectiveness as a systematic tool for classifying and evaluating dietary lifestyle patterns among Korean young adults.

SOYBEAN ISOFLAVONE INTAKE AND ESTROGEN RECEPTOR DEFINED BREAST CANCER MORTALITY SYSTEMATIC REVIEW

Reiko Suzuki[1]; Kokoro Machida[1]
[1]Nutrition, Japan Women's University Mejiro Campus, Bunkyo City, Japan

BACKGROUND AND OBJECTIVES
Breast cancer is the most common cancer in women globally [1]. However, survival rates have improved substantially due to early detection through widespread breast cancer screening and modern medical treatments. It suggested that studies do not indicate an increased risk for breast cancer survivors who consume soy, but the current evidence is reported to be insufficient [1].We conduct a systematic review of the current epidemiological research evidence on the association between soy isoflavones intake and the risk of estrogen receptor-defined breast cancer mortality, leading to the dietary support of breast cancer survivors.
METHODS
We conducted a systematic literature search with Pubmed. Last searched date was January 10, 2023.
RESULTS
A total of 56 studies were identified. Six prospective cohort studies [2] [3] [4] [5] [6] [7] and one meta-analysis [8] were selected. In addition, we extracted two prospective cohort studies [9, 10] from one meta-analysis and finally adopted eight prospective cohort studies and one meta-analysis.
CONCLUSIONS
In overall, five of eight studies reported that high soy isoflavone intake was associated with a statistically significant reduction in breast cancer mortality. A statistically significant reduction in breast cancer mortality with higher soy isoflavone intake has been reported three of the five studies for ER+ tumors, two of four studies for ER- tumors. No studies reported a statistically significant increase in breast cancer mortality risk with higher intakes of soy isoflavones.

ANEMIA AND ITS ASSOCIATED RISK FACTORS AMONG YOUNG CHILDREN, ADOLESCENT GIRLS, AND NON-PREGNANT WOMEN OF REPRODUCTIVE AGE IN LEBANON

James Wirth[1]; Amirhossein Yarparvar[2]; Carla El-Mallah[1]; Maya Kozeiha[3]; Nadeen Hilal[4]; Omar Obeid[5]; Lima Working Group[6]

[1]GroundWork, GroundWork, Fläsch, Switzerland; [2]Nutrition, UNICEF, Beirut, Lebanon; [3]Nutrition, Mercy USA, Beirut, Lebanon; [4]Nutrition, Ministry of Public Health, Beirut, Lebanon; [5]Nutrition and Food Sciences, American University of Beirut, Beirut, Lebanon; [6]Nutrition, Nutrition Working Group, Beirut, Lebanon

BACKGROUND AND OBJECTIVES

Anemia affects over 1.9 billion people globally (25% of the population), and disproportionately affects children, adolescents, and women. This study examines anemia prevalence and risk factors among children (6–59 months), adolescent girls (15–19 years), and non-pregnant women 15-49 years of age in Lebanon.

METHODS

Data from a 2023 nationally representative cross-sectional survey were analyzed. Multivariable poisson regressions were used to calculate the adjusted prevalence ratio (aPR) for anemia of variables significantly associated with anemia in bivariate analysis, separately for children (6-59 months), pre-menarched adolescent girls (10-19 years), menstruating adolescent girls (10-19 years), and non-pregnant women (15-49 years).

RESULTS

The adjusted prevalence ratio (aPR) for anemia was higher in children with iron deficiency (aPR 2.14), vitamin A deficiency (VAD; aPR 1.97), inflammation (aPR 1.49), stunting (aPR 1.7), and inadequate household sanitation (aPR 1.36). Among pre-menarche and menstruating adolescent girls, anemia was significantly associated with iron deficiency (aPR 3.07 and 3.88, respectively) and inflammation (aPR 1.61 and 1.41, respectively). Vitamin A deficiency was also associated with a higher risk of anemia in menstruating girls (aPR 1.67). In non-pregnant women, anemia was associated with iron deficiency (aPR 3.2), vitamin A deficiency (aPR 1.93), and severe menstrual bleeding (aPR 1.2).

CONCLUSIONS

Anemia control programs should aim at the prevention of the main predictors of anemia in various population groups by reducing iron and vitamin A deficiencies and addressing the main drivers of inflammation.

TEACHING FOOD-BASED DIETARY GUIDELINES TO ADOLESCENTS USING THE PEER LEARNING METHOD

Laurene Boateng[1]; Osafo Elizabeth Appiah[1]; Matilda Asante,[1]
[1]Department of Dietetics, University of Ghana, Accra, Ghana

BACKGROUND AND OBJECTIVES
Food-Based Dietary Guidelines (FBDGs) provide evidence-based recommendations for promoting healthy eating habits. There is a need to evaluate effective methods for teaching the recently launched Ghana Food Based Dietary Guidelines to improve awareness and understanding among adolescents. Peer learning is one such strategy that fosters student participation and interaction, potentially enhancing comprehension and retention of nutritional knowledge. This study aimed to assess the effectiveness of a peer learning intervention in teaching and learning of the Ghana Food-Based Dietary Guidelines among adolescents.
METHODS
A pretest-posttest study design was used to evaluate adolescents' knowledge of the FBDGs before and after a peer learning intervention. Participants took a standardized knowledge test at baseline, after which were divided into groups for peer-led discussions and activities on selected FBDG topics with the aid of a faciitator. Post-intervention, students took the standardized test again to measure knowledge improvements. Data were analysed using SPSS version 26. A paired t-test was conducted to compare pretest and posttest knowledge scores, and a chi-square test and correlation analysis was used to assess relationship between nutritional status (Body Mass Index (BMI)) and baseline nutritional knowledge.
RESULTS
A total of 36 students aged 12 -15 years in a junior high school participated in the study with majority of participants being males (55.6%) and majority having a normal BMI (61.1%). Post-intervention assessments showed an improvement in FBDGs knowledge, with the percentage of students scoring "Excellent" rising from 58.3% to 75%, although this improvement was not statistically significant ($p = 0.121$). A moderate but statistically significant negative correlation ($r = -0.328$, $p = 0.025$) was observed between BMI and pretest scores, suggesting that higher BMI was associated with lower baseline nutritional knowledge.
CONCLUSIONS
Peer learning can be a viable approach to nutrition education, particularly in resource-limited settings where access to professional teachers may be constrained. This study supports the incorporation of FBDGs into school curricula as a means of improving dietary behaviours from an early age, which is crucial for long-term health outcomes.

ASSESSING CHALLENGES TO IFA SUPPLEMENTATION ADHERENCE AND ANEMIA CONTROL AMONG SCHOOL-GOING ADOLESCENT GIRLS

Samraggi Roy[1]; Sirimavo Nair[2]; Ebbie Thomas[3]
[1]Foods and Nutrition, The Maharaja Sayajirao University of Baroda, Vadodara, India; [2]Nutrition and Fortification, Food Safety and Standards Authority of India, New Delhi, India; [3]Department of Community Sciences, GMERS Medical College Gotri, Vadodara, India

BACKGROUND AND OBJECTIVES
Anemia remains a significant public health challenge in India, disproportionately affecting women and adolescents, with 80.3% of adolescent girls in Bankura District affected (NFHS-5). Addressing their nutritional needs is essential to breaking cycles of malnutrition and related chronic conditions. This study explores adherence to the Iron Folic Acid (IFA) supplementation program (60 mg elemental iron and 500 mcg of Folic acid as per government protocols), gaps in service delivery, and dietary practices. It highlights adolescent girls as a pivotal stage in the lifecycle, emphasizing their critical role in addressing public health nutrition challenges and priorities.
METHODS
A cross-sectional design was used, employing non-probability purposive sampling. The study included 100 school-going adolescents (15–18 years) and 30 frontline health workers (FLWs) (18 ASHAs, 12 AWWs). Data collection involved a Knowledge, Attitudes, and Practices (KAP) survey, anthropometric measurements, dietary recall, and interviews. Statistical methods, including chi-square and t-tests, were applied to analyze relationships between variables.
RESULTS
Among adolescents, 56% had normal BMI-for-age, while 22% showed mild thinness. Dietary diversity was 86.66% consuming high levels of processed foods. IFA compliance was low (39%), with taste identified as a significant barrier ($p = 0.001$). Poor anemia knowledge was observed among 89% of adolescents, while 91.67% of frontline workers demonstrated average knowledge. A significant correlation ($p<.05$) indicated that FLWs' knowledge was not effectively transmitted to adolescents. However, gaps were evident, as many adolescents failed to follow WASH guidelines ($p<.05$). Key challenges included inadequate training for FLWs, weak coordination among ASHAs, AWWs, and school personnel, and insufficient anemia-related information from teachers. 78% of adolescents lacked hemoglobin checks, and 26% reported menstrual issues. School support systems were found to inadequately monitor IFA consumption and provide effective counselling.
CONCLUSIONS
Significant gaps in IFA compliance and adolescent nutrition, compounded by insufficient training and supervision of FLWs, were identified; thus, improving FLW training is crucial. Strengthening multi-sectoral collaboration and enhancing government support to advance adolescent health and anemia control efforts needs to be critically addressed.

INTERVENTIONS TO REDUCE ANAEMIA IN LOW- AND MIDDLE-INCOME COUNTRIES: AN EVIDENCE GAP MAP

Daniel Lopez de Romana[1]; Mandana Arabi[1]; Shannon Shisler[2]; Ashiqun Nabi[3]
[1]Research and Development Unit, Nutrition International, Ottawa, Canada; [2]Synthesis and Reviews Office, International Initiative for Impact Evaluation, Washington D.C., United States of America; [3]Synthesis and Reviews Office, International Initiative for Impact Evaluation, London, United Kingdom

BACKGROUND AND OBJECTIVES
Evidence about interventions to tackle the myriad causes of anaemia is growing. Previous evidence mapping has focused on a subset of relevant factors, interventions, or populations. The objectives of this EGM are: 1) identify and describe the characteristics of impact evaluations (IEs) and systematic reviews (SRs) which evaluate the effects of interventions to reduce anaemia or that address the determinants of anaemia in low-and-middle income countries (L&MICs); 2) summarize findings from high- and medium-confidence SRs; 3) identify primary evidence gaps and synthesis gaps
METHODS
Relevant literature was searched across 12 academic databases and eight grey literature sources to identify EIs and SRs. We used EPPI Reviewer to organize and screen the imported search RESULTS. We extracted data on various study characteristics from the included studies (year of publication, study design geography, population characteristics, interventions and outcomes). We critically appraised and rated the identified SRs with confidence ratings of low, medium, or high using an adapted version of the SURE checklist. We followed the PRISMA guideline for reporting reviews
RESULTS
2,870 reports were included (2,196 unique IEs and 195 unique SRs). Of the 195 SRs, 57 were appraised as high or medium confidence. Most IEs took place in Africa and South-East Asia. Approximately 81% of IEs focused on interventions addressing the direct causes of anaemia, with most of these focusing on nutrition, and fewer studies on other direct causes of anaemia. Far fewer IEs evaluated interventions on intermediate (6.5%) and underlying (1%) risk factors. Approximately 15% of the IEs evaluated multicomponent interventions. Of the 57 SRs, most focused on interventions to address direct causes of anaemia (n=53), such as nutrition (n=34) and chronic disease/infectious diseases (n=18). The SRs indicate the potential of several interventions to address direct causes of anaemia and in reducing anaemia. The online, interactive tool can be accessed using the following link
CONCLUSIONS
The EGM tool offers a large well-organized body of evidence that decision-makers can customize to their areas of interest and use when designing and funding anaemia policies, interventions, and program evaluations. It also highlights gaps that policymakers, funders, researchers, and other stakeholders can prioritize to further expand our collective knowledge regarding how to reduce the prevalence of anaemia globally

EPO5_054

SELF-REGULATION FOR (UN)HEALTHY FOOD MARKETING TO CHILDREN

Alie De Boer[1]
[1]Food Claims Research Centre, Maastricht University, Venlo, Netherlands

BACKGROUND AND OBJECTIVES
Nutrition and health claims on labels, pictures in stores, graphics and slogans on websites and social media: voluntary food information is strongly used by food marketeers to reach specific target groups. Various initiatives are taken worldwide to ensure fair information provision, and particularly to protect vulnerable groups such as children from these intentional and non-intentional influencing strategies. Many policies focus on self-regulation, by producers. In this study, I analyse the effects of self-regulation on food marketing to children.
METHODS
Using a case study approach, I study food marketing practices targeting children in the Netherlands. Cases from self-regulatory organisations were selected to represent different marketing strategies, including information, graphics and visuals used on labels, in stores, at events and online. Next to examining the compliance of these practices with self-regulatory guidelines established by industry bodies, as well as WHO guidelines on food marketing to children and national nutrition guidelines.
RESULTS
Even though standards exist that should be adhered to, children are still highly exposed to marketing practices that stimulate unhealthy foods. Particularly online communication often does not adhere to the national advertising code. With the advertising code being less strict in categorising healthy versus unhealthy foods, also foods that do not fall within the nutritional guidelines may still use marketing targeting children
CONCLUSIONS
The RESULTS from this case study highlight that self-regulation is insufficiently effective in protecting children from unhealthy food marketing practices. In line with studies in other countries, self-regulatory measures are insufficiently aligned with nutrition & health-based policies to stimulate children to choose healthier food products. This particularly holds for new forms of advertising, such as influencer's use of social media to promote foods to children. More stringent regulatory measures, which can be effectively enforced, are needed to support children in making healthier food choices.

HOW TO ACHIEVE AN INTERCULTURAL APPROACH TO IMPLEMENT THE HEALTHY EATING PERUVIAN LAW?

Lita Palomares-Estrada[1, 2, 3]; Guadalupe Sifuentes-Martinez[2]; J. Jaime Miranda[4, 5, 6]; Anne Marie Thow[7]; Nicole Probst-Hensch[8]; Frank Wieber[3, 9]; Julia Dratva[3, 1]

[1]Faculty of Medicine, Universität Basel, Basel, Switzerland; [2]Faculty of Sciences and Engineering, School of Nutrition, Universidad Peruana Cayetano Heredia, Lima, Peru; [3]Institute of Public Health, Department of Health Sciences, ZHAW Zürich University of Applied Sciences, Winterthur, Switzerland; [4]Sydney School of Public Health, Faculty of Medicine and Health, University of Sydney, Sydney, New South Wales, Australia; [5]Department of Medicine, School of Medicine, Universidad Peruana Cayetano Heredia, Lima, Peru; [6]CRONICAS Center of Excellence in Chronic Diseases, Universidad Peruana Cayetano Heredia, Lima, Peru; [7]Menzies Centre for Health Policy, School of Public Health, Sydney, New South Wales, Australia; [8]Department of Epidemiology and Public Health, Swiss Tropical and Public Health Institute (Swiss TPH), Allschwil, Switzerland; [9]Department of Psychology, University of Konstanz, Konstanz, Germany

BACKGROUND AND OBJECTIVES

In Peru, the Law 30021 for the "Promotion of Healthy Eating in Children and Adolescents" promotes an intercultural approach; however, Peruvian food varies depending on each region, and implementing healthy eating is a great challenge. This research abstract aims to identify the main recommendations from stakeholders to achieve an intercultural approach in the implementation of the healthy eating Peruvian law.

METHODS

A qualitative research design was employed. We developed 31 in-depth, semi-structured, one-on-one interviews among governmental (n=16) and non-governmental (n=15) stakeholders from Peru. An interview guideline was designed and tested by experts in the topic. The interviews were transcribed, coded and categorized by two researchers. This analysis focuses specifically on the intercultural approach in healthy eating promotion.

RESULTS

The interviewees from the governmental sector indicated that the implementation at the local and regional level of the "Dietary guidelines for the Peruvian population" is key for promoting and achieving healthy eating with an intercultural approach. Nutritional educational strategies regarding healthy eating must be designed, developed and tailored according to the Peruvian natural regions: coast, highlands and jungle. Enhancing the consumption of the affordable, available and nutritious local foods, as well, cultural awareness of eating patterns of the Peruvian population from the different regions was considered relevant. Training health professionals, schoolteachers, and community leaders is recommended to identify the local food resources and to promote healthy eating customized to the local and regional context. From the non-governmental sector suggested that the nutritional education should consider the inclusion of the Peruvian native languages. The nutrition professionals should master the intercultural competencies to participate in the implementation of healthy eating policies. Training people from the communities and involving them in the design of healthy eating programs and policies was evaluated as very important. Finally, leveraging the leadership and strengthening the decentralization of the regional and local governments, likewise, political decision, surveillance and monitoring on the local, regional and national level were recommended.

CONCLUSIONS

To achieve a successful intercultural approach in the implementation of the healthy eating Peruvian law is essential to addressing intercultural aspects, involving professionals and community leaders, tailoring the nutritional education, and decentralizing governments.

CURRENT STATUS OF SUPPLEMENT USE FOR JAPAN JUNIOR HIGH SCHOOL ATHLETES

Akiyo Shiohara[1]; Yousuke Nagashima[2]; Ayana Mitsume,[2]; Inoshita Akane[2]; Akiko Horikawa[3]
[1]Depertment of Nutrition and Health Sciences Faculty of Food and Nutritional Sciences, Toyo University Asaka campus, Saitama, Japan; [2]Department of Nutrition and Health Sciences, Musashigaoka Junior College, Saitama, Japan; [3]Faculty of Human and Social Sciences, Department of Sport Sciences, Tokyo International University, Saitama, Japan

BACKGROUND AND OBJECTIVES
In recent years, the use of supplements and functional foods in children has increased in Japan, and there are concerns about the nutritional status of users. Therefore, we summarized how the nutrient intake status of supplement users compared to non-users in children who play sports in which supplement users are observed, and decided to use it as a reference for future nutrition education.
METHODS
In April 2024, a questionnaire survey and a nutrition survey using Self-administered diet history questionnaire (DHQ) were conducted on 37 junior high school soccer players who had not received nutrition education so far. The participants were divided into two groups: 20 people who took supplements (tablets) and 17 people who did not take supplements, and compared the nutrient sufficiency rates from foods other than supplements. We used the dietary reference intakes for Japan and the standards of the Japan Sports Association. Significance probabilities of less than 5% were considered significant.
RESULTS
The group taking supplements had a higher carbohydrate sufficiency rate than the non-supplement group, but the non-supplement group had higher sufficiency rate for other energy and nutrients.Significant differences were found between the two groups in protein, lipids, vitamin A, vitamin B_1 ($p<0.05$), and carbohydrates ($p<0.01$). The current RESULTS differ from previous findings, which showed that the group taking supplements had a better regular diet than non- supplement group. It was speculated that anxiety about daily nutrient intake may trigger the habit of taking supplements that can be easily ingested.
CONCLUSIONS
Although supplements are useful for dealing with consumption during exercise, it is necessary to communicate the benefits of taking nutrients from food so as not to rely too much on nutritional intake from supplements.

ASSESSING THE RELIABILITY OF A NATIONAL FOOD FREQUENCY QUESTIONNAIRE: INSIGHTS BY SEX AND AGE GROUP

Paula Moliterno[1]; Elias Acevedo,[2]; Victor Prieto,[3]; Raquel Rodríguez,[4]; Geraldine Sena,[2]; Mariana Simoncelli,[2]; Luisa Saravia,[5]
[1]Österreichisches Akademisches Institut für Ernährungsmedizin (ÖAIE), Österreichisches Akademisches Institut für Ernährungsmedizin (ÖAIE), Wien, Austria; [2]Departamento de Nutrición Poblacional, Edificio Parque Batlle - UdelaR, Montevideo, Uruguay; [3]Area de Investigación, Edificio Parque Batlle - UdelaR, Montevideo, Uruguay; [4]Departamento de Nutrición Básica, Edificio Parque Batlle - UdelaR, Montevideo, Uruguay; [5]Centro de Posgrado, Edificio polivalente, Mont, Uruguay

BACKGROUND AND OBJECTIVES
Accurately assessing dietary intake at a population level is crucial for understanding the relationships between diet and prevalent diseases and informing public health recommendations. In Uruguay, it was necessary to develop a national food survey method to achieve this. Before its widespread use, the reliability and validity of a food frequency questionnaire (FFQ) must be studied, as reliability can vary between different age and sex groups. This study aimed to evaluate the reliability of a new national FFQ according to sex and age group.
METHODS
A national convenience sample of 323 adult participants (60.1% women) who completed an online FFQ twice, 15 days apart, for reliability analysis was included. Qualified trained personnel helped administration. The normal distribution of calories and nutrients obtained from the 63-item FFQ was assessed using Kolmogorov-Smirnov tests. Energy-adjusted Pearson or Spearman correlations between nutrients were assessed to measure reliability according to sex and age group (young adults < 65 years; older adults ≥ 65 years). A $p < 0.05$ was considered significant.
RESULTS
Overall, the FFQ showed good reliability. Depending on the nutrient, reliability correlation coefficients after adjusting for energy ranged from 0.55 to 0.73 in women, from 0.41 to 0.72 in men, from 0.48 to 0.75 in young adults, and 0.45 to 0.70 in older adults. Reliability coefficients for calories were lower for men (r=0.42) and older adults (r=0.50) compared to women (r=0.57) and adults (r=0.54). Higher energy-adjusted correlation coefficients were observed for women compared to men. In women, good reliability coefficients were obtained for saturated fatty acids (r=0.70), vitamin A (r=0.71), D (r=0.73), and calcium (r=0.71); in men, vitamin D (r=0.72). In young adults, vitamin A (r=0.72) and D (r=0.75) showed very good reliability, while in older adults, the latter occurred for vitamin D and calcium (r=0.70 each).
CONCLUSIONS
The new FFQ achieved good reliability for assessing habitual dietary intake in both sexes and the adult age group.

NUTRITIONAL INTAKE AND EATING HABITS IN CHILDREN WITH AUTISM AND THE RISK OF CARIES DEVELOPMENT

Maria Nikolova[1]; Lilia Doichinova[2]
[1]Department of Epidemiolgy and Hygiene, Faculty of Medicine, Medical University of Sofia, Sofia, Bulgaria;
[2]Department of Pediatric Dentistry, Faculty of Dental Medicine, Medical University of Sofia, Sofia, Bulgaria

BACKGROUND AND OBJECTIVES
Children with autism have specific eating patterns - dietary restrictions, but also high consumption of foods with high sugar concentrations, affecting their oral health. The aim of the study was to assess the relationship between eating habits and carbohydrate intake in children with autism and the development of dental caries.
METHODS
Thirty children with autism aged 5 to 12 years were studied. A 7-day food diary was used to assess nutrition and eating habits, which is the most reliable tool for assessing actual dietary intake in these children.
RESULTS
The data show that half of the children are at high risk of developing dental caries, as they report frequent intake of carbohydrate foods. ⅓ Children have a low caries risk and limited carbohydrate intake, and the remaining 17% of children have a medium risk of developing dental caries and eating carbohydrate foods rarely between meals. The RESULTS show that in their daily diet there are many risky foods such as junk foods. High values of the D1MFT index above 4 have been reported.
CONCLUSIONS
Unhealthy eating habits have been identified as an important risk factor for the oral health of children with autism and should be limited in between meals and the consumption of beverages and highly processed foods high in sugar, fat and salt, at the expense of snacks with high biological density.

THE INFLUENCE OF DIETARY INTAKE ON THE HEALTH STATUS OF CHRONICALLY ILL PATIENTS: A CASE STUDY OF HYPERTENSIVES AND DIABETICS PATIENTS ATTENDING HEALTH CARE

Kingsley Pereko[1]; Sister-Hattie Asmah,[2]; Francis Asumadu[1]; Lord Agyei-Nkrumah[1]
[1]Community Medicine, University of Cape Coast, Cape Coast, Ghana; [2]School of Medical Sciences, University Of Cape Coast, Cape Coast, Ghana

BACKGROUND AND OBJECTIVES
Chronic diseases such as hypertension and diabetes is on the rise as a result of industrialization, increased life expectancy, and poor lifestyles. This has resulted in higher health expenditures, a rise in morbidities, and a higher death rate. Diet is a significant factor in the development and prognosis of these diseases. Notable gap exists in comprehending the specific influence of dietary intake on the health of chronically ill patients. This study sought to explore the dietary habits of patients with hypertension and diabetes and its effects on their health at Cape Coast Teaching Hospital (CCTH) in the central region of Ghana
METHODS
The study employed a cross-sectional design spanning 1 month, purposively sampling 300 respondents from clients visiting the hospital. Primary data about sociodemographic profiles, dietary behaviours of patients, and health outcomes were collected and subsequently analyzed using descriptive and inferential statistics.
RESULTS
The average age of respondents is 59 years, SD 11.9. About 85.7% had primary to high school education, 43% were married, and 30% were not employed. Only 37% are on special recommended diets. less than half (45%) regularly eat fruits, and only 47% eat at a set time each day. About 43% eat late at night and oily foods are consumed by 40.3% of the respondents. Energy drinks or alcohol is consumed by 48.3% of the respondents. About 94% of respondents regularly eat home-cooked foods. The respondents' food choices are mostly influenced by their appetite and about 58.3 are aware of foods that influence their health status. A significant association was found between following a dietary plan and recent episodes of high blood sugar in the immediate past month ($X=21.4$ $p<0.001$) as well as the frequency of episodes of high blood sugar ($X=43.1$, $p<0.001$). Following a specific dietary plan was also significantly associated with heart attack, stroke, and retinopathy episodes respectively. Eating fruits or vegetables regularly was significantly associated with blood sugar values, stroke, and retinopathy episodes. Eating at set times is significantly associated with recent episodes of high blood pressure, blood sugar value, and stroke respectively. Late-night eating is associated with recent episodes of high blood sugar and frequency of episodes in a month as well as emergency room visits. Eating oily foods was associated with recent episodes of high blood sugar and frequency of episodes in a month.
CONCLUSIONS
In chronically ill patients dietary habits and lifestyle does have influence on their health outcomes.
CONFLICTS OF INTERESTS
The authors have no conflict of interest.

ADHERENCE STRATEGIES ADOPTED BY COMMUNITY WOMEN FOR BALANCED-ENERGY PROTEIN SUPPLEMENTATION DURING PREGNANCY IN RURAL BANGLADESH

Nazrana Khaled[1]; Atiya Rahman[1]; Pragna Paramita Mondal[1]; Mary De Boer[2]; Hasmot Ali[3]; Hafizur Rahman[3]; Eleonor Zavala[2]; Anna Kalbarczyk[2]; Towfida Siddiqua[3]; Kaosar Afsana[1]; Parul Christian[2]; Andrew Thorne-Lyman[2]
[1]BRAC James P Grant School of Public Health, BRAC University, Dhaka, Bangladesh; [2]Center for Human Nutrition and Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, United States of America; [3]JiVitA, Maternal and Child Health & Nutrition Research Project, Rangpur, Bangladesh

BACKGROUND AND OBJECTIVES
The World Health Organization recommends Balanced Energy Protein (BEP) supplements for pregnant women in undernourished populations as an intervention to reduce the risk of adverse birth outcomes yet few programs exist implementing BEP. Adherence has been problematic with other nutrition interventions in pregnancy. As part of a cluster-randomized trial in rural Bangladesh, fortified BEP supplements were delivered to women's homes, and for daily consumption and provided guidance by community health research workers (CHRWs) hired for the project. This included a leaflet with instructions, a calendar, tupperware to keep the supplements within eyesight, routine monthly visits to replenish supplies, and mid-monthly phone calls to promote adherence. In addition, they were counseled on other strategies such as being self-aware and asking family members to remind them. We sought to understand women's perspectives on their own adherence to supplementation and the support they received for this during the trial.
METHODS
Thirty-two in-depth interviews were conducted with women who had received BEP supplements during pregnancy during the trial. RESULTS are based on preliminary coding of interviews that will be fully coded for the presentation. In addition, each woman was asked to rank 9 pictorial cards depicting various strategies to remind them to take the BEP product daily and to explain the reason for their ranking.
RESULTS
Adherence to BEP supplementation in the trial was high (>85%). Women employed various strategies to remember to eat the BEP product. About half of the women said they remembered to take the supplements on their own volition (47%), reflecting a high level of motivation among participants. Nearly a third of the women (31%) felt that reminders from family members had been helpful. Keeping the product stored within eyesight (19%) was also helpful.
CONCLUSIONS
Adherence to BEP supplementation was influenced by self-motivation, support from family members and storing the supplement within eyesight in addition to home-based and regular delivery and guidance and support provided by community health workers in this rural context in Bangladesh. These findings have programmatic implications. Funding: Bill and Melinda Gates Foundation (grant number INV-033381)

BACKGROUND AND OBJECTIVES
Front-of-package (FOP) nutrition labels are designed to provide consumers with easily accessible and understandable nutritional information at the point of purchase, potentially guiding healthier food choices. Different formats of FOP nutrition labels are used worldwide. This study investigates preferences for proposed designs of Ghana´s FOP nutrition labels as well as their salience (participants' perceptions of noticeability, readability, and believability) and their influence on food product choices.
METHODS
A cross-sectional survey of 2468 Ghanaian consumers. Participants were recruited nationally across demographic, gender, urban, and rural residency. Data were collected on how often participants interact with food labels and their familiarity with nutrition information panels. To assess preferences and perceptions of FOP label designs, participants were shown images of different label types - octagonal, triangular, and rectangular - in three colors: black, red, white, and a combination of these. A positive logo was also included to represent healthier food choices.
RESULTS
About half of the 2,468 respondents were females. Food label awareness, literacy, and usage were low: 16% of the respondents did not know how to read food labels. Among those who could, 13.4% never read them, and 25.7% reported reading food labels sometimes. About three-quarters (73.6%) of the respondents had never seen FOP warning labels on food packages. Despite this, 83.4% believed that FOP warning labels would be "very helpful" in identifying whether a food is healthy or unhealthy. There was overwhelming support for mandatory warning labels on foods high in sugar, salt, or fat, with 93% agreeing. Respondents favored designs with bold text and striking colors, such as red and black, regardless of the nutrient or substance of interest salt, sugar, fat, or non-sugar sweeteners) or label shape (octagonal, triangular, or rectangular). Labels that incorporated visual symbols (e.g., sugar cubes, spoons) and used cautionary colors like red to signify danger were preferred. Logos featuring FDA Ghana inspired greater trust.
CONCLUSIONS
Ghanaian consumers strongly support the use of warning labels for foods high in sugar, salt, and fat, with a preference for designs that combine bold visuals, cautionary colors, and culturally resonant elements. Positive logos promoting health and family also resonated well.

DIET-WIDE ASSOCIATION STUDY OF FOODS, NUTRIENTS AND HIP FRACTURE RISK: A PROSPECTIVE COHORT STUDY OF 21,369 INCIDENT CASES AMONG 542,068 POSTMENOPAUSAL WOMEN

Yang Tao[1]; Timothy J. Key[1]; Gillian K. Reeves[1]; Keren Papier[1]; Tammy Y.N Tong[1]
[1]Nuffield Department of Population Health, University of Oxford, Oxford, United Kingdom

BACKGROUND AND OBJECTIVES
Previous research on diet and hip fracture risk has mainly focused on selected foods and nutrients. We investigated the associations between dietary factors and hip fracture risk using a diet-wide association study.
METHODS
The study population comprised 542,068 postmenopausal women in the Million Women Study. Dietary information was assessed using a validated short food frequency questionnaire in 2000-2004, and calibrated with one 24-hour dietary recall collected on a sub-sample 10 years later. Cox regression was used to estimate hazard ratios (HR) and 95% confidence intervals (CI) for associations between 99 dietary factors and risk of incident hip fractures, ascertained through electronic linkage to national hospital records.
RESULTS
After an average of 18.3 years of follow-up, 21,369 incident hip fractures occurred. In multivariable-adjusted models, 55 of the 99 dietary factors were significantly associated with hip fracture risk after correction for multiple testing (False Discovery Rate <0.05). The five foods most strongly associated with hip fracture risk (based on p value) were chicken (HR, 95% CI = 0.83, 0.79-0.87 per 20 g/day), vegetables (0.87, 0.84-0.90 per 100 g/day), fruits (0.87, 0.82-0.91 per 200 g/day), chips (1.13, 1.09-1.18 per 25 g/day), and fizzy drinks (1.18, 1.11-1.24 per 50 g/day). The five nutrients most strongly associated with hip fracture risk were protein (0.80, 0.75-0.85 per 15 g/day), zinc (0.82, 0.77-0.87 per 2 mg/day), carotene (0.91, 0.88-0.94 per 1000 µg/day), fibre (0.88, 0.85-0.92 per 5 g/day), and alcohol (0.91, 0.87-0.94 per 20 g/day). Neither milk nor total dietary calcium was associated with risk. The RESULTS were consistent in stratified analyses by body mass index, smoking, alcohol consumption, baseline health status, and physical activity, as well as in sensitivity analyses excluding the first five years of follow-up.
CONCLUSIONS
Many dietary factors were associated with hip fracture risk: several “healthy” foods were associated with lower risk, while some “unhealthy” items were associated with higher risk. Further research is needed to assess whether these associations might reflect causal relationships.
CONFLICTS OF INTERESTS
The authors have no conflict of interest.

CALORIC RESTRICTION AND WEIGHT LOSS IN LACTATING WOMEN: EVIDENCE FROM A SYSTEMATIC REVIEW

Lara Lima,[1]; Ligia Garcia[2]; Nicolie Oliveira,[3]; Karla Danielly Ribeiro,[3]
[1]Campus Russas, Universidade Federal do Ceará, Russas, Brazil; [2]Faculty of Health Sciences of Trairi, Federal University of Rio Grande do Norte, Santa Cruz, Brazil; [3]Department of Nutrition, Federal University of Rio Grande do Norte, Natal, Brazil

BACKGROUND AND OBJECTIVES
Lactating women face the challenge of adopting a diet that supports adequate breast milk production, ensuring optimal infant development, while also contributing to maternal health and the recovery of pre-pregnancy weight. Evidence suggests that caloric restriction may be an effective strategy for weight management in the general population; however, its effects on the health of lactating women remain incompletely understood. Objective: To evaluate the effects of caloric restriction diets on weight loss in lactating women
METHODS
The PUBMED, Web of Science, Scopus and Bireme/LILACs databases were searched for relevant articles until September 2024. All published controlled trials, on caloric restriction during lactation were considered. Data extraction covered study details, outcomes and limitations. The JADAD scale was employed to assess methodological quality.
RESULTS
The analysis included three studies involving 105 participants (Table 1). No self-reported changes in breastfeeding practices were observed among the lactating women in these studies.
Table 1. General characteristics of the documents included in the review. I,Intervention Group; C, Control Group.

Author (Year)	Controlled trial	Participants (N)	Caloric Restriction	Intervention Duration	% Weight Loss	JADAD scale
Strode (1986	non-randomized	I:22, C:8	20% a 30%	1 week	-0.07%	0 (low)
McCrory (1999)	randomized	I:22, C:23	35% + Vitamins and Minerals	11 days	-2.78%	3 (high)
Bertz (2012)	randomized	I:15, C:15	500 Kcal/day	12 weeks	-11.94%	3 (high)

CONCLUSIONS
The availability of randomised clinical trials in the scientific literature remains limited. A 12-week intervention with caloric restriction (500 kcal/day) proved more effective for weight loss in lactating women without any self-reported detriment to breastfeeding. Further research is necessary to evaluate the effects of this dietary intervention on breast milk composition and infant health.

INTERVENTIONS TO PROMOTE HEALTHIER FOOD RETAIL ENVIRONMENTS: CHARACTERISTICS, BARRIERS AND FACILITATORS

Melissa Yasmin Alves Tarrão[1]; Mariana Julião Guilarducci[1]; Ana Paula Bortoletto Martins[2]; Patricia Constante Jaime[2]

[1]Postgraduate Program in Public Health Nutrition, School of Public Health - University of São Paulo (USP), São Paulo, Brazil; [2]Department of Nutrition, School of Public Health - University of São Paulo (USP), São Paulo, Brazil

BACKGROUND AND OBJECTIVES

The retail environment influences food choices, whether through the nudging and marketing of unhealthy foods or the absence of healthy foods. It can influence eating practices, health and nutritional status of individuals and populations. Therefore, interventions in the food retail are being carried out around the world, but little is known about their design, target audience and what are the barriers and facilitators. This study aimed to map interventions to promote healthier food retail environments, characterize and identify the respective barriers and facilitators.

METHODS

A scoping review was conducted to answer the question: How are the interventions to promote healthier food retail environments designed, and which are their barriers and facilitators of interventions?" The search was conducted using descriptors and operators "(environment) AND (food retail) OR (consumer food environment) AND intervention" in five international and regional databases. Review studies, those not derived from scientific studies and that did not address interventions in food retail, were excluded.Data extraction was performed in Google spreadsheets, and barriers and facilitators were entered into an Implementation Science framework.

RESULTS

A total of 1,048 articles were found, but after the screening and eligibility confirmation phase, only 25 articles were included. More than half of the interventions were developed in the United States of America (USA) (n=17), in urban areas (n=15) and in small retail businesses (n=19), such as corner stores, neighborhood stores, convenience stores and supermarkets. Regarding the scope, 17 interventions were independent actions and 8 were supported by policies, programs and ordinances. Most of the interventions (n=21) targeted specific populations such as: populations with low socioeconomic conditions, indigenous people, Afro-descendants or Hispanics. The most frequent barriers were: financial constraints; lack of technical support; influence of business relationships, high employee turnover; and lack of materials.The most frequent facilitators were: partnership with stakeholders and the local community and financial incentives for participating retailers.

CONCLUSIONS

Food retail interventions are being developed primarily in the USA, in small stores, with some actions being independent and others supported by local programs, policies, and ordinances. The most frequent barriers refer to the external and internal context of food retail, and the facilitators refer to the external context.

BACKGROUND AND OBJECTIVES
Non-communicable diseases (NCDs) related to inadequate diets are a major public health concern, affecting the global population. Approximately 70% of adults worldwide face serious health risks associated with overweight or obesity, hypertension, and diet-related complications. Evaluating dietary intake and its relationship with NCDs is crucial for establishing evidence-based nutritional guidelines to improve population health. Food Frequency Questionnaires (FFQs) are widely used tools to measure habitual dietary intake by estimating average food consumption over extended periods. During 2022 and 2023, a 63-item FFQ was developed to assess dietary intake among adults. This study aimed to evaluate the validity of the new FFQ compared to three 24-hour dietary recalls (R24h) in adult men and women.
METHODS
A convenience sample of 328 adults (60% women) completed the online FFQ and three R24h, including two weekday recalls and one weekend recall, within a three-week period. Nutrient and energy data from the FFQ were analyzed for normal distribution using Kolmogorov-Smirnov tests. To assess validity, energy-adjusted Pearson or Spearman correlation coefficients between nutrient intakes from the FFQ and R24h were calculated by sex. Statistical significance was set at $p < 0.05$.
RESULTS
The FFQ demonstrated fair validity overall. In women, energy-adjusted correlation coefficients ranged from 0.18 (calcium) to 0.49 (Vit. D), with poor correlations (<0.3) observed for protein, fat, MUFA, PUFA, Vit. E, iron, and potassium. Fair correlations (0.3 to 0.49) were found for fiber, carbohydrates, fatty acids, Vit. A, Vit. D, Vit. B12, and calcium. Among men, correlation coefficients ranged from 0.23 (protein) to 0.51 (calcium). Calcium showed good validity (0.51), while fair correlations were observed for protein, carbohydrates, fiber, Vit. B12, iron, and potassium.
CONCLUSIONS
The newly developed FFQ demonstrated fair validity when compared to R24h, with performance varying across nutrients and sexes. These findings suggest that the FFQ is a useful tool for assessing habitual dietary intake in adults, although further refinement may enhance its accuracy for certain nutrients.

PARTICIPATORY FORMATIVE RESEARCH TO IMPROVE COMPLEMENTARY FEEDING PRACTICES IN OAXACA, MEXICO

Jillian A. Emerson[1]; Claudia Ivonne Ramirez Silva[2]; Natalie Copuroglu[3]; Enrique Rios Espinosa[4]; Maria Isabel Sandoval Ayala[5]

[1]Programs Division, Vitamin Angel Alliance, Goleta, United States of America; [2]Dept. of Maternal, Child, and Adolescent Nutrition, National Institute of Public Health, Cuernevaca, Mexico; [3]N/A, Independent Consultant, Mexico City, Mexico; [4]Programs Division, Vitamin Angel Alliance, Mexico City, Mexico; [5]Behavioural Insights and Design Studio, Thinkplace US, Mexico City, Mexico

BACKGROUND AND OBJECTIVES

In Mexico, malnutrition remains a public health problem despite improvements in child stunting in recent years. Sub-optimal complementary feeding (CF) practices are prevalent, but more research is needed to understand the related contextual factors and underlying barriers and facilitators to optimal CF practices, in order to design effective interventions. The objective was to understand CF practices and identify the main factors serving as barriers and facilitators to optimal CF practices at the individual (mother/caregiver), family, community, and health facility levels, in Oaxaca State.

METHODS

Communities were purposively selected to comprise a mix of urban/rural and indigenous/non-indigenous settings in the regions of Central Oaxaca, Tehuantepec, and Pinotepa. Qualitative methods included in-depth interviews, focus group discussions, photodiaries, and household observations. Participants were mothers/caregivers of children 6-23 months of age, fathers, grandmothers, community leaders, and health workers.

RESULTS

There were 104 participants. Most mothers/caregivers had little knowledge of optimal CF practices (as per World Health Organization guidelines). Although most children received an appropriate number of meals/snacks per day for their age, the quality of their diet was lacking, reflected in poor dietary diversity and inappropriate consistency/quantity of foods. Few children ages 6-11 months were fed animal-source foods, such as eggs or meat, or other protein sources like beans, due to fears of choking, misconceptions, and cultural norms. Many children were fed liquid broths due to cultural norms and the misperception that broths were sufficiently nutrient-dense. Feeding of unhealthy foods and beverages was not a common practice. Health workers had little knowledge of nutrition, and counseling on CF was not integrated in any routine child health services.

CONCLUSIONS

Dietary diversity, in particular increasing feeding of animal-source foods, and increasing the quantity/consistency of foods in the period from 6-11 months of age were identified as priority behaviors for interventions. The findings will be used in a participatory human-centered design process to develop and test interventions to improve CF practices and strengthen the capacity of health workers to provide quality counseling on CF.

AVAILING HEALTH SERVICES- A STUDY ON SOCIAL BARRIERS AND PERCEPTIONS AMONG WOMEN OF REPRODUCTIVE AGE GROUP

Ebbie Thomas[1]; Samraggi Roy[2]; Rohini Saran[3]; Anita Makhijani,[4]; Sirimavo Nair[5]
[1]Department of Community Sciences, GMERS Medical College Gotri, Vadodara, India; [2]Foods and Nutrition, The Maharaja Sayajirao University of Baroda, Vadodara, India; [3]Nutrition and Health, PATH, New Delhi, India; [4]Nutrition, NIPCCD, New Delhi, India; [5]Nutrition and Fortification, Food Safety and Standards Authority of India, New Delhi, India

BACKGROUND AND OBJECTIVES
Anemia remains a critical health issue among pregnant and lactating women in low- and middle-income countries, significantly contributing to morbidity and mortality. In India, persistent challenges in adherence to anemia control programs and the adoption of healthy nutritional habits exacerbate this issue. This study investigates the behavioral and societal factors influencing health service utilization and nutrition practices among women of reproductive age. By exploring community perceptions, behavioural barriers, and gender stereotypes, the study highlights the critical need for a multi-faceted approach to address anemia and promote healthier nutritional outcomes at the grassroots level.
METHODS
The observational study was conducted in four Gram Panchayats of one of the blocks on the eastern side of India. Focus group discussions (FGDs) were used to explore community perceptions, behavioral barriers, and the role of gender stereotypes in shaping health and nutritional outcomes among pregnant women, lactating mothers, and their respective mothers-in-law.
RESULTS
FGDs revealed multiple barriers to anemia control program adherence. Key issues included poor consumption of iron and folic acid-rich foods, dislike for Iron and Folic Acid (IFA) tablets, forgetfulness, and inadequate awareness of anemia. Service-related gaps, such as insufficient counselling, inadequate supply of IFA tablets, and infrastructural challenges, compounded the problem. Gender disparities emerged as a significant factor, with unequal distribution of household labor, restricted access to education, and entrenched stereotypes limiting women's ability to prioritize their health and nutrition.The findings also highlighted that many women lacked knowledge about the importance of anemia prevention and WASH practices. Limited community engagement and weak intersectoral collaboration further hindered program implementation, leaving vulnerable populations underserved.
CONCLUSIONS
Addressing anemia among women requires a multi-faceted approach involving nutrition-sensitive and specific interventions. Strategies must focus on enhancing nutrition education, improving healthcare access, and promoting gender equality to combat barriers at the grassroots level. Strengthening multi-sectoral coordination and ensuring adequate resource allocation are critical to improving outcomes in ongoing anemia control programs.
