Higher mortality rates of black Africans, especially in rural areas, are attributed to complications of DM and other non-communicable diseases such as cerebrovascular disease and hypertensive heart disease, which is in line with the self-reported information of hypertension, DM and high cholesterol given by the study sample. The lack of dietary diversity combined with high intake of refined starches and sugar likely contribute to the mortality and morbidity in this rural community. Further interventions can be addressed by local clinics and improving dietary intake. This can assist with the 2030 nutrition goals to reduce the risk of non-communicable diseases such as hypertension and DM in rural areas to improve the South African health status of adults.

CAN DIETITIANS LEAD THE WAY FOR ORAL HEALTH PROMOTION IN THE EATING DISORDER CLINICAL SETTING?

Tiffany Patterson Norrie[1]; Lucie Ramjan,[1]; Mariana Sousa,[2]; Ajesh George,[3]
[1]School of Health Sciences, Western Sydney University Campbelltown Campus, Campbelltown, Australia; [2]Faculty of Health, University of Technology Sydney, Ultimo, Australia; [3]School of Nursing and Midwifery, Western Sydney University Parramatta Campus, Parramatta, Australia

BACKGROUND AND OBJECTIVES
Individuals with an eating disorder (ED) are five times more likely to have poor oral health, regardless of ED subtype. Research involving individuals who have experienced a mental illness like an ED, have documented barriers such as shame or fear of judgment as deterrents from seeking dental care. The role of non-dental health professionals providing pre-emptive oral health promotion (OHP) has been gaining traction in recent years. However, there is limited research investigating the perceptions and acceptability of individuals with an ED towards oral health and the potential role of dietitians in this area. Hence, the aim of this study is to explore the role of dietitians in OHP within ED clinical settings. Specifically, the objectives are to synthesise current evidence on the role of ED clinical dietitians and OHP; explore the perceptions of individuals with a lived experience of an ED regarding their experience of oral health and; to explore the knowledge, attitudes and practices of dietitians in general, and in ED clinical settings about OHP.

METHODS
A sequential mixed methods study was undertaken across four phases involving a scoping review, quantitative and qualitative studies. Participants included Dietitians and individuals with a lived experience of an ED.

RESULTS
The findings from the literature review showed some dietitians were already using OHP in their practice and this was further supported by recommendations from prominent dietetic organisations that supported the role of dietitians providing oral health promotion. A significant gap identified in both the scoping review, national survey and interviews with dietitians showed a dearth in training and professional resources to support the role of OHP in dietetic practice. Importantly, dietitians felt that OHP was part of their role. Qualitative interviews with individuals with a lived experience of an ED detailed the impacts of poor oral health on their self-esteem, and recovery. Both individuals with an ED and dietitians were receptive to the concept of a dietitian led oral health promotion program.

CONCLUSIONS
The findings show support from both dietitians and individuals with a lived experience of an ED towards optimising the role of dietitians in the ED clinical setting to include OHP. Further research is required to develop and pilot test a basic screening tool and resources to support dietetic practice in OHP. Further, clear guidelines need to be developed to assist and encourage dietitians in incorporating OHP into their practice.

CONFLICTS OF INTERESTS
The authors have no conflict of interest.

IDENTIFICATION OF NATURAL BIOACTIVE COMPOUNDS AS POTENTIAL INHIBITORS OF ADIPOGENESIS: AN IN SILICO ANALYSIS

Elena Murcia García[1]; Ascensión López-Avilés,[2]; Horacio Pérez-Sánchez[3]; Miguel Carmena Bargueño[4]; Alejandro Rodríguez Martínez[5]; Juan José Hernández-Morante[2]
[1]Research Unit for Eating Disorders, UCAM Universidad Católica San Antonio de Murcia, Guadalupe, Spain; [2]Research Unit for Eating Disorders, Ucam, Murcia, Spain; [3]Structural Bioinformatics and High Performance Computing (BIO-HPC) Research Group, UCAM Universidad Católica San Antonio de Murcia, Guadalupe, Spain; [4]Structural Bioinformatics and High Performance Computing (BIO-HPC) Research Group, UCAM, Murcia, Spain; [5]Structural Bioinformatics and High Performance Computing (BIO-HPC) Research Group, UCAM, MUR, Spain

BACKGROUND AND OBJECTIVES

The prevalence of obesity has become a significant global health concern, driven by sedentary lifestyles and unhealthy dietary patterns (1). This condition is closely linked to the accumulation of adipose tissue through a process known as adipogenesis, which involves the differentiation of preadipocytes into mature adipocytes (2). Natural bioactive compounds have gained increasing attention due to their potential to inhibit adipogenesis and offer safe alternatives for obesity management (3). Computational approaches, particularly ligand-based methods, provide valuable techniques for identifying and predicting the bioactivity of compounds with known anti-adipogenic effects reported in literature (4). By targeting key molecular pathways involved in this process, our objective is to offer insights into their therapeutic potential and lay the groundwork for future experimental validation and anti-obesity strategies.

METHODS

Ligand-based virtual screening calculations have been employed using the MetaScreener tool (https://github.com/bio-hpc/metascreener) to select molecules as bioactive compounds with adipogenesis inhibition activity. Next, the top 100 compounds were chosen for additional visual analysis. Finally, we carried out a consensus. This procedure allowed the identification of 60 compounds simultaneously present in all computational techniques, which indicates their high potential as inhibitors of adipogenesis.

RESULTS

From all 60 potential molecules, our RESULTS showed that those derived from plant sources demonstrated promising activity in inhibiting adipogenesis. This activity is similar to that reported in the literature for well-known bioactive compounds, which are recognized for their ability to modulate adipocyte differentiation . These findings suggest that the compounds under investigation may also possess potential anti-adipogenic effects.

CONCLUSIONS

In silico studies offer a systematic approach to identify new bioactive compounds with potential anti-adipogenic activity. Our computational research has highlighted compounds with notable in silico potential to inhibit adipogenesis by targeting key molecular pathways involved in adipocyte differentiation. These compounds are currently being further explored for their efficacy in obesity management through in vitro analysis.

VALIDITY OF BODY MASS INDEX AND GLYCATED HEMOGLOBIN FOR EVALUATING METABOLIC SYNDROME

laura rojas[1]; Natalia Avellaneda Perdigón[1]; Lynett Florez Daniela[1]; Paula Trujillo María[1]; Fernanda Vergara Montoya María[1]; García Montoya Gabriela[1]; Alejandra Nieto Maria[1]; Russi Amparo[2]; Luis Gustavo Celis[1]
[1]medicina, universidad de la sabana , bogotá Colombia; [2]Nutricion, Asociacion colombiana de nutricionistas y dietistas, bogotá, Colombia

BACKGROUND AND OBJECTIVES
Metabolic syndrome is currently considered a public health problem that has had an exponential increase secondary to nutritional habits and physical activity of the population at a global level, which requires a continuous re-evaluation of the parameters used for diagnosis and treatment. Although body mass index (BMI) and glycated hemoglobin are commonly used, they have significant limitations. This study aims to identify the most cost-effective parameters for clinical application, optimizing patient treatment, outcomes, and prevention.

METHODS
A literature review was conducted in various databases to evaluate the parameters used for diagnosis and monitoring of metabolic syndrome, focusing on the limitations of BMI and glycated hemoglobin.

RESULTS
BMI has notable limitations for assessing obesity, as it does not allow differentiation between muscle mass and body fat, being more useful as a population-level marker rather than as a precise tool for individualized patient assessment. The cost-effective alternatives identified include abdominal circumference, lipid profile, C-reactive protein, fibrinogen, inflammatory cytokines and indices such as lipid accumulation product and cardiometabolic index, being highly sensitive and specific. (1)
With the introduction of Continuous Glucose Monitoring (CGM), glycated hemoglobin has been discontinued for glycemic control, especially in insulin-dependent diabetes. Although CGM is promising, it has limitations and should be complemented with glycated hemoglobin for optimal control. (2)

CONCLUSIONS
BMI and glycated hemoglobin, when used in isolation, require re-evaluation as diagnostic tools for metabolic syndrome. This study proposes to incorporate parameters and innovative technologies that impact early diagnosis and in turn the prognosis of patients.

IMPACT OF A 3-WEEK HYPOCALORIC DIET AND EXERCISE ON BODY WEIGHT AND LIPID PROFILES IN OBESE CHILDREN

Ivana Djuricic[1]; Jelena Kotur-Stevuljevic[2]; Branko Subosic[3]; Snezana Lesovic[4]
[1]Department of Bromatology, Faculty of Pharmacy, University of Belgrade, Belgrade, Serbia; [2]Department of Biochemistry, Faculty of Pharmacy, University of Belgrade, Belgrade, Serbia; [3]Biochemical Laboratory, University Children's Hospital, Belgrade, Serbia; [4]Special Hospital, Cigota, Zlatibor, Serbia

BACKGROUND AND OBJECTIVES
Children's obesity is a significant public health issue affecting millions of children worldwide. It is characterized by excessive body fat that negatively impacts children's health and well-being. The main goal of this study was to assess the effect of a hypocaloric diet combined with physical activity on body weight, body mass index (BMI), and lipid profiles in obese children.

METHODS
Thirty-six hospitalized obese children (17 boys and 19 girls) aged 12-18 years underwent a 3-week hypocaloric diet with proper nutritional value (1200-1500 kcal/day) and practiced individual aerobic physical activities at least 3 hours/day. Serum lipids (total cholesterol (TC), high-density lipoprotein (HDL)-cholesterol and triglycerides (TGs)) were measured using standard enzymatic methods, while low-density lipoprotein (LDL)-cholesterol was determined using the Friedwald equation. The obtained RESULTS were used to calculate two parameters: risk for cardiovascular diseases (RFCVD; TC—HDL-cholesterol) and index of atherosclerosis (IA; LDL-cholesterol—HDL-cholesterol).

RESULTS
After three weeks of diet and exercise, body weight and BMI significantly decreased (8.6% and 10.7%; $p<0.001$, respectively) in obese children. All lipid parameters (TC, LDL and TGs) significantly reduced, $p<0.001$, except HDL-cholesterol with no significant changes ($p=0.05$). A significant reduction was also found for RFCVD and IA (24.2% and 36.8%; $p<0.001$, respectively).

CONCLUSIONS
This study highlights the positive impact of a hypocaloric diet combined with aerobic physical activity on body weight, BMI, and lipid profiles in obese children. The significant reductions in cardiovascular risk factors underscore the effectiveness of this intervention in improving the overall health and well-being of obese children. These findings emphasize the importance of structured dietary and exercise programs in early prevention and management strategies to combat childhood obesity and its associated health risks.

ASSOCIATION BETWEEN INTERLEUKIN8-251 POLYMORPHISM, HELICOBACTER PYLORI INFECTION, AND DIETARY VITAMIN C INTAKE WITH THE RISK OF GASTRIC PRECANCEROUS LESIONS

Yeon Joo Lee,[1]; Dongkyu Lee,[1]; Jeongin Han,[1]; Chang Soo Eun,[2]; Dong Soo Han,[2]; Hyun Ja Kim[1]
[1]Dept. of Food and Nutrition, Gangneung-Wonju National University, Gangneung-si, Korea, Republic of; [2]Dept. of Internal Medicine, Hanyang University Guri Hospital, Guri-si, Korea, Republic of

BACKGROUND AND OBJECTIVES
This study aimed to investigate the effects of interleukin 8-251 (IL8-251) polymorphism, *Helicobacter pylori* (*H. pylori*) infection, and dietary vitamin C intake on gastric precancerous lesions, atrophic gastritis (AG) and intestinal metaplasia (IM), and to evaluate the interaction effects of IL8-251 genotypes according to the presence of *H. pylori* infection or dietary vitamin C intake.

METHODS
This cross-sectional study used data from a baseline survey of the Yangpyeong cohort for cancer research. Overall, 331 voluntary participants (135 normal, 80 AG, and 116 IM) who underwent upper gastrointestinal endoscopy and agreed to participate in the genomic analysis and dietary habit survey were included. A food frequency questionnaire was used to obtain the dietary vitamin C intake and *H. pylori* infection was diagnosed using the campylobacter-like organism test.

RESULTS
IL8-251 polymorphisms and *H. pylori* infection were independently associated with the risk of AG and/or IM. *H. pylori*-positive was associated with the risk of IM in participants with IL8-251 AT type (odds ratio [OR] = 4.85; 95% confidence interval [95% CI] = 1.96–11.99) and AA type (OR = 8.51; 95% CI = 2.31–31.31), compared to TT type with *H. pylori*-negative. Low vitamin C intake was associated with the risk of IM in the IL8-251 AT type (OR = 3.29; 95% CI = 1.43–7.60) and AA type (OR = 5.82; 95% CI = 1.59–21.27) compared to the IL8-251 TT type with a high vitamin C intake.

CONCLUSIONS
IL8-251 genotype was the important risk factor of AG and IM, and *H. pylori*-positive and low vitamin C intake were associated with the risk of AG or IM in IL8-251 AA or AT genotype.

THE EFFECT OF PERSONALIZATION OF A COMBINED LIFESTYLE INTERVENTION ON HABITUAL FOOD CONSUMPTION EVALUATED WITH THE EETSCORETM

Wilrike J Pasman[1]; Dagmar J Smid,[1]; Kristel Kamstra,[1]; Iris M De Hoogh,[1]; Tim Van Den Broek,[1]; Johanneke E Oosterman,[1]; Suzan Wopereis[1]
[1]Microbiology & Systems Biology, Netherlands Applied Research Institute TNO, Leiden, Netherlands

BACKGROUND AND OBJECTIVES
Combined Lifestyle Interventions (CLI) are programs used for people with chronic lifestyle related diseases focusing on improving food intake, physical activity, sleep and/or stress coping skills. The reimbursed Dutch CLI SLIMMER was enriched with personalisation factors that resulted in additional weight loss and improved retention. The aim of the current study was to examine the effect of the six-months personalized SLIMMER-CLI on habitual food consumption.

METHODS
In this cluster-allocated open-label study, 54 persons (age 49.8±11.8 yrs; BMI 33.6±4.6 kg.m-2) participated in the personalized SLIMMER-CLI (intervention) and 24 persons (age 47.3±11.1 yrs; BMI 34.6±5.0 kg.m-2) participated in the regular SLIMMER-CLI (control). Personalization, i.e. the adaptation of the combined lifestyle intervention to personal needs and preferences, included shared decision making, continuous monitoring and feedback, goal setting, and adaptation of the advice based on a person's biology and behaviour. Adherence to the Dutch dietary guidelines was assessed with the Dutch Healthy Eating Index at baseline and at six months using data from the online EetScoreTM questionnaire (doi: 10.1017/S0007114521004499).

RESULTS
The per protocol analysis showed that both groups changed their habitual food intake after six months SLIMMER-CLI. Main effects indicated that adherence to the Dutch dietary guidelines significantly increased for vegetables, whole grain products, unhealthy food choices, salt intake, sugar-sweetened beverages and processed meat for both groups, resulting in an increase in the total Dutch Healthy Diet Index Score at month 6. Within group statistics showed that adherence to the Dutch dietary guidelines with respect to salt intake improved more in the personalized SLIMMER-CLI as compared to regular SLIMMER-CLI. Within the personalized SLIMMER-CLI only, adherence scores for whole-grain product consumption and fats and oils correlated with waist circumference and waist-hip ratio.

CONCLUSIONS
Adherence to the Dutch dietary guidelines improved after six months of SLIMMER-CLI in both groups. For whole-grain product and fats and oils adherence also correlations with waist circumference and waist-hip ratio were found.

AMARANTH PROTEIN ISOLATE (AMARANTHUS CRUENTUS L.) PROMOTES A NORMOLIPIDEMIC EFFECT IN A DIET RICH IN SATURATED FAT AND MODULATES THE ACTIVITY OF THE ENZYME HMG-COA REDUCTASE

Rosana Soares-Freitas[1]; Bianka Salvador,[1]; Cintia Silva[1]; Gloria Guizelinni[1]; Jose Alfredo Areas[1]
[1]Nutrição, Universidade de São Paulo, São Paulo, Brazil

BACKGROUND AND OBJECTIVES
Hypercholesterolemia and the resultant cardiovascular diseases represent the primary causes of mortality worldwide. Some foods, including amaranth, have been shown to reduce the risk of these diseases developing. The objective of this study was to determine the effect of amaranth proteins on cholesterol homeostasis in hamsters fed a diet high in saturated fat. The study also examined the impact of amaranth proteins on the expression of mRNA related to cholesterol metabolism, fatty acids profile, and the activity of the enzyme HMG-CoA reductase in the liver of the hamsters.

METHODS
The hamsters were divided into three groups (n = 8/group): Group N (AIN93, 20% casein), Group H (cholesterol and saturated fat, 20% casein), and Group I (cholesterol and saturated fat, 20% amaranth protein). The hamsters were fed for 21 days. At the conclusion of the experimental protocol, the animals were anesthetized and a comprehensive set of biological samples was collected for analysis. These samples included blood and liver tissue. Total cholesterol, fractions, and triacylglycerols were analyzed in the plasma. Liver analysis encompassed total lipids, total cholesterol, fatty acid profile, and the expression levels of the genes Srebf2, Ldlr, Abca1, Abcg1, Abcg5, Abcg8, Lxrα, Ampk, and the activity and expression of the enzyme HMGCoA-reductase.

RESULTS
The RESULTS obtained from this study are as follows: As anticipated, the H diet resulted in elevated cholesterol levels; however, the amaranth protein isolate effectively maintained total cholesterol, triacylglycerol, and fraction concentrations, comparable to the N group. A comparative analysis revealed a lower deposition of lipids and total liver cholesterol in groups N and I compared to group H, thereby indicating the protective effect of amaranth. Furthermore, groups N and I exhibited higher levels of polyunsaturated fatty acids and a greater polyunsaturated/saturated ratio. While the relative expression of the analyzed genes remained consistent across groups, group I exhibited a reduced activity of the HMG-CoA reductase enzyme in comparison to group H.

CONCLUSIONS
These findings suggest that amaranth protein can impede an escalation in the levels of both circulating and hepatic lipids, even in the context of concurrent consumption of a diet with a high degree of saturation. This effect appears to be, at least in part, attributable to a decrease in the activity of the HMG-CoA reductase enzyme.

ASSESSING HIDDEN TRANS FAT SOURCES IN REFINED VEGETABLE OILS: A MULTI-COUNTRY ANALYSIS TO INFORM GLOBAL TFA POLICY IMPLEMENTATION

Liz Drummond[1]; Rachel Kouwe,[1]; Tania Albuquerque[2]; Carla Motta,[2]; Helena Soares Costa[2]; Laura Cobb[1]
[1]Cardiovascular Health, Resolve to Save Lives US, New York, United States of America; [2]Food and Nutrition Department, Instituto Nacional De Saude Doutor Ricardo Jorge, Lisbon, Portugal

BACKGROUND AND OBJECTIVES
World Health Organization (WHO) has been working toward the global elimination of industrially produced *trans* fat (iTFA) through the REPLACE initiative since 2018. The initiative has successfully introduced mandatory, best practice regulations in more than 45 countries since 2018. WHO recommends one of two policy options: 1) limit iTFA to 2% of total fat in all fats, oils and foods, or 2) ban the production and use of partially hydrogenated oils (PHO). The application of high temperatures during the deodorization stage of oil refining can lead to the conversion of unsaturated fatty acids to TFA. Typically, the *trans*isomers created through this process range from 0.5-2% percent of total fat. However, evidence from Bangladesh(1) and China(2) has shown that some vegetable oils exceed the WHO recommended limit, and have a higher than expected *trans* fat content, likely due to prolonged exposure to high temperatures. This unexpected source of TFA could mean that the impact of TFA intake on heart disease is underestimated; that relying on PHO bans may have limited efficacy, and that TFA surveillance activities may overlook important TFA sources. Resolve to Save Lives in collaboration with the Instituto Nacional de Saúde Doutor Ricardo Jorge (INSA) and collaborators in low and middle-income countries, is conducting a multi-country assessment to determine the prevalence of high TFA in refined vegetable oils. The study aims to 1) measure the levels of iTFA in commonly used cooking oils in study countries, 2) compare the prevalence of iTFA in commonly used cooking oils across study countries, and 3) establish whether price or type of oil influences iTFA content in cooking oils.

METHODS
Our study will map the available vegetable oils from vendors in 8 countries. In each country, up to 20 oils will be collected, key nutrient and label information will be recorded. Oils will be analyzed using gas chromatography with flame ionization detection at INSA's lab. Data will be collected and analyzed between January and June 2025

RESULTS
Samples from 8 countries will be analyzed according to the WHO Laboratory Protocol on Measuring TFA and reporting as a percentage of TFA of the total fatty acids in oils. RESULTS will be compared across oil types and countries.

CONCLUSIONS
This study will reveal important information about sources of *trans* fat in the diets of many low and middle-income countries and potentially lead to significant changes in plans for TFA policy adoption and implementation.

BACKGROUND AND OBJECTIVES

Breast cancer (BC) is the neoplasm with the highest incidence, prevalence and mortality in women worldwide. Folate metabolism participates in nucleotide biosynthesis and regulation of DNA expression. Multiple of enzymes and a wide range of vitamins participate in this path, such as folate, vitamins B2, B6, and B12. The aim of this study is to assess the impact of single nucleotide polymorphisms (SNPs), and nutrients related to folate metabolism on breast cancer risk within the EPIC-Spain cohort.

METHODS

A case-control study nested in the European Prospective Investigation into Cancer and Nutrition (EPIC)-Spain cohort was conducted with 269 incident BC cases in women and 472 non-cases. EPIC was the source of demographic, clinical and dietary information. Genetic data were obtained from wide genotyping through Infinium Global Screening Array (Illumina®) and utter imputation. SNPs selection was done according to 1) GWAS Catalog evidence; 2) Minor allele frequency; 3) Linkage disequilibrium. Association between genetic and nutritional variables with BC risk was performed using $\chi 2$ tests and logistic regression, individually and using risk scores.

RESULTS

Median age was 48.3 and 51.2 years in cases and controls, respectively. Menopause status, tobacco consumption and oral contraceptives consumption were associated with a higher risk of BC risk. Among a total of 18 SNPs in 14 genes selected, RESULTS suggested that *MTHFS* rs4778734, in the recessive model, might be associated with a higher risk of developing BC (OR = 1.30; 95%CI = 1.10-1.59; p = 0.009) after multiple comparison adjustment. Otherwise, neither the other SNPs or the assessed nutrients (folate, B2, B6, B12, and alcohol) nor the risk scores showed a significant association with BC risk.

CONCLUSIONS

Our findings suggest that genetic variants in genes related to folate metabolism may influence BC development. However, this association was not conclusive when analyzing the nutrients involved. This may be partly due to implicit errors in the estimation of the intake of these nutrients, as well as their bioavailability, lack of repeated measurements, etc. Further larger studies including nutritional biomarkers are needed to confirm these RESULTS.

CALORIC AND FAT INTAKE AMONG STATIN USERS IN SERBIA

Milica Zrnic Ciric[1]; Vanja Todorovic[1]; Una Sijan[1]; Brizita Djordjevic[1]; Ivana Baralic[2]; Miodrag Ostojic[3, 4, 5]; Ivan Stankovic[1]

[1]Department of Bromatology, University of Belgrade-Faculty of Pharmacy, Belgrade, Serbia; [2]Hospital Pharmacy, Zvezdara University Medical Center, Belgrade, Serbia; [3]Faculty of Medicine, University of Belgrade, Belgrade, Serbia; [4]Department of Cardiology, University Clinical Centre of the Republic of Srpska, Banja Luka, Bosnia and Herzegovina; [5]Department of Medical Sciences, Serbian Academy of Sciences and Arts, Belgrade, Serbia

BACKGROUND AND OBJECTIVES

Cardiovascular diseases (CVDs) remain the leading cause of death worldwide, significantly contributing to increased disability and healthcare costs. Serbia is no exception, with CVDs accounting for 47% of all deaths, making them the leading cause of mortality in the country. Dietary risks rank second in the global burden of CVDs attributable to selected modifiable risk factors. Adherence to dietary recommendations plays a crucial role in the prevention of CVDs, both before and alongside pharmacological interventions. This study evaluated the quality of diet, specifically regarding fat intake, among statin users.

METHODS

Data on demographic, clinical, and lifestyle factors were collected, using a series of interviewer and self-completion questionnaires. Data on total caloric intake, total fat intake, saturated fat intake, and dietary cholesterol intake were calculated using 24-hour dietary recalls for three non-consecutive days. The average daily intake for each subject was calculated as the mean of the three 24-hour dietary recalls.

RESULTS

In total, 70 participants on chronic atorvastatin therapy (20 mg) [age: 63.3 ± 7.8 yrs; 25 female, 55 male; BMI: 27.1 ± 3.5 kg/m2] completed all questionnaires and were included in the analysis. Of these participants, 77% were eligible for secondary prevention of cardiovascular events, and 51% reported a positive family history of CVDs. Patients with diabetes represented 23% of the study population. The average daily energy intake with 24-h dietary recall was 1768 ± 490 kcal/day. The RESULTS indicated that the intake of total fats (39%), saturated fats (14%), and cholesterol (221 mg) exceeded the recommended dietary values.

CONCLUSIONS

These findings suggest suboptimal dietary behaviors among patients on chronic statin therapy. Public health initiatives and dietary monitoring are needed to enhance the understanding of the impact of diet on health within this population.

MULTICOMPONENT NUTRITIONAL APPROACH PROTOCOL AND ASSESSMENT OF ITS IMPACT ON THE HEALTH OF BRAZILIAN WOMEN WITH OBESITY

Glauce Dias da Costa[1]; Irene Da Silva Araújo Gonçalves[1]; Danielle Cabrini[2]; Juliana Farias de Novaes[1]; Rosangela Minardi Mitre Cotta[1]; Leticia Milagres Paiva[3]; Marina Tosatti Aleixo[1]; Ana Clara Gutierrez Diniz Souza[1]; Carla De Souza Rocha Rocha[4]; Ana Caroline Alves Souza[1]; Andressa Alvarenga Silva[1]; Bianca Guimarães De Freitas[1]

BACKGROUND AND OBJECTIVES
Obesity is a complex issue influenced by political, relational, behavioral, social, and health factors. The overload of social roles and responsibilities of women, social stigma, and aesthetic pressure exacerbate the condition, making more humanized and comprehensive approaches necessary. The objective was to develop a protocol for a multicomponent nutritional approach and assess its impact on the health of Brazilian women with obesity.

METHODS
A comprehensive literature review on multicomponent nutritional interventions, official documents on obesity and communication techniques was conducted by an interdisciplinary team. The developed protocol was applied in a randomized clinical trial over 6 months and included 89 adult women with obesity, randomly assigned to the following groups: control group (G1), individual multicomponent approach (G2), and individual multicomponent approach combined with group meetings (G3). The study was approved by the Ethics Committee of the research institution. Participants in G1 followed a diet with a 500 to 1000 kcal/day deficit aimed at weight loss. G2 participated in an average of 10 individual sessions based on the developed protocol, while G3 combined this approach with group meetings focused on social support and experience sharing. Assessments were conducted at the beginning and end of the intervention and included anthropometric measurements, body composition using DXA, biochemical analyses, and the use of scales to assess stress, anxiety, and depression. Statistical analyses were conducted using SPSS.

RESULTS
The protocol integrated political, relational, environmental, behavioral, and health dimensions, using tools for each dimension, culminating in special attention to mental health, movement/physical activity, spirituality, sleep, and nutrition. All groups showed reductions in waist circumference and fasting blood glucose, a decrease in body fat percentage, and an increase in lean mass. G1 did not show significant changes in anxiety, while G2 and G3 exhibited significant reductions. G2 also showed a decrease in depression symptoms.

CONCLUSIONS
The multicomponent approach was effective in psychoemotional aspects. All groups showed improvements in fasting blood glucose, body fat percentage, and lean mass. The study emphasizes the need for public policies that address the emotional and social issues of women with obesity. The protocol offers an innovative, low-cost approach to obesity treatment, especially within public health systems, focusing on overall well-being.

HYPOTHESIS ABOUT LINKS BETWEEN SOME BIOLOGICAL MARKERS AND SOME TYPE 2 DIABETES COMPLICATIONS

Mariem Letaief[1, 2]; Rachdi Rim[3]; Ben Amor Nadia[4]; Faten Mahjoub[2]; rym ben othman[2]; Olfa Berriche[2]; Henda Jamoussi[2]
[1]Endocrinology , Diabetes and Nutrition department, Hospital Emile Muller, Mulhouse, France; [2]A, institut national de nutrition et de technologie alimentaire de tunis, tunis, Tunisia; [3]Department A, Institut De Nutrition, Tunis, Tunisia; [4]Research Unit UR18ES01 on "Obesity", National Institute of Nutrition & Food Technology of Tunis, Tunis, Tunisia

BACKGROUND AND OBJECTIVES
Diabetes is a chronic multifactorial disease with increasingly frequent complications. The aim of our study was to investigate associations between some biological markers and some complications of type 2 diabetes.

METHODS
Our study is retrospective conducted on type 2 diabetes patients with at least one degenerative complication. This study took place between May 2023 and August 2024. Assessment of diabetic neuropathy was made by the DN4 score (positive if >=4).

RESULTS
A total of 82 patients were included. There was a female predominance (gender ratio:1.28). The average age was 61.09 years old ± 10.11. The mean duration of diabetes was 12.78 years ± 9.21. Obesity was present in 33.9% of the cases. Chronic renal failure was present in only 6.2% of cases.Two-thirds (66.7%) of the patients were on insulin therapy.The major complications observed were respectively: diabetic retinopathy (34.4%), diabetic neuropathy (31.2%), and diabetic nephropathy (29.3%). The median of DN4 score was 2 IQR[0; 4].The mean HbA1c was 12%± 2.96%. The mean of serum calcium level, phosphoremia, magnesemia, uremia and uratemia were respectively 2.37 mmol/l ±0.10; 1.14 mmol/l ±0.17; 0.75 mmol/l ±0.09; 5.87mmol/l± 1.67 and 279.88 µmol/l± 98.80.
As for the clearance of creatinine, it had a mean of 93.54 ml/min ± 20.41.The median of microalbuminuria was 9mg/24h IQR[5; 40]. There was a positive correlation between phosphoremia and DN4 score (p=0.009; r= 0.269), between phosphoremia and microalbuminuria (p=0.049; r=0.226), between magnesemia and the duration of diabetes (p=0.022; r=0.255), between magnesemia and uremia (p=0.022; r=0.257).
As for the negative correlation, it was observed between serum calcium level and microalbuminuria (p=0.020; r=0.-259), between BMI and microalbuminuria (p=0.023, r=-0.293), between uratemia and HBA1C (p=0.046; r=-0.224), between duration of diabetes and creatinine clearance (p=0.019; r=-0.263).

CONCLUSIONS
As phosphoremia increases, neuropathy increases, while nephropathy is associated with higher magnesemia and lower serum calcium level. These two complications seem to be associated. On the other hand, the older diabetes is, the more magnesemia and uremia decrease and clearance of creatinine increases; no controlled diabetes seems to be associated with low urate levels.

DIETARY INTAKE OF CALCIUM AND PHOSPHOROUS: ARE THEY ADEQUATE IN CHRONIC KIDNEY DISEASE PATIENTS IN SERBIA?

Marija Takic[1, 2]; Slavica Rađen,[3, 4]; Milica Zeković[1, 2]; Brankica Terzić,[5, 4]; Danijela Ristic-Medic[6, 2]
[1]Group for Nutrition and Metabolism, Institute for Medical Research, University of Belgrade, Beograd, Serbia; [2]Centre of Research Excellence in Nutrition and Metabolism, Institute for Medical Research, University of Belgrade, Beograd, Serbia; [3]Institute of Hygiene, Military Medical Academy, Belgrade, Serbia; [4]Faculty of Medicine, University of Defense, Belgrade, Serbia; [5]Clinic of Nephrology, Military Medical Academy, Beograd, Serbia; [6]Group for Nutritional Biochemistry and Dietology,Institute for medical reserach, Center of Research Excellence in Nutrition and Metabolism, Belgrade, Serbia

BACKGROUND AND OBJECTIVES
Disturbances in bone and mineral metabolism are highly prevalent among patients with chronic kidney disease (CKD), significantly affecting their quality of life and morbidity. Dietary calcium restriction is often the first-line intervention to mitigate the progression of these disorders. However, inadequate calcium intake can be as detrimental as excessive exogenous calcium load. Concurrently, elevated dietary phosphorus intake in known to exacerbate bone remodeling process. Despite the importance of these nutrients, data on their dietary intake in CKD patients, especially within the Serbian population, remain scarce. Therefore, this study aimed to assess the dietary intake of nutrients essential for bone health, calcium and phosphorus, in a cohort of CKD patients.

METHODS
This study included 77 patients with CKD, (36 pre-dialysis, 41 on hemodialysis). Three repeated 24-h recalls were used for assessment of dietary intake. Serum levels of fasting glucose, total, LDL-, and HDL-cholesterol, triacylglycerol, urea, creatinine, parathyroid hormone, and vitamin D were determined using standardized commercial assay kits. Statistical analyses were conducted using the Mann-Whitney U test and Pearson's correlation test.

RESULTS
Inadequate dietary intake of calcium and phosphorous was found in 61% and 69% of CKD patients, respectively. In this cohort, the estimated median daily intake was 716 mg for calcium and 934 mg for phosphorus. No statistically significant differences were observed in calcium and phosphorus intake between the pre-dialysis and hemodialysis groups. In two patients, total daily calcium intake surpassed the suggested maximum of 1500 mg, whereas in 45 patients, it was below the recommended 800 mg/day (recommended value: 800-1000mg, and not more than 1500 mg/day). In all cases of inadequate phosphorus intake, consumption exceeded the CKD-recommended threshold of 800 mg/day, with a strong positive correlation observed between phosphorus and protein intake (Pearson's index 0.906, $p<0.001$). Finally, the median calcium-to-phosphorus intake ratio was 0.769, indicating a suboptimal balance far below the recommended range of 1–2:1.

CONCLUSIONS
The RESULTS of this study indicate that nutritional management in CKD should prioritize meeting requirements for calcium and phosphorous, essential nutrients for bone health. Such interventions could play a pivotal role in mitigating bone and mineral metabolism disturbances and improving patient outcomes.

PERINATAL HEALTH STATUS OF WOMEN WITH PRE-PREGNANCY DIABETES MELLITUS AND ITS RELATIONSHIP WITH INFANT HEALTH

Ya-Ling Wang[1]; Sing-Chung Li[2]; Chiao-Ming Chen[3]
[1]Department of Food and Nutrition, Taichung Veterans General Hospital Library, Taichung, Taiwan; [2]School of Nutrition and Health Sciences, College of Nutrition, Taipei Medical University, Taipei, Taiwan; [3]Department of Food Science, Nutrition, and Nutraceutical Biotechnology, Shih Chien University, Taipei, Taiwan

BACKGROUND AND OBJECTIVES
The prevalence of diabetes has been increasing annually, with a noticeable trend toward younger age groups. Women's increased access to education and participation in the workforce may contribute to delayed childbearing. In the past, pregnancies among women with diabetes were primarily associated with type 1 diabetes. However, in recent years, there has been a rising trend in pregnancies among women with type 2 diabetes.
This study analyzes past electronic medical records from the hospital to investigate the effectiveness of nutritional therapy and to identify common dietary issues among pregnant women with diabetes. The findings aim to serve as a reference and guide for future nutrition education initiatives.

METHODS
To investigate the blood sugar control status of women with pre-gestational diabetes in the past 2012-2022 by reviewing medical records.
Sampling criteria: 1. Pregnant patients with type 1 and type 2 diabetes
2. Newborns born to mothers with type 1 and type 2 diabetes
The data were analyzed using SPSS statistical software for descriptive and inferential statistics.

RESULTS
We reviewed electronic medical records from Taichung Veterans General Hospital from 2012 to 2022, identifying a total of 118 cases were diagnosed with diabetes prior to pregnancy. The data indicated that there were no statistically significant differences in age, DM type, or mode of delivery between subjects who received nutrition education and those who did not. We found that both groups had a high proportion of cesarean deliveries, with 69.8% in the with ND group and 66.7% in the without ND group. The pre-pregnancy BMI in the without ND group was significantly higher than that in the with ND group; however, there was no statistically significant difference in weight gain during pregnancy between the two groups. Of these, The distribution of nutrition counseling in each trimester was: 27 times in the first trimester, 9 times in the second trimester, and 5 times in the third trimester, totaling 41 times, accounting for about 34.7%. Blood sugar and HbA1c levels dropped significantly before and after nutrition counseling (p=0.001, 0.002).

CONCLUSIONS
This suggests that multiple sessions of nutrition education help individuals better understand dietary control concepts and effectively implement dietary control plans.

HEALTH-RELATED QUALITY OF LIFE AMONG PEOPLE LIVING WITH HYPERTENSION AND DIABETES CO-MORBIDITY IN RURAL BANGLADESH

Tanni Jhilik[1]; Sita Kumari[2]; Shahriar Mashuk[3]; Meghna Chakravartty[4]; Tanmoy Sarkar[3]; Md. Mokbul Hossain[2]; Fahmida Akter[2]; Malay Kanti Mridha[4]
[1]Centre for Non-communicable Disease and Nutrition, BRAC JPGSPH, BRAC University, Dhaka, Bangladesh, Dhaka, Bangladesh; [2]James P Grant School of Public Health, BRAC University, Dhaka, Bangladesh; [3]School of Public Health, BRAC James P Grant School of Public Health, Dhaka, Bangladesh; [4]BRAC James P Grant School of Public Health, BRAC University, Dhaka, Bangladesh

BACKGROUND AND OBJECTIVES
The growing prevalence of hypertension and diabetes is leading to a rising number of individuals with hypertension and diabetes co-morbidity. Individuals with any comorbidity often show poorer health status. The objective of this study was to assess the health-related quality-of-life status among individuals living with hypertension and diabetes comorbidity in rural Bangladesh and identify factors associated with quality of life.

METHODS
This cross-sectional quantitative study was conducted in a rural setting in Bangladesh. A total of 387 participants were recruited from an ongoing non-communicable disease surveillance project of BRAC James P Grant School of Public Health. To capture data on health-related quality of life, the EuroQoL-5D-5L scale was used. UK utility value set scores were utilized to get final index scores for health-related quality of life. Scores were categorized into three levels (poor, average, and good) by separating into three equal quartiles. Ordinal logistic regression was used to examine associations with various factors using STATA 17.0.

RESULTS
The average age of the participants was 54.13 years, with a majority being women (61.76%), unemployed (59.92%), and one-fourth of the participants lacking formal education (25.32%). The mean quality of life status score was 0.749 (±0.23). A majority (65.89%) of the participants reported problems in the pain and discomfort dimension among five dimensions of EuroQoL-5D-5L scale. Increasing age (AOR = 0.97, 95% CI: 0.95 to 1.00, p = 0.004), being female (AOR = 0.29, 95% CI: 0.13 to 0.63, p = 0.002), having other diseases (AOR = 0.43, 95% CI: 0.26 to 0.69, p = 0.000), consuming less amount of food with high salt content (AOR = 0.49, 95% CI: 0.29 to 0.85, p = 0.01) were found to have lower odds of poor health-related quality of life.

CONCLUSIONS
Since consuming less amount of food high in salt was found to have a link with less chance of having a poor quality of life, the government of Bangladesh should focus on educating people to adopt healthy eating practices with food having less salt in the rural context. In addition, a longitudinal study is needed to better understand the relationships between various factors and how they may influence one another in evaluating quality of life. Integration of measures to improve quality of life in the existing health care can also enhance the well-being of individuals with hypertension and diabetes co-morbidity.

APPLYING CANCER PREVENTION RECOMMENDATIONS AT POPULATION LEVEL: A POLICY BLUEPRINT

Ioana Vlad[1]; Kate Oldridge-Turner,[1]; Christelle Clary[2]; Kate Allen[2]; Helen Croker[2]; Mitrou Panagiota[2]
[1]Policy and Public Affairs, World Cancer Research Fund International, London, United Kingdom; [2]Science and Policy, World Cancer Research Fund International, London, United Kingdom

BACKGROUND AND OBJECTIVES

There is well established evidence that diet, body weight, nutrition and physical activity influence cancer risk. The WCRF/AICR Cancer Prevention Recommendations [1] summarise this evidence in easy-to-understand statements addressed at individuals that, taken together, constitute an overall way of living healthily to prevent cancer. They have been proven to lower cancer risk [2] and impact living well with and beyond cancer [3]. To encourage the adoption of those recommendations by all and lower cancer risk, governments need to implement population-level policies that create environments promoting healthy behaviours, with regards to diet, weight, alcohol, breastfeeding and physical activity.

METHODS

We mapped the best available evidence on cancer risk, as summarised by the WCRF/AICR Cancer Prevention Recommendations, against policy advice for population-level cancer prevention. We did this by integrating existing World Cancer Research Fund International policy tools, such as the NOURISHING and MOVING policy frameworks, and current World Health Organization (WHO) guidance relevant to cancer prevention policy. The latter includes the WHO noncommunicable diseases (NCDs) Best Buys, the Global action plan on physical activity, the Global action plan on alcohol, and the International Code of Marketing of Breastmilk Substitutes.

RESULTS

The policy blueprint presents a package of policy recommendations across 8 key policy areas that apply across diet, weight, alcohol, breastfeeding and physical activity and includes principles for policy design and implementation. The potential co-benefits of cancer prevention policies in relation to prevention of NCDs, contributing to sustainability targets, reversing health inequities, addressing commercial determinants of health and fulfilling human rights are also assessed, as well as potential trade-offs when policy goals do not align. Accompanying policy factsheets present in-depth analysis on how to each relevant cancer risk factor can be addressed through population-level policies.

CONCLUSIONS

A resource for policymakers and advocates, the Policy Blueprint integrates for the first time WCRF/AICR's Cancer Prevention Recommendations with population-level policy advice. It promotes an integrated approach to policy development on healthy diets and weight, breastfeeding, physical activity and to reduce alcohol intake, with the aim of preventing cancer and supporting healthier environments for people living with and beyond cancer.

DIGITAL ASSESSMENT OF LIFESTYLE ADHERENCE TO CANCER PREVENTION GUIDELINES AMONG BRAZILIAN BREAST CANCER SURVIVORS

Jaqueline Schroeder de Souza[1]; Nathalie Kliemann[2]; Lilian Cardoso Vieira[3]; Patricia Faria Di Pietro[4]
[1]Post Graduate Program in Nutrition, UFSC, Joinville, Brazil; [2]Research, Oncology Research Center, Florianópolis, Brazil; [3]Post Graduate Program in Nutrition, Federal University of Santa Catarina, Imbituba, Brazil; [4]Post Graduate Program in Nutrition, Federal University of Santa Catarina, Florianópolis, Brazil

BACKGROUND AND OBJECTIVES
Breast cancer is the most common cancer among women globally and in Brazil. After treatment, recurrence has a 48.5% chance within 5 years post-diagnosis. Modifiable factors like inadequate diet and sedentary lifestyle are strongly linked to both primary and secondary cancers, with breast cancer survivors showing worse dietary and lifestyle patterns compared to the general population. This underscores the importance of adhering to evidence-based healthy lifestyle recommendations, such as those published in 2018 by the World Cancer Research Fund (WCRF) and the American Institute for Cancer Research (AICR). Lifestyle self-assessment tools can promote adherence to these recommendations by motivating behavioral changes. However, no self-assessment questionnaire for adherence to the WCRF/AICR recommendations has been identified for the Brazilian breast cancer survivors. Therefore, this study aimed to evaluate adherence to the WCRF/AICR recommendations among Brazilian women using a self-administered instrument.

METHODS
This cross-sectional pilot study utilized a self-administered digital instrument specifically developed for the research. The tool was applied to women with breast cancer in the southern region of Brazil. The instrument evaluated components of the WCRF/AICR recommendations, including body weight, eating habits, and alcohol consumption. The components generated an individual score and a total score (sum of components with a range of 0 to 10 points). Scores were classified as follows: low adherence (0-3 points), moderate adherence (4-7 points), and high adherence (8-10 points), reflecting the level of compliance with the recommendations.

RESULTS
The study included 44 participants with an average age of 49 years. The average total score was 7 points (standard deviation 1.05), indicating moderate adherence to the WCRF/AICR recommendations. Participants had a mean body mass index (BMI) of 27.8 kg/m², which is classified as overweight for adults according to the World Health Organization. The average daily consumption of fruits and vegetables was 429 g, meeting the recommended intake of plant-based foods. However, regular alcohol consumption was reported by 27 participants (61.3%), which may represent a risk factor for cancer recurrence.

CONCLUSIONS
The self-administered instrument identified vulnerable aspects of the participants' lifestyle, underscoring the importance of educational interventions in primary care to promote cancer prevention and reduce the risk of recurrence.

ASSOCIATION OF NUTRITIONAL THERAPY WITH CLINICAL OUTCOMES IN CRITICALLY ILL COVID-19 PATIENTS: A RETROSPECTIVE OBSERVATIONAL STUDY

Ling Shen[1]
[1]Department of Food & Nutrition, National Yang Ming Chiao Tung University Hospital, Yilan, Taiwan

BACKGROUND AND OBJECTIVES
The COVID-19 pandemic has challenged ICU care globally. Studies show that appropriate nutritional therapy can improve outcomes and recovery for COVID-19 patients. This study analyzes data from severe cases in our ICU to assess how enteral nutrition affects hospitalization length and respirator use duration.

METHODS
This study is a retrospective analysis to identify patients with severe COVID-19 who were admitted to the ICU at our institution from January 2021 to December 2022.
Independent sample t-tests and one-way ANOVA were used to explore the differences in ICU stay length and total hospitalization days across variables. Subsequently, Pearson correlation analysis was conducted to investigate the relationships between continuous variables and chi-square tests were applied to examine the differences in mortality rates at discharge among patients with different characteristics.

RESULTS
A total of 122 cases were included in the statistical analysis. Most patients were discharged alive, totaling 90 cases (73.8%). The average ICU stay was 9.52 ± 9.53 days. Patients who required mechanical ventilation tended to have longer ICU stays. Higher serum albumin levels were associated with shorter ICU stays, while patients with hypophosphatemia had longer ICU stays than those without. The deceased patients had significantly lower average weight and BMI than the survivors. A regression model analysis showed that the type of ventilator used, duration of ventilator use, serum albumin levels, and the presence of hypophosphatemia jointly influenced the length of ICU stay, with an explanatory power of 74.5%.

CONCLUSIONS
The study found that initial nutritional status, especially weight, BMI, and serum albumin levels, significantly impacted COVID-19 patient outcomes. Higher serum albumin levels were linked to shorter ICU stays, and early caloric and protein intake improved survival rates. Monitoring and correcting serum phosphate levels also helped reduce ICU stay length. Overall, good nutritional care was crucial for better recovery, shortening both ICU and total hospital stay durations.

EFFECTS OF THE BURDEN OF MEDICAL EXPENSES ON MEDICAL CARE IN PATIENTS WITH TYPE 1 DIABETES MELLITUS

Hiroyuki Horio[1]; Kanna Maeno[1]
[1]School of Health and Nutrition, Department of Nutrition, Tokaigakuen University, Nagoya, Japan

BACKGROUND AND OBJECTIVES
[BACKGROUND AND OBJECTIVES**]** Type 1 diabetes requires lifelong insulin therapy, which is essential for survival. This necessity of continuous, life-sustaining treatment is believed to have significant impacts not only on the physical aspects of a patient's life but also on psychological and social dimensions. Additionally, many patients are diagnosed in childhood, and it is said that the financial burden and anxiety about their future are extremely significant. However, there is a lack of nationally collected survey data on these issues. To address this, the Japan IDDM Network, a certified non-profit organization and a national body for type 1 diabetes patients, conducted a survey. The purpose was to understand the living conditions related to treatment among type 1 diabetes patients and their caregivers. The collected data serves as foundational material for making policy recommendations to the government regarding the current challenges faced by these patients.

METHODS
[Method] The survey targeted type 1 diabetes patients and their families across Japan. It was conducted via an online questionnaire set up by the Japan IDDM Network from January to March 2024. The number of respondents was 780.

RESULTS
[RESULTS] Among the respondents, 30.1% experienced onset of the disease before the age of 10, which was the largest group, followed by those in their teens and twenties. The monthly out-of-pocket medical expenses were less than 10,000 yen for 37.3% of respondents and less than 20,000 yen for 41.4%. The perceived burden of monthly medical expenses was reported as follows: 33.5% found it "very heavy," 21.9% found it "somewhat heavy," and 25.0% indicated that while it was "not heavy," they still desired a reduction.

CONCLUSIONS
[CONCLUSIONS**]** In the individual responses to the survey, there were pressing comments such as: "Medical expenses are high," "I want to use a pump, but the additional cost would be too burdensome," "It's difficult to make ends meet with living expenses," "The cost of snacks for managing hypoglycemia is a burden," "I have to take time off work to attend medical appointments," and "The proportion of medical expenses to my income is too large. " It was found that, especially for younger patients, the out-of-pocket medical expenses constitute a significant portion of their income, and financial assistance for using beneficial medical devices is insufficient.

A CHANGE-POINT REGRESSION MODEL FOR ESTIMATING THE EFFECTS OF FUNCTIONAL FOODS ON MUSCLE STRENGTH IN THE ELDERLY

Kohsuke Hayamizu[1]; Yui Kuramochi[1]; Kenji Uchida[2]; Kohtaro Takeuchi[3]; Masanori Wakida[4]; Toshimitsu Suga[3]
[1]Department of Health Pharmacy, Yokohama University of Pharmacy, Yokohama, Japan; [2]Food Function R & D Center, Nissui Corporation, Minato,Tokyo, Japan; [3]Physical Medicine and Rehabilitation, Kansai Medical University Medical Center, Moriguchi,Osaka, Japan; [4]Faculty of Rehabilitation, Kansai Medical University, Hirakata,Osaka, Japan

BACKGROUND AND OBJECTIVES

The change-point regression model (CPRM) is a valid method of analysis for assessing the effectiveness of nutraceuticals and functional foods. When clinical trials are conducted using muscle strength as an indicator in the elderly, it is difficult to analyze using the usual testing methods due to the large individual differences in muscle strength. In the present study, we applied CPRM to the analysis of the leg muscle-strengthening effects of fish protein supplementation in the elderly (Alaska pollock protein（APP） study) and investigated its usefulness.

METHODS

CPRM：Consider the following CPRM for between-group comparisons of RCT,

$yi = \alpha + b1xi + b2I(xi - xcp)(xi > xcp)gi + ei \quad (i = 1,2,3,\ldots n)$

where n is the number of participants, yi is the leg muscle strength at the study's end of participant i, xi is the leg muscle strength at baseline of participant i, xcp is a constant, gi is the group indicator (control = 0; treatment = 1), and $I(\cdot)$ is an indicator function defined as $I(xi > xcp) = 1$, if $xi > xcp$ and as 0 otherwise. The proposed method was applied to APP study data, and the merit of the proposed method was demonstrated by comparing it with the conventional method.

RESULTS

Applied to the APP study data, the RESULTS showed that the CPRM was indicated more fitting to data and power of statistical analysis was stronger than the conventional method. The RESULTS of the CPRM analysis showed that the significant increase in leg muscle strength with APP is effective when the pre-intervention leg muscle strength is 15.5 (kgf) or higher (p=0.03).

CONCLUSIONS

We have proposed a new approach to evaluate the efficacy of functional foods on muscle strength in the elderly based on a CPRM, and the merit of the method was demonstrated by comparing it with the conventional method.

THE PREVALENCE OF FOOD ADDICTION AND ITS ASSOCIATION WITH FAST FOOD CONSUMPTION PATTERNS IN DIABETIC PATIENTS: A CROSS-SECTIONAL STUDY

Emmanuel Oyebamiji[1]; Blessing Mkhwanazi[1]; Muthulisi Siwela[1]
[1]Dietetics and Human Nutrition, University of KwaZulu-Natal - Pietermaritzburg Campus, Pietermaritzburg, South Africa

BACKGROUND AND OBJECTIVES
Diabetes mellitus, including both type 1 and 2 diabetes, as well as other subtypes, is a significant public health issue in many parts of the world. The interlink between Diabetes and food addiction (FA) is complex due to the link with overweight/obesity, which is a significant risk factor for diabetes. Given the increasing prevalence of diabetes and its related complications, this study looks to evaluate diabetic management that focuses on dietary adherence and food addiction among diabetic patients.

METHODS
A total of 101 patients who are being managed for diabetes mellitus at University College Hospital were recruited. Participants completed the questionnaire on FA, using the modified Yale food addiction scale and Scoff Eating Disorder Scale for eating disorders; the participants' socio-demographic data and dietary habits were considered. Data were analyzed using SPSS, version 29.20. A p-value <0.05 was regarded as statistically significant.

RESULTS
The vast majority (86.1%) of the respondents were food addicted, and 55.4% of them were females. Approximately 64.3% of the respondents who indicated being obese were aged above 60 years. The RESULTS showed no significant relationship between FA and other determinants. Moreover, we found a significant relationship between BMI and age, marital status, occupation, and diabetes type. Furthermore, BMI was found to be significantly correlated with weight and FBS. The RESULTS in this sample study show that FA was significantly associated with eating fast food, sleeping too much, anxiety, and feeling afraid as if something awful might happen.

CONCLUSIONS
The research findings show that FA is high in diabetic patients, which exposes them to more complications of diabetes, causing adverse health consequences, and this dangerous dietary pattern directly compromises their therapy in the management of diabetes and metabolic control and confers medical complication risk and is associated with increased mortality and morbidity in diabetes which is caused by mental health.

PREVALENCE AND ASSOCIATED BODY COMPOSITION FACTORS OF SARCOPENIA IN COMMUNITY-DWELLING OLDER ADULTS

Boshi Wang[1]; Zhang Jiayu[1]; Nong Chenyu[1]; Shao Lin[1]; Liu Peng[1]
[1]Clinical Nutrition Department, Peking University People's Hospital, Beijing, China

BACKGROUND AND OBJECTIVES
The objective of this investigation was to examine the frequency and determinants related to body composition of sarcopenia among aging individuals residing in the Beijing community through implementation of the diagnostic criteria for sarcopenia outlined by the 2019 Asian Working Group for Sarcopenia (AWGS).

METHODS
A cross-sectional examination employing multistage cluster sampling was conducted on a sample consisting of 933 individuals aged 50 years or above. The study utilized the AWGS 2019 criteria for muscle mass, muscle strength, and physical function to gauge sarcopenia. Additionally, data on demographic characteristics, anthropometry, and body composition were collected. Logistic regression analysis was carried out to ascertain the relationships between sarcopenia and correlated factors.

RESULTS
The study found that the overall prevalence of sarcopenia was 8.3%. Sex ($p<0.001$) and body mass index (BMI $p<0.001$) were determined to have a significant association with the occurrence of sarcopenia. The adjusted analyses demonstrated that with each standard deviation increase in fat-free mass index (OR=0.02, of 95%), skeletal muscle mass (OR=0.17, of 95%), and other body composition indicators (including Total Body Water, Intracellular Water, Protein, Soft Lean Mass, BMI, Body Cell Mass, OR<0.60, of 95%), the risk of sarcopenia decreased by more than 40%. Certain straightforwardly accessible anthropometric indices such as upper arm circumference (correlation coefficient 0.94(0.9-0.97), 0.97(0.95-1), 1.01(0.99-1.03) respectively, of 95%), waist circumference (0.94(0.92-0.96), 1.01(0.99-1.03), 1.02(1-1.03), of 95%), hip circumference (0.93(0.9-0.96), 0.99(0.97-1.02), 1.02(1-1.04), of 95%), waist-to-hip ratio (0.93(0.87-1), 1.04(1-1.08), 1(0.97-1.03), of 95%), body fat percentage (1(0.98-1.02), 1.02(1-1.04), 1.01(0.99-1.02), of 95%), and phase angle (0.91(0.89-0.93), 0.96(0.94-0.98), 0.99(0.98-1), of 95%) exhibited substantial correlation with skeletal muscle index, muscle strength or physical performance. However, no noteworthy link between sarcopenia and most variables associated with physical function was discovered.

CONCLUSIONS
The findings of the study highlight the prevalence of sarcopenia among the aging residents of Beijing. Certain easily measured anthropometric indices demonstrated strong correlation with muscle strength or physical performance, thereby providing an avenue for screening and diagnosing sarcopenia in older people who may not be able to undergo grip strength or physical function assessments.

ADEQUATE TRACE ELEMENT INTAKE MIGHT AMELIORATE MAJOR ADVERSE KIDNEY EVENTS IN CRITICALLY ILL PATIENTS

YI-CHIA HUANG[1]; Tsai-Jung Wang,[2]; Wei-Ru Lin,[1]
[1]Department of Nutrition, Chung Shan Medical University, Taichung, Taiwan; [2]Department of Critical Care Medicine; Division of Nephrology, Department of Internal Medicine, Taichung Veterans General Hospital, Taitung, Taiwan

BACKGROUND AND OBJECTIVES
Critically ill patients might have altered trace element metabolism and frequently appear concurrent with acute kidney injury (AKI). We assessed the association of trace element intake with kidney function outcomes in critically ill patients.

METHODS
We included patients older than 20 years old and stayed in the intensive care unit (ICU) for more than 48 hours. Patients were allocated to non-AKI or AKI groups based on whether they occurred AKI at admission. The patients' clinical and hematological data were collected, and plasma selenium, zinc, and copper concentrations were measured on the ICU's 1st day and 7th day. The mean 7-day nutrient intake from enteral nutrition and intravenous fluid infusions was recorded and calculated. The outcome of kidney function was applied to the major adverse kidney events within 14 days and 28 days (MAKE14 and MAKE28) based on the patient's dialysis provision, sustained loss of kidney function, and/or death on the 14th and 28th day after admission to the ICU.

RESULTS
AKI occurred in 56 out of 124 patients (54.8%) at admission. AKI patients had significantly lower estimated glomerular filtration rate levels and higher serum creatinine concentration than non-AKI patients on the 1st and 7th days in the ICU. Non-AKI patients had a significantly higher mean 7-day energy, protein, carbohydrate, fat, selenium, zinc, and copper intake than AKI patients. Mean selenium, zinc, and copper intakes were negatively associated with MAKE14 and MAKE28 after adjusting for potential confounders. However, plasma selenium, zinc, and copper concentrations on the 1st and 7th days had no association with MAKE14 or MAKE28.

CONCLUSIONS
Adequate intake of trace elements might ameliorate major adverse kidney events in critically ill patients. (This study was supported by a grant from the National Science and Technology Council, Taiwan. NSTC 112-2320-B-040 -009 -MY3)

A CHANGE-POINT REGRESSION APPROACH FOR ESTIMATING THE THRESHOLD DOSE (TD) -COMPARISON OF RR AND RD-

Yui kuramochi[1]; Kohsuke Hayamizu[1]
[1]Department of Health Pharmacy, Yokohama University of Pharmacy, Yokohama, Japan

BACKGROUND AND OBJECTIVES

The change-point regression model (CPRM) is a valid method of analysis for assessing the effectiveness of nutraceuticals and functional foods. The model is characterized by including the threshold dose (TD) for analysis. In addition, we reported the usefulness of the weighted CPRM (w-CPRM), which is weighted by the heterogeneity between clinical trials in a meta-analysis for amino acid safety assessment. We used the risk difference (RD) for the dependent variable when fitting the data to the model, thus avoiding the problem of zero cells. However, RD cannot assess the intensity of risk and the risk ratio (RR) must be used as the dependent variable to assess intensity. To achieve this, the solution to the zero-cell problem is a challenge. Therefore, in this study, we investigated the pre-processing for RR data and the new w-CPRM application for RR data. The RESULTS were also compared with those obtained using RD data.

METHODS

The w-CPRM shows below.

$\omega i^* yi = \omega i^* \beta \mathrm{I}(xi > xcp)(xi - xcp) + \omega i^* \varepsilon i$

where yi and xi are the logarithmic transformation value of RR and dose for the i-th study, respectively, and xcp is the unknown change point or threshold. $\mathrm{I}(\cdot)$ is an indicator function defined as $\mathrm{I}(xi > xcp) = 1$ if $xi > xcp$ and is 0 otherwise. ωi is the weight of the i-th study with DerSimonian-Laird method.

We added 0.5 to both cells respectively when the either cell was 0 for solving the problem of zero cells.

RESULTS

Applied to the L-Arg study data, the RESULTS showed that 7480mg/ one-time dose as the TD. That is quite close to the TD when RD data was used (7531mg/ one-time dose). The feasibility of applying CPRM was confirmed by comparing it to a linear regression model with AIC as an index.

CONCLUSIONS

We found that w-CPRM can use RR as well as RD when RR data insert to the model after the problem of zero cells appropriately modified. This approach helps to estimate the TD using RR data that wasn't used before. ADAPTING A NUTRITION-RELATED QUALITY OF LIFE MEASURE TO A CANCER POPULATION

Karin Jontell[1]; Elin Lövestam[1]; Camilla Sköld[2]; Helena Igelström[3]; Evelina Liljeberg,[3, 4, 1]
[1]Department of Food Studies, Nutrition and Dietetics, Uppsala University, Uppsala, Sweden; [2]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden; [3]Department of Women's and Children's Health, Uppsala University, Uppsala, Sweden; [4]Geriatrics, Rehabilitation Medicine and Pain Centre, Uppsala University Hosptial, Uppsala, Sweden

BACKGROUND AND OBJECTIVES

The association between malnutrition and quality of life among patients with cancer is well-known. An understudied aspect in this population is whether nutrition interventions, beyond improving nutrition status, can enhance nutrition-related quality of life. However, concise questionnaires for assessing this in the context of cancer-related malnutrition is lacking. The Satisfaction With Food-related Life scale (SWFL-scale) has been validated in several languages, including Swedish, but not for a cancer population. This study aimed to assess the face validity of the SWFL-scale(1) in a cancer population with malnutrition or risk of it.

METHODS

The SWFL-scale was tested through cognitive interviews using the verbal-probing technique (2). Six patients treated for cancer (head and neck cancer, n = 5; lung cancer, n=1), recruited via patient organizations, participated. It consists of five questions, with responses on a seven-point Likert scale. The measure is intended to assess a broad perspective on food and meals, including planning, shopping, cooking, and the act of eating. Interviews were conducted in Swedish and were recorded. Ethical approval was obtained for the study.

RESULTS

Of the five SWFL questions, three were easy to understand and answer and should remain unchanged for this patient group (Table 1). Although food and meals are distinct concepts, combining the terms encouraged broader thinking. Two questions needed minor rephrasing in the Swedish translation. For instance, "conditions of my life" was difficult to relate to "regard to food" which could possibly be explained by respondents having faced a cancer diagnosis. Overall, the patients found the scale to capture relevant aspects.

Table 1 The questions included in the SWFL scale and RESULTS

Food and meals are positive elements in my life	Unchanged
I am generally pleased with my food	Rephrased
My life in relation to food and meals is close to my ideal	Unchanged
Food and meals give me satisfaction in daily life	Unchanged
With regard to food, the conditions of my life are excellent	Rephrased

CONCLUSIONS

The SWFL scale is a suitable tool, with minor refinements needed in the translation to Swedish of two questions, for use in a population with cancer. Utilizing this scale in studies on nutrition therapy for cancer-related malnutrition could help determine if nutrition-related quality of life is affected. However, further assessment of construct validity is needed.

FROM INSIGHTS TO ACTION: NURSING EDUCATION TO IMPROVE ORAL NUTRITION SUPPLEMENTS ADMINISTRATION IN ACUTE CARE

Kejendran Mangaikarasu[1]; Carmen Wong[1]; Lim En Jie[1]; Quek Soo Wen[2]; Li Xiaolan[3]; Cherie Tong Chung Yan[1]
[1]Dietetics Department, Sengkang General Hospital, Singapore, Singapore; [2]Ward 67 (Medical), Sengkang General Hospital, Singapore, Singapore; [3]Ward 28 (Surgical), Sengkang General Hospital, Singapore, Singapore

BACKGROUND AND OBJECTIVES

Malnutrition worsens patient outcomes and increases healthcare costs. Barriers to effective nutritional care, including knowledge gaps and staff attitudes, are well-documented (van den Berg et al., 2023). Observational findings at an acute care hospital revealed poor adherence to Oral Nutritional Supplement (ONS) administration. A quality improvement initiative with nursing staff used focus groups to identify key barriers, including limited knowledge, workflow challenges, and attitudes toward ONS. This initiative aimed to pilot a nursing education programme to address barriers and enhance ONS-related practices.

METHODS

A training programme covering malnutrition, nutrition importance, ONS types, and practical strategies was piloted with 50 nurses. Pre- and post-training questionnaires assessed knowledge, confidence, and attitudes. Mann-Whitney U tests, chosen for non-parametric data, compared pre- and post-training responses. Cohen's *d*, calculated using means and pooled standard deviations, quantified effect sizes. *p*-values <0.05 were considered statistically significant. Participants' feedback assessed satisfaction and relevance.

RESULTS

All outcomes showed p<0.001, indicating a high level of statistical significance, including malnutrition (U=133.0, p<0.001, d=2.6) and the importance of nutrition (U=290.0, p<0.001, d=2.0). Confidence in explaining ONS rationale to patients and families also increased (U=385.0, p<0.001, d=1.5). Intentions to implement ONS-related practices improved significantly: encouraging patients to take ONS (U=571.0, p<0.001, d=1.2), checking adherence (U=684.5, p<0.001, d=1.0), and considering patient preferences during handovers (U=538, p<0.001, d=1.2). Participants rated the training highly (94%), intended to apply the knowledge (92%), and 80% recommended annual retraining. Qualitative feedback highlighted the programme's practical relevance. Large effect sizes, typical of impact evaluations, reflect the training's impact on knowledge and confidence.

CONCLUSIONS

This initiative demonstrates the effectiveness of a tailored nursing education programme in improving knowledge, confidence, and ONS-related practices. Statistically significant improvements and high satisfaction validate its relevance. Mandatory training aligned with behavioural change models can sustain long-term clinical improvements. This programme offers a scalable approach to address global malnutrition through tailored clinical education.

HOW DO DIETITIANS FROM THE PROVINCE OF QUEBEC LEVERAGE EATING PLEASURE IN THEIR WORK WITH HIGHER WEIGHT INDIVIDUALS?

Julia Lévy-Ndejuru[1]; Alexandra Bédard,[1]; Catherine Bégin,[1, 2]; Ariane Bélanger-Gravel,[3, 1]; Sophie Desroches,[1]; Andréanne Michaud,[4, 1]; Véronique Provencher,[1]; Simone Lemieux,[1]
[1]Centre Nutrition, Santé et Société (NUTRISS), INAF, Université Laval, Québec, Canada; [2]School of Psychology, Université Laval, Québec, Canada; [3]Department of Information and Communication, Université Laval, Québec, Canada; [4]Quebec Heart and Lung Institute Research Centre, Université Laval, Québec, Canada

BACKGROUND AND OBJECTIVES
Many people with higher weight are preoccupied with their body size and food consumption(1). This can lead them to consult dietitians to change their eating habits. Eating pleasure is a promising approach to promote both healthy eating and a positive relationship with food(2). This qualitative study explores if and how eating pleasure is used by dietitians in their clinical interventions with higher weight individuals.

METHODS
Registered dietitians (n=19) from various clinical settings in the province of Quebec, Canada, were recruited online through social media and the research center's website. After filling out a sociodemographic questionnaire, they participated in an in-depth online interview exploring their use of eating pleasure in their clinical practice when working with higher weight patients, including key areas of intervention as well as barriers and facilitators. Semi-structured interviews were conducted by a PhD student and transcribed verbatim by two research assistants. They were then reviewed, imported and thematically analyzed using the NViVo software based on a coding frame created by the research team. The first five interviews were double coded by the PhD student and the research coordinator, and all discrepancies were discussed and resolved. The PhD student coded the remaining interviews, which then were reviewed by the research coordinator.

RESULTS
All dietitians reported leveraging eating pleasure in their clinical practice with higher weight patients. Key areas of pleasure-based interventions were 1) Food preparation 2) Food preferences, 3) Health considerations, 4) Social experiences, and 5) Psychological/physical state surrounding food intake. The most frequently named barrier to the use of eating pleasure was patients having a negative relationship with food (e.g., food guilt). Aspects of the sociocultural environment were also considered barriers to using eating pleasure, particularly those related to weight stigma and diet culture. Dietitians mentioned that patients who expressed openness to eating pleasure was an important facilitator. They also mentioned that different methods could be useful in facilitating the adoption of a pleasure-based clinical practice, such as establishing trust and addressing pleasure-related myths.

CONCLUSIONS
Dietitians working with higher weight individuals use eating pleasure in various aspects of their practice. Future research focusing on leveraging eating pleasure to promote healthy eating among this population should include strategies fostering a positive relationship with food and build resilience against weight stigmatizing messages.

ASSOCIATION BETWEEN OXIDATIVE BALANCE SCORE AND THE PROGNOSIS OF COLORECTAL CANCER PATIENTS

Caixia Zhang[1]
[1]Department of Epidemiology, School of Public Health, Sun Yat-sen University, Guangzhou, China

BACKGROUND AND OBJECTIVES
Colorectal cancer is one of the most common malignant tumors globally. Research has demonstrated that oxidative stress plays a significant role in the development and progression of colorectal cancer. The oxidative balance score (OBS) is a comprehensive measure that evaluates the burden of oxidative stress in individuals by considering both pro-oxidative and antioxidant dietary and lifestyle factors. However, few studies have examined the relationship between OBS and colorectal cancer prognosis. This study aimed to evaluate the association between OBS and the prognosis of colorectal cancer patients.

METHODS
A total of 2799 colorectal cancer patients from the Guangdong Colorectal Cancer Cohort, enrolled at baseline in 2010, were followed for mortality outcomes through 2023. Dietary data were collected using a food frequency questionnaire, which assessed the participants' diet over the year prior to their diagnosis. The OBS includes dietary components such as phytochemicals, vitamins, minerals, and fats, as well as lifestyle factors including smoking, alcohol consumption, obesity, and physical activity. A higher OBS score reflects greater exposure to antioxidants. Multivariable Cox proportional hazards regression models were used to estimate the hazard ratios (HR) and 95% confidence intervals (CI) for the association between the OBS and both all-cause mortality and colorectal cancer-specific mortality. Subgroup analyses were conducted based on cancer site.

RESULTS
The RESULTS showed that OBS was significantly and inversely associated with both overall mortality and colorectal cancer-specific mortality. The adjusted HRs for individuals in the highest versus the lowest quartile of OBS were 0.79 (95% CI: 0.63-1.00) for overall mortality and 0.77 (95% CI: 0.60-0.98) for colorectal cancer-specific mortality. Subgroup analysis by cancer site revealed that a high OBS was significantly associated with improved overall and colorectal cancer-specific survival in patients diagnosed with rectal cancer.

CONCLUSIONS
These findings suggest that a high OBS may be linked to better survival outcomes in colorectal cancer patients.

ASSOCIATION BETWEEN ANEMIA AND ORAL HEALTH OF UNDERSERVED US PREGNANT WOMEN

Brenda Abu[1]; Yan Wu[2]; Kevin Fiscella[3]; Jin Xiao,[2]
[1]Wegmans School of Health and Nutrition, Rochester Institute of Technology, Rochester, United States of America; [2]Eastman Institute for Oral Health, University of Rochester School of Medicine and Dentistry, Rochester, United States of America; [3]Family Medicine, University of Rochester Medical Center, Rochester, United States of America

BACKGROUND AND OBJECTIVES
To assess the effects of anemia, pica practices, and oral health status among pregnant women.

METHODS
A cross-sectional study was conducted among pregnant women in New York. Demographic, medical history, and oral hygiene practice data were collected using validated questionnaires. Comprehensive oral examinations included DMFT (decayed, missing, filled teeth), DMFS (decayed, missing, filled surface), and periodontal status (plaque index (PI) and bleeding on probing (BOP). We compared the oral clinical measures among participants with anemia and non-anemia, and pica and without pica using the Fisher exact, Independent sample t-tests, and Mann-Whitney U tests on SPSS software.

RESULTS
Among 20 women enrolled (8 (40%) with pica and 12 (60%) without pica), 25% had an anemia history, and the mean gestational age was 25.55 ± 8.8 weeks. Women with pica reported markedly higher prevalence of anemia (50%) compared to non-pica participants (8.3%) ($p < 0.05$). The pica group exhibited worse oral health, showing more decayed-missing-filled teeth and surfaces than the non-pica counterparts ($p < 0.05$). The overall mean DMFT and DMFS were 5.6 ± 4.4 and 9.85 ± 9.1 respectively. The total mean PI was 0.67 ± 0.5 and BOP was 3.2 ± 5.6. Anemia was not associated with DMFT, DMFS, BOP, or PI.

CONCLUSIONS
Pica practices were associated with maternal poor oral health. As these novel findings could have critical implications for oral diseases and treatment, during pregnancy, we recommend the study is replicated with a larger sample size and explore mechanisms.

CREATION OF A TOOL FOR IMPLEMENTING A 2:1 KETOGENIC DIET IN CHILDREN - IMPROVING THE DIETARY MANAGEMENT OF CHILDREN WITH REFRACTORY EPILEPSY AND NEUROMETABOLIC DISEASES

Myriam Granville[1, 2]; Hafsa Ahnifi,[3]; Aude Pace[3]
[1]Dietetic, Hôpital Delta, Auderghem, Belgium; [2]Dietetic, Haute École Léonard de Vinci, Woluwe-Saint-Lambert, Belgium; [3]Dietetic, Queen Fabiola Children's University Hospital, Bruxelles, Belgium

BACKGROUND AND OBJECTIVES

Fasting has long been described as a treatment for epilepsy. The ketogenic diet induces the same physiological processes as prolonged fasting by providing energy from lipids rather than carbohydrates. It has therefore been used since 1921 as a non-pharmacological treatment for refractory epilepsy. It is also indicated for certain metabolic disorders. The classic versions of this extremely restrictive diet (4:1 and 3:1 ratios) completely exclude starchy foods.In recent years, a new ratio has emerged: 2:1 (2g of fat to 1g of protein and carbohydrate). This allows starchy foods to be consumed in small quantities.
The aim of this work is to make it easier for parents of children on a 2:1 ketogenic diet to choose starchy foods. This will be done by creating a tool that shows the carbohydrate equivalents of different types of starch, including new products that have appeared on the market in recent years (e.g. legume based pasta).

METHODS

The work was carried out in several stages. The first was to revise the recipes created by the partner hospital for this project in a 2:1 ratio to meet the nutritional goals of the most recent consensus on the ketogenic diet. The second step was to create a database containing a large number of starchy foods from different regions of the world and to create 5g carbohydrate equivalents for them. The final and most important step was to create the tool itself. This involved a preliminary survey of families and caregivers about dietary difficulties. This stage made it possible to define the needs of the target group.

RESULTS

A 29-page ring binder has been produced. It contains a brief explanation of the diet and the types of starch, calculated equivalents (150), recipes (12) and resources. The recipes included in the tool have all been tested. An evaluation was carried out by the partner hospital’s Dietetics and Metabolism teams. They gave our tool an overall score of 9/10. An evaluation with parents of patients is still to be carried out to assess the practical aspect of the tool, whether the objectives set have been achieved and whether it meets the expectations of the target group.

CONCLUSIONS

The ketogenic diet is a complicated and restrictive therapeutic diet, but it has been shown to be effective in the treatment of certain epilepsies and metabolic disorders. This tool, after evaluation with patients' families, could be a way to facilitate the implementation of this diet. By tasting recipes with patients, this work has also shown that it is possible to compose appetising meals with a 2:1 ketogenic ratio.

STAKEHOLDER INVOLVEMENT IN DEVELOPING A HOME-BASED POST DISCHARGE BREASTFEEDING SUPPORT INTERVENTION FOR INFANTS UNDER 6 MONTHS RECOVERING FROM MALNUTRITION TREATMENT

Fridah Munene[1]; Jones Caroline[2]; Martha Mwangome[3]
[1]Research, KEMRI-Wellcome Trust Research Programme, Kilifi, Kenya; [2]University of oxford, University of Oxford, London, United Kingdom; [3]Clinical research, KEMRI-Wellcome Trust Research Programme, Kilifi, Kenya

BACKGROUND AND OBJECTIVES
Guidelines recommend malnourished infants under 6 months (U6M) re-establish exclusive breastfeeding during inpatient care, with community-based follow-up. However, LMICs often lack structured community support. This study engaged stakeholders to develop a home-based breastfeeding support intervention for U6M infants discharged from malnutrition treatment.

METHODS
The study used a participatory approach, reviewing policies and conducting workshops. National guidelines were sourced from Kenya's health portal, international ones from WHO, and relevant PubMed studies were reviewed. Snowball sampling identified stakeholders for interviews, and purposive sampling was used for workshop participants. Three workshops refined intervention components through iterative discussions.

RESULTS
The review identified 12 guidelines and 10 publications on post-discharge care. Literature emphasized intensive counseling, family inclusion, IEC materials, SMS reminders, and frequent visits. Stakeholders proposed components included nutrition counseling, social support, home follow-up by Community Health Promoters (CHPs), food rations, and hands-on skills like knitting. Workshops recommended peer-based breastfeeding counseling, targeted food support for malnourished mothers, SMS reminders, and linking mothers to CHPs. The finalized intervention involves three home visits and three phone calls for individualized breastfeeding support by a peer, establishing a breastfeeding buddy, and linking mothers to CHPs for social support.

CONCLUSIONS
The intervention addresses risk factors identified in literature. Testing among 20 mother-infant pairs shows feasibility and acceptability. An ongoing clinical trial will evaluate its effectiveness in improving clinical outcomes.

NUTRITIONAL AND INFLAMMATORY MARKERS ASSOCIATED WITH SERUM INFLIXIMAB TROUGH CONCENTRATIONS IN CROHN'S DISEASE

Xiangrui Li; Ying Xie; Bo Gao; Guiju Sun[1]; Xiaoqi Zhang; Xiaotian Chen
[1]Department of Nutrition and Food Hygiene, School of Public Health, Southeast University, Nanjing, China

BACKGROUND AND OBJECTIVES
Infliximab (IFX) has been shown to be effective in inducing and maintaining remission in Crohn's disease (CD). A higher serum IFX level is associated with a better biochemical, endoscopic, or histological response. A serum IFX level of 3μg/ml is the concentration required for CD treatment. Studies have shown that nutritional and inflammatory status of patients correlates with serum IFX concentrations. This study aims to investigate the nutritional and inflammatory indicators that are correlated with IFX concentration and explore the potential predictors of IFX concentration.

METHODS
This study included 112 CD patients who were admitted tothe research hospital and treated with IFX from October 2019 to December 2022. By compared patients with IFX concentrations ≥ 3μg/ml and those below 3μg/ml at week 14 to investigate the relationship between IFX concentrations and nutritional and inflammatory markers. Receiver operating characteristic (ROC) was adopted to analyze the potential efficacy of these indicators in predicting serum IFX concentrations. Logistic regression analysis was performed to evaluate the potential influencing factors of serum IFX levels.

RESULTS
The Hgb, serum ALB and hand grip strength in patients with serum IFX concentration ≥ 3μg/ml were significantly higher than those in patients with serum IFX < 3μg/ml ($P < 0.05$), while serum sedimentation rate (ESR) and antibodies to infliximab (ATI) positive ratio were significantly lower than those in patients with serum IFX < 3μg/ml group ($P < 0.05$). ROC analysis showed that serum ALB, Hgb and hand grip strength had predictive value for serum IFX concentration ≥ 3μg/ml, and the cutoff values were 37.5g/L and 129.5g/L,19.3kg, respectively. ESR had predictive value for IFX serum concentration < 3μg/ml. The cutoff value was 35mm/h. In multivariate Logistic regression, it was found that serum ALB ≥ 37.5g/L, ESR ≤ 35 mm/h, hand grip strength and ATI were potential influencing factors for serum IFX concentration ≥3μg/ml ($P < 0.05$). And the combined predictor generated by these indicators had better predictive value than the single indicator. The serum concentration of IFX was significantly correlated with the clinical remission of CD patients during the IFX maintenance period ($P < 0.05$).

CONCLUSIONS
Hgb, serum ALB, ESR, grip strength and ATI were potential influencing factors of IFX concentration. Monitoring nutritional and inflammatory markers is helpful to assess IFX concentrations in patients with CD.

ASSOCIATION BETWEEN OLFACTORY CAPACITY, BODY MASS INDEX AND EATING BEHAVIORS IN ADOLESCENTS

Ana Obregon[1]; Duran Aguero Samuel[2]; Karina Oyarce[3]; Gary Goldfield[4]
[1]Nutrición y dietética, San Sebastián University, Concepción, Chile; [2]Carrera de Nutrición y dietética, San Sebastián University, Providencia, Chile; [3]Carrera de Tecnología Médica, San Sebastián University, Concepción, Chile; [4]CHEO Research Institute, Children's Hospital of Eastern Ontario (CHEO), Ottawa, Canada

BACKGROUND AND OBJECTIVES

Childhood obesity is a significant global public health problem. The availability of energy-dense and highly palatable foods and increased powerful cues can override homeostatic satiety signals by influencing brain areas related to reward, emotion and olfaction. Olfaction is a sensory function associated with food preferences, intake, and obesity . The olfactory system is linked to the nervous system and can regulate food intake by sensing the metabolic state. Additionally, there is an inverse association between olfactory capacity and body mass index. However, no studies have assessed the possible effect of eating behavior traits on the relation between olfactory capacity and obesity. Aim: To evaluate if the association between olfactory capacity, eating behaviour traits and body mass index in adolescents aged 10-16 years**.**

METHODS

Methods: A cross-sectional study with a sample of 141 Chilean adolescents (45 % female; 56 % male) were recruited. We found that the sample was underweight (7%) and normal weight (36.3%), overweight (27.2%) and obese (29.2%). Anthropometric measurements (weight, height, BMI Z-score), eating behavior, and olfactory capacity was assessed. Eating behavior was assessed using the Child Eating Behavior Questionnaire (CEBQ), and the Food Reinforcement Value Questionnaire (FRVQ). Olfactory capacity was assessed using the Sniffing sticks test method.

RESULTS

RESULTS: Preliminary data show that male showed higher food responsiveness, enjoyment to food and lower satiety responsiveness scores in relation to female (p £ 0.05). In relation to olfactory capacity, adolescents with excess nutrition (overweight and obesity) showed lower discrimination, olfactory identification and TDI score (p=0.05).There was a significant inverse correlation between food responsiveness and olfactory threshold (r = -0.23; p<0.05) and a positive correlation between satiety responsiveness and odor identification score (r = 0.28; p < 0.05).

CONCLUSIONS

CONCLUSIONS: We observed a preliminary association between obesogenic eating behaviors traits and poorer olfaction. These findings may have implications for the understanding of the relation between olfaction and excess energy intake leading to obesity.

EFFECT OF ORAL PROBIOTIC LACTOBACILLUS JOHNSONII TCI250 OR WHITE POMEGRANATE EXTRACT ON SYMPTOMS, OXIDANT STRESS AND ANTIOXIDANT CAPACITY FOR BACTERIAL VAGINOSIS

Shih Chien Huang[1]; Hao Ling Chou[1]; Yun Han Liao[2, 3]
[1]Department of Nutrition, Chung Shan Medical University, Taichung, Taiwan; [2]Department of Obstetrics and Gynecology, School of Medicine, College of Medicine, Chung Shan Medical University, Taichung, Taiwan; [3]Department Department of Obstetrics and Gynecology, Chung Shan Medical University Hospital, taichung, Taiwan

BACKGROUND AND OBJECTIVES
Bacterial vaginosis (BV) is the most common cause of vaginal dysbiosis in women, characterized by a depletion of l*actobacilli* and an overgrowth of anaerobic pathogens. Although antibiotic treatment is effective in the short term, recurrence remains a significant clinical challenge. Recent studies suggest that probiotics may play a role in managing and preventing BV. And extracts of white pomegranate (*Punica granatum* Linn) exhibit potent antioxidant and antimicrobial properties, which may contribute to the inhibition of vaginal pathogen growth and the maintenance of vaginal health. This study aimed to evaluate the effect of heat-killed *Lactobacillus johnsonii* TCI250 or white pomegranate extract on symptoms, oxidative stress, and antioxidant capacity in women with BV.

METHODS
Forty-five women with BV were enrolled in this double-blind, placebo-controlled clinical trial. Participants were randomly assigned to three groups: group A (TCI250 heat-killed *Lactobacillus johnsonii* 100mg, n=15), group B (white pomegranate extract 500mg, n=15), and group C (placebo, n=15). Each group received daily supplementation for 8 weeks. The Nugent score, vulvovaginal signs and symptom, oxidative stress, and antioxidant capacity were evaluated at baseline and after 8 weeks of intervention.

RESULTS
The average age of the participants was 27.6 ± 5.2 years, with an adherence rate of 96.3%. No significant changes in Nugent scores were observed in any group. Regarding vulvovaginal symptoms, vaginal discharge and vaginal odor significantly improved in all groups after 8 weeks. Group B showed a reduction in oxidative stress, approaching statistical significance (TBARS: 0.8±0.4 vs 0.6±0.1 μM, p=0.055). Additionally, white pomegranate extract appears to improve itching, (β=-1.374, p=0.057).

CONCLUSIONS
Administration of white pomegranate extract for 8 weeks appears to reduce oxidative stress and improve more symptoms compared to *Lactobacillus johnsonii* TCI250, although the study's statistical power was insufficient. Future research with larger sample sizes and microbiome analysis is necessary to investigate the effects of *Lactobacillus johnsonii* TCI250 and white pomegranate extract on the management of BV.

COMBINING METAGENOMICS AND METABOLOMICS TO EXPLORE MICROBIOTA-METABOLITE DYNAMICS IN HUMAN METABOLIC HEALTH

Jaime Alonso-Allende Baselga[1, 2]; Ana Romo-Hualde,[1, 2]; Jose Ignacio Riezu-Boj,[1, 2, 3]; Fermín I. Milagro[1, 2, 3, 4]; Paula Aranaz Oroz[1, 2, 3]

[1]Center of Nutrition Research, University of Navarra, Pamplona, Spain; [2]Food Science and Physiology Department, University of Navarra, Pamplona, Spain; [3]A406 - Nutrición personalizada y síndrome metabólico, Navarra Institute for Health Research (IdiSNA), 31008 Pamplona, Spain, Pamplona, Spain; [4]Centro de Investigación Biomédica en Red de la Fisiopatología de la Obesidad y Nutrición, Carlos III Health Institute, Avenida de Monforte de Lemos, Madrid, Spain, Madrid, Spain

BACKGROUND AND OBJECTIVES

The imbalance in the composition and function of the gut microbiota (dysbiosis) has a significant impact on the development of various metabolic disorders, including obesity. However, it remains unclear which microbial taxonomic groups pose a higher or lower risk for obesity and how they relate to the development of metabolic disorders. This study aims to analyse the gut microbiota of Spanish volunteers with normal weight and obesity, explore the relationship between significantly differential bacterial taxa and various physiological variables and with plasma metabolites linked to either adverse or healthy metabolic states.

METHODS

Data from 298 adult volunteers were classified into LOW or HIGH obesity levels according to an obesity index based on the combination of three parameters: body mass index, fat mass, and waist circumference. Differences in the abundance of families, genera, and species between the two groups were studied, both combined and separated by sex. We also examined how the identified taxa correlated with the variables of the obesity index and with statistically significant metabolites associated with high or low obesity levels.

RESULTS

Most of the identified taxa were reduced in individuals with high obesity index (n=162), such as *Gemmiger quciabialis*, *Bifidobacterium longum*, and *Bacteroides cellulosilyticus*, among others. Additionally, these individuals were characterized by an increase in the specie *Clostridium fessum*, whose abundance showed positive correlations with the three variables of the obesity index. In addition, this was the only taxon that showed a statistically significant positive correlation with phosphatidylethanolamine, which was the only metabolite that was found significantly more abundant in the high obesity group.

CONCLUSIONS

Our study reveals that the microbiota of individuals with a high obesity index shows increased abundance of *Clostridium fessum*, correlated to an increase of plasma phosphatidylethanolamine levels. These RESULTS suggest a potential role for this species and this metabolite in the development of this condition and represent a therapeutic target for its control.

HARNESSING ARTIFICIAL INTELLIGENCE TO IMPROVE DIETARY ASSESSMENT FOR PRECISION NUTRITION

Lauren E Au[1]; Christabel A Domfe[2]; Boateng Bannerman[3]; Silas Bempong[3]; Peter Mccloskey[4]; Charles D. Arnold[1]; Gloria K Folson[3]; David P Hughes[4]; Aulo Gelli[5]
[1]Department of Nutrition, University of California, Davis, Davis, United States of America; [2]Nutrition, University of California, Davis, Davis, United States of America; [3]Noguchi Memorial Institute for Medical Research, University of Ghana, Accra, Ghana; [4]Department of Entomology, Pennsylvania State University, State College, PA, USA, United States of America; [5]Poverty, Gender, and Inclusion Unit, International Food Policy Research Institute, Washington D.C., DC, USA, United States of America

BACKGROUND AND OBJECTIVES
Technologies for precision nutrition research are in high demand in part because nutrition impacts the health of individuals differently. However, the effectiveness of precision nutrition research can be hindered by a lack of accurate tools and the reliance on time-intensive methods for assessing individual dietary intake. Leveraging artificial intelligence (AI) has the potential to enhance the accuracy of dietary intake assessment.
Objective: To conduct a pilot study of the PlantVillage Food Recognition and Nudging Insights (FRANI) mobile AI application by capturing images, recording portion weights of commonly consumed foods, and performing image annotation.

METHODS
Data collection occurred in the University of California Davis Dining Commons (DC) during the summer of 2024, following a 2-week menu cycle. It involved image capture and weighing of foods in two waves: Wave 1 consisted of real-life images of foods taken right before consumption, while Wave 2 consisted of images taken in two contexts – single foods in four standard portions and combination foods as they are typically eaten. Seasonal foods that were not served during the summer will be captured in the fall and winter quarters to expand the food database further. Image annotation and subsequent semantic segmentation model training are currently underway to train PlantVillage FRANI to recognize foods in images.

RESULTS
Approximately 4,000 images representing 251 food classes, along with food portion data (in grams), were collected during the 2024 summer menu cycle. The initial semantic segmentation model was trained with 984 annotated images and achieved a Mean Intersection over Union (MIOU) = 0.441. While these initial RESULTS were promising, visual inspection of the prediction masks suggested that additional Wave 1 training images would help further improve the model's performance.

CONCLUSIONS
Collaboration with the dining commons demonstrated the ease and feasibility of collecting food data in a U.S. college setting to train the AI model. The outcome of this pilot will set the stage for a validity study that compares the accuracy of FRANI to weighed food records and a feasibility study that will investigate the effectiveness of FRANI for future precision nutrition interventions.

MALNUTRITION IN PATIENTS WITH DIGESTIVE CANCER: EVALUATION AND MANAGEMENT STRATEGIES

Hanaa Merzougui[1]; Aya Guira[2]; Aya Gherdis[2]
[1]FACULTY OF MEDECIN PHARMACY's departement, Blida University 1, Ouled Yaïch, Algeria;
[2]Pharmacy, Faculté de Pharmacie, El Biar, Algeria

BACKGROUND AND OBJECTIVES
Malnutrition is a common complication in patients with digestive cancer, negatively impacting prognosis and quality of life. Proper nutritional management is crucial to improving clinical outcomes.
Objective: This study aims to assess the effectiveness of nutritional management strategies in patients with digestive cancer and identify optimal practices.

METHODS
A retrospective cohort study was conducted in the oncology department and the day hospital unit of the Cancer Center in Blida. The study included 102 patients diagnosed with digestive cancer between January 2023 and March 2024.
Both malnourished and non-malnourished patients were evaluated using their medical records and a questionnaire. Data collected included nutritional status indicators such as body weight changes during treatment, body mass index (BMI), dietary intake, and serum albumin levels to assess the severity of nutritional risk. The prevalence of malnutrition was determined, along with demographic characteristics and risk factors associated with malnutrition.

RESULTS
The analysis, with a significance threshold of 0.05, revealed that malnutrition is prevalent among digestive cancer patients (61%), particularly in those with esophageal and liver cancer (100%). The primary diagnostic method was monitoring patients' weight variations.
Regarding malnutrition management, the most common approach was oral nutrition, including dietary and hygienic advice, implemented in 18% of cases. Nutritional interventions were effective in more than half of the patients.
Despite limitations such as a shortage of nutritionists and adequate equipment, as well as the high mortality rate associated with digestive cancers, the RESULTS are promising. They highlight the importance of systematic malnutrition screening protocols from the time of digestive cancer diagnosis.

CONCLUSIONS
The findings underscore the need for enhanced efforts to improve nutritional management through systematic screening and strengthened collaboration among oncologists, nutritionists, and other healthcare professionals to ensure a more coordinated and effective approach.

IN VITRO AND IN VIVO STUDIES ON ANTI-INFLAMMATORY EFFECTS OF ARTEMISIA INDICA WILLD VAR. ORIENTALIS (PAMP.) H. HARA

Junichi Nagata[1]; Tomoya Takata[2]; Goki Maeda[3]
[1]Life, Environment and Applied Chemistry, Fukuoka Institute of Technology, Fukuoka, Japan; [2]Quality Control Group, Godo Shusei Distillation Column, Asahikawa, Japan; [3]Nago Branch, Okinawa Prefectural Agricultural Research Center, Nago, Japan

BACKGROUND AND OBJECTIVES
Artemisia princeps Pamp. (mugwort) has been used as a folk remedy including hemostatic, relieving skin itching, anti-inflammatory and so on. We focused on the anti-inflammatory effects of *Artemisia indica* Willd var. *orientalis* (Pamp.) H. Hara (nishi-yomogi), a species closely related to *Artemisia indica* var. *maximowiczii* （Nakai） H. Hara (Japanese mugwort). However, there is little information about the anti-inflammatory effects of nishi-yomogi polyphenol to date. Therefore, in this study, we examined the anti-inflammatory effects of nishi-yomogi from Ishigaki and Kume Islands, which have different morphological characteristics using a mouse macrophage cell and an acute inflammation animal model.

METHODS
Polyphenols were extracted from the freeze-dried powder with methanol. Cytotoxicity was examined using the MTT assay. The inflammatory mediator productions, gene and protein expressions in LPS-treated RAW264.7 cells were measured using the Griess method, ELISA kit, real-time PCR and western blotting, respectively. Polyphenol profiles were examined by HPLC. In an acute inflammation study, each polyphenol was administered intraperitoneally to SD rats, followed by administration of carrageenan to the footpad. The footpad volume was measured by plethysmometer. Data are shown as mean ± SEM. For cytotoxicity, each value was compared with the control using the Dunnett test, and for other, comparisons between groups were performed using the Tukey. Differences were considered significant at less than 5%.

RESULTS
From the MTT assay, in vitro study was performed at the concentration of 3 μg/ml polyphenol. In the case of in vitro study, Kume nishi-yomogi polyphenol significantly ($P<0.05$) suppressed NO production, and iNOS and TLR4 gene expressions compared to control, and was also observed the pronounced decreases in the iNOS and TLR4 protein expression levels in the LPS-treated cells. The HPLC RESULTS showed that Kume nishi-yomogi contained an unknown component not found in other mugwort. While, in the case of in vivo study, intraperitoneal administration of Kume nishi-yomogi polyphenol slightly reduced footpad swelling compared to the other groups.

CONCLUSIONS
The anti-inflammatory effects of Kume nishi-yomogi polyphenol were suggested by our studies. Daily consumption of Kume nishi-yomogi might contribute to reduce the inflammation in the body.

PHENOTYPING METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE FROM AN IMMUNOLOGICAL, METABOLIC, AND GUT MICROBIOME PERSPECTIVE

Méabh Ní Chathail[1, 2]; Christopher E Shannon[3, 1]; Sinéad Mullin[1, 2]; Anna Ledwith[4]; Stephen Cunningham[4]; Sarah E Lawler[1, 2]; Pamla Singh[5]; Suzanne Norris[5]; Frederick J. Sheedy[4]; Helen Roche[1, 2, 6]
[1]Conway Institute, University College Dublin, Dublin, Ireland; [2]Nutrigenomics Research Group and IFH, School of Public Health, Physiotherapy, and Sports Science, University College Dublin, Dublin, Ireland; [3]School of Medicine, University College Dublin, Dublin, Ireland; [4]School of Biochemistry and Immunology, Trinity College Dublin, Dublin, Ireland; [5]Hepatology Department, St James's Hospital, Dublin, Ireland; [6]Institute for Global Food Security, Queen's University, Belfast, United Kingdom

BACKGROUND AND OBJECTIVES
Metabolic dysfunction-associated steatotic liver disease (MASLD) and the progressed subtype, metabolic dysfunction-associated steatohepatitis (MASH), represent two common hepatic manifestations of obesity, presenting as dysfunctional metabolism, hepatic steatosis, insulin resistance, visceral adiposity, hyperlipidaemia, and hypertension. It is hypothesised that chronic low-grade inflammation and gut microbiome dysbiosis play vital roles in the pathogenesis of MASLD and progression to MASH. This research aims to phenotype the immunological, metabolic, and gut microbiome phenotype associated with MASLD/MASH and determine if transplantation of gut microbiomes via FMT from individuals with MASLD or MASH is sufficient to induce a MASLD/MASH phenotype in the mice.

METHODS
Individuals with MASLD (n=20) and MASH (n=16) were recruited for metabolic and inflammatory phenotyping and provided stool samples for microbiome analysis. Innate immune training (IIT) and whole blood stimulation (WBS) assays were carried out to analyse inflammatory responses. Dysbiotic MASLD and MASH gut microbiomes were transplanted via FMT into antibiotic-cleansed recipient mice which were fed HFD or SFD for 8 weeks. Fasting glucose and insulin were measured and 16S rRNA sequencing was carried out to phenotype the gut microbiomes of MASLD/MASH individuals and the recipient mice.

RESULTS
Despite no differences in fasting/postprandial insulin/glucose levels between MASLD/MASH individuals, IIT assays revealed a correlation between capacity to undergo IIT and liver stiffness score, indicating that MASH individuals were less likely to mount a sufficient IIT response, and MASLD individuals were more likely ($p=0.0411$). The IIT and WSB responses were highly heterogenous. Decreases in MASH vs MASLD IL-1β concentrations measured from viral-stimulated WBS reinforces the observed overall decrease in inflammatory responses in MASH vs MASLD ($p=0.0483$). There was reduced glucose tolerance in the MASH HFD mice vs MASLD HFD mice ($p<0.05$). There was an increase in fasting insulin and HOMA-IR in the MASH recipient mice vs MASLD recipient mice ($p<0.01$).

CONCLUSIONS
These RESULTS highlight differences in MASLD and MASH inflammatory profiles and reveal that transplantation of the gut microbiome alone is sufficient to induce phenotypic differences in the MASLD/MASH recipient mice. Current work is focusing on understanding the relationship between progression of disease and reduced inflammatory responses. Characterisation and exploration of the donor and mice recipient microbiomes is also ongoing.

EFFICACY OF PROBIOTIC-CONTAINING BUCCAL TABLETS ON HALITOSIS: AN IN VITRO AND IN VIVO STUDY

Yanyi Zheng[1]; Yang Hou[1]; Yujie Peng[1]; Zerong Lu[1]; Chaoran Zhang[1]; Jingya Huang[1]; Hua Zhang[1]; Lingling Zhao[1]
[1]Family Nutrition and Care, H&H Group, Guangzhou, China

BACKGROUND AND OBJECTIVES
Halitosis, recognized by an unpleasant odor emanating from the oral cavity, affects approximately 27.5% of individuals in China. Recently, probiotics have been investigated as an alternative treatment or prevention for halitosis, through modulation of oral microbiota, and inhibition of oral pathogens (e.g., *Fusobacterium nucleatum*). Evidence suggests that probiotics may alleviate bad breath within a short timeframe. Therefore, this study aimed to evaluate the inhibitory effect of specific probiotics (*L. helveticus* R0052, *L. rhamnosus* R0011 and *B. longum* R0175) on *F. nucleatum* ATCC25586 in vitro and to assess the impact of the probiotic-containing tablets on individuals with halitosis in vivo.

METHODS
The antimicrobial activity of the three selected probiotics was assessed based on their proportions in the tablet formulation. Biofilm formation was quantified using crystal violet staining. The effect of orally taken probiotics-containing tablets was investigated through a double-blind, placebo-controlled clinical trial involving 45 participants (aged 25-45 years) suffering from obvious bad breath (VSC＞150 ppb). Participants were randomly assigned into three groups, namely, control group (CG; placebo), low-dose group (LG; 3.3 billion CFU) and high-dose group (HG; 10 billion CFU). VSC levels were measured using OralChroma CHM-2 at baseline, 5 minutes (5 min) and 1 hour (1 h) after taking the tablets.

RESULTS
Co-culturing *F. nucleatum* ATCC25586 with the three probiotics resulted in a 97.47% reduction in the biofilm formation of *F. nucleatum* ATCC25586 ($p < 0.05$). In the clinical trial, both LG and HG exhibited significant decreases in VSC levels at both timepoints compared to baseline measurements ($p < 0.05$). In comparison to CG, the VSC level in HG decreased by 65.2% after 5 min ($p = 0.047$) and by 71.5% after 1 h ($p = 0.035$), while the reduction observed in LG was not statistically significant. This indicates that the efficacy of the probiotics-containing tablets in improving oral odor may be dose-dependent.

CONCLUSIONS
In summary, these findings suggest that the combination of *L. helveticus* R0052, *L. rhamnosus* R0011 and *B. longum* R0175 serves as an effective antimicrobial alternative against *F. nucleatum* ATCC25586. Furthermore, its breath-freshening effect on individuals with halitosis could persist for more than one hour following a single application.

NUTRITIONAL INTERVENTIONS IMPROVE THE MENTAL HEALTH AND QUALITY OF LIFE OF HEAD AND NECK CANCER PATIENTS

Sneha Patnaik[1, 2]; Shieh Tzong-Ming[3]; Shih-Min Hsia[4]; Yin-Hwa Shih[5]; Sharma Khemraj[6]
[1]Department of Healthcare Administration, Asia University, Taichung, Taiwan; [2]School of Public Health, KIIT-Deemed to be University, Bhubaneswar, India; [3]School of Dentistry, China Medical University Yingcai Campus, Taichung, Taiwan; [4]School of Nutrition and Health Science, Taipei Medical University, Taipei, Taiwan; [5]Healthcare Administration, Asia University, Taichung, Taiwan; [6]Asst. Director, International Relations, KIIT University, Bhubaneswar, India

BACKGROUND AND OBJECTIVES
Patients with head and neck cancer often encounter challenges with nutrition, which can negatively impact their mental health and overall quality of life. Our systematic review and meta-analysis was conducted to evaluate the effects of nutritional interventions on mental health and quality of life in patients undergoing treatment for head and neck cancer.

METHODS
A comprehensive literature search was conducted using five electronic databases (PubMed, CINAHL, ProQuest, Medline, and Scopus) to identify all potentially relevant RCTs and Quasi-experimental studies published in English between 2018-2024. Two reviewers evaluated the titles and abstracts before the full-text review. The Joanna Briggs Institute's critical appraisal tool was used to appraise the quality of studies. Meta-analysis was conducted using CMA software ver 3.0. The I2 test was used to assess between-study heterogeneity, and Egger's test qualitatively evaluated the presence of publication bias.

RESULTS
Four articles met the inclusion criteria and were subsequently incorporated into the meta-analysis. The forest plots reported significant improvement in quality of life metrics (SMD = 0.862, 95%CI: 0.349, 1.376, P=0.001) and reduction in anxiety (SMD = -0.941, 95%CI: -1.342, -0.540, P=0.000) and depression (SMD = -0.747, 95%CI: -0.993, -0.501, P=0.000) compared to controls. Symmetry in funnel plots and p-value >0.05 in Egger's regression test negates the presence of publication bias.

CONCLUSIONS
Our findings underscore the significant benefits that nutritional support provides for the mental health and quality of life of head and neck cancer patients. They also stress the importance of incorporating dietary strategies into their comprehensive treatment regimens.

SEX-DEPENDENT URINARY HIPPURIC ACID AS A BIOMARKER OF FRUIT AND NUTS INTAKE BASED ON THE EAT-LANCET INDEX

Edwin Fernandez-Cruz[1, 2]; Víctor de la O[1, 2]; Cristina M. Fernández-Diaz[3]; Núria Amigó-Grau[4]; Pilar Matía-Martín[5]; J. Alfredo Martinez[6, 2]
[1]Facultad de Ciencias de la Salud, UNIR | Universidad Internacional de La Rioja, Logroño, Spain; [2]Cardiometabolic group, IMDEA Food Institute, CSIC-UAM Campus, Madrid, Spain; [3]Molecular Oncology Group / GENYAL Clinical Trials Platform, IMDEA Food Institute (Madrid), Madrid, Spain; [4]Ciències Mèdiques Bàsiques, Universitat Rovira i Virgili, Tarragona, Spain, Spain; [5]Endocrinology and Nutrition Department, Hospital Clínico San Carlos. Instituto de Investigación Sanitaria San Carlos (IdISSC), Madrid, Spain, Spain; [6]Department of Endocrinology and Medicine, University of Valladolid, Valladolid, Spain, Spain

BACKGROUND AND OBJECTIVES

Assessing nutrient intake is crucial for understanding body homeostasis and interpreting the relationship between diet and health outcomes (1). Nutritional balance measurement (inputs/outputs) have traditionally relied on dietary questionnaires and quality indices (2). However, these methods are limited by the subjective nature of the questionnaires and the variability inherent in food composition tables (3). Such methodological inconsistencies can be partially addressed by developing biochemical markers of nutritional intake (4), which provide an objective tool to link dietary consumption with urinary metabolite excretions (5). In this context, hippuric acid has been associated with the intake of certain vegetable foods and products (6). The aim of this study is to evaluate the validity of determining hippuric acid excretion as a biomarker for fruit and nut consumption and to explore the potential influence of sex on these relationships.

METHODS

An NMR analysis was performed to study targeted metabolites (n=34) in urine samples from 138 participants (69,7% F), concerning the Dietary Deal project (ref. AC21/00038). Urinary metabolite concentrations were categorized based on median adherence to the EAT-Lancet index (7) through medians (≤p50 or >p50), using a validated Food Frequency Questionnaire (FFQ) to assess energy and dietary intake (8). Hypothesis-based correlations were performed to identify associations between the metabolites and the 14 groups included in the EAT-Lancet index. Linear regression analyses were conducted to explore the relationship between urinary hippuric acid output and the consumption of fruits and nuts, once adjusted for demographic, as well as energy-related and appropriate food variables.

RESULTS

The use of the EAT-Lancet index, stratified by medians, allowed the discrimination between high and low dietary intake of fruits ($p=0.012$), nuts ($p<0.001$), poultry ($p<0.001$), and milk or dairy products ($p=0.010$) but no other foods. Sex appears to influence urinary concentrations of hippuric acid ($p=0.020$), with a mean higher concentration of 44,7% in females, as found in other investigations. Regarding hippuric acid concentrations, an association with FFQ nut estimated consumption is found for the first time ($p = 0.049$), along with a corroborated trend with fruit FFQ intake ($p = 0.057$).

CONCLUSIONS

Hippuric acid shows great potential as a dietary biomarker for nut and fruit intake in healthy populations, where sex should be accounted to assess food consumption.

PHYSICAL CAPACITIES IN CONSTITUTIONAL THINNESS AND ANOREXIA NERVOSA ARE DIFFERENTIALLY ALTERED

Ahmad Noureddine[1, 2, 3]; Natacha Germain[1, 2, 4]; Margaux Leboulleux,[1]; Jade Ledoux,[1]; Chloé Exbrayat,[1, 4]; Leo Feasson,[3, 5]; Aurélia Gay[1, 6]; Baptiste Ravey[2, 6]; Catherine Massoubre[1, 2, 6]; Guillaume Y Millet[3]; Bogdan Galusca[1, 2, 4]; David Hupin,[7]

[1]TAPE research group, Jean Monnet University - North Campus Hospital, Saint-Priest-en-Jarez, France; [2]Eating disorder Reference center, Jean Monnet University - North Campus Hospital, Saint-Priest-en-Jarez, France; [3]Inter-university Laboratory of Human Movement Biology, F-42023, Jean Monnet University, Saint-Étienne, France; [4]Department of Endocrinology, Jean Monnet University - North Campus Hospital, Saint-Priest-en-Jarez, France; [5]Department of Clinical and Exercise Physiology, Jean Monnet University, Saint-Étienne, France; [6]Department of Psychiatry, Jean Monnet University - North Campus Hospital, Saint-Priest-en-Jarez, France; [7]Department of Clinical and Exercise Physiology INSERM U 1059, Jean Monnet University, Saint-Étienne, France

BACKGROUND AND OBJECTIVES

Physical capacities (PC) are linked to body weight and consequently body composition. Anorexia nervosa (AN) and constitutional thinness (CT) are two distinct conditions characterized by low body weight with different body composition and muscle phenotype. Data suggest altered PC in AN, whereas scarce recent studies indicate similar PC in CT, with no direct comparison between the two thin populations. This study aims to fill this gap and compare PC in women with AN, CT and a normal-weight control group (CON).

METHODS

A total of 84 women were included: 29 with AN, 24 with CT, and 31 healthy normal-weight women as CON. Leg extension and handgrip strength measurements as well as cardiopulmonary exercise testing (CPET) were performed. Subjective fatigue was also evaluated using the FACIT-F questionnaire. Pulse wave velocity and baroreflex sensitivity were recorded before the CPET. Fatigability was also assessed through the QIF test in a subset of 7 AN, 6 CT and 15 CON.

RESULTS

Maximal voluntary force in upper and lower body were both significantly lower in AN and CT compared to CON. Fatigue was lower in CON (FACIT-F score: 45.1±2.7) than in AN (32.8±2.7; $p=0.0003$) and CT (29.8±3.1, $p<0.0001$). VO2peak, maximal aerobic power (MAP) and VO2 at the first and second ventilatory threshold were significantly lower in CT and AN than in CON. MAP was significantly higher in CT than in AN. Exhaled gas volume was significantly lower in AN than in CON. Maximal lactate concentration was found to be higher in AN than CT and CON and lower in CT than in CON. The number of stages performed during the QIF test was significantly lower in CT than in CON (6.3±1.5 vs. 7.9±1.1, $p<0.05$), but no differences were observed between the groups for other parameters of the QIF test.

CONCLUSIONS

This study highlights both lower aerobic and muscular capacities in both AN and CT, with greater impact in CT. If these alterations in AN may directly be linked to undernutrition, they might appear more linked to deconditioned and altered muscle phenotype in CT. Subjective fatigue assessments showed a higher self-reported fatigue for both AN and CT, contrasting with relatively normal objective RESULTS. These findings have clinical implications. In AN, physical condition should be evaluated to tailor and time the implementation of an adapted exercise program appropriately. In CT, further examination of the potential role of adapted physical training in improving muscular and aerobic capacity, reducing fatigue, enhancing well-being, and supporting weight and muscle mass gains is warranted in this population.

CONFLICTS OF INTERESTS

EPO7_041

EXPLORING IRON DEFICIENCY IN PERNICIOUS ANAEMIA: A SURVEY OF DIAGNOSIS, TREATMENT AND MANAGEMENT PRACTICES

Alfie Thain[1]; Petra Visser[2]; Kathryn Hart[1]; Kourosh Ahmadi[1]
[1]Faculty of Health and Medical Sciences, University of Surrey, Guildford, United Kingdom; [2]Chief Officer, The Pernicious Anaemia Society, Bridgend, UK, United Kingdom

BACKGROUND AND OBJECTIVES
Pernicious anaemia (PA) is an autoimmune condition characterised by vitamin B12 deficiency due to the destruction of gastric parietal cells and subsequent loss of intrinsic factor [1]. Iron deficiency (ID) is commonly observed in PA and can present as ID with or without anaemia, single-occurrence ID, or recurrent ID, all of which pose unique management challenges. Despite its prevalence, formal guidelines for screening or managing ID in PA patients are lacking [2–4]. To address these gaps, this study investigates the diagnosis, management, and screening of ID among PA patients, with or without anaemia.

METHODS
An online survey was developed using Qualtrics and distributed to approximately 2068 members of the Pernicious Anaemia Society (PAS) to collect data on demographic characteristics, medical history, ID diagnosis and treatment, monitoring practices and symptoms. Ethical governance approval was provided by the University of Surrey's Research Innovation & Impact Office (EGA ref: 0499). Participant responses were anonymised and analysed descriptively using R software (2024.09.1+394).

RESULTS
Data collection is ongoing, but interim analysis was conducted for 202 participants (n=159 (79%) female; mean age 61, range: 24-91 years). Among respondents, n=119 (59%) reported experiencing ID, 61 experienced this both before AND after their PA diagnosis, while n=27 and n=31 reported ID occurring only before or after, respectively. Among those reporting recurring ID (n=74), n=30 (41%) indicated their ID was not well-managed. Iron tablets were the most common first-line treatment for those with iron deficiency n=81 (71%), followed by iron infusions n=10 (9%). Improvements in iron levels were reported by n=67 (59%), while n=37 (33%) had no follow-up blood tests. Symptom improvement following treatment was reported by n=64 (58%). Monitoring for ID was infrequent, with nearly 80% of participants (n=142) reporting no monitoring. Finally, n=49 (43%) of participants could not differentiate symptoms of iron deficiency from those of PA.

CONCLUSIONS
Iron deficiency among PA patients is often recurrent, poorly managed, and infrequently monitored, with variable treatment outcomes and insufficient follow-up. These findings highlight the need for clinical guidelines to address gaps in monitoring and treatment, considering the unique aetiology of ID and potentially overlapping symptoms in this population. Such efforts could enhance the diagnosis, monitoring, and management of PA-associated iron deficiency, ultimately improving outcomes and quality of life for patients.

BACKGROUND AND OBJECTIVES

Obesity and excessive adiposity have been associated with microbiota dysbiosis as well as with metabolic and homeostatic dysregulations (1). Some obesity phenotypes (e,g, Android vs Gynoid shapes) as well as sex have been related with different cardiometabolic risks rates (2), but the influence of the body fat morphological distribution has been scarcely investigated concerning interactions with microbiota abundance and taxonomic diversity. This study aims to analyze the relationship between waist circumference (WC), metabolic markers, and gut microbiota in women categorized by phenotypes based on fat accumulation according to the waist perimeter.

METHODS

A cross-sectional study was conducted including women (n=219) stratified in two groups based on the median WC (97 cm). Anthropometric measurements, body composition, and relevant metabolic markers were evaluated (3). Gut microbiota analyses based on 16S rRNA sequencing were studied employing hypothesis-driven statistical models. Beta diversity was assessed using PERMANOVA test (4).

RESULTS

Participants with high WC (>97 cm) exhibited higher body mass index (32.7 kg/m² vs. 24.5 kg/m², $p<0.001$), body fat percentage (43.4% vs. 32.5%, $p<0.001$), and visceral fat (11.0% vs. 6.5%, $p<0.001$), compared to the low WC group, respectively. Metabolic markers also differed significantly, with higher HOMA-IR (2.5 vs. 1.4, $p<0.001$), triglycerides (109.5 mg/dL vs. 80.0 mg/dL, $p<0.001$), and CRP (3.0 mg/L vs. 1.0 mg/L, $p<0.001$) in the high WC group. Fecal microbiota beta diversity evidenced statistically significant differences between both groups ($p=0.031$). *Prevotella* and *Bacteroides* showed discriminative opposite trends depending on the two analyzed fat distribution phenotypes.

CONCLUSIONS

This study highlights the significant associations between waist circumference (WC), metabolic markers, and gut microbiota composition in women. Findings reveal that individuals with the higher WC phenotype exhibit distinct metabolic outcomes, altered gut microbiota diversity, and specific bacterial profiles (e.g., *Prevotella* and *Bacteroides*) linked to fat distribution phenotypes. These RESULTS underscore the interplay between adiposity patterns and microbiota, offering newer insights into obesity-related health risks for precision nutrition.

NUTRITIONAL STATUS IS ASSOCIATED WITH PHYSICAL AND COGNITIVE PERFORMANCE OF OLDER ADULTS: A CROSS-SECTIONAL ANALYSIS OF THE CAPACITY OF OLDER INDIVIDUALS AFTER NUT SUPPLEMENTATION (COINS) TRIAL

Jeew Hettiarachchi[1]; Ilili Feyesa Regassa[1]; Robin M Daly[1]; Elena S George[1]; Ekavi N Georgousopoulou[2, 3]; David Scott[1]; Brenton J Baguley[1, 4]; Sze-Yen Tan[1]
[1]Institute for Physical Activity and Nutrition (IPAN), Deakin University, Geelong, Australia; [2]Discipline of Nutrition and Dietetics, Faculty of Health, University of Canberra, Canberra, Australia; [3]School of Medicine Sydney, University of Notre Dame Australia, Sydney, Australia; [4]Allied Health Research, Peter MacCallum Cancer Centre, Melbourne, Australia

BACKGROUND AND OBJECTIVES
Nutritional status is associated with both physical and cognitive performance in older adults. The Mini Nutrition Assessment (MNA) is a validated tool to assess older adults' nutritional status. This study aimed to investigate whether MNA scores are associated with physical and cognitive performance of community-dwelling older adults.

METHODS
This is a cross-sectional analysis of baseline data from the Capacity of Older Individuals after Nut Supplementation (COINS) randomised, controlled trial (ACTRN 12622001291774) that included adults aged ≥65 years and at-risk for falls. Participants were screened for malnutrition risk using MNA, consisting of i) MNA-Screening (range 0-14; at-risk/ malnourished if <11), and ii) MNA-Assessment (range 0-16, no cut-offs) components, with both MNA screening and assessment scores summed to iii) MNA-Total (range 0-30; at-risk/malnourished if <23.5). Appendicular lean mass (ALM) was measured using dual-energy x-ray absorptiometry. Physical performance (muscle strength, gait speed, balance and muscle power), was objectively measured using standard tests. Global cognitive performance was measured using the validated Montreal Cognitive Assessment (MoCA, range 0-30). Linear regression analyses were performed with age and sex as covariates.

RESULTS
120 participants were included (70% females, age=74.8±4.5y) in the analysis. MNA-Screening, MNA-Assessment and MNA-Total scores were (median [IQR]) 14 [12.0-14.0], 14 [13.5-15.0] and 27.5 [26.0-28.4] respectively. Malnutrition was found in 18 (15.0%) and 8 (6.7%) participants based on MNA-Screening and MNA-Total. Higher MNA-Screening scores were associated with higher ALM [β=1.28 (SE 0.45), p=0.006] and knee extension strength [β=1.36 (SE 0.65), p=0.039]. Higher MNA-Assessment scores were associated with faster gait speed [β=0.04 (SE 0.01), p=0.007], shorter timed up-and-go time [β=-0.19 (SE 0.09), p=0.035], and better MoCA scores [β=0.65 (SE 0.20), p=0.001]. Higher MNA-Total scores were also associated with higher ALM [β=0.80 (SE 0.33), p=0.018]. Malnutrition risk status, determined by MNA-Screening (but not MNA-Total), was associated with lower ALM [β=-3.98 (SE 1.19), p=0.001], but not strength, physical or cognitive performance.

CONCLUSIONS
In community-dwelling older adults, MNA-Screening scores were associated with muscle mass and strength, whereas the MNA-Assessment scores were associated with physical and cognitive performance. The differential associations found with various MNA component scores may be explained by the distinctive aspects of malnutrition risks they assessed.

MICROBIOTA-DIRECTED COMPLEMENTARY FOOD IMPROVES LINEAR GROWTH IN CHILDREN RECOVERING FROM SEVERE ACUTE MALNUTRITION

Ishita Mostafa[1]; Steven Hartman[2]; S. M. Tafsir Hasan[1]; Michael Barratt[2]; Jeffrey I. Gordon[2]; Tahmeed Ahmed[1]
[1]Nutrition Research Division, icddr,b, Dhaka, Bangladesh; [2]Center for Gut Microbiome and Nutrition Research, Washington University School of Medicine, St. Louis, St. Louis, United States of America

BACKGROUND AND OBJECTIVES

Globally, stunting affects ~150 million children under five, while wasting affects nearly 50 million. Severe acute malnutrition (SAM) is a major global health problem affecting 19 million children under five. There is limited knowledge regarding the children who were diagnosed with SAM, underwent therapeutic dietary intervention, were discharged as cured,and presented any outcome when followed for a longer period.

METHODS

Following treatment for SAM, we enrolled 124 children aged 12–18 months with moderate acute malnutrition (MAM). In a previously reported RCT, we observed a significant improvement in weight gain among these children who received microbiota-directed complementary food (MDCF) as dietary supplementation after three months of intervention. We monitored these children for two years following the intervention, measuring their weight-for-length, weight-for-age, and length-for-age z-scores every six months.

RESULTS

Children who received MDCF demonstrated significantly higher LAZ scores over time during follow-up compared to those who received ready-to-use supplementary food [linear mixed-effects model: b (95% CI) for MDCF X Month = 0.006 (0.003, 0.009); P < 0.001].

CONCLUSIONS

MDCF treatment of Bangladeshi children with post-SAM MAM produced significant improvements during intervention and reduced stunting during follow-up. These RESULTS indicate the effectiveness of supplementary foods for undernourished children and the sustainability of growth during the follow-up period. We suggest conducting prospective cohort studies with longer intervention periods to observe nutritional outcomes in these vulnerable child groups.

DYNAMIC CHANGES IN NUTRITIONAL AND SKELETAL MUSCLE INDICES AS PREDICTORS OF 5-YEAR SURVIVAL IN LIVER TRANSPLANT RECIPIENTS

YA-TZU TSAO[1]; I-Hsin Tseng[2]; Shih-Wei Nien[2]; I-Hsin Lin[2]
[1]Department of Medical Nutrition Therapy, Linkou Chang Gung Memorial Hospital, Taoyuan City, Taiwan;
[2]Department of Medical Nutrition Therapy, Linkou Chang Gung Memorial Hospital, Taipei, Taiwan

BACKGROUND AND OBJECTIVES
Nutritional status and muscle mass changes affect liver transplant outcomes. This study examined the prognostic value of changes in prognostic nutritional index (ΔPNI) and psoas muscle index (ΔPMI) on survival and mortality in liver transplant patients.

METHODS
A retrospective cohort study of 124 patients analyzed ΔPNI, ΔPMI, survival days, and mortality using Pearson correlation, logistic regression, and Kaplan-Meier survival analysis.

RESULTS
ΔPNI and ΔPMI significantly predicted mortality (ΔPNI: Exp(B) = 0.932, p = 0.006; ΔPMI: Exp(B) = 0.453, p = 0.002). A weak positive correlation was found between ΔPNI and ΔPMI (r = 0.253, p = 0.005).

CONCLUSIONS
Post-transplant changes in PNI and PMI are critical predictors of survival, emphasizing the need for targeted nutritional and rehabilitative interventions to improve outcomes.

ANALYSIS OF FACTORS INFLUENCING PRE-DIABETES IN RURAL CHINA AND EVALUATION OF INTERVENTION EFFECTS

Wang Shaokang[1, 2]; Lanlan Gui[1]; Xingyi Jin[3]
[1]Public health, Southeast university, najing, China; [2]Clinical Medical Research Center for Plateau Gastroenterological Disease of Xizang Autonomous Re, Xizang Minzu University, Xizang, China; [3]Public health, Southeast university, Nanjing, China

BACKGROUND AND OBJECTIVES
Pre-diabetes mellitus (PDM) is an inevitable stage in the development of DM, and it is also one of the high-risk factors of DM. This study intends to investigate the prevalence of PDM in rural middle-aged and elderly people, analyze its influence factors. At the same time, as to find potential biomarkers that can reflect blood glucose levels and be used for subsequent intervention effect analysis.

METHODS
A total of 4,158 eligible residents were recruited. The significant factors were screened by single factor analysis, and then the independent influence factors of PDM were studied by multifactorial logistic regression. 30 patients with normal blood glucose, 30 people with PDM and 30 people with DM were selected to form the control group, PDM group and DM group. Differential metabolites and key metabolic pathways were screened by principal component analysis, orthogonal partial least squares discriminant analysis, topological analysis of metabolic pathways and enrichment analysis. The intervention time was 3 months. Questionnaire survey, physical examination and biochemical test were conducted before and after the intervention. In addition, the levels of potential biomarkers in each group were detected after the intervention.

RESULTS
The detection rate of PDM in rural middle-aged and elderly population in Huai'an City, Jiangsu Province was 23.91%.The metabolites from normal blood glucose individuals to PDM and then to DM change with the change of fasting blood glucose and glycosylated hemoglobin, mainly involving amino acids and their derivatives, fatty acids and their derivatives, carbohydrates, organic acids and their derivatives. In addition, 1,5-anhydroglucitol can be used as a potential biomarker to reflect blood glucose levels. The occurrence of PDM and DM may be related to alanine, aspartic acid and glutamic acid metabolism, taurine and hypotaurine metabolism, glycine, serine etc.Three intervention programs can prevent or delay the occurrence and development of DM to a certain extent. Among them, the intervention program of diet combined with exercise has the best effect, followed by the effect of simple diet intervention, and finally the exercise intervention. It is necessary to pay attention to the dietary structure of rural PDM population with crop planting as the main means of survival and provide dietary guidance to prevent or delay the development of PDM into DM.

CONCLUSIONS
The RESULTS of this study show that the prevalence of PDM in rural middle-aged and elderly people living in Huaian City, Jiangsu Province for a long time is high.

DIETARY MODULATION FOR THE HYPERTENSION RISK GROUP IN KOREANS: A CROSS-SECTIONAL STUDY

Youngmin Han[1]; Ryun Huh[1]; Sun Ha Jee[1]
[1]Graduated school of public health, Yonsei University, Sinchon Campus, Seoul, Korea, Republic of

BACKGROUND AND OBJECTIVES
Hypertension (HTN) is a critical global health issue, contributing to high morbidity and mortality rates. Representative risk factors for HTN include aging, genetics, obesity, alcohol drinking, smoking, and diet. Dietary interventions like the Dietary Approaches to Stop HTN (DASH) diet plan are effective in preventing and managing HTN. We intend to comprehend the influence of eating patterns on HTN applying multiple risk factors.

METHODS
Among the Korean Cancer Prevention Study-II subjects, those who responded to the dietary questionnaire were included in this study. Individuals were grouped into four groups: optimal (*n*=7,712), normal (*n*=1,220), high normal (*n*=3,655), and HTN (*n*=4,355) according to the 2022 HTN treatment guidelines of Korea. Factor analysis was performed to identify major dietary patterns based on nutritional data obtained from a brief dietary questionnaire, including 17 food items. Finally, we conducted a moderation effect analysis to evaluate the contribution of these dietary patterns on the HTN risk score calculated by genetic variables, body mass index, alcohol consumption, and smoking status.

RESULTS
Three principal dietary patterns (Korean, Western, and New diets) were detected. Those foods placed high on the factor loading on the Korean diet pattern include grain, mixed protein sources, vegetables, and Kimchi. The Western diet pattern is centered on sugar, eggs, and oil, whereas the New diet pattern is defined by a high consumption of fruits and dairy products and a low sugar intake. In a moderation effect analysis, the Korean diet showed no significant effect on HTN risk in the HTN high-risk population, whereas the Western diet prevented HTN risk. The New diet presented a beneficial effect with a statistical significance borderline.

CONCLUSIONS
The nutritional moderation effect was proven in the HTN risk group, defined by various risk factors, including heredity, obesity, alcohol consumption, and smoking status. If the findings are validated by longitudinal investigation, our findings could serve as the basis for developing dietary guidelines for HTN.

EPO7_051

CITRUS POLYPHENOLS POTENTIATE ANTI-OBESITY EFFECT OF GREEN TEA

Hirofumi Tachibana[1]; Ren Yoshitomi[1]; Motofumi Kumazoe[1]; Yoshinori Fujimura[1]
[1]Department of Bioscience and Biotechnology, Kyushu University - Ito Campus, Fukuoka, Japan

BACKGROUND AND OBJECTIVES
Green tea, a widely consumed beverage in Asia, contains green tea polyphenols effective against obesity, especially epigallocatechin-3-O-gallate (EGCG), but must be consumed in an impractically huge amount daily to elicit its biological effect. Metabolic profiling-based data mining showed that eriodictyol, a type of citrus polyphenol, enhances the anticancer effect of green tea polyphenol EGCG 1). This study aimed to evaluate the anti-obesity effect of a combination of EGCG or green tea and citrus polyphenols.

METHODS
C57BL/6J mice were fed a normal diet, high-fat and high-sucrose diet (HF/HS), HF/HS with green tea extract diet, HF/HS with eriodictyol diet, or HF/HS with green tea extract and eriodictyol diet. In a randomized, placebo-controlled, double-blinded, and parallel-group-designed clinical trial, 60 healthy Japanese males and females aged 30–75 years consumed green tea combined with α-glucosyl hesperidin, a type of citrus polyphenol at doses that have not been previously reported to exert anti-obesity effects by themselves in any clinical trial for 12 weeks.

RESULTS
In mice fed with high-fat/high-sucrose diet, green tea and eriodictyol combination prevented weight gain. At week 12, green tea combined with α-glucosyl hesperidin prevented weight gain and reduced body mass index (BMI) compared with the placebo. Especially in those aged < 50 years, triglyceride and body fat percentage decreased at week 6, visceral fat level and body fat percentage decreased at week 12; body weight, BMI, and blood LDL/HDL ratio also decreased.

CONCLUSIONS
Taking green tea combined with α-glucosyl hesperidin prevents weight gain, and the anti-obesity effect of green tea combined with α-glucosyl hesperidin was more pronounced in people aged < 50 years.

FROM POLYGENIC RISK TO DIETARY BALANCE: EXPLORING FAT INTAKE AND DEMENTIA RISK

Shuo Jiang[1]; Jingqi Zhou[1]; Jiawen Huang[1]; Hui Wang[1]
[1]School of public health, Shanghai Jiao Tong University School of Medicine, Shanghai, China

BACKGROUND AND OBJECTIVES

The relationship between dietary fat intake and dementia remains controversial, and the influence of genetic risk profiles on this association is poorly understood. This study examines the interactions between genetic factors related to fat intake, disease susceptibility, and various types of dietary fats in influencing the risk of all-cause dementia.

METHODS

This study analyzed 97,765 adults of European ancestry from the UK Biobank. Participants without cognitive impairment or dementia at baseline (2006–2010) who completed at least two dietary assessments were included in the study and followed until 2022. Dietary fat intake, including specific fatty acids, total cholesterol, and fats from vegetable and animal sources, was evaluated using 24-hour dietary recalls conducted from 2009 to 2012. A polygenic risk score (PRS) based on 12 single nucleotide polymorphisms was used to assess genetic variability in fat intake. PRS for dementia and *APOE* genotype (ε2 and ε4 status) were also calculated to evaluate disease predisposition. Associations between dietary fat intake and incident dementia were analyzed using multivariable-adjusted Cox proportional hazards models in the overall sample and subgroups defined by genetic variation.

RESULTS

During a median follow-up of 10.5 years, 985 cases (97.3/100,000 person-years) of all-cause dementia were identified. Non-linear associations were observed for various dietary fats. Total fat, total cholesterol, monounsaturated fatty acids, vegetable fat intake, and the vegetable-to-total fat ratio exhibited U-shaped relationships with dementia risk. Conversely, n-3 and n-6 polyunsaturated fatty acids showed L-shaped associations, with optimal intake thresholds of 1.43 g/day and 9.51 g/day, respectively. The association between cholesterol intake and dementia was stronger in participants with moderate-to-high PRS for fat intake (*P* for interaction=0.024). Similarly, the relationship between the vegetable-to-animal fat ratio and dementia risk was more pronounced in non-*APOE* carriers (*P* for interaction=0.035).

CONCLUSIONS

Dietary fat quantity and composition significantly influence dementia risk. Moderate fat consumption and a balanced intake of fats from animal and vegetable sources may provide protective effects. Personalized dietary recommendations, tailored to individual genetic backgrounds, are crucial for dementia prevention, particularly regarding cholesterol intake and the vegetable-to-total fat ratio.

CONFLICTS OF INTERESTS

RISK OF MALNUTRITION IS ASSOCIATED WITH LOWER HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH CHRONIC KIDNEY DISEASE TREATED WITH HEMODIALYSIS

Mikaela Dietrichson[1]; Karin Windahl,[2, 3]; Ylva Orrevall,[4, 5]; Harriët Jager-Wittenaar,[6, 7, 8]; Jenny Stenberg,[9]; Sandra Einarsson,[1]

BACKGROUND AND OBJECTIVES

Malnutrition is a common complication in chronic diseases, such as chronic kidney disease (CKD), and is linked to poorer survival rates and reduced health-related quality of life (HRQoL). The aim was to investigate the association between risk of malnutrition and physical HRQoL in patients with CKD treated with hemodialysis.

METHODS

A cross-sectional study was conducted at a university hospital in Sweden, and patients with CKD (age ≥18 years) treated with hemodialysis (duration >3 months) were recruited in August-September of 2024. Risk of malnutrition was assessed as part of clinical routine, using the Scored Patient-Generated Subjective Global Assessment Short Form (PG-SGA SF). This instrument includes scoring of items related to body weight, food intake, nutrition impact symptoms (NIS), and activity and function as self-reported by the patient. Cut-off score for risk of malnutrition was set at ≥4 points. HRQoL was measured with RAND-36, a 36-item instrument that assesses eight health concepts including both physical and mental health. Of the RAND-36, the physical HRQoL concepts energy/fatigue, physical functioning and role limitations due to physical health were assessed. Higher scores for the concepts (0-100) indicate better perceived health. Demographic and medical data were collected from the Swedish Renal Registry. The Mann-Whitney U-test was used to test for differences in HRQoL between those with or without risk of malnutrition.

RESULTS

In total, 69 of 74 eligible patients gave their written consent to participate, i.e., 43 men and 26 women. Mean age was 66.6 ±14.6 years and 25 patients (missing n=9) had diabetes. Mean time on dialysis was 48.9 months (min 3.7, max 198.8) and 30 patients (missing n=6) had risk for malnutrition. In total, 52 patients responded to both RAND-36 and PG-SGA SF. In patients with risk of malnutrition, all HRQoL concepts related to physical health were significantly lower; energy/fatigue (median HRQoL score 40 vs. 55, *p=0.003*), physical functioning (median HRQoL score 25 vs. 55, *p=0.020*), role limitations due to physical health (median HRQoL score 0 vs. 50, *p=0.002*).

CONCLUSIONS

In patients with CKD treated with hemodialysis, HRQoL concepts related to physical health are impaired in patients with risk of malnutrition. Finding patients at risk of malnutrition in time is of utmost importance, so that nutritional interventions can be timely initiated, with the aim to prevent low physical HRQoL.

BACKGROUND AND OBJECTIVES

Polyphenols are bioactive compounds present in plants, recognized for their potential protective effects against chronic diseases. However, dietary polyphenols undergo extensive metabolism, during digestion in the small intestine and later in the the gut, where the microbiota generates news compounds that may have distinct biological activities (Del Rio et al., 2013). This study aimed to profile a broad panel of urinary phenolic compounds derived from dietary polyphenols and explore their associations with adherence to the Mediterranean diet (MedDiet), as well as with its individual components.

METHODS

Data from a nested case-cohort study within the PREDIMED trial involving 1,180 participants was used for this study. A state-of-the-art methodology capable of detecting 150 urinary phenolic compounds using quadrupole time-of-flight liquid chromatography-tandem mass spectrometry was employed. Adherence to the MedDiet was assessed using the validated Mediterranean Diet Adherence Screener (MEDAS) questionnaire (Schröder et al., 2011). Correlations between individual standardized metabolites with the MEDAS score, as well as with each food component, were performed using Pearson correlation coefficient (ρ).

RESULTS

A total of 65 phenolic metabolites were identified and quantified in urine, primarily comprising phase-2 and microbial metabolites of dietary polyphenols. Most metabolites showed positive correlations with overall MedDiet adherence as assessed by MEDAS. When analyzing individual items included in the MEDAS, metabolites exhibited the strongest positive associations with consumption of fruits, wine and nuts. Specifically, fruit intake correlated with flavonoids and phenolic acids derived from them ($\rho > 0.1$) (Neveu et al., 2010). Wine consumption was associated with stilbene-derived metabolites ($\rho > 0.3$), such as resveratrol, and tyrosol derivatives ($\rho > 0.09$) (Neveu et al., 2010). Nuts intake showed correlations with urolithins and their phase-2 metabolites, originating from dietary ellagitannins ($\rho > 0.15$) (Garcia-Villalba et al., 2022).

CONCLUSIONS

This study identified a diverse panel of urinary phenolic metabolites linked to dietary polyphenols and their associations with MedDiet adherence and specific food components. These findings pave the way for the development of a novel urinary fingerprint to assess intake of specific foods and their role in diet-related health outcomes.

THE EFFECT OF DIETARY FIBER INTAKE ON NUTRITION IN HEMODIALYSIS PATIENTS

Hung-Lien Wu[1]; An-Bang Wu[2]; Te-Hui Kuo[3]
[1]Department of Nutritional Services , National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan; [2]Division of Nephrology, Department of Internal Medicine, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan; [3]Department of Internal Medicine, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan

BACKGROUND AND OBJECTIVES
Dietary fiber intake is often lower in hemodialysis (HD) patients, because of decreased intake of fruits and vegetables for restricted dietary potassium. The objectives of the study was to investigate the effect of dietary fiber intake on nutrition in our HD population.

METHODS
We include 102 HD patients, mean age 61.8± 12.4 years old, we assessment fiber intake, subjective global nutritional assessment (SGA), macronutrients, anthropometry. Mean dietary fiber intake is 11.9 g ± 2.7 g/day, all patients were divided dietary fiber intake <=11.0 g/day (low fiber group) and dietary fiber intake > 11.0 g/day (high fiber group).

RESULTS
Lower dry weight (58.4 ±10.9 vs 64.1 ±15.1 kg, $P < 0.005$) and BMI (22.3 ± 3.6 vs 24.8 ± 4.9 kg, $P < 0.005$) in the higher fiber group than low fiber group. In SGA, high fiber group had significantly higher score than low fiber group in appetite score (6.1 ± 0.8 vs 5.5 ± 1.3 score, $P < 0.01$) , GI function score (6.1 ± 0.8 vs 5.5 ± 1.3 score, $P < 0.05$) , metabolic stress score (5.6 ± 0.8 vs 5.1 ± 1.0 score, $P < 0.05$) , total score (5.7± 0.6 vs 5.2 ± 0.9 score, $P < 0.005$). Total daily energy (1849 ± 332 vs 1558 ± 320 kcal/day, $P < 0.0001$ and 32.1 ± 5.1 vs 27.5 ± 5.4 kcal/ IBW kg, $P < 0.0001$), protein (1.3 ± 0.2 vs 1.1 ± 0.2 g/IBW Kg, $P < 0.001$), and carbohydrate (228.4 ± 53.2 vs 190.2 ± 37.1 Kcal/day, $P < 0.05$) in high fiber group had significantly higher than low fiber group. In anthropometry, high fiber group had significantly lower than low fiber group as mid-arm circumference (MAC) (26.3 ± 3.3 vs 28.1 ± 3.7 cm, $P < 0.05$) and triceps skinfold thickness (TS F) (18.2 ± 10.2 vs 24.1 ± 11.8 mm, $P < 0.05$), but in muscle strength, HGS and PS had higher in the higher fiber group than low fiber groups, but there were no significantly difference.

CONCLUSIONS
Higher dietary fiber intake in HD patients had good nutritional status, higher energy and protein intake, and lower body fat. In clinical practice, we suggested HD patients to intake more dietary fiber.

UNVEILING SEX DIFFERENCES: HOW TRADITIONAL CALORIC RESTRICTION OR TIME-RESTRICTED EATING IMPACT EMOTIONAL EATING IN ADULTS WITH FATTY LIVER DISEASE

LORENA LOPEZ LORA[1]; Laura Rubio Gordón[1]; Jose Antonio Celada[1]; Yolanda Jimenez Perez[1]; Andrés López González[1]; José María Ordovás[1]; Lidia Daimiel Ruiz[1]
[1]NUCONEP, IMDEA Food, UAM + CSIC, Madrid, Spain

BACKGROUND AND OBJECTIVES
The Emotional Eating Questionnaire (EEC) assesses the relationship between emotions and eating habits, particularly in response to emotions like stress or anxiety. ECC RESULTS can affect parameters such as physical activity and total energy intake. Differences in body composition and physical activity between sexes may influence intervention outcomes, making sex-based segmentation crucial for improving accuracy and relevance in nutritional studies. This study evaluates the impact of traditional caloric restriction and time-restricted eating on emotional eating in male and female adults with fatty liver disease.

METHODS
We aim to recruit 177 participants, aged 50-70 years, with a BMI of 25-40 kg/m² and incipient fatty liver disease assessed by the FLI index. Participants are randomly allocated into three groups: control group (CG) following an unrestricted Mediterranean diet (MedD), CR group (25% energy-reduced MedD), and TRE group (14-hour daily fasting). The six-month intervention includes assessments at 0, 3, and 6 months for BMI, visceral fat index, waist circumference, fat mass %, and lean mass. Emotions impact on eating behaviour was evaluated using the CCE questionnaire, and group differences in CCE changes were analysed with ANCOVA adjusted for age and sex. Linear regression examined baseline CCE scores relationship with changes in weight and body composition, adjusted by age and sex.

RESULTS
Both TRE and RC groups increased the CCE score, although this increase was greater and significant only in RC group. TRE showed a decrease in the CCE score in comparison with RC group. The sex segregation analyses showed that men decreased the CCE score in both intervention arms, but this decrease was significant only in TRE group. However, women increased CCE score in both groups, although only the increase in RC group was significant. A higher baseline CCE was associated with an increase in muscle mass, BMI and physical activity in men.

CONCLUSIONS
TRE improves the impact of emotions on eating behaviour more in men, while it worsens the impact of emotions on eating behaviour less in women to traditional calorie restriction. In men, high emotional components are linked to greater motivation for physical activity and increased muscle mass. These findings highlight the need for further research on the intersex variable in the emotional modulation of nutritional outcomes, a critical factor for designing targeted interventions.

POTENTIAL BIOMARKERS FOR SARCOPENIA BASED ON METABOLISM, STEROID HORMONE AND INFLAMMATION

Jiayu Guo[1]; Kang Yu[1]
[1]Clinical Nutrition, Peking Union Medical College Hospital, Beijing, China

BACKGROUND AND OBJECTIVES

Sarcopenia, a prevalent condition affecting 10-27% of older adults [1], is linked to various biological processes such as metabolism, hormone regulation, and inflammation [2]. Easily measurable biomarkers that provide early and precise assessment of sarcopenia are crucial but remain inadequate [3-5]. This study aimed to identify potential biomarkers for sarcopenia based on these mechanisms and to assess their impact on muscle-related parameters.

METHODS

Serum samples were collected from 44 individuals aged 65 and older, divided into a sarcopenia group and an age-matched control group. These samples were analyzed for metabolic profiles, steroid hormone levels, and inflammation markers. Using t-tests and the OPLS-DA analysis, we identified biomarkers that significantly differed between the two groups. After adjusting for confounding factors, such as gender, age, and lifestyle, we examined the association between these biomarkers and muscle-related parameters through multiple linear regression.

RESULTS

Our RESULTS revealed that individuals with sarcopenia had notably different levels of cortexolone, dehydroepiandrosterone (DHEA), IL-6, and 74 metabolites primarily related to lipid and lipoprotein metabolism, amino acids, and fatty acids. Specifically, creatine levels were negatively correlated with skeletal muscle mass index (SMI) (β=-0.01, P=0.038) and grip strength (β=-0.20, P=0.004), while DHEA levels were positively correlated with both SMI (β=0.08, P=0.032) and grip strength (β=0.81, P=0.034). Additionally, Fructose (β=-0.22, P=0.049) and DPA (β=-0.37, P=0.043) levels were negatively associated with SMI, meanwhile methylmalonyl-carnitine levels showed a positive correlation with grip strength (β=4.51, P=0.009).

CONCLUSIONS

Several biomarkers related to metabolism, steroid hormones, and inflammation were identified and validated as being associated with sarcopenia-related parameters. These findings suggest potential biomarkers for early detection and intervention, though further validation is needed.

BACKGROUND AND OBJECTIVES

Intermittent fasting is emerging as an effective intervention to improve cardiovascular risk parameters. However, the RESULTS are contradictory. This study evaluates the effects of three dietary approaches: Mediterranean diet, caloric restriction (CR), and time-restricted eating (TRE), on anthropometric measures, including body composition.

METHODS

We aim to recruit 177 participants, men and women 50-70 years old with BMI-25-40 Kg/m2 and incipient fatty liver disease assessed by the FLI index. Participants are randomly allocated into three groups: control group (CG) following an unrestricted Mediterranean diet (MedD), CR group (25% energy-reduced MedD) , and TRE group (14 hour of daily fasting). The intervention lasts six months, with anthropometric and body composition assessments at 0, 3 and 6 months. Measured outcomes included body mass index (BMI), visceral fat index, waist circumference, fat mass percentage, and lean mass (kg). Body composition was evaluated with a Tanita scale and dual-energy X-ray absorptiometry (DEXA). Changes over time were analyzed using mixed linear models with time, age, and sex as fixed effects and participant as a random effect. The agreement between Tanita and DEXA was assessed.

RESULTS

All groups showed significant reductions in waist circumference. Visceral fat index improved significantly in the CR and TRE groups. BMI improved significantly in the TRE group. Fat mass significantly decreased in the CR and TRE groups, while lean mass remained unchanged with DEXA in all groups. Tanita measures indicated a significant lean mass decrease in the CR group. Notably, Tanita underestimated fat mass and overestimated lean mass compared to DEXA.

CONCLUSIONS

Preliminary RESULTS suggest that TRE improves body composition parameters more than CR without compromising lean mass. Discrepancies between Tanita and DEXA highlight the importance of measurement method selection in assessing body composition.

COMPARISON OF CT AND BIA IN THE ASSESSMENT OF BODY COMPOSITION IN ELDERLY PATIENTS WITH SARCOPENIA

Qiong Wang[1]; Kang Yu[1]
[1]Clinical Nutrition, Peking Union Medical College Hospital, Beijing, China

BACKGROUND AND OBJECTIVES
Sarcopenia is defined as a syndrome with decline in muscle mass and strength associated with functional decline. Accurate methods for assessing body composition in elderly patients with sarcopenia are essential to determine muscle condition as well as monitor therapeutic interventions. The purpose of our study was to compare the accuracy of measurements of body composition made using analysis of computed tomography (CT) scans at the L3 vertebral level, and bioelectrical impedance analysis (BIA).

METHODS
The diagnosis of sarcopenia were based on the definition of primary sarcopenia produced by the Asian Working Group for Sarcopenia (AWGS). CT and BIA were performed in 34 patients recruited from a clinical trial investigating age-related sarcopenia with no more than seven days apart. CT image slices at the third lumbar vertebrae (L3) level were analyzed using SliceOmatic V4.2 software (Tomovision, Montreal, Canada) to calculate the surface area of the muscle tissue and adipose tissue.

RESULTS
Our RESULTS show strong correlations between fat-free mass on CT and BIA ($r=0.8696, P<0.0001$) and fat mass on CT and BIA ($r=0.9255, P<0.0001$). On Bland–Altman analysis, two methods showed ideal consistency. Average bias for fat-free mass on CT and BIA was -4.3289 with 95% limits of agreement (LOA) of –10.0020 to 1.3443. For fat mass on CT and BIA, average bias was 2.8717, with LOA of –1.8720 to 7.6155.

CONCLUSIONS
Our study showed that BIA underestimated fat mass and overestimated fat-free mass compared with CT when assessing sarcopenia. If patients with sarcopenia are overestimated by using the BIA method to assess muscle mass, appropriate treatments including nutritional and exercise interventions may be delayed and may affect prognosis.

DISTINCT POSTPRANDIAL METABOLIC AND INFLAMMATORY RESPONSES IN HEALTHY INDIVIDUALS VS PATIENTS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE AND METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS

Sinéad Mullin[1]; Christopher E Shannon[2]; Sarah E Lawler[3]; Méabh Ní Chathail[1]; Pamla Singh[4]; Norris Suzanne[4]; Helen Roche[5]
[1]Nutrigenomics Research Group, Conway Institute, and Institute of Food and Health, School of Public Health, Physiotherapy, and Sports Science, University College Dublin, Dublin, Ireland; [2]Nutrigenomics Research Group, Conway Institute, and School of Medicine, University College Dublin, Dublin, Ireland; [3]Nutrigenomics Research Group and Conway Institute, University College Dublin, Belfield, Dublin 4, Ireland, Dublin, Ireland; [4]Hepatology Department, St James's Hospital, Dublin, Ireland; [5]Nutrigenomics Research Group, UCD Conway Institute, School of Public Health, Physiotherapy and Sports Science, Institute for GFS, QUB., Dublin, Ireland

BACKGROUND AND OBJECTIVES
Metabolic dysfunction-associated steatotic liver disease (MASLD) is a spectrum of conditions from simple steatosis to metabolic dysfunction-associated steatohepatitis (MASH), characterized by inflammation and fibrosis. Low-grade systemic inflammation, possibly driven by crosstalk between immune and metabolic pathways, may play a crucial role in the progression to MASH, wherein dietary responses and/or microbiome metabolites may contribute to this inflammatory-fibrotic state. This research aimed to explore whether postprandial metabolic and inflammatory responses to dietary triggers, e.g. saturated fat or fructose, may provide insights into the mechanisms driving the MASLD-MASH transition. Or indeed, better define MASLD vs MASH phenotypes.

METHODS
34 patients with obesity and MASLD and 10 non-obese healthy controls were recruited. Patients with MASLD were stratified according to liver fibrosis score (FibroScan; F0/1 MASLD, n = 18; F2/3 MASH, n = 16). MASLD, MASH, and healthy completed a high-fat mixed meal test (46g fat (33g saturated fat), 50g carbohydrates, 10g protein). MASLD and MASH also completed a high-fructose / glucose challenge (75g fructose, 25g glucose). Blood samples were drawn over 6-hours to evaluate metabolic (glucose, insulin, triglycerides (TAG), non-esterified fatty acids (NEFA)), inflammatory (IL-6) and metabolite responses. *Ex-vivo* cytokine (IL-1β, IL-6, CCL3) responses to bacterial (TLR2/4) and viral (TLR7/8) ligands were determined in whole blood.

RESULTS
Insulin resistance, determined by HOMA-IR, was greater in MASLD and MASH vs healthy. Postprandial increases in glucose, insulin and TAG were significantly greater in patients with MASLD and MASH compared to healthy, but were similar between MASLD and MASH. Plasma IL-6 responses were also similar between MASLD and MASH. Interestingly whole blood inflammatory profiles were distinctly different. MASLD, but not MASH, exhibited greater whole blood cytokine responses to bacterial and viral ligands compared to healthy. The IL-1β response to viral ligands was higher in MASLD versus MASH.

CONCLUSIONS
The preliminary data suggests that whilst a continuum of postprandial metabolic dysfunction presents in MASLD vs MASH, there are nuances with respect to inflammatory responses which may/may not explain fibrotic disease progression.

STUDY ON THE EFFECTS OF CHOLESTEROL LOWERING AND ANTIOXIDANT EFFECTS OF PHYTOSTEROLS AND PHYTOSTEROLS COMBINED WITH PHOSPHOLIPIDS ON SUBJECTS WITH ELEVATED BLOOD CHOLESTEROL MARGINS

Guiju Sun[1]; Hui Xia[2]; Wang Liao[1]; Shaokang Wang[1]
[1]School of Public Health, Southeast University, Nanjing, China; [2]Department of Nutrition and Food Hygiene, School of public health, Southeast University, Nanjing, China

BACKGROUND AND OBJECTIVES
It has been reported that Phytosterols (PSs) have cholesterol-lowering effects, but due to their poor oil solubility and insolubility in water, their bioavailability is low, which may affect the other health effects of PSs. Phospholipids (PLs) as emulsifiers can significantly improve the solubility of PSs. The aim of this study was to examine the effects of PSs and PSs combined with PLs in the prevention and management of disorders associated with dyslipidemia.

METHODS
This study has passed the ethical qualification examination of the Ethics Committee of Dongtai People's Hospital (ethics approval number: 2023-dtry-K048-PJ). A total of 88 volunteers were included and randomly assigned to 3 groups based on inclusion and exclusion criteria. Placebo control was adopted. Each person in the phytosterols group (PS group) took 2g phytosterols +1.3g wheat starch daily, each person in the phytosterols + phospholipids group (PS+PL group) took 2g phytosterols +1.3g phospholipids daily, and each person in placebo group (CON group) took 3.3g wheat starch daily. The samples were divided into capsules and taken with meals. The intervention duration was 2 months. Blood samples were collected and serum liver and kidney function, blood lipids, lipid metabolizing enzymes and oxidative stress related indexes were measured.

RESULTS
A total of 88 eligible volunteers were included, including 29 in PS group, 30 in PS+PL group and 29 in CON group. After 2 months of intervention, the serum levels of TC, LDL-C and ApoB in the two intervention groups were decreased. From the longitudinal comparison, serum alanine aminotransferase (ALT) and lactatedehydrogenase (LDH) of PS+PL group were significantly decreased ($P < 0.05$). Serum ALT level was markedly decreased ($P < 0.05$) in PS group too. After 2 months of intervention, oxLDL content, MDA content, MPO activity and ROS fluorescence value in serum were reduced in the two intervention groups significantly, while CAT activity and GSH-Px activity were significantly increased ($P < 0.05$). Compared with CON group, serum ox-LDL content, MPO activity and ROS fluorescence in PS+PL group and PS group significantly decreased after intervention. After intervention, visceral fat area (VFA) in CON group was significantly increased, while body weight, waist circumference and diastolic blood pressure were significantly decreased in PS+PL group ($P < 0.05$).

CONCLUSIONS
PSs and PSs and PLs combined intervention can significantly improve the lipid metabolism and oxidative stress level of this population.

A MISALIGNMENT BETWEEN GENETIC AND SUBJECTIVE CHRONOTYPES INCREASES SATURATED FAT INTAKE. THE MYFOOD4SENIOR PROJECT

Cristina ÁLvarez-Martín[1]; María Benavent[1]; Matilde Sousa[1]; Violeta Fajardo[1]; Angela García-González[1]; María Purificación González[1]; Natalia Ubeda[1]; María Achón[1]; Rocío de la Iglesia González[1]; Elena Alonso-Aperte[1]
[1]Departamento de Ciencias Farmacéuticas y de la Salud, CEU San Pablo University, Madrid, Spain

BACKGROUND AND OBJECTIVES
Chronobiology and its influence on physiological and behavioural processes have significant potential in healthy aging. Chronotype is determined by the rs1801260 *CLOCK* single nucleotide polymorphism, but life-long training and social environment may develop a different chronotype. The aim of the present study was to identify people with misalignment between genetic chronotype and acquired daily habits, and to test whether this may affect body composition or dietary intake.

METHODS
A total of 120 individuals aged 65 and older were genotyped and classified as morning or evening types according to *CLOCK* rs1801260. The Horne and Östberg morningness-eveningness questionnaire was used to measure genotype subjectively and categorize individuals as morning, intermediate or evening types according to their preferred daily routines and habits. If the questionnaire RESULTS did not align with the genotype, a misalignment between subjective chronotype and genetic predisposition was identified. A validated 3-day dietary record was used to record diets, and BIA to measure body composition.

RESULTS
According to the questionnaire, 55.8% were classified as morning types, 42.5% as intermediate types, and 1.7% as evening types. However, regarding the genetic predisposition for the *CLOCK* gene, 49.2% were found to be morning types (A/A) and 50.8% were evening types (A/G + GG). We observed that 54.1% of those genetically identified as evening types followed morning type habits. A misalignment between the subjective and genetic chronotypes was observed in 70.8% of the individuals. No association was found between chronotype misalignment and the body fat, consumption of fruits, vegetables and legumes, or the intake of omega-3 fatty acids. However, a significant association was found between the intake of saturated fatty acids and chronotype misalignment ($p = 0.005$). Specifically, 92.9% of individuals with chronotype misalignment were identified as having inadequate dietary consumption of saturated fatty acids by the diet ($p = 0.005$).

CONCLUSIONS
Despite genetic predisposition, life-long acquired habits can lead to the development of one chronotype over another. This phenomenon may affect dietary intake, particularly with regard to saturated fat intake.

SELF-REPORTED GASTROINTESTINAL DISCOMFORT, CAN FERMENTED SKIM MILK POWDER OFFER RELIEF?

Martina Rooney[1]; Bernadette Finnerty,[2]; Grace Bennett[3]; Eimear Gregory,[4]; Clíona Ní Chonnacháin[5]; Conor Carey,[2]; Emma Feeney[4]; Alice Lucey[2]
[1]Co-Centre for Sustainable Food Systems, University College Dublin, Dublin, Ireland; [2]School of Food and Nutritional Scienes, University College Cork, Cork, Ireland; [3]Quadram Institute, Quadram Institute, Norwich, United Kingdom; [4]Institute for Food and Health, University College Dublin, Dublin, Ireland; [5]School of Agriculture and Food Science, University College Dublin, Dublin, Ireland

BACKGROUND AND OBJECTIVES
Gastrointestinal discomfort is widespread and carries both economic and social consequences (1). Limited evidence exists on potential dietary treatments to support gastrointestinal health in non-inflammatory bowel disease (IBD) populations. In-vitro studies have demonstrated that targeted fermented dairy products may have the capability to improve human gut health (2). This study aims to investigate the potential of a fermented skimmed milk powder to improve digestive health and quality of life in a non-patient cohort.

METHODS
In an 8-week parallel, double-blind randomised controlled trial, *n* 146 adults aged 20-45 years with self-reported gastrointestinal symptoms consumed 20g/day of a fermented skimmed milk powder (FSMP), skimmed milk powder (SMP) or maltodextrin. Groups were allocated on a 3:1:1 basis. Validated questionnaires were used to collect information pre- and post-intervention using the Functional Digestive Disorders Quality of Life (FDDQoL) (3), the Bristol Stool Form Scale (BSFS, 4) and Patient Assessment of Constipation Quality of Life (PACQoL) (5). ANOVA adjusting for baseline values, age, sex, baseline BMI and study site was performed using SPSS. The trial is registered as ISRCTN17696788.

RESULTS
A total of *n* 89 (64%) female subjects completed the trial, with a mean ± SD age of 34.9 ± 5.8 years and a BMI of 26.1 ± 4.4 kg/m2. In preliminary analyses, a 'normal' stool consistency was reported by *n* (49.1%) pre-intervention, and *n* 21 (38.2%) post-intervention, with no differences in response across groups (P=0.183). Within the 'Discomfort' domain of the FDDQoL, comfort score increased by a greater extent in the SMP group (16.1 ± 0.1) vs FSMP (6.9 ± 0.8, P=0.029) and maltodextrin (2.1 ± 1.3, P=0.11) compared to baseline. There were no differences in any PACQoL domains across groups at baseline or in response to treatment.

CONCLUSIONS
Sub-clinical gastrointestinal discomfort is prevalent in populaitons worldwide, although studies in non-patient/non-IBD cohorts are lacking. Preliminary analysis indicates FSMP and SMP may have some beneficial effects on aspects of functional digestive disorder in a non-clinical cohort, compared to an energy-mathed maltodextrin control. Further analysis will determine the potential of fermented or non-fermented skimmed milk powder to releive gastrointstinal symptoms in a non-patient cohort.

A NOVEL PERSONALISED NUTRITION INTERVENTION WITH TAILORED BEHAVIOURAL SUPPORT TO PROMOTE LEGUME CONSUMPTION IN UNIVERSITY STUDENTS

Patrick Elliott[1]; Lauren Devine[1]; Eileen Gibney[1]; Aifric O'sullivan[1]
[1]UCD Institute of Food and Health, School of Agriculture and Food Science, University College Dublin, Dublin, Ireland

BACKGROUND AND OBJECTIVES
Personalised nutrition (PN) interventions have primarily focused on using differences in biological traits to generate PN advice (1). Such advice is purported to promote larger, more appropriate, and sustained changes in dietary behaviour relative to generic dietary advice (2). However, evidence on the effect of PN interventions on dietary behaviour change is mixed, particularly when behavioural support is balanced between intervention and control groups (3,4). As populations must move towards eating sustainable and healthy diets (SHDs), PN interventions that provide tailored behavioural support may enhance the consumption of less commonly eaten foods central to SHDs, such as legumes. This feasibility trial sought to test the efficacy, feasibility, and acceptability of a novel PN intervention incorporating tailored behavioural support for improving legume intakes in young, healthy university students.

METHODS
Young, healthy university students (aged 18–30 years) were recruited from the UCD PLAN'EAT Living Lab (5). Intervention development was guided by the Behaviour Change Wheel (6). Intervention group participants received a PN intervention plus tailored behavioural support based on their primary self-selected barrier to legume consumption. Control group participants received a PN intervention without tailored behavioural support. At baseline, participants completed ≥2 24-hour dietary recalls, received a PN report detailing a recommendation to improve their legume intake, and underwent an in-person diet counselling session with a nutritionist. After ~4 weeks, participants completed ≥2 24-hour dietary recalls. Change in legume intake was measured using analysis of covariance. All data analysis was conducted using R (v.4.3.1).

RESULTS
A total of 59 students were randomised to a control or intervention group (*n*=57 entered the trial; *n*=41 female; *n*=16 male). Of those randomised to the intervention group, 14 (50%) selected 'lack of convenience' as their top barrier to eating more legumes, whereas 7 (25%) reported 'lack of cooking skills' and 7 (25%) reported 'lack of habit'. Preliminary RESULTS suggest that legume intakes have improved in both the control and intervention groups.

CONCLUSIONS
RESULTS will help to shed light on the efficacy of tailoring behavioural support to individuals within PN interventions, and will guide the development of a larger trial focused on promoting SHDs in UCD PLAN'EAT Living Lab participants.

EFFET OF A COMMUNICATION PROGRAM ON THE DIETARY BEHAVIOUR OF THE YOUNG FEMALE HANDBALL TEAM

Sidonie Mahougnon KIKI DJIVOH[1]; Kpèdétin Wilfrid Dieu-Donné AGBODJOGBE[2]; Stève Marjelin Donan FALOLA[3]; Paul Carel Houeto[4]; Laurette Benjamine Abègnonhou LIGAN[3]; Jean - Marie FALOLA[5]
[1]STAPS / INJEPS, Université d'Abomey-Calavi (UAC - Entrée principale), Abomey Calavi, Benin; [2]Sciences et Techniques des Activités Physiques et Sportives (STAPS) /INJEPS, UAC, Abomey Calavi, Benin; [3]STAPS/Institut National de la Jeunesse, de l'Education Physique et du Sport (INJEPS), UAC, Abomey Calavi, Benin; [4]STAPS / INJEPS, UAC, Abomey Calavi, Benin; [5]Sciences et Techniques des Activités Physiques et Sportives / INJEPS, université d'abomey-calavi, Cotonou, Benin

BACKGROUND AND OBJECTIVES
When preparing for top-level competitions, Beninese women handballers from different regions follow the same diet. However, they do not have a nutritional education and communication program to help them adopt performance-enhancing eating behaviour. Despite rigorous physical and technical-tactical preparation, they do not reach the continental level of the Challenge Trophy. The aim of the study was to determine the effect of a nutritional education and communication program offered in 2019 to Benin young female handball players on their eating behaviour.

METHODS
This is an intervention study conducted with 36 handball players aged 13 to 19, selected through a non-random method and the exhaustive selection technique at the training camp of the 2019 Challenge Trophy tournament. Data on physiological, social, cultural and psychological determinants of eating behaviour were collected by observation and questionnaire, as appropriate, before and after the intervention. Descriptive statistics were used to analyze the data, and the McNemar test was employed to analyze contingency tables.

RESULTS
Fifteen of the 36 players significantly improved their eating behaviour from zero at baseline to good ($p = 0.0001$). Physiological, social, cultural and psychological determinants of eating behaviour all improved with $p = 0.0001$.

CONCLUSIONS
The proposed PC+PEN led to a significant improvement in the eating behaviour of young female handball players in preparation for the 2019 Challenge Trophy. The nutrition education sessions and the consideration of the players' food preferences in their diet could have a greater impact in a future study.

NUTRITIONAL INTERVENTIONS AND GENETIC RISK: INSIGHTS INTO GESTATIONAL WEIGHT GAIN AND GLYCEMIC CONTROL IN PREGNANT WOMEN WITH DIABETES, CONSIDERING THE RS9939609 FTO POLYMORPHISM

Katherine Bittencourt Mendes Leitão De Jesus[1]; Karina Dos Santos[1, 2, 3]; Eliane Lopes Rosado[1, 3]; Ana Carolina Proença Da Fonseca[4]; Laísa Ramos Rodrigues[1]; Esther Dos Santos Silva[1]; Ana Luísa Da Silva Carvalho[1]; Camille De Sampaio Sinquini[1]; Ludmilla Gomes De Souza[1]; Luiza Jurado Piay[1]; J. Alfredo Martinez[5, 6]; Claudia Saunders[1]

BACKGROUND AND OBJECTIVES

Diabetes mellitus (DM) significantly increases the risk of adverse outcomes of pregnancy. Glycemic control and the adequacy of gestational weight gain (GWG) are key strategies to mitigate such effects [1]. In this context, the rs9939609 (T>A) polymorphism in the Fat Mass and Obesity Associate Gene (FTO) may negatively influence dietary intake, body weight, and blood glucose levels [2]. This study aimed to evaluate the influence of the rs9939609 polymorphism on dietary intake, GWG, and glycemic control in pregnant women with pregestational DM.

METHODS

This cross-sectional study included pregnant women with pregestational DM attending a public maternity hospital. All women received insulin treatment and were provided with nutritional support specific to managing DM during pregnancy. Participants were genotyped for the rs9939609 polymorphism and dietary intake was assessed using a Food Frequency Questionnaire (FFQ) applied within 12 weeks before delivery. GWG adequacy was classified based on the Institute of Medicine guidelines [3] and glycemic control was assessed using glycated hemoglobin (HbA1c). Statistical analyses included conventional robust tests.

RESULTS

The study involved 68 women with 31.57 years old (SD 6.06), 41.2% had type 1 DM and 58.8% had type 2 DM. The pregestational BMI was 29.65 kg/m2 (SD 5.74), without difference comparing the genotypes. The GWG adequacy, glycemic control, and dietary intake differed between genotypes. Women with the AT genotype reported a higher daily caloric and carbohydrate intake compared to those with the AA genotype (2221.69 Kcal vs. 1757.84 Kcal, p=0.05; 1080,17 Kcal vs. 820,58 Kcal, p=0.04) and exhibited higher HbA1c than AA carriers (6,77% vs. 5,78%, p=0.03). However, carriers of the AA genotype had a higher prevalence of excessive GWG (70%) compared to the AT (30.4%) and TT (28.6%) genotypes (p=0.045) at the time of the dietary assessment.

CONCLUSIONS

These RESULTS suggest that women carrying the AA genotype experienced excessive GWG despite consuming fewer calories and carbohydrates, while exhibiting better glycemic control compared to those with the AT genotype. It appears that dietary recommendations should be tailored according to genotype to prevent GWG and improve glycemic control. Women with DM who carry the rs9939609 polymorphism may require a tailored personalized dietary approach to optimize pregnancy outcomes.

RELATIONSHIP BETWEEN BONE MINERAL METABOLISM AND NUTRITIONAL STATUS: INTERPLAY OF ALBUMIN, PHOSPHORUS, CALCIUM, AND TRIGLYCERIDES IN HEMODIALYSIS PATIENTS

Caterina Tiscornia[1]; Fabián Vasquez[2]; Francisca Peña[3, 4]; Valeria Aicardi[5]
[1]Escuela de Nutrición y Dietética, Universidad Finis Terrae, Providencia, Chile; [2]Escuela de Nutrición y Dietética, Universidad Finis Terrae, Santiago, Chile; [3]Escuela de Nutrición y Dietética, Facultad de medicina y ciencias de la salud, Universidad Mayor, Santiago, Chile; [4]Nutrición, Fundación de salud renal integral (FUSAR), Santiago, Chile; [5]Unidad de Diálisis, Clínica Indisa, Santiago, Chile

BACKGROUND AND OBJECTIVES
Albumin is an essential marker of nutritional status in hemodialysis (HD) patients, whose levels may be indirectly influenced by metabolic factors such as phosphorus, calcium, and triglycerides, through inflammatory processes and metabolic alterations characteristic of this population. Therefore, the aim of this study was to determine the association between albumin levels and phosphorus, calcium, and triglyceride parameters in HD patients, identifying their role as indicators of nutritional status.

METHODS
Data from 168 patients on three-weekly HD were analyzed. Pearson correlations between albumin and metabolic indicators (phosphorus, calcium, triglycerides) were evaluated. Subsequently, multiple linear regression analysis was performed with albumin as the dependent variable and phosphorus, calcium, and triglycerides as predictors to evaluate their joint effects.

RESULTS
Phosphorus presented a positive and significant association with albumin ($r=0.278$, $p<0.001$), while calcium ($p=0.137$) and triglycerides ($p=0.092$) did not show significant relationships. The multiple linear regression model explained 8.7% of the variability in albumin levels. Phosphorus was the only significant predictor ($\beta=0.057$, $p<0.001$), highlighting its crucial role in nutritional status. Although triglycerides showed a trend close to significance ($p=0.058$), calcium had no statistically significant influence ($p=0.207$).

CONCLUSIONS
The RESULTS of the study highlight that phosphorus is a significant predictor of albumin levels, while calcium and triglycerides did not show clear relationships. This highlights the role of mineral metabolism, specifically phosphorus, in the nutritional status of HD patients. The positive relationship between phosphorus and albumin could be associated with higher protein intake, given that protein sources are usually rich in organic phosphorus. These findings underscore the importance of individualizing nutritional strategies in HD patients, balancing the need for adequate protein intake to maintain optimal albumin levels with organic phosphorus management to prevent complications related to mineral metabolism. This integrated approach could optimize both nutritional status and clinical outcomes in this population.

THE PARADOX OF ADIPOSITY IN HEMODIALYSIS: NUTRITIONAL AND CARDIOMETABOLIC INSIGHTS FROM DIABETIC AND NON-DIABETIC PATIENTS

Valeria Aicardi[1]; Caterina Tiscornia[2]; Lucia Del Vecchio[3]; Ivano Bagaretti[4]; Fabián Vásquez[2]; Vincenzo La Milia[4]

[1]Unidad de Diálisis, Clínica Indisa, Santiago, Chile; [2]Escuela de Nutrición y Dietética, Universidad Finis Terrae, Providencia, Chile; [3]Department of Nephrology and Dialysis, Sant'Anna Hospital, ASST Lariana, Como, Italy, Milano, Italy; [4]Department of Nephrology and Dialysis, Ospedale Edoardo Bassini, Cinisello Balsamo, Milano, Italy

BACKGROUND AND OBJECTIVES

Coronary heart disease is the leading cause of mortality among hemodialysis (HD) patients, closely associated with nutritional deterioration and chronic inflammation. The theory of reverse epidemiology (RE) suggests that greater adiposity might confer survival advantages in HD patients, despite its known links to inflammation and metabolic complications. Understanding this paradox is critical to addressing the nutritional and cardiometabolic challenges in this population. This study aimed to assess nutritional deficiencies in diabetic (DM) and non-diabetic (NDM) patients undergoing HD at an Italian dialysis center and to analyze the impact of long-term HD on cardiometabolic parameters, considering the implications of RE.

METHODS

This cross-sectional study included 60 chronic HD patients (DM:n=18, mean age: 73.1 ± 11.4 years; NDM:n=42, mean age:64.3±18.5 years). Nutritional indicators (brachial muscle area [AMB], brachial fat area [AGB], lean tissue index [LTI], fat tissue index [FTI]), biochemical markers (transferrin, vitamins B9, B12, D, bicarbonate, creatinine, albumin), inflammatory markers (C-reactive protein [CRP], ferritin), residual diuresis, years on dialysis, and cardiometabolic parameters (lipid profile, glycemia, calcium-phosphorus ratio) were measured. Statistical analyses included descriptive statistics, Student's t-test, and Pearson correlation, using SPSS version 11.0. A p-value <0.05 was considered statistically significant.

RESULTS

DM patients exhibited a significantly higher FTI (12.6 ± 5.0) compared to NDM patients (9.1 ± 5.5; p=0.03). Longer HD duration correlated with decreased AMB (p=0.02), elevated CRP levels indicating increased inflammation (p=0.01) and reduced pre-dialysis blood urea nitrogen (pre-BUN) levels (p=0.02) in both DM and NDM groups. No significant differences in other nutritional indicators were observed between the two groups.

CONCLUSIONS

The nutritional status of DM patients on HD is notably compromised, characterized by an imbalance between excess adiposity and reduced lean mass, often associated with HD-related protein-energy wasting. Chronic inflammation, exacerbated by prolonged HD and malnutrition, contributes to reduced protein intake, as reflected in lower pre-BUN levels. Interestingly, RE suggests that higher adiposity may provide a survival advantage in HD patients, despite its potential to intensify inflammation. Further research is needed to elucidate the complex interplay between adiposity, inflammation, and survival outcomes.

DNA METHYLATION OF AMINO ACID TRANSPORTER GENE IN THE HUMAN PLACENTA ASSOCIATED WITH OFFSPRING GROWTH AND BODY COMPOSITION

Perla Pizzi Argentato[1]; Alexandre Ferro Aissa[2]; Jorge Augusto Petroli Marchesi[3]; Naiara Naiana Dejani[1]; Liania Alves Luzia[1]; Ester Silveira Ramos[3]; Patrícia H.C. Rondó[1]
[1]Department of Nutrition, Universidade de São Paulo, São Paulo, Brazil; [2]Department of Morphology and Genetics, Federal University of São Paulo, São Paulo, Brazil; [3]Department of Genetics, Universidade de São Paulo, São Paulo, Brazil

BACKGROUND AND OBJECTIVES
The human placenta exhibits a unique DNAm profile that is characterized by large hypomethylated regions interspersed with hypermethylated regions. The epigenetic regulation of amino acid transporters in maternal-fetal tissues is poorly understood. This study investigated the DNA methylation (DNAm) status of the amino acid transporter SNAT1 and its gene expression in uterine decidua and placental villi and the association of the findings with maternal-fetal-neonatal parameters.

METHODS
Pregnant women from the Araraquara Cohort Study (n=64) were followed up during pregnancy until delivery. Uterine decidua and placental villus samples were collected to assess DNAm levels by methylation-sensitive restriction endonuclease qPCR. Fetal growth and newborn body composition were assessed by ultrasonography and plethysmography, respectively. Univariate and multiple linear regression models were used to explore the associations of DNAm with markers of fetal and neonatal growth and body composition.

RESULTS
DNAm of SNAT1 in uterine decidua was associated with fetal thigh muscle (p=0.025) and newborn thoracic circumference (TC) (p=0.002) and fat-free mass (p=0.041). In placental villi, DNAm of SNAT1 was associated with fetal thigh muscle mass (p=0.049) and newborn TC (p=0.039) and head circumference (HC) (p=0.023)

CONCLUSIONS
SNAT1 was associated with multiple fetal-neonatal growth and body composition parameters, particularly those related to the muscle mass compartments.

IMPLEMENTATION OF THE GLIM NUTRITIONAL SCREENING IN ELDERLY PATIENTS ON CHRONIC HEMODIALYSIS: A NEW NUTRITIONAL ASSESSMENT TOOL

Valeria Aicardi[1]; Caterina Tiscornia[2]; Beatrice Porcari[3]; Mariagiulia Magatti[3]; Giulio Pucci[3]; Sara Visca[3]; Mariagiulia Tettamanti[3]; Elena Luisetto[3]; Gianvincenzo Melfa[3]; Lucia Del Vecchio[3]

BACKGROUND AND OBJECTIVES
Malnutrition is a prevalent condition in elderly hemodialysis (HD) patients, underscoring the need for accurate diagnostic tools applicable to this population. The Global Leadership Initiative on Malnutrition (GLIM) proposes diagnostic criteria that combine phenotypic (such as weight loss, low body mass index, and reduced muscle mass) and etiologic (such as insufficient intake and inflammation) factors. However, validation of these criteria in the specific context of chronic kidney disease (CKD) remains limited. The aim of this study was to evaluate the applicability of the GLIM criteria in CKD patients on HD to identify more effective strategies for the diagnosis and management of malnutrition in this population.

METHODS
Retrospective study in 123 patients on chronic HD (mean age 77,3 ± 6,57 years, M/F 98/25, 43,1% with diabetes). All participants underwent routine nutritional assessment (anthropometry, bioimpedance (BIA) and nutritional screening by Mini nutritional assessment (MNA) and prognostic assessment using the multidimensional prognostic index (MPI). According to the GLIM criteria, a patient was considered malnourished if he/she met at least one phenotypic criterion and one etiological criterion (which, in the case of HD patients, is inherently met).

RESULTS
MNA showed a low specificity, which led to consider all patients within the GLIM criteria. 32% of patients could not undergo evaluation by BIA, mainly due to exclusions related to cardiovascular criteria. Among the patients evaluated with BIA, 23% had a reduced lean mass index (LTI). In total, 44,6% of patients met the phenotypic criteria defined by GLIM, which allowed us to identify 17 additional patients at risk of malnutrition. Those meeting GLIM criteria tended to have a higher dialysis adequacy ratio (KT/V), lower parathyroid hormone (PTH) levels, and decreased triglyceride and serum albumin values. On the other hand, no significant association was found between GLIM criteria and the presence of cognitive impairment or mobility problems. However, 31,4% of patients reported loss of appetite during the last three months, together with digestive problems, chewing or swallowing difficulties.

CONCLUSIONS
Implementation of the GLIM criteria may facilitate earlier diagnosis and guide personalized nutritional interventions, helping to prevent progression to more severe conditions such as sarcopenia and functional decline. The GLIM criteria represent a promising advance in the assessment of malnutrition in CKD patients on HD.

IMPACT OF AN INTRADIALYTIC EXERCISE PROGRAM ON BODY COMPOSITION, PHYSICAL FUNCTIONALITY, CARDIOMETABOLIC CONDITION AND QUALITY OF LIFE IN HEMODIALYSIS PATIENTS: A PILOT STUDY

Caterina Tiscornia[1]; Mauricio Rios[2]; Matias Armijo; Bárbara Becerra[3, 4]; Francisca Peña[5, 6]; Javiera Contreras[2]; Pamela Suazo[2]; Rocio Pedroche[2]; Pamela Elizalde[2]; Alvaro Morales[2]; Fabián Vásquez[1]; Valeria Aicardi[7]

BACKGROUND AND OBJECTIVES
Patients undergoing hemodialysis (HD) experience physical deterioration and heightened cardiovascular risk, which adversely affect their quality of life and clinical outcomes. Regular physical activity can counteract these effects by enhancing muscle mass, aerobic capacity, physical functionality, and dialysis efficiency. This pilot study aimed to evaluate the impact of an aerobic and resistance exercise program on body composition, physical functionality, cardiometabolic status, and quality of life in adults and elderly patients undergoing HD.

METHODS
A three-month quasi-experimental study was conducted with 13 HD patients (mean age 58.3 ± 9.1 years) receiving tri-weekly dialysis, of whom 9 completed the intradialytic exercise program. The intervention included three supervised weekly sessions lasting 45–60 minutes during the first two hours of dialysis. Sessions consisted of warm-up exercises (low-intensity joint mobility), aerobic activities (treadmill walking), resistance training (elastic bands), and cool-down stretches. Pre- and post-intervention assessments included anthropometric measurements (e.g., BMI, brachial circumference [BC], tricipital skinfold [TCP], brachial muscle area [BMA], % total body fat [%TBF]), functional tests (hand grip strength, Timed Up and Go test), biochemical markers (e.g., albumin, creatinine), and quality-of-life evaluations using the SF-12 questionnaire.

RESULTS
Significant improvements were observed in lean body mass (31.35 ± 6.04 kg to 32.00 ± 4.11 kg; p=0.045) and BC (29.45 ± 3.40 cm to 30.21 ± 3.51 cm; p=0.034). Quality of life also improved significantly in the mental health domain of the SF-12 (p=0.049). However, changes in %TBF, calf circumference, hand grip strength, albumin, and creatinine levels were not statistically significant.

CONCLUSIONS
The RESULTS demonstrate the positive impact of intradialytic exercise on the health and well- being of patients, showing improvements in body composition, physical functionality, and quality of life. This pilot study is a promising model for integrating exercise as a therapy in HD. However, the small sample size, short duration and heterogeneity limit the generalizability of the RESULTS. Therefore, a second phase of the study with a larger sample size and prolonged follow-up is planned, as well as the incorporation of nutritional support to strengthen the findings.

BACKGROUND AND OBJECTIVES

Frailty increases the risk of needing nursing care and significantly affects the life and functional prognosis of older individuals. Early detection and tailored interventions are crucial for maintaining and enhancing their life functions. Recognizing distinct clinical phenotypes is essential for devising appropriate interventions. This study aimed to explore diverse frailty phenotypes, focusing on poor nutrition in older Japanese individuals through observational research. In addition to nutritional assessments, metabolic products were also measured and examined to gain a deeper understanding of the frailty phenotypes.

METHODS

Twenty-one nursing home residents underwent a comprehensive survey covering physical, blood, dietary, cardiac, cognitive, nutritional, nursing care, frailty, agitated behavior, metabolic products, and gut microbiome assessments (high-throughput 16S rRNA gene sequencing). Using clustering analysis with 239 survey items (excluding gut microbiome), participants were classified into subgroups based on clinical phenotypes, and group characteristics were compared through analysis.

RESULTS

Individuals with moderate or severe frailty and suspected dementia formed subgroups with distinct clinical phenotypes based on nutritional, defecation, metabolic, and nursing care statuses. The gut microbiome significantly varied among these groups ($p = 0.007$), indicating its correlation with changes in clinical phenotype. Nutritional status differences suggested poor nutrition as a differentiating factor in the core clinical phenotype. The analysis of metabolic products further confirmed the relationship between nutritional status and frailty phenotypes.

CONCLUSIONS

This study proposes that the gut microbiome differs based on the clinical phenotype of Japanese older individuals with frailty, and targeted interventions addressing the gut microbiome may contribute to preventing frailty in this population.

OBESITY AND LIPID-RELATED INDICES FOR PREDICTING METABOLIC-ASSOCIATED STEATOTIC LIVER DISEASE IN RENAL TRANSPLANT RECIPIENTS IN TAIWAN

I-Hsin Tseng[1]; I-Hsin Lin[2]; Shih-Wei Nien[2]; Yi-Ming Wu[2]; Hsu-Han Wang[3]; Nien-Chieh Yang[4]; Ta-Ho Wu[4]; Te-Chih Wong[4]

[1]Department of Medical Nutrition Therapy, Taipei Chang Gung Memorial Hospital, Taipei, Taiwan; [2]Department of Medical Nutrition Therapy, Linkou Chang Gung Memorial Hospital, Taoyuan, Taiwan; [3]Department of Urology, Linkou Chang Gung Memorial Hospital, Taoyuan, Taiwan; [4]Department of Nutrition and Health Sciences, Chinese Culture University, Taipei, Taiwan

BACKGROUND AND OBJECTIVES

The association between metabolic-associated steatotic liver disease (MASLD) and obesity-related indices has typically been analyzed in isolation, with limited comparative evidence, particularly in renal transplant recipients (RTRs). This cross-sectional study aimed to assess the predictive performance of various obesity and lipid-related indices for identifying MASLD in RTRs in Taiwan.

METHODS

Participants aged 18 years or older were recruited from a single-center hospital. Data on height, weight, waist circumference (WC), triglycerides, and fasting blood glucose were collected from medical records to calculate body mass index (BMI), body roundness index (BRI), lipid accumulation product (LAP), and triglyceride-glucose (TyG) index. MASLD was determined using the hepatic steatosis index (HSI), calculated as 8 × (aspartate aminotransferase/alanine aminotransferase ratio) + BMI + 2 (if diabetic) + 2 (if woman). Predictive performance was evaluated using receiver operating characteristic (ROC) curves, with areas under the curve (AUCs) categorized as good (0.7-0.9).

RESULTS

Among the participants, 25.55% (57.14% male) were classified as having MASLD (HSI > 36). The ROC analysis indicated that BRI had the highest predictive ability (AUC = 0.843), followed by WC (AUC = 0.833), LAP (AUC = 0.829), and TyG (AUC = 0.722).

CONCLUSIONS

BRI demonstrated the strongest predictive performance for identifying MASLD in RTRs, with WC also exhibiting substantial diagnostic potential. These findings suggest that anthropometric-related indices provide better predictive ability for MASLD screening in RTRs, while lipid-related indices also offer reasonable predictive performance.

DISTINCTIVE IMPLICATIONS OF BASAL BLOOD GLUCOSE AND POSTPRANDIAL GLUCOSE INCREMENT AMONG WOMEN WITH GESTATIONAL DIABETES MELLITUS AND POTENTIAL FOR PRECISION NUTRITION

Yuanqing Fu[1]; Ke Zhang[1]; Meng Ye[1]; Sha Lu[2]; Zelei Miao[1]; Wanglong Gou[1]; Meiqi Shi[2]; Wensheng Hu[3]; Ju-Sheng Zheng[1]
[1]School of Medicine, Westlake University, Hangzhou, China; [2]Department of Obstetrics and Gynecology, Hangzhou Women's Hospital (Hangzhou Maternity and Child Health Care Hospital), Hangzhou, China; [3]Women's Hospital School of Medicine, Zhejiang University, Hangzhou, China

BACKGROUND AND OBJECTIVES
The glycemic response to identical meals is highly variable among healthy individuals[1], but little is known about the personalized postprandial glucose response among pregnant women with gestational diabetes mellitus (GDM) and its relationship with the birth outcomes.

METHODS
Based on the previously reported WeBirth cohort[2], we included 1,789 pregnant women with available continuous glucose monitoring (CGM) data. These participants were connected to a CGM sensor for 14 days and daily food intakes were recorded. Moreover, 1,224 women participated in a one-day standard meal intervention while connected to the CGM sensor. In the subsequent statistical analysis, the participants were divided into a discovery cohort and a validation cohort according to their recruitment time before or after the onset of the COVID-19 pandemic. Logistic regression was applied to examine the associations between CGM-derived indices and adverse birth outcomes (i.e., LGA, large-for-gestational-age birth; SVN, small vulnerable neonate).

RESULTS
We constructed a series of indices from the CGM data collected on the day of the intervention, including area under the curve (AUC), time in range (TIR) and mean blood glucose (MBG). We further subtracted the incremental area under the curve (iAUC) from the AUC, also yielding the index indicating the basal blood glucose level (basal AUC). We found that AUC on the day of the intervention was positively associated with LGA ($p<0.01$ for both discovery and validation cohort). Moreover, the basal AUC, which exhibited small inter-individual variations (CV, 11.1%), drove the identified associations ($p<0.01$ for both discovery and validation cohort), whereas the iAUC, characterized by large inter-individual variations (CV, 37.2%), was not significantly associated with the risk of adverse birth outcomes. This indicates that occasionally tested basal AUC may reflect long-term glycemic control, whereas the iAUC is more dynamic and sensitive to consumed meals. By integrating the repeatedly measured iAUC and the glycemic load (GL) of the corresponding meals, we further created a Personalized Glycemic Sensitivity Index (PGS) at the single-subject resolution, to quantify the personalized glycemic sensitivity. The PGS was positively associated with the risk of SVN ($p<0.05$).

CONCLUSIONS
The AUC encompasses two dimensions of postprandial glucose response: basal AUC and iAUC, each indicating distinct clinical implications for GDM. The iAUC-derived PGS quantifies personalized glycemic sensitivity to GL, exhibiting great potential for personalized nutrition.

[4]Department of Nutrition and Health Sciences, Chinese Culture University, Taipei, Taiwan; [5]Department of Urology, Linkou Chang Gung Memorial Hospital, Taoyuan, Taiwan

BACKGROUND AND OBJECTIVES
Obesity is an established risk factor for cardiovascular disease (CVD) and has been increasing globally over the past 40 years. CVD is the leading cause of mortality in post renal transplant recipients (RTRs). Well nutritional status is a protective factor of CVD. However, relevant published study in RTRs is limited.

METHODS
A total of 299 RTRs were enrolled in this cross-sectional study from 2016 to 2024. Nutrition assessment data were retrieved from medical records. Statistical analysis was performed using SPSS Statistics software, 27 version.Particitants were categorized into the following groups based on their body mass index(BMI) an the presence of metabolic abnormalities(fasting glucose<100mg/dL,triglyceride<150mg/dL,HDLcholeserol≥40mg/dL for men or ≥50mg/dL for women,and blood pressure<130/85mg/dL)：Normal-weight group(NW), Normal-weight with metabolic abnormalities group(NWMA),Obesity with normal metabololism group(ONM), Obesity with metabolic abnormalities group(OMA).

RESULTS
The characteristics data showed that individual with a NW have higher caloric and protein intake compared to those with OMA in RTRs. Protein and vitamin B6 intake were showed higher trend of individuals with OMA compared to those with a NW in RTRs. No significant difference in physical activity levels regardless of obesity or metabolic abnormality status in RTRs. In the body composition analysis RESULTS, fat-free mass is significantly higher in individuals with obesity or metabolic abnormalities and skeletal muscle mass is significantly higher in individuals with OMA compared to those with a NW in RTRs.

CONCLUSIONS
OMA was associated with lower muscle mass and protein intake. Further interventional study may focus on this association and prevents obesity and metabolic syndrome in RTRs.

ARE REGISTERED DIETITIANS READY TO TAKE RESPONSIBILITY FOR PRESCRIPTION OF PARENTERAL NUTRITION AND INTRAVENOUS NUTRIENTS?

Bianca Kroukam[1]; Janicke Visser[1]; Anna-Lena Dutoit[2]; Daan Nel[3]
[1]Department of Global Health, Division of Human Nutrition, Faculty of Medicine and Health Sciences, Stellenbosch University, Cape Town, South Africa; [2]Department of Dietetics, Groote Schuur Hospital, Cape Town, South Africa; [3]Centre for Statistical Consultation, Stellenbosch University, Stellenbosch, South Africa

BACKGROUND AND OBJECTIVES
Parenteral nutrition (PN) and intravenous (IV) nutrients are Schedule III and IV substances and require advanced knowledge and comprehensive training to optimise nutrition support and minimise risks. The objectives of this study were to determine the knowledge of registered dietitians (RDs) in South Africa (SA) regarding PN and IV nutrients, and to explore the attitudes, practices, and factors influencing the recommendation of PN and IV nutrients.

METHODS
A mixed methods approach with an explanatory sequential design was used. Registered dietitians (N=145) participated in an online self-administered questionnaire and semi-structured interviews were undertaken with purposively selected individuals (N=6).

RESULTS
Most participants (64%, n=93/145) actively recommend PN/IV nutrients and felt RDs should have the authority to prescribe (77%, n=108/140). Only 11% (n=11/104) had a good knowledge score >65%. Those practicing for ≥7 years or with additional training demonstrated significantly better knowledge scores ($p<0.001$ and $p=0.002$), emphasising the need for additional training (PN: $p=0.019$; IV nutrients: $p=0.018$). Findings underscored RDs' pivotal role in PN/IV nutrients prescription. It also revealed knowledge gaps pertaining pharmaceutical aspects, IV nutrients and prescribing rights.

CONCLUSIONS
There is a disparity between RDs' perceived competence and their actual knowledge of PN and IV nutrients. RDs need more education and training to ensure their competency and confidence in the discussion, recommendation and management of PN and IV nutrients for adults. The research suggests a need for clarity on legal responsibilities in prescribing rights to ensure consistency in prescription practices between health care professionals and health sectors in SA.

PECTIC OLIGOSACCHARIDS (POS) FROM POTATO EXHIBIT DIFFERENT BIOACTIVITIES BASED ON THEIR STRUCTURAL DETAILS SUCH AS MOLECULAR WEIGHT AND DEGREE OF METHYLATION

Caroline Perreau[1]; Ludivine Gras[2]; Gerald Chene[3]; Laure Saias[3]; Pieter Van Den Abbeele[4]; Clementine Thabuis[1]
[1]Life Sciences R&D, Roquette Frères, Lestrem, France; [2]Process R&D, Roquette Frères, lestre, France; [3]R&D, Ambiotis, Toulouse, France; [4]R&D, Cryptobiotix, Ghent, Belgium

BACKGROUND AND OBJECTIVES

Pectins are colloidal fibers strongly studied and recognized for health benefits such as improvements of blood lipids with a decrease in cholesterol levels and blood glucose management, thus conferring them regulatory health claims. They are complex polysaccharides with different structural subparts: homogalacturonan (HG), rhamnogalacturonan-l (RG-I), and substituted galacturonans. RG-I has been called the "hairy region" of pectin and are known to be a preferential substrate of different gut bacteria, thus conferring prebiotic properties to pectins. These high molecular weight (Mw) molecules can be hydrolyzed into smaller size compounds: pectic oligosaccharides (POS), that can offer different properties such as higher solubility and lower viscosity than the parent molecules.

METHODS

We investigated here the role of structural details such as Mw and degree of methylation (DM) on parameters linked to immunity and inflammation using Caco2 (derived Carcinoma colonic cells) /PBMC (Peripheral Blood Mononucleic Cells) coculture and *ex vivo* fermentation models. Pectins and POS fine structures (sugar composition and ramifications) are very different depending on their vegetal origins, making impossible their strict comparison in one study. Thus, gathering information from literature and our own tests, correlations between structural details and parameters related to immunity and inflammation could be established.

RESULTS

Using the CaCo2/PBMC model to mimic epithelium passage and communication towards immune cells, we observed an immune-stimulation as PBMC secreted pro inflammatory cytokines such as IL-1β and TNF-α. To the contrary, when PBMC were stimulated using LPS (Lipopolysaccharides) to simulate inflammation, when exposed to POS, PBMC induced a decrease in the secretion of the same pro-inflammatory cytokines. This effect was observed for both tested Mw, showing a role of DM in this bioactivity. In the colonic ex vivo experiment, Mw was key in the response of gut microbiota to POS in the medium with a higher SCFA (Short Chain Fatty Acids) production for the higher Mw prototype.

CONCLUSIONS

By understanding the impact of structural details on the mechanisms of action of bioactive pectins and POS, we propose here a way to choose the accurate ingredient targeting precise health benefits for each kind of population.

THE EFFECT OF PROBIOTIC SUPPLEMENTATION ON STRESS AMONG UNIVERSITY STUDENTS: A RANDOMIZED, CONTROLLED TRIAL

Essra Noorwali,[1]; Wafaa Abusudah[1]; Fatmah Bakhdar[2]; Dania Bin-Ali[1]; Amani Alshinawi[1]; Heba Maimany[1]; Asma Bawazir[1]; Raghad Mutlaq[1]; Layan Barnawi[1]; Bshayer Murshed[1]; Bayan Aljared[1]; Abeer Aljaadi[1]
[1]Clinical Nutrition, Umm Al-Qura University, Makkah, Saudi Arabia; [2]Pharmacology and Toxicology Department, Umm Al-Qura University, Makkah, Saudi Arabia

BACKGROUND AND OBJECTIVES
Probiotics' role in stress alleviation has gained attention due to their potential to modulate the gut-brain axis (1). However, research on university students, who face significant academic stress, is limited (2,3). This study examined the effect of probiotic supplementation on stress levels among Saudi students.

METHODS
This randomized controlled trial involved healthy Saudi university students aged≥18 years with moderate or high Perceived Stress Scale (PSS) scores (4). The study was registered on ClinicalTrials.gov (NCT06464484). Validated English and Arabic versions (5) of the PSS were used. Exclusion criteria were chronic illnesses, psychiatric conditions, use of medications or supplements in the past month, pregnancy, breastfeeding, smoking, and low stress scores (0–13). Participants were randomized into an intervention group receiving probiotic capsules (Lactobacillus rhamnosus GG, 6×10^9 CFU, Dicoflor 60) once daily for 30 days and a control group receiving no intervention. Stress levels (PSS), anthropometrics, and bowel function (6) were collected at baseline and endline.

RESULTS
Out of 121 screened participants, 15 were excluded for recent medication, supplement, or laxative use, and 19 for low stress scores or prior rectal/anal fistula surgeries. Eighteen did not complete the trial, resulting in a final sample of 69. Participants had a mean±SD age of 21.5±2.3 years, 55% were males, and 40.6% had BMI≥ 25 kg/m2 (overweight/obesity). At baseline, there were no significant differences in mean age, BMI, or stress scores. At endline, stress scores were significantly reduced in both the intervention (22.82±4.58 vs. 14.21±6.05, $p<0.001$) and control groups (23.63±4.05 vs. 21.17±5.68, $p<0.05$) using paired t-test. However, the intervention group had lower stress scores at four weeks compared to the control group (14±6.05 vs. 21.17±5.68), using two sample t-test. This difference remained significant in the regression analysis when adjusting for baseline stress scores. No significant sex differences in stress scores were observed.

CONCLUSIONS
Probiotic supplementation effectively reduced stress scores in Saudi university students, irrespective of baseline stress levels and sex, indicating its potential as a stress management intervention for high-risk groups.

SOLUBLE PREBIOTIC FIBER PROMOTES BENEFICIAL SACCHAROLYTIC BACTERIA IN HIGH AND LOW FIBER DIET POPULATIONS

Caroline Perreau[1]; Thomas Carton; Diego Tomassi; Lou Beuvin[2]; Clementine Thabuis[1]; Laetitia Guérin-Deremaux[1]
[1]Life Sciences R&D, Roquette Frères, Lestrem, France; [2]Biometrics & Data Science, Biofortis, Saint-Herblain, France

BACKGROUND AND OBJECTIVES
Soluble prebiotic fibers positively shift microbiota composition, stimulating beneficial metabolites like short-chain fatty acids and providing health benefits. Host factors, including diet, might influence individuals' microbiome and shape their responses to prebiotics. This study aimed to evaluate the effects of a soluble prebiotic fiber on microbiota composition and function in two populations with differing dietary fiber intake: high or low.

METHODS
In a multicenter, randomized, placebo-controlled, double-blinded, parallel study, 124 subjects were recruited. This included 67 individuals with high fiber consumption (≥ 25 g/day) and 57 individuals with low fiber consumption (≤ 15 g/day). Participants were divided into two arms and consumed either 15 g of NUTRIOSE® FB06 soluble fiber (SF) or 15 g of GLUCIDEX® 21 (placebo) over a 4-week period. Fecal samples were collected at the beginning and end of the supplementation period. Microbiota composition and function were assessed using Shotgun metagenomics. The data were analyzed with a generalized linear mixed model, considering fixed effects such as visit, product, group, baseline value of the study endpoint, second and third interactions, and subject as random effect.

RESULTS
A total of 112 volunteers completed the study without major deviations, 58 in the placebo arm (25 low fiber, 33 high fiber) and 54 in the SF arm (25 low fiber, 29 high fiber). No significant differences in microbiota diversity were observed between the SF and placebo arms at baseline and across the study. However, after 4 weeks of consumption, the SF arm showed a significant higher relative abundance of the *Parabacteroides* genus compared to placebo arm (5.466% vs 1.437%, $p<0.0001$) that was similar in high and low fiber consumption subgroups (5.63% and 5.25% respectively, $p<0.0001$ in both subgroups). Beyond this pronounced effect, some differences in response were observed between high and low fiber consumers. These taxonomic changes were accompanied by a higher relative abundance of α-glucosidase (high fiber group only, $p=0.0008$) and beta-glucosidase-related genes (overall, $p=0.0014$) in SF compared to placebo.

CONCLUSIONS
Despite some differences in microbiota composition between high and low fiber consumption subgroups, overall, the intake of soluble prebiotic fiber in both subpopulations induces changes in the composition and function of the microbiota by promoting the proliferation of saccharolytic bacteria.

A CROSS-SECTIONAL STUDY ON ORAL FRAILTY AND APPETITE IN COMMUNITY-DWELLING OLDER ADULTS

KIWAKO OKADA[1]; Chiharu Uno[1]; Masafumi Kuzuya[2]
[1]Nutrition, Nagoya University of Arts and Sciences, Nisshin, Japan; [2]Geriatric, MEITETSUhospita, Nagiya, Japan

BACKGROUND AND OBJECTIVES
The older adults are steadily increasing, and problems in medical care and nursing care have made health management and the extension of healthy life expectancy an urgent issue for older adults. In order to prevent older adults from transitioning to a state requiring long-term care, it is important to prevent and improve frailty, which is the pre-stage of long-term care. In recent years, oral frailty has been attracting attention as an important factor seen in the early stages of frailty, and it is known that older adults with oral frailty are at a higher risk of developing malnutrition than healthy older, but the relationship with appetite and oral frailty has not been clarified. Therefore, this study was conducted to clarify the relationship between appetite and oral frailty, to prevent oral frailty, and to demonstrate effective measures to deal with frailty.

METHODS
The subjects of the analysis were 212 community-dwelling older adult (98 men and 114 women) who participated in the Nagoya Longitudinal Follow up for Healthy Elderly (NLFS-HE). The survey consisted of questionnaires (basic information, frailty index, appetite questionnaire: Council on Nutrition Appetite Questionnaire-J (CNAQ-J), Dietary Intake Status: a brief-type self-administered diet history questionnaire, dietary variety score (DVS)) and actual measurements (physical measurements, oral function assessment, etc.). The subjects were classified into a healthy (robust) group as those who met the Oral Frailty 5-item Checklist (OF-5) criteria for less than two items, and an OF group as those who met two or more items.

RESULTS
Of the subjects analyzed, 90 people (42.5%) were in the OF group. Significant differences were observed between the OF group and the robust group in age, sex, Frailty index, number of medications taken, CNAQ, and DVS. As a result of the binary logistic regression analysis, the nutrition-related indices that were associated with OF were CNAQ-J (OR: 0.78, 995% CI: 0.74 –0.91) and DVS (OR: 0.85, 95% CI: 0.81–0.95).

CONCLUSIONS
These RESULTS indicate that oral frailty is associated with reduced appetite and food diversity. They also suggest that these associations may lead to malnutrition and progression of frailty.

COMPARISON OF MUSCLE MASS MEASURED BY CT AND BIOELECTRICAL IMPEDANCE ANALYSIS IN CHINESE PATIENTS WITH GASTRIC CANCER: A CROSS-SECTIONAL STUDY

Xiangrui Li[1]; Xiaotian Chen[1]; Jiashu Yao[1]; Wenqing Chen[1]; Qing Zhao[1]; Yue Xu[1]; Bo Gao[1]
[1]Department of Clinical Nutrition, Nanjing Drum Tower Hospital, Nanjing, China

BACKGROUND AND OBJECTIVES
Muscle mass reduction highly representing sarcopenia is an independent risk factor for poor prognosis of cancer, which is mainly assessed by CT scan as the gold standard. Bioelectrical impedance analysis (BIA) is radiation free and simple approach to evaluate muscle mass. However, accuracy of BIA in evaluating muscle mass and diagnosing muscle reduction is unclarified. Moreover, the cutoff value of BIA for indicating sarcopenia risk in Chinese gastric cancer population remains unclear. The aim of the present study was to investigate the accuracy of BIA in muscle evaluating and to identify the cutoff value of diagnosing muscle reduction in Chinese gastric cancer population.

METHODS
A total of 163 gastric cancer patients were consecutively enrolled. CT scan was utilized to measure skeletal muscle mass at L3 slice. Muscle mass was also evaluated by BIA method. The correlations of muscle mass between CT and BIA methods were assessed. Data consistency was analyzed by intraclass correlation coefficient (ICC). The optimal cut-off value of skeletal muscle mass was obtained by receiver operating characteristic curve (ROC) to diagnose muscle reduction.

RESULTS
There were 44 females and 119 males enrolled. The mean skeletal muscle mass measured by CT and BIA were 118.81±24.54 cm2 and 25.11±4.37 kg in overall patients, respectively. The mean SMI measured by BIA was 9.42±1.09 kg/m2. Skeletal muscle mass index (SMI) by CT was significantly correlated with that measured by BIA ($r=0.727$, $p<0.001$). The ICC between two methods was 0.903, indicating an excellent consistency. The sex-specific best cut-off values of SMI obtained by BIA were 9.46 kg/m2 in men and 8.72 kg/m2 in women in Chinese gastric cancer population, respectively.

CONCLUSIONS
Muscle mass assessed by BIA showed highly correlation and satisfactory consistency with that measured by CT scan. The best cut-off values of for SMI indicating sarcopenia risk in Chinese gastric cancer population obtained from BIA were 9.46 kg/m2 in males and 8.72 kg/m2 in females, respectively.

DEVELOPMENT OF A FOOD COMPOSITION DATABASE TO ASSESS THE DIETARY INTAKE OF PLANT BIOACTIVES

Costanza Michelini[1]; Federica Bergamo[1]; Francesca Scazzina[1]; Daniele Del Rio[1]; Alice Rosi[1]; Pedro Mena[1]
[1]Department of Food and Drug, University of Parma, Parma, Italy, Italy

BACKGROUND AND OBJECTIVES

Increasing evidence shows how plant-based diets can exert beneficial health effects, particularly on the prevention of chronic diseases. (Poly)phenols and carotenoids are the most studied phytochemicals, but many others, such as phytosterols, glucosinolates, and alkaloids, may be involved in promoting human health. However, the dietary intake of these bioactive molecules remains difficult to assess, due to the lack of phytochemical food composition databases (FCDs). The aim of this work was filling this gap by developing a FCD, named PhytoFooD (Phytochemical Food Database), covering the main dietary phytochemicals. The most relevant compounds from the four main phytochemical classes were considered: (poly)phenols, terpenoids, *N*-containing compounds, and miscellaneous phytochemicals.

METHODS

Twelve online international FCDs (i.e. FNDDS, eBASIS, Phenol-Explorer, etc.) were used to collect information about the concentration of these molecules in foods. Foods from all international FCDs were matched to the Italian database BDA, which served as reference FCD, based on food name and macronutrient concentrations. Then, phytochemical concentrations reported for each single FCD were included into our database. A literature search on Scopus was conducted for the collection of additional data. Different inclusion/exclusion criteria were set to guarantee data quality. Once all data were collected, three statistical tests were used to verify the presence of outliers. Central and deviation measures, as well as a quality index of the final data were calculated for each food and compound.

RESULTS

Data for more than 800 phytochemicals in about 600 different foods were collected. Fourteen phytochemical subclasses, including (poly)phenols and *N*-containing compounds (alkaloids, glucosinolates, etc.), have been developed, while the remaining families (terpenes and miscellaneous) will be developed in the coming months.

CONCLUSIONS

The lack of phytochemical FCDs is still an issue that needs to be addressed to properly estimate the intake of these bioactives in human populations, to achieve a more comprehensive and detailed view of different dietary patterns and their potential impact on human health.

THE CROSSLINK AMONG INFLAMMATION, OXIDATIVE STRESS AND INTESTINAL MICROBIOTA IN PREGNANCY-RELATED COMPLICATIONS

Miao Miao[1]; Dai Yongmei[1]; Zhang Yue[1]; Mu Juan[1]
[1]Nutrition Department, Women's Hospital of Nanjing Medical University（Nanjing Maternity and Child Health Care Hospital）, Nanjing, China

BACKGROUND AND OBJECTIVES
Pregnancy is a complex and continuously changing physiological process. With the increase in gestational age, a series of physiological changes, including hormone, metabolism, and immune, lead to the microbiota shift of pregnant women. Growing studies have shown that the dysbiosis of microorganisms is closely related to adverse pregnancy complications.

METHODS
We determined and compared the gut microbiota communities in the feces of gestational diabetes mellitus (GDM), Autoimmune diseases (AD), pregnancy-induced hypertension (PIH), and Hyperlipidemia (HPL) with healthy pregnant women using 16S rRNA gene sequencing and then investigated the relationships among gut microbiota, cytokines, and the four pregnancy complications.

RESULTS
Compared with the healthy pregnant group, microbial α diversity was increased in the GDM group while β diversity was decreased in the PIH group. At the phylum level, the abundance of *Bacteroidetes* was increased, while the abundance of Actinobacteria was decreased in GDM, AD, PIH, and HPL groups. T-test analysis found 28 differentially abundant taxa among the five groups. The pro-inflammatory cytokines in GDM, AD, PIH, and HPL serum were higher than in the control group. In addition to alterations in gut microbiota composition, we also found that *Lachnospiraceae_ND3007_group*, *Coxiella*, *Chloroplast*, *Mitochondria*, and *Bacteroides* were positively correlated with glycemic indicators and proinflammatory cytokine. Meanwhile, *Faecalibacterium*, *RF39*, *Clostridia_UCG-014*, *Ruminococcus*, and *Sellimonas* had negative correlations with HbA1c and FBG. Several genera, including *Faecalibacterium*, *Bifidobacterium*, *Dialister*, *Agathobacter*, and *Escherichia-Shigella* showed a significant and positive association with anti-inflammatory cytokines.

CONCLUSIONS
Overall, the human gut microbiome was involved in various pathophysiological pathways closely related to the pathogenesis of pregnancy complications, including inflammatory responses, and glucose and lipid metabolism. The gut microbiota may represent a potential noninvasive diagnostic and therapeutic strategy for pregnancy complications. Our study will expand the knowledge of maternal and infant health from the gut microbiota perspective, aiding in developing new preventive and therapeutic strategies for pregnancy complications based on intestinal microecology.

BACKGROUND AND OBJECTIVES

Genetic polymorphism of *methylene-tetrahydrofolate reductase (MTHFR)* at C677T locus modifies one-carbon metabolic flow to result in elevated blood homocysteine (Hcy) associated with increased Alzheimer's disease (AD) risks. Recent advances document blood pTau217 as the surrogate biomarker to predict risk of Alzheimer's AD-associated cognition dysfunction. Relationship between *MTHFR C677T* , dietary and blood biomarkers of methyl donor nutrients as to blood pTau and cognition dysfunction is unexplored.

METHODS

To test the hypothesis, this study recruited a total of 197 individuals including controls, SCD, MCI and AD from NTUH and FJH hospitals. Each patient underwent a Mini-Mental State Examination (MMSE) evaluated by a neurologist and had their plasma pTau tested through blood sampling. Germ line genetic polymorphisms of MTHFR C677T and APOE ε4 allele were genotyped in lymphocytes. Additionally, semi-quantitative food frequency questionnaires (FFQ) were collected to assess dietary one-carbon nutrient intake.

RESULTS

MTHFR C677T genotypes were assoiated with TMAO levels. For MTHFR CT/TT variants, energy-adjusted total choline levels were significantly and inversely associated with pTau levels (beta: -2.35, p = 0.01), whereas energy-adjusted free choline and phCH were positively and significantly associated with ptau levels. (beta: 1.85 and 1.91, respectively). Entering phosphocholine overrides total choline and its derivatives intakes effect to predict pTau variation (beta: -0.47, p = .05). Entrance of plasma Hcy and TMAO negated, whereas entrance of plasma methyl-donors status strengthen PhCH (beta: -.52, p = 0.02) prediction power for pTau variation. Entrance of energy-adjusted folate negated total choline intake prediction power on pTau levels (beta: .64, p = .03), whereas entrance of plasma TMAO and Hcy negated not only folate intake but also BMI/education prediction power for pTau. Interestingly, the relationship between dietary, blood markers, and pTau prediction was wiped out in individuals with MTHFR CC genotype.

CONCLUSIONS

The data suggest that the relationship between Pcho intake and ptau levels may be mediated by cellular one-carbon metabolism and SNP.

BACKGROUND AND OBJECTIVES

The risk of zinc deficiency is high among preschool-aged children (PSC) in many low- and middle-income settings. Data on zinc status are needed to guide the design and evaluation of interventions to improve zinc nutrition but are often limited. Technical, logistical, and financial constraints contribute to the dearth of high-quality plasma/serum zinc (PZC) data. A new portable X-ray fluorescence technique (XRF) has been developed to measure nail zinc concentrations (NZC). The current study aimed to compare the new XRF technique for measuring NZC against the reference, Inductively Coupled Plasma Optical Emission Spectroscopy (ICP-OES) method.

METHODS

The current study involved a sub-sample (n=54) of PSC enrolled in a trial of multiply-fortified salt in Punjab, India. Fingernail clippings were collected at enrollment using sterilized child safety clippers. To remove environmental contaminants, nail clippings were manually scraped with a ceramic blade to remove debris. Then, the nail samples underwent sonication in 0.5 ml of 5% Triton X-100 for 10 min, followed by 3 cycles of vortexing in 1ml of OmniTrace water for 10 sec, and were dried at 60°C for 12-18 h. NZC in the samples were determined non-destructively using the portable XRF system, followed by ICP-OES analysis. The association between NZC measured with XRF vs ICP-OES was investigated using Spearman correlational analysis and Bland Altman plots.

RESULTS

Mean ± SD child age was 36.7±13.2 months. The prevalence of child stunting was 7.4%. NZC using XRF was 88.6 ± 17.3 ug/g and the corresponding NZC using ICP-OES was 110.8 ± 18.5 ug/g. The correlation between NZC measured with XRF vs. ICP-OES was strong ($\rho = 0.71$; $p < 0.0001$). The mean difference ± SD [lower limit of agreement, upper limit of agreement] between XRF and ICP-OES for NZC was -22.2 ± 13.5 [-48.7, 4.2] ug/g. The RESULTS of the association between NZC and serum zinc are forthcoming.

CONCLUSIONS

The strong and positive correlation between NZC using XRF vs ICP-OES is promising and shows that the XRF can be used to measure NZC in PSC. Though NZC cut-offs for zinc deficiency have not been established yet, the lack of agreement between the two methods suggests the XRF method may not be useful for assessing zinc deficiency at the population level. Further analysis will evaluate the correlation and agreement between NZC using XRF and ICP-OES and PZC, which is the recommended biomarker for measuring zinc status in PSC.

ALTERED CHOLINE INTAKES ARE ASSOCIATED WITH COGNITIVE DYSFUNCTION AND GUT MICROBIOTA DYSBIOSIS: A PILOT STUDY IN NUTRITION AND ALZHEIMER'S DISEASES PREVENTION

Chao-Yun Wang[1]; Ming-Lu Lin[2]; Hui-Hsuan Shih[2]; Ya-Wen Hsueh[2]; Yu-Chen Cheng[3, 4]; Chang-Sheng Kuo[5]; Hui-Chen Lo[2, 1]; Chun-Li Su[6]; Chi-Ying Huang[7]; Feng-Sheng Wang[8]; Da-Fu Chen[9]; Rwei-Fen S. Huang[2, 1]
[1]Ph.D. Program in Nutrition and Food Science, Fu Jen Catholic University, New Taipei, Taiwan; [2]Department of Nutritional Science, Fu Jen Catholic University, New Taipei, Taiwan; [3]Department of Neurology, Fu Jen Catholic University Hospital, New Taipei, Taiwan; [4]School of Medicine, College of Medine, Fu Jen Catholic University, New Taipei, Taiwan; [5]Department of Nutrition, Fu Jen Catholic University Hospital, New Taipei, Taiwan; [6]Graduate Program of Nutrition Science, School of Life Science, National Taiwan Normal University, Taipei, Taiwan; [7]Institute of Biopharmaceutical Sciences, College of Pharmaceutical Sciences, National Yang Ming Chiao Tung University, Taipei, Taiwan; [8]Department of Chemical Engineering, National Chung Cheng University, Chiayi, Taiwan; [9]Department of Neurology, National Taiwan University Hospital, Taipei, Taiwan

BACKGROUND AND OBJECTIVES
Preclinical studies have documented the effects of choline intake, as metabolized by gut microbiota, on the production of Trimethylamine-N-Oxide (TMAO), homocysteine levels, and markers of cognitive dysfunction. However, human studies remain limited. The study aims to investigate if altered choline intakes are associated with cognition dysfunctional markers and gut microbiota dysbiosis and the working mechanism.

METHODS
Subjects were grouped into Control (N=19), Subjective Cognitive Decline (SCD, N=13), and Cognitive Decline (CD, N=21). Each subject underwent Mini-Mental State Examination (MMSE), Clinical Dementia Rating (CDR), and semi-quantitative Food Frequency Questionnaires (FFQ), and plasma analysis of pTau, TMAO, and homocysteine (HCY). Gut microbiota were analyzed using Kinnex 16S rRNA kit and MicrobiomeAnalyst 2.0. Associations between CD biomarkers and the fecal microbiome were assessed by LASSO regression of standardized, centered log-ratio transformed genera in R 4.3.1.

RESULTS
We stratified participants by adequate choline intake (adult Female: 400 mg, Male: 450 mg) into high and low intake groups. The microbial diversity of the control group was distinctively different from the SCD and CD groups. In the control group, *Blautia_A* negatively correlated with cognitive decline, CDR, and TMAO (Coefficient: -8.79E-06) but positively with HCY (Coefficient: 0.01) under high choline intake. *Anaerostipes* also showed a negative association with TMAO under high choline intake (Coefficient: -0.0002). *Fusobacterium_A_varium* was enriched in the SCD group (high choline) and the CD group (low choline) but positively correlated with CDR (Coefficient: 0.1) only under low choline intake. In the CD group, *Parabacteroides_merdae* correlated with disease progression, Ptau, and negatively with MMSE. It was negatively associated with HCY (Coefficient: -0.01) under high choline intake but positively with CDR under low choline intake. *Anaerobutyricum hallii* positively correlated with HCY (Coefficient: 0.02) only under low choline intake. Choline intake modulated the gut microbiota's effects on HCY and cognitive decline. However, microbiota in the control group may utilize choline through distinct pathways, reducing TMAO while increasing HCY.

CONCLUSIONS
Our data revealed that the microbiota stability of the control group was independent of choline intake. Microbiota dysbiosis of the CD group was associated with cognitive dysfunctional markers, which could be modified by dietary choline intake.

THE EFFECT OF MEDIUM-CHAIN FATTY ACIDS OR MEDIUM-CHAIN TRIGLYCERIDES ON GLYCAEMIC CONTROL: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

Shokri-Mashhadi Nafiseh[1]; Bächle Christina[2]; Edyta Schaefer[3]; Janett Barbaresko[3]; Sabrina Schlesinger[2]
[1]Institute for Biometrics and Epidemiology, German Diabetes Center (DDZ), Auf'm Hennekamp, Düsseldorf, Germany, Düsseldorf, Germany; [2]Institute for Biometrics and Epidemiology, German Diabetes Center (DDZ), Düsseldorf, Germany; [3]Intstitute for Biometrics and Epidemiology, German Diabetes Center, Düsseldorf, Germany

BACKGROUND AND OBJECTIVES
Intake of dietary long-chain triacylglycerols (LCTs) with medium-chain fatty acids (MCFAs) or medium-chain triacylglycerols (MCTs) may have mixed effects on cardiometabolic health, with some evidence suggesting they can modestly reduce body weight and composition without adversely affecting lipid profiles. However, the effects of MCFAs and MCTs on glycaemic biomarkers remain poorly understood. Therefore, we conducted a systematic review and meta-analysis to evaluate the impact of dietary intake or supplementation of MCFAs and MCTs on glycaemic parameters in adults.

METHODS
A systematic search was conducted in four databases from inception up to 30 June 2024. RCTs investigating the effect of MCFAs or MCTs on fasting blood glucose (FBG), hemoglobin A1c (HbA1c), fasting insulin, and HOMA-IR compared to a control group were included. Records were excluded when studies reported the effect of co-interventions, conducted on pregnant women, children, or adolescents. Summary mean differences and corresponding 95% confidence intervals were calculated using a random-effects model.

RESULTS
Overall, 18 publications with 22 effect sizes were included in the meta-analyses, focusing on healthy individuals (n = 9), type 2 diabetes (n = 2), obesity (n = 2), and other conditions like cancer, mild cognitive impairment, or hypertriglyceridemia (n = 5). The mean age of the trial participants ranged from 20 to 75 years. Two studies used MCFAs, while the rest employed MCT oil or MCT-based formulas, with intervention durations ranging from 4 days to 24 weeks. Participants in the control groups mostly consumed long-chain fatty acids (n=13), while others receiving placebo (n=4) or low doses of MCTs (n=1). Most RCTs included both men and women, except for three that included only men and one only woman.The overall RESULTS indicated no improvement in FBG (MD = 0.02 mg/dL; 95% CI: -1.59, 1.62; n = 22; I2=83%), HbA1c (MD = -0.3%; 95% CI: -0.17, 0.11; n = 5; I2=31%), or HOMA-IR (MD = 0.06 units; 95% CI: -0.39, 0.51; n = 5; I2=42%), but a small reduction in fasting insulin levels (MD = -0.42 μU/L; 95% CI: -0.81, -0.02; n=12; I2=84 %) in the MCTs group compared to the control group.

CONCLUSIONS
Our findings suggest that MCFA and MCT supplementation may have no effect on glycaemic control, and reductions in fasting insulin levels were minimal. Further research could focus on identifying specific subpopulations or conditions where MCTs and MCFA might have a more pronounced effect.

MEAL TIMING AND LAST MEAL TIME RELATES TO METABOLIC PARAMETERS IN HEALTHCARE ROTATING NIGHT SHIFT WORKERS

Daniela González[1]; Rebeca Peralta[1, 2]; Andrea Marín[1]; Daniel Riveros[1]; Pamela Rojas[1]; Rodrigo Villegas[3]; Rodrigo Chamorro[1]

[1]Department of Nutrition, University of Chile, Santiago, Chile; [2]Nutrition and Food Programs, National Institute of Food and Nutrition, Ministry of Public Health and Social Welfare, Asunción, Paraguay; [3]Biostatistics Program, School of Public Health, University of Chile, Santiago, Chile

BACKGROUND AND OBJECTIVES

Optimal functioning of the circadian system is of paramount importance to achieve proper health. A circadian disruption occurs when sleep-wake and eating-fasting rhythms are not aligned with the light-dark cycle. One of the main circadian disruptors comprises shift work, which alters physiological processes such as digestion, energy expenditure, blood pressure, and overall metabolism. Shift work alters eating patterns and typical eating window (time elapsed between the first and last meal of the day) time. We aimed to evaluate the eating timing and eating window length associated with metabolic parameters in rotating night shift workers (NSW).

METHODS

Were studied fifty-five adults, between 18 and 65 years old, before recruitment in a randomized trial assessing the circadian and metabolic effects of restricting daily eating time. In a clinical evaluation, weight, height, waist and neck circumference, blood pressure, and heart rate were evaluated. A fasting blood sample was used to measure glycemia, insulin, blood lipids, and ultra-sensitive c-reactive protein (usCRP) levels. The type and timing of each meal and eating window duration were evaluated through a 24-hour recall survey. Based on the mean timing of the last meal of those with full dataset, we compared those participants with (n=18, Early-Last, EL) and without (n=26, Late-Last, LL) food intake after 21:00h.

RESULTS

Participants were young adults (34.8 ± 8.9 years), primarily female (96% F), with a mean BMI (29.6 ± 4.5 kg/m2), 50.0% having obesity. The mean eating window was 12.2 ± 2.1 h/day, and the last meal averaged 21.4 ± 1.8 h. Eating window and meal frequency were higher in the LL group (both $p<0.001$). The time of the last meal, excluding breakfast and lunchtime was associated with higher glycemia levels (rho, 0.42, $p=0.011$). Both EL and LL groups had similar anthropometrics, vitals, serum glucose and insulin, and HOMA-IR. However, LDL-cholesterol ($p=0.043$) was lower, and usCRP level tended to be higher ($p=0.054$) in the LL group.

CONCLUSIONS

The eating window and meal frequency were higher in those with food intake after 21:00h. The late timing of the last meal relates to increased glycemia, blood lipids, and inflammation status in healthcare NSW. Further research should evaluate the circadian and metabolic effects of modifying the eating window duration in this group.

USE OF METABOTYPING TO IDENTIFY INDIVIDUALS WITH DIFFERENT TRIGLYCERIDES RESPONSE CURVES AFTER INTAKE OF HIGH FAT MEALS

Jiaying Hu[1]; Matteo D'alessandro[2]; Patrik Hansson[3, 4, 1]; Kirsten Bjørklund Holven[1, 5]; Magne Thoresen[2]; Stine M Ulven[1]

BACKGROUND AND OBJECTIVES

Metabotyping is a novel concept in precision nutrition that groups people based on their shared metabolic characteristics. However, most studies use data from a single meal for metabotyping. We have previously performed a randomized controlled cross-over meal study with four different high fat meals with similar fat content from different dairy products (Hansson et al., 2019). We observed a large variation in individual triglyceride (TG) response, and in this current project, we aim to identify different groups of triglyceride responders and define their metabolic and biological profile.

METHODS

Forty-seven healthy adults (fourteen males) aged 25-46 y with BMI 21.0-25.8 kg/m2 were included for analysis. Metabolic parameters were measured before intake of each of the four meals and at 2, 4, 6h postprandially. Lipoprotein subclasses were measured using nuclear magnetic resonance. The incremental area under the curve (iAUC) was calculated for metabolic parameters and lipoprotein subclasses.

A latent class mixed model was applied to analyse the data. This method identifies subgroups in the population by modelling both the trajectory over time and the effect of different meals, while allowing for individual variability.

RESULTS

Four different subgroups (clusters) were identified. Since one cluster included only two subjects, we continued with three clusters (n = 45). Cluster 1 (n = 18) displayed low TG response to the meals, cluster 2 (n = 21) had the highest TG peak at 2h and returned to baseline at 6h, and cluster 3 (n = 6) had a continuous high TG level after 2h. Significant differences ($p < 0.05$) between the clusters were found for sex, fat mass, and visceral adipose tissue (VAT); cluster 3 had significantly higher mean VAT than cluster 1. Regarding other biochemical parameters, glucose-iAUC and GlycA-iAUC showed significant differences between the clusters, with the largest GlycA-iAUC in cluster 3.

CONCLUSIONS

This work revealed three response groups based on dynamic postprandial TG changes. The latent class mixed model was able to accommodate different types of data and took the meal differences into account. Since the model assigned a probability to each cluster, the repeated measures increased the reliability of clustering RESULTS. This approach holds a potential to be used for detecting metabolic dysfunctions, and it aids in delivering personalised nutritional interventions.

FOOD AVOIDANCE IN ANOREXIA NERVOSA:AN EXPERIMENTAL PARADIGM ASSOCIATING GAZE MONITORING DURING PREFERENCE FOOD EVALUATIONS TASKS AND THE WILLINGNESS TO EAT WITH DIFFERENT CALORIC VALUE

Amale Zemmahi[1, 2, 3, 4]; Justine Debatisse[4]; Natacha Germain[3, 1, 2]; Justine David[4]; Mathilde Roullot[4]; Elise Metereau[4]; Louis Carrier[5]; Catherine Massoubre[6, 1, 3]; Léon Tremblay[4]; Bogdan Galusca[1, 2, 3]
[1]Centre Référent TCA, Hospital Nord, Saint-Priest-en-Jarez, France; [2]Endocrinologie, Hospital Nord, Saint-Priest-en-Jarez, France; [3]TAPE research group, Jean Monnet University - North Campus Hospital, Saint-Priest-en-Jarez, France; [4]Neurosciences, Institute Of Science Cognitives, Bron, France; [5]TCA, Clinique Saint-Vincent de Paul, Lyon, France; [6]Psychiatry, Hopital nord, Saint-etienne, France

BACKGROUND AND OBJECTIVES
Anorexia Nervosa (AN) is a severe psychiatric disorder characterized by excessive food restriction and avoidance of high-calorie and high-fat foods, stemming from an intense fear of weight gain. These maladaptive behaviors reflect a conflict between the "willingness-to-eat" and the fear of negative outcomes associated with eating. Such behaviors often lead to poor nutritional intake, exacerbating health risks. While avoidance of nutrient-rich foods is a hallmark of AN, the underlying cognitive and emotional mechanisms driving these maladaptive decisions remain poorly understood.

METHODS
This study involved 67 patients with anorexia nervosa and 37 healthy controls. AN patients were subdivided for several analysis in two groups: those with restrictive form (AN-R, n=30) and those combining both restrictive and bulimic behaviors (AN-B, n=37). We developed an experimental paradigm to investigate the link between these cognitive disturbances by monitoring gaze (eye tracking) during three tasks aimed at evaluating the health, taste and preference values of food pics divided in three categories according to their caloric content: hypo- intermediate and hyper-caloric foods. Moreover, we evaluated the reject rate and quantity wanted of each food item to compose their meal.

RESULTS
Both patient’s subgroups showed significant attentional avoidance of high-calorie food stimuli, characterized by reduced fixation durations compared to controls ($p < 0.01$). Gaze patterns predicted decision-making, with longer fixation durations on selected food items significantly correlating with participants' eventual acceptance of those items, while shorter fixation durations were associated with food items that were ultimately rejected ($p < 0.001$). Intermediate foods were more likely to be “accepted” over high-calorie items ($p < 0.001$) but avoided when compared to low-calorie options ($p < 0.001$). In the willingness-to-eat task, AN-B patients exhibited heightened stress and greater fixation on avoidance areas compared to AN-R ($p < 0.001$).

CONCLUSIONS
Crucially, our findings reveal that while food avoidance in AN is primarily visual, actual food choices are strongly influenced by contextual comparisons. Patients consistently preferred lower-calorie options, with AN-B patients showing greater challenges in decision-making. Individual responses varied. This personalized understanding of food acceptance and avoidance offers promising opportunities for targeted therapeutic strategies aimed at gradually reintroducing and revaluing nutrient-dense foods in the treatment of AN.

USING COMPUTED TOMOGRAPHY (CT) AND THE GLOBAL LEADERSHIP INITIATIVE ON MALNUTRITION (GLIM) TO PREDICT SURVIVAL IN CURATIVE AND ADVANCED CANCER PATIENTS

Clodagh Scannell[1]; Erin Stella Sullivan[2, 1]; Ross Dolan[3]; Josh Mcgovern[3]; Marie Fallon[4]; Barry Laird[4]; Derek Power[5]; Aoife Ryan[1]
[1]School of Food & Nutritional Sciences, University College Cork, Cork, Ireland; [2]Department of Nutritional Sciences, King's College London, London, United Kingdom; [3]Academic Unit of Surgery, University of Glasgow, Glasgow, United Kingdom; [4]Department of Palliative Medicine, University of Edinburgh, Edinburgh, United Kingdom; [5]Department of Medical Oncology, Mercy University Hospital, Cork, Ireland

BACKGROUND AND OBJECTIVES
Despite debilitating consequences, cancer-associated malnutrition is underdetected due to the lack of a standardised diagnosis. The GLIM criteria were established in 2018 in order to standardise the diagnosis of malnutrition. The aim of this study was to determine the association between GLIM-diagnosed malnutrition and overall survival in a large cohort of patients with mixed-cancer types. This is the first study to stratify patients according to treatment intent (curative, active palliative vs. supportive care only) and is one of the largest studies to identify reduced muscle mass using CT analysis of body composition.

METHODS
Patients receiving anti-cancer treatment for solid tumours were enrolled in a cross-sectional study to examine nutritional status between 2011-2016. The GLIM criteria was retrospectively applied. CT images at the third lumbar vertebrae (L3) were used to quantify skeletal muscle index and categorised according to previously published cut-points. Survival analysis was carried out using Kaplan-Meier curves and Cox-Regression.

RESULTS
Of 1405 patients, 53% were male. Mean(SD) age was 62(12) years, 45% were gastrointestinal cancers and 60% had metastases. In total, 40% were diagnosed with GLIM-malnutrition (15% had stage 1 moderate and 26% had stage 2 severe malnutrition). Median follow-up was 102 months (95% CI: 100-105 months). Median survival for those without malnutrition was 30 months (95% CI 24–37 months), versus 11 months (95% CI 7 – 15 months, $p<0.001$) for stage 1 moderate and 10 months (95% CI 8–12 months $p<0.001$) for stage 2 severe malnutrition. Multivariate analysis (controlling for gender, age, cancer site, Eastern Cooperative Oncology Group performance score and treatment intent) demonstrated poorer overall survival [HR: 1.504 (95% CI 1.238–1.820), p<0.001] in stage 1 moderate malnutrition and HR:1.565 (1.345–1.828, p<0.001) for stage 2 severe malnutrition. Stage 2 severe malnutrition was significantly more prevalent in the supportive care cohort (33%) when compared to patients being treated with curative intent (18%, $p=0.004$).

CONCLUSIONS
This study is one of the largest studies to date which uses CT analysis to accurately identify reduced muscle mass and confirms that the GLIM criteria can be used to predict overall survival in a large mixed-cancer cohort. These findings suggest that malnutrition, regardless of GLIM severity ranking has a significant impact on overall survival. Future research should focus on determining oncology specific cut-points for the GLIM criteria.

INVESTIGATING THE USE OF BIOLOGICALLY-BASED COMPLEMENTARY AND ALTERNATIVE MEDICINE (BBCAM) IN PEOPLE LIVING WITH AND BEYOND CANCER IN IRELAND

Clodagh Scannell[1]; Erin Stella Sullivan[2, 1]; Karen Matvienko-Sikar[3]; David Robert Grimes[4]; Derek Power[5]; Aoife Ryan[1]

[1]School of Food & Nutritional Sciences, University College Cork, Cork, Ireland; [2]Department of Nutritional Sciences, King's College London, London, United Kingdom; [3]School of Public Health, University College Cork, Cork, Ireland; [4]TCD Biostatistics Unit, Trinity College Dublin, Dublin, Ireland; [5]Department of Medical Oncology, Mercy University Hospital, Cork, Ireland

BACKGROUND AND OBJECTIVES

Biologically-based complementary and alternative medicine (BBCAM) use is common among cancer survivors. BBCAM can interact with conventional treatments, and unregulated products may cause harm. This study aimed to determine the prevalence, types, and motivations for BBCAM use among cancer survivors.

METHODS

An online survey assessed clinical characteristics and CAM use in participants >18yrs who had received cancer treatment in Ireland from 2018-2022. The survey was widely advertised in clinical settings and online through charity organisations. The survey was completed anonymously on Castor EDC. The National Center for Complementary and Integrative Health definitions were used, and examples of BBCAM were given to participants before questions were posed about their use. These examples included vitamin/mineral supplements not prescribed by a dietitian or doctor, herbal remedies, alternative diets, food supplements and various pseudomedicines. BBCAM use was characterised both pre-diagnosis and post-diagnosis. Perceived safety, reasons for use and possible risks and benefits were explored. Analyses were carried out in SPSS. Chi-square tests and Bonferroni corrections for multiple testing were applied to determine differences between groups in BBCAM use.

RESULTS

Amongst 295 respondents (77% female, mean age 53 years), BBCAM use increased from 28% pre-diagnosis to 34% post-diagnosis ($p<0.001$). For BBCAM users (n=97, 33%), 'daily-use' increased from 38% to 72% ($p<0.001$) post diagnosis. Common types included: mineral/vitamin supplements (84%), dietary supplements (e.g. turmeric, coenzyme-Q10) (78%), herbal remedies/botanicals (e.g. mistletoe, St. John's Wort, echinacea, ginseng) (50%), cannabis (21%), and other natural products (laetrile, shark cartilage, apricot kernels) (19%). Biological medicines (GcMAF, immuno-augmentative therapy) were used by 12% of BBCAM users. Special diets including dairy free (32%), gluten-free (19%), intermittent fasting (17%), ketogenic diet (15%), juicing/detox (10%) were also common. Perceived benefits included: improved well-being (63%) and reduced psychological stress (59%).

CONCLUSIONS

BBCAM use increases after a cancer diagnosis. Patient perceived benefits highlight potential gaps in the current healthcare model, indicating a need for greater emphasis on safe survivorship care. Healthcare professionals should ask people living with and beyond cancer about their use of BBCAM and explore unmet needs, such as poorly controlled symptoms.

ASSOCIATION OF CIRCULATING METABOLITES WITH GENETIC RISK, LIFESTYLE, AND FAMILY HISTORY OF DIABETES

Masato Takase[1]; Nakaya Naoki[1]; Kogure Mana[1]; Rieko Hatanaka[1]; Nakaya Kumi[1]; Chiba Ippei[1]; Tokioka Sayuri[1]; Motoike Ikuko[2]; Hishinuma Eiji[3]; Koshiba Seizo[3]; Tamiya Gen[4]; Hozawa Atsushi,[1]
[1]Preventive Medicine and Epidemiology, Tohoku Medical Megabank Organization, Sendai, Japan; [2]Genome Analysis Division, Tohoku Medical Megabank Organization, Sendai, Japan; [3]Advanced Research Center for Innovations in Next-Generation Medicine, Tohoku University, Sendai, Japan; [4]Center for Advanced Intelligence Project, RIKEN, Sendai, Japan

BACKGROUND AND OBJECTIVES
Previous studies have shown that family history of diabetes, genetic predisposition, and lifestyle factors independently influence the risk of developing diabetes (1-3). Although these factors help stratify diabetes risk, the underlying mechanisms remain unclear, posing challenges for personalized prevention. Metabolomic profiling may reveal novel pathways by exploring differences associated with genetic, lifestyle, and familial risks. This study aims to identify metabolite differences linked to family history, genetic risk, and lifestyle factors.

METHODS
We analyzed data from 12,461 diabetes-free Japanese individuals aged 20 years or older. Lifestyle scores, incorporating body mass index, smoking, physical activity, and gamma-glutamyl transferase (a marker of alcohol consumption), categorized participants into ideal, intermediate, or poor lifestyle groups (2). We constructed a polygenic risk score (PRS) based on type 2 diabetes loci from the BioBank Japan study (4) and combined family history, PRS tertiles, and lifestyle risk to form 18 groups. Plasma metabolites were quantified using NMR spectroscopy. First, we evaluated the relationship between family history, PRS, and lifestyle risk on diabetes development using Poisson regression models with robust variance correction to calculate relative risk (RR) and 95% confidence intervals (CIs). Second, we examined differences in metabolites across the 18 groups using multiple linear regression models.

RESULTS
Over a median follow-up of 4.3 years, 354 participants developed diabetes. Compared to individuals with no family history, low PRS, and an ideal lifestyle, high PRS increased diabetes risk even in those with no family history and an ideal lifestyle (RR, 3.49; 95% CI, 1.62–7.54). Similarly, a family history increased diabetes risk even among participants with low PRS and an ideal lifestyle (RR, 2.28; 95% CI, 1.08–4.84). Compared to individuals with no family history, low PRS, and an ideal lifestyle, Participants with no family history, an ideal lifestyle, and high PRS had significantly elevated levels of 11 metabolites, including isoleucine, creatine, ornithine, and glucose. Meanwhile, those with an ideal lifestyle, low PRS, and a family history showed elevated levels of 13 metabolites including histidine, threonine, arginine, and proline.

CONCLUSIONS
Several metabolites may serve as targets for diabetes prevention interventions tailored to an individual's genetic and lifestyle profile.

SAFETY, TOLERABILITY AND WEIGHT REDUCTION FINDINGS OF ORAL AMYCRETIN: A NOVEL AMYLIN AND GLUCAGON-LIKE PEPTIDE-1 RECEPTOR CO-AGONIST, IN A FIRST-IN-HUMAN STUDY

Vanessa Folope Leborgne[1]; Agnes Gasiorek[2]; Arne Heydorn[2]; Katrine Kirkeby[2]; Cassandra Key[3]; Soren Toubro[2]; Line Hollesen Schefe[2]; Kirsten Dahl[2]; Julie B. Hjerpsted[2]; Andreas Vegge[2]
[1]Medical affairs, Novo Nordisk, Puteaux, France; [2]Clinical pharmacology, Novo Nordisk A/S - site Måløv, Måløv, Denmark; [3]Clinical research unit, ICON Development Solutions, San Antonio, United States of America

BACKGROUND AND OBJECTIVES
Obesity is a major global health burden with limited treatment options. Amidst investigations into the potential synergy beyond glucagon-like peptide-1 receptor agonists (GLP-1RAs), the combined efficacy of the amylin analogue cagrilintide and the GLP-1RA semaglutide is being explored as a subcutaneous treatment solution. This study introduces amycretin, a novel protein-based unimolecular amylin and GLP-1 receptor co-agonist for once-daily oral administration. The aim of this first-in-human study was to investigate the safety, tolerability, pharmacokinetics and weight loss effects of single and multiple oral doses of amycretin in participants with overweight or obesity.

METHODS
In this first-in-human, single-centre, placebo-controlled, double-blinded study (NCT05369390), participants with a BMI of 25.0–39.9 kg/m2 without diabetes were randomised to receive once-daily oral amycretin (n=95) or placebo (n=29). The study consisted of three parts: single-ascending dose (Part A, 1–25 mg), 10-day multiple-ascending dose (Part B, 3–12 mg) and 12-week multiple-ascending dose (Part C, 3–2×50 mg) parts. The primary endpoint was the number of treatment-emergent adverse events (AEs), while secondary endpoints included AUC and Cmax for plasma amycretin. Change in body weight from baseline was evaluated as a key exploratory endpoint.

RESULTS
At week 12, the mean change in body weight (amycretin 50 mg, –10.4% [SD, 4.6]; amycretin 2×50 mg, –13.1% [SD, 4.8]) was significantly greater with oral amycretin versus placebo (–1.1% [SD, 2.6]; $p<0.0001$ for both doses) (Fig. 1). The majority of AEs reported were mild to moderate in severity and related to gastrointestinal discomfort (i.e. nausea and vomiting), and decreased appetite. These AEs occurred in a dose-proportional manner, with low tolerability for dose levels ≥18 mg when amycretin was administered as a single dose and ≥12 mg when administered for 10 consecutive days. However, by introducing stepwise dose escalation, all tested dose levels up to and including 2×50 mg had acceptable safety and tolerability profiles.

CONCLUSIONS
Daily oral amycretin treatment in adult participants with overweight or obesity and without diabetes demonstrated acceptable safety and tolerability profiles and led to remarkable reductions in body weight over only 12 weeks. The lack of weight loss plateauing indicates the possibility of achieving further weight reductions with extended treatment. The RESULTS underscore the promising potential of amycretin as an anti-obesity medication.

ORAL SEMAGLUTIDE 50 MG ONCE DAILY IMPROVES PHYSICAL FUNCTIONING IN THE OASIS 1 TRIAL

Vanessa Folope Leborgne[1]; Domenica Rubino[2]; Thomas Holst-Hansen[3]; Tobias Karlsson[4]; Kirsi H Pietiläinen[5]; Andrea Traina[6]; Sean Wharton[7]; Thomas Wadden[8]
[1]Medical, Novo Nordisk, Puteaux, France; [2]Medical, Washington Center for Weight Management and Research, Arlington, United States of America; [3]Statistical Department, Novo Nordisk, Søborg, Denmark; [4]Medical Affairs, Novo Nordisk, Søborg, Denmark; [5]Abdominal Center, Obesity research unit, research program for clinical metabolism, university Helsinki Hospital, Helsinki, Finland; [6]Medical affairs, Novo Nordisk Inc.,, Plainsboro Township, United States of America; [7]Medical, McMaster University - Toronto Campus, Toronto, Canada; [8]Department of psychiatry, Perelman School of Medicine at the University of Pennsylvania : Division of Rheumatology, Philadelphia, United States of America

BACKGROUND AND OBJECTIVES
In OASIS 1, the estimated mean percentage body weight change from baseline to week 68 was –15.1% with once-daily oral semaglutide 50 mg and –2.4% with placebo; comparable to weight loss with once-weekly subcutaneous semaglutide 2.4 mg. In this analysis, the impact of semaglutide vs placebo on physical functioning (PF) was evaluated based on patient-reported data from the Impact of Weight on Quality of Life-Lite Clinical Trials Version (IWQOL-Lite-CT) and Short Form-36v2 Health Survey acute version (SF-36v2) instruments.

METHODS
In the OASIS 1 trial (NCT05035095), 667 adults with overweight or obesity were randomized 1:1 to semaglutide or placebo, plus lifestyle intervention. Changes from baseline to week 68 in the PF domains of the IWQOL-Lite-CT and SF-36v2 were assessed by analysis of covariance for the treatment policy estimand for all participants and for a subgroup with poor baseline PF (n=88; 13.2%) (defined as participants who responded “Poor” on PF of the Patient Global Impression of Severity questionnaire). The number of participants achieving a meaningful within-person improvement in PF in IWQOL-Lite-CT (≥14.6 points), and SF-36v2 (≥3.7 points) were also assessed. Anchor-based methods were used to derive these cut-off scores.

RESULTS
Significantly greater improvements from baseline to week 68 with semaglutide vs placebo in the IWQOL-Lite-CT PF score were observed for all participants (estimated treatment difference [ETD] 10.5 points, 95% confidence interval [CI] 7.5, 13.6) and for participants with poor baseline PF (ETD 14.4 points, 95% CI 4.4, 24.4). Similar RESULTS were observed in the SF-36v2 PF score (all participants, ETD 2.3 points, 95% CI 1.4, 3.2; participants with poor baseline PF, ETD 4.2 points, 95% CI 0.9, 7.5). Semaglutide-treated participants were more likely to achieve meaningful improvement in PF at week 68 vs placebo in the IWQOL-Lite-CT (50% vs 31%, odds ratio [OR] 2.8, 95% CI 1.9, 4.1) and in the SF-36v2 (37% vs 20%, OR 2.9, 95% CI 1.9, 4.5). Greater categorical weight loss was associated with greater improvements in PF in both instruments (data not shown).

CONCLUSIONS
Once-daily oral semaglutide 50 mg provided meaningful improvement in physical functioning in participants with overweight/obesity, including those with poor physical functioning at baseline.

PERSONALIZED HYPERTENSION RISK PREDICTION: GENETIC AND METABOLIC INSIGHTS ACROSS MENOPAUSAL STAGES

Ximei Huang[1]; Jua Park[1]; Minjoo Kim[1]
[1]Department of Food and Nutrition, College of Life Science and Nano Technology, Hannam University, Daejeon, Korea, Republic of

BACKGROUND AND OBJECTIVES
Postmenopausal women face an elevated risk of hypertension due to hormonal and metabolic changes. This study aimed to develop stage-specific hypertension risk models for premenopausal and postmenopausal Korean women by integrating genetic risk scores (GRS) with metabolic markers, facilitating more precise and personalized risk prediction.

METHODS
A total of 1,246 Korean women were classified into premenopausal (n=615; normal: n=547, hypertension: n=68) and postmenopausal (n=631; normal: n=457, hypertension: n=174) groups. Genome-wide association studies identified 11 single nucleotide polymorphisms (SNPs) associated with hypertension ($P < 1\times10^{-5}$). Four SNPs formed GRS4 for premenopausal women, and three SNPs formed GRS3 for postmenopausal women. Key metabolic predictors were identified and integrated into GRS-based predictive models.

RESULTS
In premenopausal women, age, BMI, and triglycerides were identified as significant predictors of hypertension, while brachial-ankle pulse wave velocity (ba-PWV) was the sole metabolic predictor in postmenopausal women. The integrated models demonstrated strong predictive performance, with area under the curve (AUC) values of 0.811 (95% CI: 0.756–0.867, $P < 0.001$) for premenopausal women and 0.859 (95% CI: 0.795–0.923, $P < 0.001$) for postmenopausal women.

CONCLUSIONS
Predictive models incorporating GRS and metabolic markers effectively assessed hypertension risk in premenopausal and postmenopausal women. The distinct predictors across menopausal stages underscore the importance of stage-specific, tailored risk assessment approaches. These models have potential applications in preventive healthcare and patient education and may serve as a foundation for personalized health management. Further research is needed to validate these findings across diverse populations and optimize their clinical utility.

EPO7_113

MENDELIAN RANDOMIZATION STUDY ON HS-CRP AND DYSLIPIDEMIA IN KOREANS: IDENTIFICATION OF NOVEL SNP RS76400217

Ximei Huang[1]; Youngmin Han[2]; Minjoo Kim[1]
[1]Department of Food and Nutrition, College of Life Science and Nano Technology, Hannam University, Daejeon, Korea, Republic of; [2]Institute for Health Promotion, Graduate School of Public Health, Yonsei University, Seoul, Korea, Republic of

BACKGROUND AND OBJECTIVES
High-sensitivity C-reactive protein (hs-CRP) is a marker of systemic inflammation and is associated with developing dyslipidemia. However, the causality between hs-CRP and dyslipidemia remains unresolved. This study aimed to investigate the relationship between hs-CRP concentrations and dyslipidemia and to explore the potential causal link using Mendelian Randomization (MR) analysis. High-sensitivity C-reactive protein (hs-CRP) is a marker of systemic inflammation and is associated with developing dyslipidemia. However, the causality between hs-CRP and dyslipidemia remains unresolved. This study aimed to investigate the relationship between hs-CRP concentrations and dyslipidemia and to explore the potential causal link using Mendelian Randomization (MR) analysis.

METHODS
A nested case-control study was conducted with 1,174 participants, and genotype data were analyzed using the Korean Chip. A genome-wide association study (GWAS) identified rs76400217 as a suitable instrumental variable (IV) due to its significant association with hs-CRP (P<10-8). Logistic regression models, adjusted for confounders, were used to evaluate the association between hs-CRP and dyslipidemia. MR analysis was performed using a two-stage least squares (2SLS) method, with rs76400217 as the IV to assess causality.

RESULTS
Logistic regression showed a significant association between hs-CRP concentrations and dyslipidemia (OR 2.08, 95% CI: 1.81-2.39, P<0.001). This association remained significant after adjusting for factors such as age, sex, alcohol consumption, and BMI. MR analysis using rs76400217 as IV confirmed strong associations with hs-CRP concentrations (P<0.001) in all models, but the causality between hs-CRP and dyslipidemia was not statistically significant.

CONCLUSIONS
Thus, no evidence of a causal relationship between hs-CRP and the risk of dyslipidemia was found in the Korean population. The strong observed association between hs-CRP and dyslipidemia may be due to other contributing factors rather than a direct cause.

EFFECT OF LIRAGLUTIDE TREATMENT AFTER A HYPOCALORIC DIET ON WEIGHT LOSS MAINTENANCE: IMPACT AND ROLE OF THE INTESTINAL MICROBIOTA

Rohia Alili[1]; Eugeni Belda[2]; Anne-Sophie Dulac[3]; Laurent Genser[4]; Jensen Simon[5]; Torekov Signe[6];
[1]UMRS 1269 / Nutriomics, Inserm, Paris, France; [2]Mathematical and Computer Modelling of Complex Systems Unit (UMMISCO), IRD, Bondy, France, Paris, France; [3]Department of Nutrition, Assistance Publique Hôpitaux de Paris, Hôpital Pitié-Salpêtrière, Department of Nutrition, Paris, Paris, France; [4]Service de Chirurgie, 4Assistance Publique Hôpitaux de Paris, Hôpital Pitié-Salpatière, Paris, France, Paris, France; [5]Department of Biomedical Sciences, Faculty of Health and Medical Sciences, University of Copenhagen, Denmark., Copenhagen, Denmark; [6]Department of Biomedical Sciences, Faculty of Health and Medical Sciences, University of Copenhagen, Denmark, Copenhagen, Denmark

BACKGROUND AND OBJECTIVES

Background: Weight-loss interventions in obese subjects, whether dietary or surgical, lead to significant changes in the composition of the intestinal microbiota (IM)(1). The GLP-1 receptor agonist liraglutide has been shown to be effective in weight loss, particularly when combined with physical activity(2). It may also modulate the composition of the gut microbiota, a key player in metabolic homeostasis.

Objective: Our aim is to evaluate the impact of liraglutide treatment on MI composition and maintenance of hypocaloric diet-induced weight loss (VLCD), in obese, non-diabetic individuals.

METHODS

A metagenomic approach was conducted in subjects taking part in a randomized study evaluating four groups who had previously followed a VLCD diet: 1) placebo, 2) physical exercise, 3) liraglutide treatment, and 4) liraglutide treatment combined with physical exercise. Stool samples were taken before surgery, after weight loss, and after one year of treatment.

RESULTS

VLCD shows a significant impact on gut microbiota diversity and composition, similar to other nutritional intervention studies(3). Individuals with low initial IM diversity showed a significant increase in IM diversity after VLCD. There was also an improvement in MI diversity in the liraglutide-treated groups. Forty-six bacterial groups showed significant differences in abundance trajectories among the four intervention arms.

CONCLUSIONS

VLCD significantly influences MI diversity and composition, particularly in individuals with low baseline diversity. Treatment with liraglutide shows a beneficial effect on improving IM diversity in this randomized European study.

RELIABILITY OF ARTIFICIAL INTELLIGENCE-BASED DIETARY INTAKE ASSESSMENT (AI-DIA) METHODS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Sebastian Cofre,[1, 2]; Camila Sanchez,[3]; Gladys Quezada[4]; Xaviera Lopez,[5]
[1]PhD in Epidemiology program, Pontifical Catholic University of Chile, Santiago, Chile; [2]School of Nutrition and Dietetics, Faculty of Health Sciences, Universidad Catolica del Maule, Talca, Chile; [3]Pre-Clinical Sciences, Faculty of Medicine, Universidad Catolica del Maule, Talca, Chile; [4]Department of Nutrition and Public Health, Universidad del Bio Bio, Chillan, Chile; [5]Centro de Innovación en Ingenieria Aplicada (CIIA), Universidad Catolica del Maule, Talca, Chile

BACKGROUND AND OBJECTIVES
Obtaining accurate data on dietary intake in human nutrition research is a challenging process that can affect the accuracy and reliability of the data collected (1). One of the main limitations of traditional methods, such as 24-hour recall and dietary records, is that they are based on the participant's memory and are susceptible to bias and measurement error (2). Nevertheless, the advent of artificial intelligence (AI) could remedy these issues by using machine learning (ML) algorithms to reduce biases (3). The present systematic review and meta-analysis aimed to assess the reliability of AI-based dietary intake assessment methods (AI-DIA) available in the biomedical literature.

METHODS
This systematic review was designed and conducted following the Preferred Reporting Items for Systematic Reviews and Meta-analysis (PRISMA) guidelines. The protocol was registered in the Open Science Framework database (https://osf.io/gqw6s).An exhaustive search of the EMBASE, PubMed, Scopus, and Web of Science databases was conducted to identify relevant publications from inception to November 2024. Eight studies that met the inclusion criteria were included in the statistical analysis. The risk of bias was evaluated by the ROBINS-I tool.

RESULTS
Among the studies, 41.6% utilized AI techniques based on deep learning (DL) and accuracy ranged from 79% to 89.2% for nutrient estimation. In the meta-analysis, strong correlations were observed between AI-DIA estimates and traditional methods for calories (r = 0.73, 95% CI: 0.58–0.88,p <0.001), carbohydrates (r = 0.75, 95% CI: 0.62–0.87, p <0.001), protein (r = 0.71, 95% CI: 0.55–0.86,p <0.001), and fat (r = 0.73, 95% CI: 0.62–0.84,p <0.001) (https://doi.org/10.6084/m9.figshare.28131872.v1). A moderate risk of bias was noted in 58.3% of the studies, with confounding bias being the most prevalent.

CONCLUSIONS
AI-DIA methods show promising reliability and accuracy for nutritional epidemiology. However, more robust designs are needed that allow confounding and selection biases to be controlled.

EPO7_116

DEVELOPMENT OF CLINICAL NUTRITION PROBLEM DIAGNOSTIC MATRIX FOR PRECISION NUTRITION IN KOREANS WITH TYPE 2 DIABETES

Minji Kang[1, 2]; Lee Inji[1, 2]; Park Hyunggyu[1, 2]; Lim Hyunjung[1]
[1]Department of Medical Nutrition, Kyung Hee University, Global Campus, Yongin-si, Korea, Republic of;
[2]Research Institute of Medical Nutrition, Kyung Hee University, Seoul Campus, Seoul, Korea, Republic of

BACKGROUND AND OBJECTIVES
Precision nutrition requires identifying and addressing specific nutrition problems that impact metabolic outcomes, yet systems tailored to Korean patients with type 2 diabetes are limited. This study aimed to develop a clinical nutrition problem diagnosis matrix for precision nutrition tailored to Korean patients with type 2 diabetes and evaluate its applicability in clinical settings for accurately diagnosing nutrition problems associated with metabolic risks.

METHODS
The study was conducted in two phases. Phase 1 focused on developing the matrix by collecting standardized nutrition diagnosis terminology and identifying terms commonly used for diabetes patients in Korea. Logical connections between problems (P), etiology (E), and signs/symptoms (S) were established, and clinical nutrition experts validated the matrix. Phase 2 applied the matrix to cross-sectional data from 3,553 Korean patients with type 2 diabetes, and logistic regression was used to analyze associations between nutrition problems and metabolic risk factors, including body mass index (BMI), waist circumference (WC), fasting blood glucose (FBG), and lipid levels.

RESULTS
The validity of 31 nutrition diagnosis statements was evaluated by clinical nutrition experts using a 5-point scale, with most scoring above 4.5 and all averaging over 3.5. After excluding 12 PES statements with scores below 3, 1,606 statements remained. These were applied to cross-sectional data from 3,553 patients with type 2 diabetes. Notable associations included: inconsistent carbohydrate intake (OR=1.56, 95% CI: 1.23–1.97), inadequate fiber intake (OR=1.19, 95% CI: 1.01–1.40), and limited adherence to nutrition recommendations (OR=2.22, 95% CI: 1.07–4.59), all of which increased high BMI risk. Physical inactivity heightened the risk of high WC (OR=5.69, 95% CI: 1.25–25.93). Excessive alcohol intake (OR=2.11, 95% CI: 1.08–4.11) and food medication interaction (OR=3.10, 95% CI: 1.17–8.22) were linked to high FBG.

CONCLUSIONS
The clinical nutrition problem diagnosis matrix developed in this study demonstrated its potential as a system for identifying nutrition problems and their associations with metabolic risk factors in Korean patients with type 2 diabetes. The findings suggest that addressing specific nutrition problems through personalized dietary interventions may improve clinical outcomes.

IMPACT OF LONG-TERM FASTING ON SKELETAL MUSCLE: STRUCTURE, ENERGY METABOLISM, AND FUNCTION

Robin Mesnage[1]
[1]Nutritional Sciences, King's College London Waterloo Campus, London, United Kingdom

BACKGROUND AND OBJECTIVES
Fasting is a promising tool for public health, but concerns about muscle loss prevent its acceptability in mainstream medical practice, especially in older persons. This study explored the impact of long-term fasting (12 days, 250kcal/day) on muscle structure, metabolism, and performance.

METHODS
In a prospective study of 32 subjects (16 men and 16 women; 16≤ 50 and 16>50 years-old), muscle volume, composition, relaxometry data, and lipid metabolism were assessed before, at the end, and one month after fasting. Assessments involved high- resolution 3D Dixon anatomical MR imaging, multi-echo CSE acquisitions, and single- voxel MR spectroscopy. Dynamic 31P-MRS acquisitions, quantitative MRI, maximal voluntary contraction (MVC) measures, and cardiorespiratory fitness (VO2max) were repeatedly examined throughout the protocol.

RESULTS
Average decrease of weight and skeletal muscle volumes was 5.9kg (7.4%) and 542ml (5.4%), respectively. This closely aligns with glycogen (1-2%) and bound water losses (3-4%) that are expected to reach 404-505 ml. MVC (anaerobic lactic metabolism) remained preserved in both upper and lower legs, regardless of sex or age. Unchanged T2 showed fasting did not induce structural or inflammatory changes. MRI/MRS revealed fat redistribution among tissues, with subcutaneous fat decrease and total fat fraction increase in muscle. Intramyocellular lipid pool increased while the extracellular lipid pool decreased revealing rapid lipid trafficking and rapid adaptation. The T2* increase during fasting likely stems from changes in intracellular lipid droplets configuration, with an increased proportion of lipid droplets of smaller size, optimizing accessibility of lipid fuels and mitochondrial FA. Cardiopulmonary exercise testing (VO2 max) revealed no alteration in maximal oxygen uptake during fasting, but an improved fat oxidation capability with a 10% increase in the first ventilatory threshold and a 10% decrease in the respiratory exchange ratio. Mitochondrial oxidative capacity and the rate of PCr resynthesis in muscle were maintained. Females improved their mitochondrial function at D+12, surpassing males, expressing better fat oxidation capabilities.

CONCLUSIONS
The leg muscle decrease volume is small when considering glycogen + water depletion during fasting. Fat relocates in the intracellular compartment of myocytes. Anaerobic and aerobic metabolic pathways remain unchanged after 12-day fasting.

SEVERE HEPATIC STEATOSIS IN OBESE ADULTS: STUDY OF ASSOCIATED FACTORS

Rim RACHDI[1]; Olfa Berriche[1]; Meriam Dalhoum[1]; rym ben othman[1]; Ramla Mizouri[1]; Raja Tlili[2]; Lamia Kallel[2]; Henda Jamoussi[1]
[1]A, institut national de nutrition et de technologie alimentaire de tunis, tunis, Tunisia; [2]Service de Gastro-entérologie, Hôpital Mahmoud el Matri, Ariana, Tunisie, tunis, Tunisia

BACKGROUND AND OBJECTIVES
Non-alcoholic fatty liver disease (NAFLD) prevalence is strongly linked to the obesity epidemic (1). It involves a whole spectrum of liver damage of different severity, ranging from simple, isolated steatosis to non-alcoholic steatohepatitis (NASH), which is likely to progress to cirrhosis and hepatocellular carcinoma. The aim of our study was to identify the factors associated with hepatic steatosis severity in obese adults.

METHODS
This was a descriptive cross-sectional study including obese adults over a one-year period. Patients benefited from a dietary survey, anthropometric measurements and a biological assessment. Hepatic elasticity and controlled attenuation parameter (CAP) were measured by Fibroscan.

RESULTS
We included 208 patients with a mean age of 49±12 years and a sex ratio (F/H) of 8.9. Mean body mass index (BMI) was 40.43±6.38 kg/m2. Hepatic steatosis was found in 77.4% of obese patients, and was severe in 58.7% of cases. Advanced hepatic fibrosis was found in 4.3% of patients. In univariate analysis, the factors associated with the severity of hepatic steatosis were dietary intakes of fructose (p=0.01), polyunsaturated fatty acids (p=0.023), omega 3 (p=0.016), fiber (p=0.04), vitamin C (p=0.03), manganese (p=0.01) and zinc (p=0.01), as well as weight (p=0.004), BMI (p=0.007), obesity class (p=0.035) and waist circumference (p=0.012), waist circumference to height ratio (p=0.014), ASAT (p=0.004), ALAT (p<0.001), GGT (p=0.001), ASAT/ALAT ratio (p=0.001), type 2 diabetes (p=0.021), hypertriglyceridemia (p=0.006) and metabolic syndrome (p=0.01). In multivariate analysis, the factors independently associated with advanced liver steatosis were BMI (p=0.01; OR=1.066), triglyceride levels (p=0.03; OR=1.630), ASAT levels (p=0.03; OR=1.053) and ASAT/ALAT ratio (p=0.03; OR=1.296).

CONCLUSIONS
Our RESULTS showed that severe hepatic steatosis is closely linked to nutritional, clinical and biological factors associated with obesity. Early detection is therefore essential in order to provide appropriate nutritional management targeting the associated factors.

PREVALENCE AND RISK FACTORS OF NON-ALCOHOLIC FATTY LIVER DISEASE IN OBESE ADULTS

Rim RACHDI[1]; Olfa Berriche[1]; Meriam Dalhoum[1]; rym ben othman[1]; Ramla Mizouri[1]; Raja Tlili[2]; Lamia Kallel[2]; Henda Jamoussi[1]
[1]A, institut national de nutrition et de technologie alimentaire de tunis, tunis, Tunisia; [2]Service de Gastro-entérologie, Hôpital Mahmoud el Matri, Ariana, Tunisie, tunis, Tunisia

BACKGROUND AND OBJECTIVES
With the increasing prevalence of obesity, Non-Alcoholic Fatty Liver Disease (NAFLD) is considered to be the most common chronic liver disease in the world, affecting both developed and developing countries (1). Currently, there are no national data on its frequency and risk factors in obese people. The objectives of our study were to screen for NAFLD in a population of obese adults, and to identify risk factors.

METHODS
This was a descriptive cross-sectional study involving obese adults who underwent a dietary survey, anthropometric measurements and a biological assessment. Hepatic elasticity and controlled attenuation parameter (CAP) were measured by Fibroscan.

RESULTS
The mean age of the 208 patients included was 49±12 years with a sex ratio (F/H) of 8.9. Mean body mass index (BMI) was 40.43±6.38 kg/m2. The prevalence of hepatic steatosis was 77.4%. It was severe in 58.7% of cases, and advanced hepatic fibrosis was found in 4.3% of patients. Regarding anthropometric parameters, the factors associated with hepatic steatosis were weight (p=0.001), BMI (p=0.003), class 2 obesity (p=0.04), waist circumference (p=0.003) and waist circumference to height ratio (p=0.005). The study of nutritionnal parameters revealed that hepatic steatosis was associated with dietary intakes of omega 3 (p=0.012) and zinc (p=0.03). With regard to biological parameters, the factors associated with hepatic steatosis were type 2 diabetes (p<0.001), glycated haemoglobin (p<0.001), hypercholesterolaemia (p=0.035), hypertriglyceridaemia (p=0.017), HOMA index (p=0.03), ASAT (p=0.036), ALAT (p<0.001), GGT (p=0.006), ASAT/ALAT ratio (p<0.001). In multivariate analysis, the factors independently associated with hepatic steatosis were glycated haemoglobin level (p<0.001; OR=5.302), insulin level (p=0.016; OR=1.183), HOMA index (p=0.01; OR=1.531) and ALAT levels (p=0.001; OR=1.109).

CONCLUSIONS
In the light of our RESULTS, we recommend systematic screening for NAFLD using Fibroscan, especially in the obese population and more generally in any population at risk presenting insulin resistance, type 2 diabetes or dyslipidaemia.

STUDY OF THE PREVALENCE AND ASSOCIATED FACTORS OF GLYCEMIC VARIABILITY IN TYPE 1 DIABETIC PATIENTS

Faten Mahjoub[1]; Ines Bani[1]; Rim RACHDI[1]; Ramla Mizouri[1]; Ines Lahmar[1]; Nadia Ben Amor[1]; Henda Jamoussi[1]
[1]A, institut national de nutrition et de technologie alimentaire de tunis, tunis, Tunisia

BACKGROUND AND OBJECTIVES

Glycemic variability (GV) is one of the three components of the glucose 'triumvirate' (1). Continuous glucose monitoring (CGM) has facilitated its measurement. The aims of our work were to study GV in type 1 diabetes mellitus (T1DM) and to determine the intrinsic and extrinsic factors associated with GV.

METHODS

This was a descriptive cross-sectional study including T1DM. Each patient received a CGM for 7 days. Intraday GV was defined as Coefficient of Variation (CV) >36% and/or Mean Amplitude of Glycemic Excursion (MAGE)>65mg/dl. Interday GV was defined as Mean of Daily Differences (MODD)>60mg/dl.

RESULTS

Ninety patients were included. The mean age was 16.94±2.2years. More than half of patients (62%) had a CV>36%, 96% of patients had a MAGE≥65mg/dl and 70% of patients had a MODD≥60mg/dl. Age was correlated with CV (r=0.26; p=0.012). Age at onset of diabetes was negatively correlated with CV (r=-0.3; p=0.004). The dawn phenomenon was associated with CV (p=0.016). Lipodystrophies were associated with intra-day (p=0.022) and inter-day ($p<10^{-3}$) GV. Patients on insulin analogues had a significantly lower MODD (p=0.028). The study of extrinsic factors related to the presence of GV showed that Carbohydrate intake was significantly associated with CV>36% (p=0.022). Patients with a MAGE ≥ 65mg/dl had significantly lower fiber intakes with p<10-3. Multivariate analysis showed that Carbohydrate intake (OR=2.4; p=0.022); sedentary lifestyle (OR=2.2; p=0.006); lipodysrophies (OR=6.5; p=0.011); autoimmune insulin syndrome (OR=5.6; p=0.039); quality of life score (OR=2.8; p=0.004) and dissatisfaction with treatment (OR=1.39; p=0.005) were independently associated with GV.

CONCLUSIONS

In the light of our RESULTS, we can conclude that the frequency of inter- and intra-day glycaemic variability is high in type 1 diabetics. It should therefore be systematically screened by continuous glucose monitoring.

SARCOPENIA IN PATIENTS WITH TYPE 2 DIABETES: A NEW COMPLICATION

Faten Mahjoub[1]; Rim RACHDI[1]; Sirine Feki[1]; Ramla Mizouri[1]; Ines Lahmar[1]; Nadia Ben Amor[1]; Henda Jamoussi[1]
[1]A, institut national de nutrition et de technologie alimentaire de tunis, tunis, Tunisia

BACKGROUND AND OBJECTIVES
Sarcopenia is a clinical condition defined as low skeletal muscle mass and function, leading to impaired physical performance and quality of life (1). In recent years, a strong relationship between sarcopenia and type 2 diabetes has been highlighted. Our objectives were to determine the prevalence of sarcopenia in type 2 diabetics, and to identify the associated nutritional risk factors.

METHODS
We conducted a cross-sectional study over a 4-month period, including 100 type 2 diabetic patients. We used the SARC-F to screen for sarcopenia, which was confirmed by measuring appendicular muscle mass using impedancemetry and muscle strength using the Hand-Grip test. We also carried out a dietary survey.

RESULTS
Patients had an average age of 63±5 years, with the majority (47%) aged between 45 and 54 years. The majority of the population were women (68%). The mean duration of diabetes was 15±8 years. 57% of the population were on insulin. Microangiopathic and macroangiopathic complications were prevalent in 56% and 13% of cases respectively. The prevalence of sarcopenia in type 2 diabetics was 11% (SAR+). Mean fasting plasma glucose (15.48±5.67 mmol/l vs 11.34±3.8 mmol/l; p= 0.003) and glycated haemoglobin (11.98±1.3% vs 10.67±1.6% ; p=0.013) were significantly higher in SAR+ patients than in SAR- patients, respectively. The study of nutritional risk factors revealed a calorie intake of 2350 Kcal/day in SAR+ patients, compared with 2554 Kcal/day in SAR- patients (p=NS). Protein intake was lower in SAR+ patients compared with SAR- patients (73.6±20.11 g/day versus 80.08±20.24 g/day respectively, p=NS). SAR+ patients had a higher intake of linoleic acid than SAR- patients (9.48 mg/day versus 8.79 mg/day, respectively, p=NS) as well as higher intakes of cholesterol (45.73 mg/day versus 34.22 mg/day respectively, p=NS) with a higher w6/w3 ratio, but with no significant statistical difference. Dietary fibre intake was lower in SAR+ patients (27.82 g/day versus 31.25 g/day for SAR- patients, p=NS). SAR+ patients had a lower intake of calcium (598.45 mg/day versus 605.15 mg/day), magnesium (272.09 mg/day versus 302.03 mg/day) and vitamin D (31.82 µg/day versus 36.77 µg/day) than SAR- patients, but with no significant difference.

CONCLUSIONS
Optimising glycaemic control, ensuring correct vitamin D3 status and a healthy, balanced diet would prevent the onset of sarcopenia in diabetic patients.

BDNF GENETIC VARIANTS AND THEIR ASSOCIATION WITH OBESITY-RELATED PARAMETERS IN KOREANS

Jiha Kim[1, 2]; Soyoun Lee[3, 1]; Songjoo Kang[4, 1]; Myougsook Lee[2, 1]
[1]Food and Nutrition, Sungshin Women's University, Seoul, Korea, Republic of; [2]Research Institute of Obesity Science, Sungshin Women's University, Seoul, Korea, Republic of; [3]Commercial Support, Medtronic Korea, Seoul, Korea, Republic of; [4]Finance, Hanwha Insurance, Seoul, Korea, Republic of

BACKGROUND AND OBJECTIVES
The brain-derived neurotrophic factor (BDNF) gene has been strongly associated with eating disorders. However, evidence in Koreans is limited. This study aimed to investigate potential differences in the obesity-related parameters between BDNF (rs6265) genotypes in Koreans.

METHODS
A total of 252 healthy Korean adults aged 19-64 years (men: 37, women: 215) were recruited for this study. Participants underwent genotyping, anthropometric measurements, blood tests, and dietary assessments. They were categorized into obesity (OB, including overweight) and non-obesity (non-OB) groups, and wild and mutant groups based on DTC obesity gene SNPs (FTO, MC4R, BDNF). We examined the associations between obesity and obesity-related risk markers of each SNP variation.

RESULTS
Analysis of obesity frequency by SNP genotypes of DTC obesity genes showed a significant association between the mutant of BDNF, which regulates eating patterns, and increased obesity prevalence (p=0.023). The OB group exhibited higher systolic blood pressure (SBP), triglycerides (TG), low-density lipoprotein cholesterol (LDLc), and leptin, as well as anthropometric parameters, than the non-OB group. Conversely, the non-OB group had higher RMR/BW and high-density lipoprotein cholesterol (HDLc) than the OB group. Men generally had higher values for most parameters, except for HDL-C and leptin, which were higher in women. In subgroup analyses (OB/non-OB, wild/mutant), most differences were attributed to obesity status, leading to their exclusion as potential risk factors. The OB-mutant group had the highest TG and the lowest RMR/BW, with significance after adjustment for age and sex. The OB-mutant group had higher intake of sugar, fiber, folate, phosphorus, potassium, magnesium, and cholesterol. However, after adjusting for age, sex, and total calorie intake, only sugar, folate, and potassium remained significantly higher. In contrast, the non-OB-mutant group showed the opposite patterns in the metabolic and dietary factors.

CONCLUSIONS
This study is the first to provide scientific evidence that BDNF gene variants influence obesity metabolism due to energy imbalance in the Korean population. Obese adults with the BDNF mutant showed distinct metabolic patterns compared to the non-OB-mutant, emphasizing the need for personalized precision nutrition programs for weight management. These should focus on low-fat (cholesterol) and low-sugar guidelines to reduce blood TG and enhance basal metabolic rate. Additionally, high potassium intake may help balance sodium levels, while elevated folate and phosphorus appear to increase protein consumption.

ASSESSMENT OF SMALL INTESTINAL INFLAMMATION IN ADULTS WITH ENVIRONMENTAL ENTEROPATHY IN ZAMBIA USING ORAL 15N2-L-ARGININE AND MEASUREMENT OF URINARY 15N-NITRATE BY ORBITRAP ISOTOPE RATIO MASS SPECTROMETRY

James W Weatherill[1]; Paul Kelly,[2, 3]; Douglas J Morrison,[1]
[1]SUERC, University of Glasgow, Glasgow, United Kingdom; [2]Blizard Institute, Queen Mary University of London, Newark Street, London, UK, London, United Kingdom; [3]Tropical Gastroenterology & Nutrition group, University of Zambia School of Medicine, Lusaka, Zambia

BACKGROUND AND OBJECTIVES

Nitric oxide (NO) plays a pivotal role in many physiological processes, including the pathogenesis of inflammation. NO acts as an anti-inflammatory signalling molecule and becomes over-expressed at pro-inflammatory epithelial surfaces through the sequential oxidisation of L-arginine by inducible NO synthase to form L-citrulline and NO. Once absorbed, NO is further oxidised to nitrite (NO2), and ultimately the stable form nitrate (NO3) within tissues. 15NO3 excreted into the urine via the kidneys is an indirect measure of NO production from 15N-L-arginine. Here we used an oral 15N-L-arginine bolus with a short urine collection protocol to interrogate proximal small intestinal NO production as a proxy for gut inflammation in environmental enteropathy (EE).

METHODS

Samples were collected as part of the GI Tools study from a cohort of Zambian adults with EE, who underwent a panel of biomarker assessments, including intestinal fatty acid binding protein (iFABP), gut permeability (lactulose and rhamnose), and intestinal biopsy to measure epithelial surface area (ESA). Baseline urine was collected prior to oral administration of 15N2-(guanidineimino)-L-arginine (fixed dose: 1.667 mg). A subsequent urine sample was collected at 180 mins. Urines were diluted (1:100) in ACN:MeOH (75:25, v/v) + 0.2% formic acid. The samples were analysed by in-flow injection on a ThermoScientific Vanquish Neo HPLC coupled to an Orbitrap Exploris™ 480 Isotope Solutions system with 20 min acquisition period for NO3 isotopologues (61-65 m/z) in negative ion mode. Each sample injection was bracketed by an isotopically calibrated NO3 standard (USGS35) to produce δ15N-values relative to the internationally accepted reference for 15N (AIR). Δ15NO3, defined as 180 min δ15NO3 minus baseline δ15NO3, was calculated.

RESULTS

Δ15NO3 was measured in 37 participants (mean Δ15NO3 = 86.2, SD = 71.5 per mil). There was significant positive correlation between Δ15NO3 and iFABP ($r = 0.44$; $p = 0.007$) and negative correlation between Δ15NO3 and ESA ($r = -0.42$; $p = 0.019$). There was a trend towards a positive correlation between Δ15NO3 and lactulose:rhamnose ratio (LRR; $r = 0.41$, $p = 0.054$).

CONCLUSIONS

This simple, non-invasive test demonstrates the potential of oral 15N-L-arginine and urinary 15NO3 to measure localised gut inflammation in the proximal small intestine in environmental enteropathy.

EPO7_126

GUT BIDIRECTIONAL AMINO ACID TRANSPORT IN ENVIRONMENTAL ENTEROPATHY IN ZAMBIAN ADULTS

Mahek Jain[1]; James W Weatherill,[1]; Eleanor Mckay,[1]; Douglas J Morrison,[1]; Paul Kelly,[2, 3]
[1]SUERC, University of Glasgow, Glasgow, United Kingdom; [2]Blizzard Institute, Blizzard Institute, Queen Mary University London, London United Kingdom; [3]Tropical Gastroenterology & Nutrition Group, University of Zambia School of Medicine, Lusaka, Zambia

BACKGROUND AND OBJECTIVES

Environmental enteropathy (EE) is a subclinical intestinal phenomenon common in Low- and Middle-Income Countries and is associated with growth failure, impaired cognitive development, poor vaccine response, and nutrient deficiencies (1,2). Gut barrier damage observed in EE has been shown to result in leakage of essential nutrients by confocal laser endomicroscopy (3). This study aimed to investigate Indispensable Amino Acid (IAA) transport, Bidirectional Transmucosal Amino Acid Flux (BTAAF) and gut permeability in Zambian adults to gain insights into intestinal barrier function and nutrient transport in EE.

METHODS

80 participants (33 M, 47 F; mean age 34.0 (SD 10.8)) were recruited from Misisi, Lusaka where EE is highly prevalent. Participants were given 5g lactulose and 1g rhamnose followed by a primed pseudo constant infusion of 13C6-phenylalanine (0.6 mmol/kg) orally through repeated oral drinks every 20 mins and 2H5-phenylalanine (0.6 mmol/kg) by continuous intravenous infusion for 240 mins. Plasma was collected serially over this period and a single intestinal aspirate and mucosal biopsy was also captured for morphometry at 240 mins. IAAs were purified for analysis by LC-MS. Uptake of amino acids (BTAAFin) was calculated by the plasma ratio 13C6-Phe/Phe relative to the plasma ratio 2H5-Phe/Phe. Efflux of amino acids from the plasma into the intestine (BTAAFout) was calculated by the intestinal aspirate ratio 2H5-Phe/Phe relative to the plasma ratio 2H5-Phe/Phe; theoretically this ratio can vary from 0 to 1 representing zero to full isotopic equilibration. Urine lactulose (%L) and rhamnose (%R) excretion was analysed by LC-MS and lactulose:rhamnose ratio (LRR) was calculated.

RESULTS

Mean (SD, n) BTAAFin was 1.4 (4.9; n=69) and BTAAFout was 3.7 (10.1; n=66) calculated and their correlations with measures of gut permeability analysed (Table 1).

Table 1: Correlation between BTAAFin and BTAAFout and %L, %R, and LRR.

	BTAAFin	BTAAFout
%L	0.01 (95% CI: -0.2, 0.2; p = 0.89)	-0.07 (95% CI: -0.33, 0.2; p = 0.6)
%R	0.12 (95% CI: -0.15, 0.337; p = 0.37)	0.04 (95% CI: -0.23, 0.32; p = 0.73)
LRR	-0.06 (95% CI: -0.33, 0.2; p = 0.63)	-0.12 (95% CI: -0.38, 0.15; p = 0.37)

CONCLUSIONS

Significant IAA leakage into the intestine in >66% of participants (BTAAFout >0.54) were observed and many may represent additional loss (or additional requirements) of IAAs. No correlation was observed with markers of gut permeability suggesting IAA leakage occurs independently of changes in gut permeability.

CONFLICTS OF INTERESTS

PROTECTIVE EFFECTS OF ORIENTAL MEDICINE MIXTURES (CNIDIUM OFFICINALE, PUERARIA LOBATA OHWI, AND LEONURUS JAPONICUS) AGAINST OXIDATIVE STRESS AND INFLAMMATION IN VASCULAR DYSFUNCTIONS IN OX-LDL INDUCED HUVECS OVARIECTOMIZED RATS

Joohee Oh[1]; Hyun-Sook Kim[1]
[1]Department of Food and Nutrition, Sookmyung Women's University, Seoul, Korea, Republic of

BACKGROUND AND OBJECTIVES
Menopause is a natural part of aging in women, often leading to estrogen deficiency, which can contribute to vascular dysfunctions.

METHODS
In this study, we examined the antioxidant and anti-inflammatory effects of extracts from *Cnidium officinale*, *Pueraria lobata* Ohwi, and *Leonurus Japonicus* (CPL) and their potential to alleviate vascular dysfunction in ox-LDL-induced HUVECs and ovariectomized rats.

RESULTS
The findings indicated that the CPL extracts reduced levels of VCAM-1 (vascular cell adhesion molecule 1) and ICAM-1 (intercellular adhesion molecule 1) by downregulating *NF-κB* (nuclear factor kappa-light-chain-enhancer of activated B cells), while enhancing the antioxidant markers *NRF2* (nuclear factor erythroid 2-related factor) and *HO-1* (heme oxygenase-1). Additionally, CPL extracts improved vascular function by upregulating *eNOS* (endothelial nitric oxide synthase) and downregulating *iNOS* (inducible nitric oxide synthase) in ox-LDL-induced HUVECs. In ovariectomized rats treated with CPL extracts for 12 weeks, improvements were observed in serum lipid profiles, vasoactive substances, tail temperature, and cardiovascular risk indicators.

CONCLUSIONS
Our RESULTS suggest that CPL extracts have potential benefits in combating cardiovascular dysfunction by enhancing the antioxidant system and reducing inflammation in both ox-LDL-induced HUVECs and ovariectomized rats.

RECOGNITION OF FOOD TYPE AND PORTIONS USING BOOSTING AND BAGGING IN ENSEMBLE LEARNING

Ying-Yueh Chu[1]; Hao Yeh[2]; Kuo-Liong Chien[3]; Hsien-Yu Fan[4]; Pey-Rong Chen[5]; Shih-Lin Hung[6]
[1]Department of Nutrition and Health Sciences, Chinese Culture University, Taipei, Taiwan; [2]Division of Endocrinology and Metabolism, Taipei City Hospital Zhongxiao Branch, Taipei, Taiwan; [3]Institute of Epidemiology and Preventive Medicine, National Taiwan University, Taipei, Taiwan; [4]School of Nutrition and Health Sciences, College of Nutrition, Taipei Medical University, Taipei, Taiwan; [5]Department of Dietetics, National Taiwan University Hospital, Taipei, Taiwan; [6]Department of Civil Engineering, National Yang Ming Chiao Tung University, Hsinchu, Taiwan

BACKGROUND AND OBJECTIVES
Dietary intake is a critical factor influencing an individual's health. Proper nutritional assessment in dietary reports, including portion analysis of various food types, plays a vital role in how effectively dietitians communicate with people. Recent advancements in deep learning (DL) within artificial intelligence have enabled the detection of food ingredients and the estimation of energy and macronutrients using available datasets. However, the automatic estimation of portion sizes for individual food types within a single meal or dish remains an unaddressed challenge. This study aimed to apply bagging and boosting ensemble learning models to evaluate the portion sizes of five food types: whole grains, vegetables, fruits, fish-egg-meat (FEM), and oil-nut-seed (ONS). Overhead images from the Nutrition5K dataset served as input, while portion sizes for the five food types were generated as outputs.

METHODS
To generate the output files for the models, portion sizes for each food type in the dishes were calculated using metadata from the Nutrition5K dataset, following the guidelines specified in Taiwan's Food Exchange Table. A total of 1,960 dishes were annotated and compiled into a CSV file. The dataset was then used to train a deep learning model based on DenseNet-121, enhanced with self-attention blocks. Furthermore, ensemble learning techniques were incorporated to improve the model's performance.

RESULTS
The RESULTS demonstrated strong correlations between the predicted and ground-truth values. For the training dataset, the correlation coefficients (r) were 0.991, 0.951, 0.921, 0.956, and 0.977 for whole grains, vegetables, fruits, FEM, and ONS, respectively. On the test dataset, r exceeded 0.96 for whole grains and FEM, while vegetables, fruits, and ONS achieved values ranging from 0.87 to 0.93. These findings underscore the robust generalization capability of the deep learning model utilizing ensemble learning approaches for this dataset.

CONCLUSIONS
Ensemble learning in DL effectively addresses issues of bias and variability by leveraging multiple learners to solve complex problems. Given the diversity and complexity in food datasets, ensemble learning proves beneficial in mitigating bias and variability caused by variations in food patterns, appearances, and portion sizes. The RESULTS of this study advance the development of personalized dietary recommendations, bringing us closer to achieving precision nutrition.

EPO7_130

CAUSAL EFFECTS OF DIETARY FIBER INTAKE ON METABOLIC SYNDROME COMPONENTS: A MENDELIAN RANDOMIZATION ANALYSIS OF THE KOREAN GENOME AND EPIDEMIOLOGY STUDY (KOGES)

Hyeju Song[1]; Jaehee Cha[1]; Subin Kim[1]; Dayeon Shin[1]
[1]Food and Nutrition, Inha University, Yonghyeon Campus, Incheon, Korea, Republic of

BACKGROUND AND OBJECTIVES
Dietary fiber intake improves blood glucose regulation and blood pressure, serving a key strategy for preventing cardiovascular disease and metabolic syndrome (MetS). However, observational studies face limitations due to confounding factors and reverse causation. This study aimed to assess the causal relationship between dietary fiber intake and components of MetS using the Mendelian Randomization (MR) approach.

METHODS
A two-sample MR analysis was conducted using data from two KoGES cohorts: the Health Examinee Study (HEXA, n=58,144) for exposure and the Ansan and Ansung Study (n=57,456) for outcomes, which included participants aged 40–69 years. Genome-wide association study (GWAS) data were adjusted for sex, age, body mass index (BMI), education, total energy intake, alcohol consumption, marital status, and physical activity. A total of 103 single nucleotide polymorphisms (SNPs) associated with dietary fiber intake were selected based on genome-wide significance ($P \leq 5 \times 10^{-8}$), and linkage disequilibrium clumping ($P \leq 0.01$, $r^2 \leq 0.05$, ± 500 kb). Causal relationships were evaluated using IVW, Weighted Median, MR-Egger regression, Simple Mode, and Weighted Mode methods. Sensitivity analyses assessed heterogeneity and outliers using Cochran's Q test, MR-PRESSO, and Q-Q plots.

RESULTS
MR analysis showed that increased dietary fiber intake significantly reduced blood pressure (MR-Egger: OR = 0.848, 95% CI: 0.743–0.967, P = 0.016) and blood glucose (IVW: OR = 0.927, 95% CI: 0.862–0.997, P = 0.041). Pearson correlation analysis revealed significant associations between dietary fiber intake and systolic blood pressure (r = 0.043, P = 3.41E-72), diastolic blood pressure (r = 0.050, P = 1.19E-96), and fasting blood glucose (r = 0.015, P = 6.53E-10). Sensitivity analyses indicated no evidence of substantial heterogeneity for blood pressure (Q = 118.071, P = 0.118) or blood glucose (Q = 101.966, P = 0.482).

CONCLUSIONS
This study confirmed significant causal effects of dietary fiber intake on reducing blood pressure and improving blood glucose regulation. Utilizing the MR approach, which effectively minimizes confounding and reverse causation, these findings provide evidence supporting a causal relationship between dietary fiber intake and key components of MetS.

EPO7_131

POSITIVE ASSOCIATION BETWEEN COMPOSITE DIETARY ANTIOXIDANT INDEX AND LEFT VENTRICULAR EJECTION FRACTION IN HYPERTENSIVE PATIENTS: A CROSS-SECTIONAL STUDY

Aya Benhedouga[1]; Hamza Saidi[1]; Abdenour Bounihi[1]; Adlane Rezzoug[2]; Sofiane Ghemri[2]; Elhadj-Ahmed Koceïr[1]
[1]Bioenergetics and Intermediary Metabolism Team, Laboratory of Biology and Organisms Physiology, University of Sciences and Technology Houari Boumediene, Algiers, Algeria; [2]Cardiology Department, EHS Dr. Mohand Maouche Amokrane, Algiers, Algeria

BACKGROUND AND OBJECTIVES
There is growing evidence that antioxidant-rich diets may prevent hypertension and its resulting left ventricular dysfunction. The Composite Dietary Antioxidant Index (CDAI) is a valid and reliable nutritional tool for evaluating the antioxidant potential of diets. Therefore, the present study aimed to investigate the association between CDAI and Left Ventricular Ejection Fraction (LVEF) in hypertensive patients.

METHODS
Participants' sociodemographic and anthropometric data were collected using an interview-administered questionnaire. Participants' dietary intakes were obtained using a 24-hour dietary recall interview method. The CDAI was calculated from the intake of six dietary antioxidants: vitamins A, C, and E, manganese (Mn), selenium (Se), and zinc (Zn). Hypertension was defined by systolic blood pressure (SBP) ≥ 130 mmHg or diastolic blood pressure (DBP) ≥ 80 mmHg or the use of antihypertensive medications. Left Ventricular Ejection Fraction (LVEF) was assessed using echocardiography.

RESULTS
A total of 141 hypertensive participants were included in the study, with an average age of 64.75 years and a mean Body Mass Index (BMI) of 29.32 kg/m². The CDAI was divided into tertiles. Ordinal regression analysis showed that LVEF was positively associated with the CDAI (OR = 1.100, 95% CI: 1.032–1.171, p = 0.003). This association remained significant after adjusting for age, sex, and BMI (OR = 1.095, 95% CI: 1.025–1.161, p = 0.006). Higher CDAI scores were associated with increased dietary intake of polyunsaturated fatty acids (p < 0.001), energy intake (p = 0.004), manganese (p = 0.024), potassium (p = 0.012), retinol (p = 0.001), selenium (p < 0.001), sodium (p = 0.002), vitamin C (p = 0.001), vitamin E (p < 0.001), and zinc (p = 0.003). Lastly, Pearson correlation analyses revealed a significant negative correlation between the CDAI and blood pressure parameters [DBP (r = −0.304, p = 0.002) and SBP (r = −0.268, p = 0.006)] and a significant positive correlation between the CDAI and LVEF (r = 0.329, p < 0.001).

CONCLUSIONS
The RESULTS of this study suggest that the CDAI is positively associated with LVEF in hypertensive patients, indicating the potential role of dietary antioxidants in maintaining cardiac function.

EPO7_133

GENDER-SPECIFIC PATHWAYS LINKING NUTRIENT INTAKE, METABOLITES, AND METABOLIC SYNDROME COMPONENTS IN KOREAN ADULTS: A STRUCTURAL EQUATION MODELING ANALYSIS

Sookyoung Park[1]; Dayeon Shin[1]
[1]Food and Nutrition, Inha University, Yonghyeon Campus, Incheon, Korea, Republic of

BACKGROUND AND OBJECTIVES
This study aimed to investigate the relationships among nutrient intake, metabolites, and metabolic syndrome components, with a focus on potential gender-specific differences in these associations.

METHODS
Data were obtained from 2,306 participants aged 40–69 years in the Korean Genome and Epidemiology Study (KoGES)-Ansan and Ansung cohorts. Four statistical methods—Wilcoxon rank sum test, logistic regression, partial least squares discriminant analysis, and group least absolute shrinkage and selection operator—identified metabolites associated with fasting blood glucose (FBG). A mixed-effects model identified four significantly different metabolites between the case group (FBG ≥ 100 mg/dL) and the control group (< 100 mg/dL). These metabolites were then analyzed using multiple structural equation models (SEMs) to explore the relationships among nutrient intake, metabolites, and metabolic syndrome components (FBG, triglyceride (TG), blood pressure (BP)) by gender.

RESULTS
The final model demonstrated a good fit to the data: $\chi^2(58) = 239.485$, CFI = .988, TLI = .981, RMSEA = .052 ($p = .296$), and SRMR = .023. Metabolites (Phosphatidylcholine acyl-alkyl C44:6 (PC ae C44:6) and HydroxySphingomyelin C14:1 (SM (OH) C14:1)) and nutrient (protein, sugar, phosphorus, vitamin B1) intake together explained 36.8% of the variance in FBG, TG, and BP for women and 51.3% for men. PC ae C44:6 and SM (OH) C14:1 exerted a significant negative influence on FBG, TG, and BP in both genders, with a stronger standardized effect in men ($\beta = -0.720$, $p < .001$) compared to women ($\beta = -0.605$, $p < .001$). Protein, sugar, phosphorus, and vitamin B1 intake showed a significant direct effect on FBG, TG, and BP only in men ($\beta = 0.103$, $p < .05$). Additionally, protein, sugar, phosphorus, and vitamin B1 intake had no statistically significant indirect effect on FBG, TG, and BP through PC ae C44:6 and SM (OH) C14:1 in men ($\beta = -0.0248$), whereas it showed a significant indirect effect in women mediated by these metabolites ($\beta = -0.0544$, $p < .05$).

CONCLUSIONS
This study revealed gender-specific pathways in the relationship between nutrient intake, metabolites, and metabolic syndrome components. Metabolites had a stronger influence in men, while nutrient intake affected women indirectly through metabolites.

Nutrient and non-nutrient intake and their relationship with metabolic markers in an Italian cohort: preliminary RESULTS from the NUTRIPOP study

Iolanda Cioffi[1]; Massimiliano Tucci[1]; Marco Rendine[1]; Alessandro Meneghini[1]; Mirko Marino[1]; Giorgia Pozzi[1, 2]; Alessandro Leone[1, 2]; Alberto Battezzati[1, 2]; Daniela Martini[1]; Patrizia Riso[1, 2]; Cristian Del Bo'[1]
[1]Department of Food, Environmental and Nutritional Sciences (DeFENS), University of Milan, Milano, Italy; [2]International Center for the Assessment of Nutritional Status (ICANS-DIS), DeFENS, University of Milan, Milano, Italy

BACKGROUND AND OBJECTIVES

The assessment of dietary intake plays a pivotal role in evaluating nutritional status, which is a prerequisite for maintaining overall health and preventing the development of chronic diseases. The aim of the present study was to explore nutrient and non-nutrient intake (e.g., polyphenols) and their relationship with metabolic markers in a group of apparently healthy free-living volunteers.

METHODS

Subjects aged ≥ 18 years and living in Northern Italy were recruited for participating in a cross-sectional study, as part of the OnFoods project (www.onfoods.it). Anthropometric measurements, including weight, height, body mass index (BMI) and waist circumference (WC) were obtained, while habitual food intake was assessed. Energy and nutrients were calculated by Metadieta software, while total polyphenols and flavonoids were retrieved from the Phenol-Explorer database. Blood samples were taken to assess several metabolic markers, and proteomic analysis.

RESULTS

In this preliminary analysis, a total of 103 subjects (35 men and 68 women) were included. Subjects showed a mean age of 40 ± 14 years and an average BMI of 22.9 ± 3.2 kg/m2, with the following waist circumference: 86 ± 10 cm in men and 77 ± 10 cm in women. Mean intake of energy was 1889 ± 630 kcal/day, while macronutrient distribution in percentage was as follows: 16 % protein, 34 % total fat (10 % saturated fat) and 50% total carbohydrates. Fiber intake adjusted for 1000 kcal was 13 ± 5 g/1000kcal/day. Polyphenol and flavonoid intake were 1281 ± 837 mg/day and 266 ± 249 mg/day, respectively. Both BMI and WC were positively associated with glucose, insulin, HOMA-IR, HDL-cholesterol, LDL-cholesterol and triglycerides, except for total cholesterol. Among dietary intake, carbohydrates were inversely correlated with HDL-C (r=- 0.256, p=0.02) but directly correlated with triglycerides (r= 0.224, p=0.02), while dietary flavonoids were inversely associated with both insulin and HOMA-IR (r=- 0.222, p=0.03).

CONCLUSIONS

Overall, RESULTS from this preliminary analysis showed that dietary habits of these volunteers seem to be in line with the Italian Dietary Guidelines, except for fiber intake. Interestingly, dietary flavonoids intake was inversely associated with serum insulin and HOMA-IR. Applying the proteomic approaches on those analysis will be pivotal for a better comprehension of nutrient and non-nutrient intake, metabolic status, and clarifying the correlations found.

EFFICACY AND SAFETY OF ORAL SEMAGLUTIDE 25 MG IN ADULTS WITH OVERWEIGHT/OBESITY: THE OASIS 4 RCT

Vanessa Folope Leborgne[1]; W. Thimothy Garvey[2]; Do Vale, Ruben Duque[3]; Tobias Karlsson[3]; Ildiko Lingvay[4]; Chaithra Shaji[5]; Domenica Rubino[6]
[1]Medical, Novo Nordisk, Puteaux, France; [2]Nutrition science, University of Alabama, Birmingham, United States of America; [3]Medical Affairs, Novo Nordisk, Søborg, Denmark; [4]Internal Medicine / Endocrinology, University of texas southwestern medical center, dallas, United States of America; [5]Biostatistics, Novo Nordisk, Bangalore, India; [6]Medical, Washington Center for Weight Management and Research, Arlington, United States of America

BACKGROUND AND OBJECTIVES
OASIS 4 (NCT05564117) was a multi-site RCT evaluating once-daily oral semaglutide (sema) 25 mg (half the dose used in OASIS 1 [NCT05035095]) vs placebo in adults with overweight/obesity.

METHODS
Eligible participants (≥18 years; BMI ≥30 kg/m2 or ≥27 kg/m2 with ≥1 weightrelated comorbidity) were randomized 2:1 to once-daily oral sema escalated to 25 mg or placebo for 64 weeks, with a lifestyle intervention. Co-primary endpoints were percent weight change and achievement of ≥5% weight loss (WL). Confirmatory secondary endpoints were achievement of ≥10% WL, ≥15% WL, ≥20% WL, and change in IWQOL-Lite-CT Physical
Function score. Efficacy data were analyzed using the treatment policy estimand with in-trial data unless stated otherwise.

RESULTS
Participants (sema n=205; placebo n=102) were mostly female (78.8%), with a mean age of 48 years, and bodyweight of 105.9 kg. Mean weight change was –13.6% in the sema group vs –2.2% in the placebo group ($p<0.0001$), and –16.6% vs –2.7% using ontreatment data. A greater proportion of participants achieved ≥5% WL (79.2% vs 31.1%), ≥10% WL (63.0% vs 14.4%), ≥15% WL (50.0% vs 5.6%), and ≥20% WL (29.7% vs 3.3%) in the sema group vs placebo (all $p<0.0001$). Greater improvements in IWQOL-Lite-CT Physical Function score were observed in the sema vs placebo groups (ETD 7.7 points, $p=0.0006$). Significant improvements in cardiometabolic risk factors were also observed with sema vs placebo. Incidence of all AEs (sema 93.1% vs 85.3%) and of AEs leading to permanent treatment discontinuation (sema 6.9% vs placebo 5.9%; mostly gastrointestinal AEs) was comparable between groups. There was a lower incidence of serious AEs in the sema group (3.9%) vs the placebo group (8.8%).

CONCLUSIONS
Once-daily oral sema 25 mg significantly reduced bodyweight, increased physical function, and improved metabolic health in adults with overweight/obesity, with comparable efficacy to sema 50 mg in the OASIS 1 trial. Safety and tolerability were consistent with the well-established profile of sema.

CAUSAL RELATIONSHIP BETWEEN KIMCHI CONSUMPTION AND ABDOMINAL OBESITY IN KOREANS: A TWO-SAMPLE MENDELIAN RANDOMIZATION STUDY

Jaehee Cha[1]; Subin Kim[1]; Hyeju Song[1]; Dayeon Shin[1]
[1]Food and Nutrition, Inha University, Yonghyeon Campus, Incheon, Korea, Republic of

BACKGROUND AND OBJECTIVES
Metabolic syndrome is a major risk factor for cardiovascular disease and diabetes, strongly influenced by lifestyle and dietary habits. However, existing observational studies have limitations in establishing causal relationships between food consumption and metabolic syndrome due to issues such as confounding variables and reverse causality. Based on previous findings suggesting that kimchi consumption may reduce the risk of metabolic syndrome, this study aimed to evaluate the causal relationship between high kimchi consumption and metabolic syndrome and its components, using two-sample Mendelian randomization (MR).

METHODS
This study included Korean Genome and Epidemiology Study (KoGES) Health Examinees (HEXA) cohort (n=57,456) and Ansan/Ansung cohort (n=5,029) to assess the causal relationship between kimchi consumption and abdominal obesity. Participants aged 40–69 years were included. Genetic variants identified through genome-wide association studies (GWAS) with a threshold of $p<5\times10^{-5}$ and linkage disequilibrium ($r^2<0.05$) were used as instrumental variables. A total of 130 single nucleotide polymorphisms (SNPs) were selected as instrumental variables. Kimchi consumption included various types such as baechu kimchi, kkakdugi, and nabak kimchi. Participants were classified into high-kimchi intake group (>75th percentile) and low-kimchi intake group (≤75th percentile). Abdominal obesity was defined as a waist circumference ≥90 cm in men and ≥85 cm in women. MR analyses were performed using MR-Egger, inverse-variance weighted (IVW), and weighted median methods. Sensitivity analyses, including leave-one-out analysis and heterogeneity tests, were conducted to ensure the robustness of the RESULTS.

RESULTS
High-kimchi intake group showed higher intake levels of key nutrients, such as energy, protein, dietary fiber, vitamin C, and folate, compared to the low consumption group. MR analysis indicated that high kimchi consumption significantly reduced abdominal obesity in the IVW model (OR = 0.84, 95% Cl = 0.707-0.997, P-value<0.05).

CONCLUSIONS
This study suggests that high kimchi consumption may contribute to a reduction in abdominal obesity among Koreans.

CLINICAL ETHICAL DILEMMA IN ADVANCING NUTRITION AND DIETETICS PRACTICE IN JAPAN

ikuko gomi[1]; Ryoko Higuchi[1]; Risa Fukuoka[1]; Asami Fujitani[2]
[1]Department of Nutrition and Dietetics, Kanagawa University of Human Services, Yokosuka, Japan;
[2]Department of Clinical Nutrition and Dietetics, Saiseikai Yokohamashi Tobu Hospital, Kawasaki, Japan

BACKGROUND AND OBJECTIVES
In the aging society of Japan, artificial hydration and nutrition (AHN) for the elderly have been provided with careful consideration through the cooperation of healthcare professionals.However, dietitians at hospitals, care facilities, and home care settings experience complicated ethical dilemmas in nutritional care practices. This study aims to clarify the ethical issues in various advanced nutritional care settings.

METHODS
Semi-structured interviews were conducted with dietitians working in elderly care, pediatric wards, ER/ICUs, psychiatric wards, and facilities for individuals with severe motor and intellectual disabilities (SMID). Regarding cases of ethical dilemma, we collected the medical background, the patient's will, and the thoughts of the related persons (family and care staff, etc.) based on bioethical principles , and qualitatively analyzed the conflicting values.

RESULTS
Nineteen cases of ethical dilemmas in the practice of nutritional care were collected and qualitatively analyzed. The ethical dilemmas in nutritional care were classified into four main categories; (1) the conflict of whether or not to respect the patient's will to refuse food or nutrition intake (at ER, elderly care, and psychiatric wards) , (2) the family or healthcare professional's intention was prioritized over the patient's will (at pediatric wards, psychiatric wards, and SMID facilities), (3) unexpected and disappointing RESULTS for patients and dietitians due to insufficient risk prediction or patient explanation (end of life cases), and (4) the imbalance between personalized approach to diet and/or nutritional care and healthcare service equity.

CONCLUSIONS
This study has revealed that ethical dilemmas occur in acute care, disability, pediatric, and other cases where it is difficult for patients to make decisions and where appropriate dietary therapy is not implemented. Dietitians should have sufficient knowledge of clinical ethics as well as clinical nutrition, and practice nutritional care that takes into account patient decision-making and quality of life.

BACKGROUND AND OBJECTIVES
Dietary changes and sedentary lifestyles observed over several years have increased metabolic disorders like obesity and type 2 diabetes. Dietary fibres may help reduce their development, particularly by positively improving the gut microbiota. This study aimed to assess the effects of short-chain fructo-oligosaccharides (scFOS) prebiotic fibre on gut microbiota, glucose homeostasis and body composition in prediabetic overweight individuals.

METHODS
In this randomized, double-blinded, placebo-controlled study, 66 participants were included and consumed either 20 g of placebo or scFOS supplement (ACTILIGHT® 950P; Beghin-Meiji; France) daily for 12 weeks. Parameters related to faecal microbiota, glucose homeostasis, and body composition were measured before (V2: randomization visit) and after the intervention (V5: end of supplement intake).

RESULTS
The mean age of participants was 50.6 ± 9.0 years, with a mean BMI of 28.2 ± 2.7 kg/m². Compliance was high, with over 97% adherence. Regarding gut microbiota (in 30 participants), α-diversity increased between V2 and V5 in the placebo arm, whereas it decreased in the scFOS arm across 3 out of the 4 different diversity indices ($p<0.004$). The effect of scFOS on α-diversity is mainly related to a clear bifidogenic effect. Indeed, the increase of the relative abundance of *Bifidobacterium* was higher in the scFOS arm compared to the placebo arm ($p=0.0202$). These changes were associated with a modification of gut fermentative activity, as shown by an increase in the levels of two SCFAs in the scFOS arm compared to a decrease in the placebo arm: acetate ($p=0.0310$) and propionate ($p=0.0062$). No significant differences were observed between the scFOS and placebo arms for markers of glucose metabolism. However, some body composition parameters displayed significant differences between arms during the follow-up. Body fat mass decreased in the scFOS arm (absolute and relative variations) while it increased in the placebo arm between V2 and V5 (medians: -0.15 kg *vs* +0.27 kg, $p=0.0400$; -0.26% *vs* +0.20%, $p=0.0273$). Conversely, lean mass (relative variation) followed the opposite trend.

CONCLUSIONS
Positive effects of scFOS supplementation were observed on gut microbiota composition and its fermentative activity, as well as on body fat mass, in prediabetic adults after a 12-week supplementation. Although no clear improvement of glucose homeostasis was observed, these findings, while preliminary, suggest that scFOS may offer benefits in areas related to gut health and body composition.

MARINE N-3 FATTY ACID TREATMENT FOR REDUCED CAROTID PLAQUES IN PATIENTS WITH TYPE 2 DIABETES: INSIGHTS FROM THE PNMD TRIAL

Jingjing Jiao[1]; Pan Zhuang[2]; Xiaohui Liu[1]; Yu Zhang[3, 2]
[1]Department of Endocrinology, The Second Affiliated Hospital, School of Public Health, Zhejiang University School of Medicine, Hangzhou, China; [2]Department of Gastroenterology, The First Affiliated Hospital of College of Medicine, Zhejiang University, Hangzhou, China; [3]Department of Food Science and Nutrition, College of Biosystems Engineering and Food Science,, Zhejiang University, Hangzhou, China

BACKGROUND AND OBJECTIVES
Carotid plaques result from a blockage or narrowing of carotid arteries associated with severe atherosclerotic cardiovascular diseases. How marine n-3 fatty acid supplementation reduces carotid plaques among patients with diabetes and whether the effect is modified by genetics remain unclear. To assess the effect of marine n-3 fatty acid supplementation on carotid plaques and interactions with genetics among patients with diabetes.

METHODS
In this 14-month double-blind, randomized controlled trial, 415 patients with type 2 diabetes (T2D) were randomly assigned to receive high-dose (3.0 g/day) or low-dose (1.5 g/day) marine n-3 fatty acids (fish oil) or placebo (refined olive oil). The primary outcome was the prevalence of carotid plaques. Secondary outcomes included changes in NMR-derived lipoprotein subclasses and their mediation effects on carotid plaques. Genetic interactions with the supplementation were also investigated.

RESULTS
383 participants (92.3%) completed the 14-month intervention and 358 patients (86.3%) completed carotid ultrasound exams. Fish oil supplementation was significantly associated with reduced prevalence of carotid plaques (P trend=0.023). Compared to the placebo, the adjusted odds ratios (95% CIs) were 0.41 (0.19-0.88) and 0.86 (0.42-1.79) for high-dose and low-dose groups, respectively. High-dose intervention significantly reduced remnant cholesterol, LDL-1-triglycerides (TG), HDL-4-TG, and HDL-3-TG, which largely mediated anti-atherosclerotic effect. Additionally, the effect was most prominent among patients with low genetic risk of remnant cholesterol and LDL. Variants of ELOVL2 (rs2295602, rs4711171, and rs3734398) significantly modified the protective effects of high-dose marine n-3 fatty acids against carotid plaques.

CONCLUSIONS
Supplementation with high-dose marine n-3 fatty acids resulted in lower prevalence of carotid plaques among T2D patients mediated by improving lipoprotein profile and modified by genetic risk of remnant cholesterol and LDL.

ELEVATED VISCERAL FAT IS ASSOCIATED WITH REDUCED FUNCTIONALITY AND INCREASED SYMPTOMS OF PAIN AND INSOMNIA IN WOMEN WITH BREAST CANCER

Mariana Souza Viera[1]; Luiza Pereira Gonçalves[1]; Vanusa Felicio De Souza Mamede[1]; Rayne De Almeida Marques-Bernabé[1]; Luisa Barcellos Leite Da Silva[2]; Deborah Minto Santos[2]; Julia Abdala Nogueira Souza[2]; Janine Martins Machado[3]; Ben-Hur Albergaria[4]; José Luiz Marques-Rocha[1, 2]; Valdete Regina Guandalini[1, 2]

[1]Postgraduate Program in Nutrition and Health, Universidade Federal do Espírito Santo - UFES (Maruípe), Vitoria, Brazil; [2]Department Integrated Health Education, Universidade Federal do Esp, Vitoria, Brazil; [3]Mastologia, Hospital Universitario Casssiano An, Vitoria, Brazil; [4]Departamento de Medicina Social, Universidade Federal do Espirito Santo, Vitoria, Brazil

BACKGROUND AND OBJECTIVES

Health-Related Quality of Life (HRQoL) encompasses various factors that influence an individual's health, such as antineoplastic treatment, changes in personal, family, and work life, as well as alterations in body composition. Among these changes, increased body fat percentage and decreased muscle mass are frequently observed. Specifically, visceral fat (VF) has been associated with an increased risk of recurrence and the development of various cancer types. This study aimed to investigate the association between HRQoL and VF in women with breast cancer (BC).

METHODS

This observational cross-sectional study was conducted with women diagnosed with BC within the past 12 months, without metastases or recurrences. HRQoL and its domains were assessed using the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 (EORTC QLQ-C30) and the Breast Cancer-specific Quality of Life Questionnaire Core 23 (EORTC QLQ-BR23). VF was measured using dual-energy X-ray absorptiometry (DXA). Multivariate linear regression models were conducted, with a significance level of $p < 0.05$.

RESULTS

The study included 114 women, with a mean age of 55.2 ± 11.3 years, predominantly Black or mixed race (65.8%), insufficiently active (70.2%), in clinical stage II (41.2%), with invasive lobular carcinoma histological subtype (69.3%), and luminal B molecular subtype (44.7%). A high prevalence of elevated body fat (86.0%) and VF (62.5%) was observed. In the final adjusted model, VF remained associated with the functional scale (β = -0.27; 95% CI -19.04 to -4.00; $p = 0.003$), physical function (β = -0.22; 95% CI -18.94 to -2.06; $p = 0.019$), and functional performance (β = -0.28; 95% CI -27.97 to -2.52; $p = 0.019$). Regarding symptoms, VF was associated with the overall symptom scale (β = 0.28; 95% CI 18.55 to 0.95; $p = 0.003$), pain (β = 0.36; 95% CI 12.44 to 39.24; $p < 0.001$), and insomnia (β = 0.23; 95% CI 3.61 to 35.80; $p = 0.017$).

CONCLUSIONS

Elevated visceral fat was associated with worsened functionality (physical and functional performance) as well as symptoms of pain and insomnia in women with breast cancer.

COMPARISON OF MEASURED BMR AND BMR ASSESSED VIA BIOIMPEDANCE IN A BRAZILIAN ADULT SAMPLE: DESCRIPTIVE STUDY

Fabíola Vieira de Mello[1]; Camila Medeiros Da Silva Mazzeti[1]; Reni Masurkevicz Berni[2]; Marceli Borges Fioravante[1]; Kellen Menezes[1]; Francine Moreira Bossan; Amina Chaim Costa; Vivian Wahrlich[3]; Luiz Antonio Dos Anjos; Bruna Paola Murino Rafacho[1]
[1]FACFAN, UFMS - UNIVERSIDADE FEDERAL DO MATO GROSSO DO SUL, Campo Grande, Brazil; [2]Unimed Campo Grande, Dietitian Reni, Campo Grande, Brazil; [3]Laboratório de Avaliação Nutricional e Funcional, Universidade Federal Fluminense, Niterói, RJ, Brazil

BACKGROUND AND OBJECTIVES
Bioimpedance impedance analysis (BIA) is an accessible tool for measuring body composition and estimating basal metabolic rate (BMR) in clinical settings. Due to its high cost, indirect calorimetry's use, considered the gold standard for measuring BMR, is not widespread (McLester et al., 2020; Karagun et al., 2024). This study aimed to compare BMR values provided by two bioimpedance devices with those from indirect calorimetry in Brazilian adults.

METHODS
Fifty participants aged between 18 and 60 years old of both sexes were evaluated, 64% female, age of 31.7 ± 9.5 years old, and BMI of 25.1± 4.8 kg/m2. BMR was measured using tetrapolar (Biodynamics 450) and octopolar (Tanita BC-418) bioimpedance devices, and indirect calorimetry (Medgraphics VO2000) (Anjos et al. 2014). Calculations used the Weir (1949) equation, with the final BMR (kcal/day) value derived by the mean of the last 20 minutes multiplied by 1440. Statistical analysis was performed using paired t-tests (QuickCalc Prism), with significance set at 5%.

RESULTS
Significant differences were observed between the two bioimpedance devices. The mean BMR measured by indirect calorimetry was 1279.42 ± 272.24 kcal/day, and was significantly lower than the mean BMR from the tetrapolar device (1632.96 ± 396.48 kcal/day, $p < 0.0001$) and the octopolar device (1540.12 ± 376.32 kcal/day, $p < 0.0001$).

CONCLUSIONS
Octopolar bioimpedance yielded RESULTS closest to indirect calorimetry compared to the tetrapolar device. However, an important difference was observed between the bioimpedance devices and indirect calorimetry. Thus, the substitution of measurements should be used with caution. THE ASSOCIATION BETWEEN CIRCULATING FATTY ACIDS PATTERNS AND THE RISK OF CARDIOVASCULAR DISEASE IN PATIENTS WITH TYPE 2 DIABETES: A CASE-CONTROL STUDY

Shashan Chen[1]; Lu Zheng[1]; Tianying Pang[1]; Lan Huang[2]; Qinwen Zhou[2]; Zheqing Zhang[2]; Yanbin Ye[1]
[1]The First Affiliated Hospital, Jinan University, Guangzhou, China; [2]School of Public Health, Southern Medical University, Guangzhou, China

BACKGROUND AND OBJECTIVES
Historically, research has primarily focused on the impact of individual FAs on cardiovascular diseases (CVD). Our study aimed to investigate the relationship between patterns of circulating FAs and the risk of cardiovascular disease in individuals with type 2 diabetes (T2DM) and CVD.

METHODS
We conducted a 1:1 age- and sex-matched case-control study of 303 Chinese patients with T2DM, comparing those newly diagnosed with CVD to controls. Serum FAs were analyzed with a Shimadzu GCMS QP2010 SE gas chromatograph coupled with a mass spectrometer. Principal component analysis (PCA) was employed to identify patterns of circulating fatty acids. Conditional logistic regression analysis was used to explore the association between circulating FA patterns and T2DM CVD.

RESULTS
A total of 22 types of serum FAs were detected. Compared to the control group, individuals with T2DM CVD had significantly lower serum levels of C22:0, C18:1 n-9, C16:0, C18:0, C20:3 n-6, C24:0, C17:0, C20:0, C15:0, C16:1 n-7, and C23:0, but higher levels of C22:6 n-3, C18:3 n-6, C20:4 n-6, and C20:5 n-3 ($P<0.05$). The FAP1 pattern (characterized by higher levels of C16:1 n-7, C23:0, C24:0, C22:0, and C18:1 n-9, and lower levels of C15:0 and C12:0) was inversely associated with CVD risk in patients with diabetes after multivariable adjustment (OR=0.40; 95% CI=0.17, 0.87; P=0.02).

CONCLUSIONS
Circulating FA patterns with higher levels of C16:1 n-7, C23:0, C24:0, C22:0, and C18:1 n-9, and lower levels of C15:0 and C12:0, may be associated with a reduced risk of T2DM CVD.

CONFLICTS OF INTERESTS

GENETIC ASSOCIATION BETWEEN COFFEE CONSUMPTION AND METABOLIC SYNDROME AND ITS COMPONENTS IN KOREAN ADULTS: A MENDELIAN RANDOMIZATION ANALYSIS

Subin Kim[1]; Jaehee Cha[1]; Hyeju Song[1]; Dayeon Shin[1]
[1]Food and Nutrition, Inha University, Yonghyeon Campus, Incheon, Korea, Republic of

BACKGROUND AND OBJECTIVES
Coffee is one of the most widely consumed beverages globally. While numerous studies have explored the relationship between coffee consumption and metabolic syndrome (MetS), their findings remain inconsistent, and the causal relationship is still uncertain. This study employed the Mendelian randomization (MR) approach to investigate the association between coffee consumption, MetS, and its components.

METHODS
This study was conducted on 64,186 Korean adults aged 40 to 69 years, extracted from the Korean Genome and Epidemiology Study (KoGES) Health Examinees (HEXA) cohort, conducted between 2004 and 2013. Coffee consumption data were collected using a Food Frequency Questionnaire (FFQ), and daily coffee intake was categorized into high-consumption (>75th percentile) and low-consumption groups (≤75th percentile). Instrumental variables (IVs) were selected based on 127 common single nucleotide polymorphisms (SNPs) associated with coffee consumption and components of MetS. The relationship between coffee consumption and MetS, as well as its components was assessed using MR analysis. MR analysis employed methods including Inverse Variance Weighted, MR Egger, Weighted Median, Weighted Mode, and Simple Mode. The MR RESULTS were further evaluated for reliability through heterogeneity tests, pleiotropy assessments, MR-PRESSO and sensitivity analyses using leave-one-out methods.

RESULTS
The MR analysis revealed significant pleiotropy among the SNPs associated with MetS and its components, leading to the interpretation of RESULTS using the MR-Egger method. Participants with genetically predicted higher coffee consumption exhibited significantly lower levels of blood glucose compared to those with lower coffee consumption (Odds Ratio [OR]: 0.588; 95% Confidence Interval [CI]: 0.442–0.782), blood pressure (OR: 0.719; 95% CI: 0.590–0.876), waist circumference (OR: 0.593; 95% CI: 0.453–0.776), triglycerides (OR: 0.655; 95% CI: 0.536–0.876), and MetS prevalence (OR: 0.797; 95% CI: 0.637–0.996) compared to those with lower coffee consumption.

CONCLUSIONS
Coffee consumption was found to be associated with a lower prevalence of MetS and its components in Korean middle-aged adults. Using MR analysis with IVs, a potential causal relationship between coffee consumption and MetS, and its components, was demonstrated.

LIFESTYLE COMBINATION PATTERNS AS KEY MODIFIABLE FACTORS FOR TYPE 2 DIABETES MELLITUS RISK IN MIDDLE-AGED KOREAN MEN

Inji Lee[1, 2]; Minji Kang[1, 2]; Hyunggyu Park[1, 2]; Hyunjung Lim[1, 2]
[1]Department of Medical Nutrition, Kyung Hee University, Global Campus, Yongin-si, Korea, Republic of;
[2]Research Institute of Medical Nutrition, Kyung Hee University, Seoul Campus, Seoul, Korea, Republic of

BACKGROUND AND OBJECTIVES
The global prevalence of type 2 diabetes mellitus (T2DM) is increasing, and in South Korea, approximately 57% of adults aged 30 and older have diabetes or prediabetes, with a higher prevalence among men. Despite advancements in treatment and combination therapies, the management rate has not significantly improved, indicating the need for a preventive approach. Although lifestyle modifications have been shown to reduce diabetes risk, most studies have used a uniform methodology, and research on individualized prevention strategies is limited. This study aimed to analyze the lifestyle combination patterns of middle-aged men in South Korea and assess the associated risk of T2DM.

METHODS
A total of 2,346 middle-aged men without T2DM at the baseline survey (2001-2002) from the community-based cohort of the Korean Genome and Epidemiology Study (KoGES) were included. The incidence of T2DM was tracked up to the 8th follow-up (2017-2018). Lifestyle combination patterns were identified through principal component and factor analyses based on baseline sociodemographic, lifestyle, anthropometric and dietary data. Cox regression analysis was performed to evaluate the incidence of T2DM according to each pattern.

RESULTS
Four lifestyle combination patterns were identified in middle-aged men: Healthy Lifestyle, Low Carb & High Protein, High SES & Irregular Lifestyle, and Obesity & Bad Eating Habits. Individuals in the second tertile of the Healthy Lifestyle pattern (Pattern 1) showed a significantly reduced risk of diabetes incidence (HR tertile 2 vs. 1 = 0.75, 95% CI = 0.62–0.90), while individuals characterized by High SES & Irregular Lifestyle (Pattern 3) and Obesity & Bad Eating Habits (Pattern 4) exhibited a significantly increased risk of T2DM (HR Pattern 3: tertile 3 vs. 1 = 1.24, 95% CI = 1.01–1.53; Pattern 4: tertile 3 vs. 1 = 2.60, 95% CI = 2.14–3.17).

CONCLUSIONS
This study confirmed that the characteristics of Pattern 3, such as frequent late-night snacking, eating out, and low physical activity, as well as the negative factors of Pattern 4, including high body fat, BMI, overeating frequency, and fast eating speed, have a greater effect on the onset of diabetes than healthy lifestyle habits. These findings emphasize the importance of variable correlations to identify priority areas for improvement and develop targeted interventions. This study highlights distinct lifestyle combination patterns and their differential impact on T2DM risk, underscoring the need for tailored preventive interventions to effectively reduce the T2DM burden.

PERSONALIZED HERBAL MIXTURE ENHANCES LINEAR GROWTH, GASTROINTESTINAL FUNCTION, DIET QUALITY, AND RESPIRATORY HEALTH IN KOREAN CHILDREN

Kijoon Kim[1, 2]; Joonsuk Lee[2]
[1]Department of Nutritional Sciences, University of Connecticut, Storrs, CT, 06269, United States of America;
[2]KIM KIJOON BOM Medical Clinic, Lotte Hotel World, Seoul, Korea, Republic of

BACKGROUND AND OBJECTIVES
Nutritional status critically affects linear growth and child development. Gastrointestinal dysfunction, presenting as nausea, epigastric pain, and abdominal pain during growth phases, can diminish food intake and nutrient absorption, impacting long-term growth. Despite its importance, research exploring the interconnected impacts of nutritional status, gastrointestinal dysfunction, respiratory health, and linear growth remains sparse. This study addresses these gaps by aiming to assess the role of personalized herbal mixtures in ameliorating gastrointestinal symptoms and enhancing nutritional and growth outcomes in Korean children.

METHODS
Through a three-month intervention study, 40 Korean children aged 3 to 12 years received personalized herbal mixtures tailored to their individual health profiles. The usual dietary intake of nutrients was estimated by the multiple source method (MSM).

RESULTS
The intervention resulted in increased intake of several nutrients, with statistically significant enhancements observed specifically in vitamin E and fiber consumption. Concurrently, there was a notable reduction in gastrointestinal symptoms among 83% of participants, including decreases in nausea, epigastric pain, and abdominal pain. Additionally, the intervention correlated with a reduced frequency of respiratory infections, suggesting improved respiratory immunity. Importantly, there was a statistically significant improvement in height-for-age Z scores ($p<0.0001$), collectively indicating enhancements in linear growth through reduced gastrointestinal symptoms, enhanced nutrient intake, and decreased frequency of respiratory infections.

CONCLUSIONS
These findings suggest that personalized herbal mixtures may facilitate growth by improving digestive and respiratory health. Further studies are warranted to explore the underlying mechanisms through which these improvements occur.

CHALLENGES AND FUTURE OF PRECISION NUTRITION

DUO LI[1]
[1]Institute of Nutrition & Health, Qingdao University, Qingdao, China

BACKGROUND AND OBJECTIVES

Precision nutrition is a hot topic that everyone is paying attention to nowadays. However, when it comes to what foods or nutrients individuals should eat and how much they should eat, we are still helpless. This study aimed to investigate the impact of individual genetic background, metabolic characteristics, physiological status, intestinal microecology, and clinical parameters on nutritional needs and intervention effects, in order to meet the needs of individual growth and development, maintain individual health and normal physiological functions, and prevent and control disease occurrence and development.

METHODS

Summarizing our recent studies and literatures in relaton to precision nutrition.

RESULTS

When it comes to what foods or nutrients individuals should eat and how much they should eat, we are still helpless. Even with full genetic testing, clinical biochemistry, and gut microbiota testing, lifestyle and dietary intake data were collected. However, when faced with dozens of pages of testing data, especially genetic testing dada, we still cannot diagnose what nutrients the patient lacks and how much they lack, what foods to eat and how much to eat. Access to genetic testing, professional dietary supplements, and personalized nutrition services may be limited by cost, geographic location and healthcare differences. Efforts need to be made to improve the accessibility and affordability of precision nutrition services to ensure fair medical services and maximize the impact on public health. In addition, the integration of genetic testing and personalized dietary recommendations has raised ethical issues related to privacy, confidentiality, informed consent, and the possibility of genetic discrimination. Ethical standards and regulatory frameworks are crucial for protecting individual rights and ensuring responsible use of genetic information in clinical practice. Clear communication of genetic RESULTS, informed consent, and adherence to ethical guidelines are crucial to ensure that personalized dietary recommendations are both effective and ethical sound. The robust scientific evidences are important considerations into integrating personized nutrition into clinical practice. Large-sample size and multi-ethnic longitudinal studies, randomized controlled trials, and meta-analyses are essential to validate research findings, establish causal relationships, and elucidate the long-term effects of personalized dietary recommendations across diverse populations and health conditions.

CONCLUSIONS

The integration of n-of-1, nutrigenetics and multi omics data will help us deepen our understanding of the relationship between individual‘s dietary nutrition and health.

BACKGROUND AND OBJECTIVES

Eggs are a highly digestible source of complete protein. While considerable research has explored diet's role in modulating gut microbiome function, little is understood about dietary factors driving protein fermentation in the colon. This study aimed to examine the impact of regular egg consumption on markers of protein fermentation in healthy adults.

METHODS

This 6-week parallel-arm randomised controlled trial examined the effects of consuming 2 eggs/day versus no eggs. Twenty-five healthy adults were randomised to either the intervention group (n=11) consuming 2 whole eggs daily or control group (n=13) avoiding eggs. 24-hour faecal collections at baseline and week 6 were analysed using liquid chromatography-mass spectrometry for short-chain fatty acids (SCFAs), branched-chain fatty acids (BCFAs), and protein fermentation metabolites. Statistical analysis used two-way ANOVA with uncorrected Fisher's least significant difference test. Data presented as median (mmol/g for SCFAs and BCFAs; μg/mg for protein metabolites).

RESULTS

No significant interaction was found between egg consumption status and timepoint regarding BCFA:SCFA ratio (p=0.8345). Similarly, key SCFAs, including acetic acid (p=0.5072), butanoic acid (p=0.2943), valeric acid (p=0.5181), and propionic acid (p=0.4577), showed no significant differences across diets and timepoints. Additionally, BCFAs also showed no significant differences across diets and timepoints, including isobutanoic (Baseline: Control=1.9, Egg=1.2; Week 6: Control=1.4, Egg=1.6; p=0.2003) and isovaleric acids (Baseline: Control=1.4, Egg=1.2; Week 6: Control=1.2, Egg=1.3; p=0.2090). Protein metabolites, including phenol (Baseline: Control=1.15, Egg=1.73; Week 6: Control=1.66, Egg=1.17; p=0.4982), p-cresol (Baseline: Control=64.71, Egg=56.71; Week 6: Control=52.24, Egg=63.88; p=0.1707), and 4-ethylphenol (Baseline: Control=0.255, Egg=0.29; Week 6: Control=0.3, Egg=0.11; p=0.4661) remained stable between groups.

CONCLUSIONS

The consumption of 2 eggs per day for 6 weeks did not significantly impact protein fermentation markers in healthy adults, as evidenced by stable BCFA:SCFA ratios and protein metabolite concentrations. Future research should explore longer interventions or diverse populations to further assess the metabolic effects of egg intake on the gut microbiome, particularly in populations with altered protein metabolism or digestive conditions.

EFFECTIVENESS OF A MOBILE-BASED NUTRITION INTERVENTION FOR THE MANAGEMENT OF SEVERE OBESITY IN CHILDREN AND ADOLESCENTS

Hyunggyu Park[1, 2]; Kyeongseob Shin[1, 2]; Minji Kang[1, 2]; Inji Lee[1, 2]; Kyunghee Park[3]; Yoonmyung Kim[4]; Hyunjung Lim[1, 2]
[1]Department of Medical Nutrition, Kyung Hee University, Global Campus, Yongin-si, Korea, Republic of;
[2]Research Institute of Medical Nutrition, Kyung Hee University, Seoul Campus, Seoul, Korea, Republic of;
[3]Department of Family Medicine, Hallym University Sacred Heart Hospital, Anyang, Korea, Republic of;
[4]University College, Yonsei University International Campus, Incheon, Korea, Republic of

BACKGROUND AND OBJECTIVES
The management of obesity in children and adolescents requires a dual approach that addresses both intake regulation for weight control and adequate caloric and nutrient intake to support growth. While mid- to long-term nutrition intervention programs are essential for effective management, relevant research in South Korea remains limited. This study aimed to evaluate the effectiveness of a six-month mobile platform-based nutrition intervention delivered via a mobile platform in reducing caloric intake and improving dietary habits among children and adolescents with severe obesity (BMI ≥ 97th percentile).

METHODS
Diagnosis of nutritional issues was identified using the Nutrition Care Process (NCP), and individualized goals were established. Dietary intake was assessed using 3-day dietary records, while dietary habits were measured using the Nutrition Quotient for Children (NQ-C) and Adolescents (NQ-A), the Diet Quality Index-International (DQI-I), the Dutch Eating Behavior Questionnaire for Children (DEBQ-C), and the Yale Food Addiction Scale for Children (YFAS-C). The frequency of specific food consumption, such as soft drinks and snacks, was evaluated using a Food Frequency Questionnaire (FFQ). Participants received monthly nutrition education materials, including webtoons, animations, and card news, delivered through a mobile platform over six months

RESULTS
A total of 221 participants were enrolled in the study, and 155 completed the intervention. Following the intervention, participants exhibited a significant reduction in average caloric intake (2117.3 ± 466.2 kcal to 1910.1 ± 457.5 kcal; $p < 0.001$). Improvements in dietary habits were observed, with increased restraint of sugary and fatty food consumption as reflected in NQ scores for both children (37.4 ± 27.8 to 47.3 ± 22.3; 44.7 ± 22.8 to 55.1 ± 20.9; $p < 0.001$) and adolescents (29.5 ± 27.1 to 40.3 ± 24.8; 40.3 ± 27.6 to 52.3 ± 23.4; $p < 0.01$). DEBQ restrained eating scores decreased significantly (14.6 ± 2.7 to 13.8 ± 2.6; $p < 0.001$). The frequency of snacking, particularly soft drink consumption, also decreased significantly (2.4 ± 4.1 times per week to 1.6 ± 2.3 times per week; $p = 0.029$).

CONCLUSIONS
The six-month mobile platform – based nutrition intervention effectively reduced caloric intake and improved dietary habits in obese children and adolescents. These RESULTS suggest that mobile platform-based interventions can be a practical and accessible approach to addressing obesity and promoting healthier eating habits in this population.

DIRECT AND INDIRECT EFFECTS OF HEALTHY NORDIC AND MEDITERRANEAN DIET PATTERNS VIA GUT MICROBIOTA ON INTERMEDIATE RISK FACTORS FOR CARDIOMETABOLIC DISEASES

Agnetha Rostgaard-Hansen[1]; Mia Klinten Grand,[2]; Anders Esberg[3]; Susanne Rosthøj,[2]; Johan Dicksved[4]; Hansen Torben[5]; Erik Pelve,[6]; Anne Tjønneland[7]; Rikard Landberg,[8]; Ingegerd Johansson,[3]

BACKGROUND AND OBJECTIVES
Evidence suggest that diet and the gut microbiota interact in the development of cardiometabolic diseases (CMD). For example, the effects of dietary fiber-rich foods on weight loss and glucose metabolism have shown to vary depending on the Prevotella-to-Bacteroides (P/B) ratio in the gut. This study investigates whether adherence to the healthy Nordic or Mediterranean diet directly or indirectly affects intermediate risk factors for CMD via mediation by gut microbiota.

METHODS
439 participants from the Diet, Cancer and Health – Next Generations MAX sub cohort were included in the study. Diet was assessed from 24-hour dietary recalls, stool samples were analyzed by 16S rRNA gene amplicon sequencing and intermediate risk factors for CMD were included. Structural equation models were used to estimate the direct and indirect effect stratified by sex, where diet, adiposity, and lipidemia were modeled as latent variables.

RESULTS
No indirect effect of adherence to the healthy Nordic or Mediterranean diet on CMD risk factors mediated by the P/B ratio was found. In women, adherence to the healthy Nordic diet and Mediterranean diets associated with lower adiposity (5.3% lower BMI per dietary adherence unit 95% CI:1.0, 9.4 and 6.2% lower BMI per unit 95% CI:1.8, 10.3). Adherence to the healthy Nordic diet and Mediterranean diets also associated with lower lipidemia (6.7% lower TG per unit, 95% CI:0.9, 12.2 and 7.6% lower TG per unit 95% CI:1.6, 13.2) and lower levels of hs-CRP (14.4% per unit, 95% CI:1.5, 25.6 and 15.0% per unit, 95% CI:2.5, 25.8), indirectly through adiposity. In men, adherence to the healthy Nordic diet associated with lower adiposity (2.3% lower BMI per unit, 95% CI:0.5, 4.0). Adherence to the healthy Nordic diet also associated with lower lipidemia (2.5% lower TG per unit, 95% CI:0.5, 4.5) and lower levels of hs-CRP (4.8% per unit, 95% CI:0.3, 9.1), indirectly through adiposity.

CONCLUSIONS
While a healthy diet is known to affect CMD risk, it does not appear to be mediated through the P/B microbiota ratio. However, our findings support that healthy diet improves intermediate risk markers including lipidemia and hs-CRP, mediated by lower adiposity.

[2]Molecular Oncology Group, IMDEA Food, CEI UAM+CSIC. Carretera de Cantoblanco, 8. 28049, Madrid, Spain

BACKGROUND AND OBJECTIVES

Nutritional strategies are increasingly recognized as pivotal in clinical research, particularly in assessing the impact of diet on health outcomes and disease prevention. **The Mentoring for Health** (*Unveiling malnutrition and metabolic changes in lung cancer patients: setting the basis for precision nutrition models*) and **DiBaN** (*Linking Intestinal Bacteria and Host Metabolism to Tackle Type 2 Diabetes with Novel Food*) projects are two significant European initiatives supported by the Horizon EIC Pathfinder Challenge, focused on integrating precision nutrition into clinical trials for lung cancer and metabolic health. Conducted at IMDEA-Food, these projects aim to develop advanced nutritional interventions for better health outcomes.

METHODS

The *Mentoring for Health* project (EU project number: 101162297) addresses malnutrition and metabolic health in non-communicable diseases (NCDs), focusing on lung cancer patients. By applying precision nutrition tailored to individual genetic and lifestyle factors with a major focus on microbiota and glycobiology, the project aims to improve quality of life and prognosis. It also fosters training and collaboration among healthcare professionals and researchers to advance clinical applications of personalized nutrition.
In parallel, the *DiBaN* project (EU project number: 101162517) explores the role of personalized diet in metabolic diseases such as obesity and diabetes type 2 making use of alternative foods as novel tools. By integrating innovative methodologies (biomarker analysis and dietary interventions), the *DiBaN* project seeks to establish tailored dietary strategies that promote long-term health improvements and reduce the risk of chronic diseases.

RESULTS

Both projects highlight the importance of nutrition in clinical trials, demonstrating how personalized dietary strategies can enhance patient outcomes. They emphasize collaboration between researchers, healthcare providers, and patients to optimize the impact of nutritional interventions.

CONCLUSIONS

In conclusion, the *Mentoring* and *DiBaN* projects exemplify the potential of precision nutrition, providing critical insights into the role of diet in health and disease.

BACKGROUND AND OBJECTIVES

Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD), the hepatic manifestation of metabolic syndrome, is closely associated with gut microbiota dysregulation. Emerging evidence highlights the potential of gut microbial profiles, or enterotypes, to modulate metabolic responses to dietary interventions. This study aimed to identify gut microbiota enterotypes and their metabolomic mediators in weight loss among subjects with MASLD.

METHODS

Ninety-eight MASLD patients were randomized to follow one of two dietary strategies (AHA or FLiO) for six months. The AHA diet followed the guidelines of the American Heart Association, while the FLiO diet was a modified Mediterranean dietary pattern. Gut microbiota composition was assessed using 16S rRNA gene sequencing, and serum non-targeted metabolomics analysis identified metabolic signatures. Mixed models were applied to examine their impact on weight loss, and mediation analysis evaluated metabolites linking enterotypes with weight loss responses.

RESULTS

At baseline, two distinct enterotypes were identified in this sample, characterized mainly by the abundance of *Prevotella* and *Bacteroides.* Participants from the Bacteroides enterotype achieved significantly higher weight loss than subjects belonging to the *Prevotella* enterotype. Mediation analyses identified that trans-3-methylthioacrylic acid mediated this association. Moreover, this metabolite could be a by-product of microbial sulfur fermentation.

CONCLUSIONS

Gut microbiota enterotypes significantly shape weight loss in MASLD, and this association is vastly mediated through metabolites. These RESULTS highlight the importance of studying the microbiome-metabolome-host network and offer potential insights for future precision nutrition strategies.

INVESTIGATION OF POSTPRANDIAL GLUCOSE RESPONSES IN HEALTHY ADULTS USING A DIGITAL CITIZEN SCIENCE APPROACHES – THE FOOD & YOU DE STUDY

Juliane Kupfer[1]; Bettina Scharl,[1]; Sebastian Gimpfl,[1]; Kurt Gedrich[1]
[1]ZIEL – Institute for Food and Health, Technische Universität München, Freising, Germany

BACKGROUND AND OBJECTIVES
Maintaining metabolic health through personalized nutrition is gaining importance in addressing public health challenges like cardiovascular diseases and type 2 diabetes. Postprandial glucose responses (PPGR) offer valuable insights into individual metabolic reactions. Emerging technologies like continuous glucose monitoring (CGM) allow real-time tracking of glucose levels. The Food & You DE study investigates inter- and intra-individual variability in PPGR among healthy adults in Germany, aiming to identify key determinants and develop predictive tools for tailoring personalized nutrition strategies.

METHODS
The study used CGM devices (FreeStyle Libre) to monitor blood glucose levels continuously over a 14-day period in 109 healthy adults. Dietary intake was logged using the MyFoodRepo app, and standardized breakfast meals were used to assess glycemic variability under controlled conditions. Data on anthropometry, physical activity, sleep quality and duration, and stress as well as hunger levels were collected via digital platforms and questionnaires. Additionally, stool samples were taken and the gut microbiome was analyzed via 16S rRNA sequencing. Key metrics for PPGR analysis included the incremental area under the curve (iAUC), mean postprandial glucose, and glucose peak. Advanced statistical models, including multiple linear regression and mixed-effects models, were used to investigate interdependencies and variability in PPGR.

RESULTS
The comparability of the metrics iAUC, postprandial glucose, and glucose peak revealed a high correlation (R ranging between 0.636 and 0.929, $p<0.001$). Age was identified as the most significant determinant of PPGR, with glucose peak as the metric: $R=0.27$, $p=0.003$ for glucose; $R=0.27$, $p=0.003$ for bread with butter; and $R=0.33$, $p<0.001$ for bread. Other factors, such as meal timing, gut microbiome composition, and morning hunger levels, demonstrated limited influence on PPGR. A multiple linear regression model, accounted for up to 33.5% of the variance in the PPGR ($p<0.020$). Importantly, age and BMI exhibited significaion interaction effects: a higher BMI amplifies the glycemic response with increasing age, while physical activity tended to mitigate this effect.

CONCLUSIONS
By leveraging CGM and digital health tools, the Food & You DE study provides valuable insights into the variability of PPGR, paving the way for the development of machine-learning algorithms to predict individual glycemic reactions. These findings hold promise for advancing personalized nutrition strategies and reducing the risk of diet-related diseases.

DIET AND NON-DIET RELATED FACTORS ASSOCIATED WITH A HIGH PREVALENCE OF ANAEMIA AND IRON DEFICIENCY IN FEMALE UNIVERSITY TEAM SPORT ATHLETES

Daniella Arrigo,[1]; Arista Nienaber,[1]; Linda Malan[1]; Mary A. Uyoga[1]; Lize Havemann-Nel[1]
[1]Centre of Excellence for Nutrition, North-West University, Potchefstroom, South Africa

BACKGROUND AND OBJECTIVES
Female athletes, including those competing in team sports, are at an increased risk for developing iron deficiency compared to their male counterparts. Poor dietary intakes, particularly low dietary iron intake, are associated with a poor iron status in female athletes. The physiological effect of exercise and menstrual losses can also contribute to the development of iron deficiency. Being a student female athlete can further increase the risk for iron deficiency due to sub-optimal diets. Limited research is available on the iron status of South African university female team sport athletes and factors, including dietary intake, that are associated with iron status. This study aimed to explore the iron status and habitual dietary intake of South African female university team sport athletes.

METHODS
Fifty-six female university hockey, netball, and soccer players, aged 18–30 years participated in this study. A quantitative food frequency questionnaire was administered to assess habitual dietary intake, and the iron status markers haemoglobin (Hb), ferritin, and soluble transferrin receptor were measured.

RESULTS
The prevalence of anaemia and iron deficiency was 46.4% and 41.1%, respectively, with the highest prevalence in soccer. Dietary intake was similar between participants with a poor vs. normal iron status, but vitamin C tended to be lower ($p = 0.068$) in the iron deficient group. Total carbohydrate inversely correlated with Hb ($r = -0.282$, $p = 0.045$). Anaemic participants weighed less (61.4 ± 9.5 vs. 67.1 ± 9.9 kg, $p = 0.034$), trained more [10.0(8.0–10.0) vs. 8.0(6.0–10.0) hours/week] and were predominantly black African compared to non-anaemic participants. Soccer players also weighed less ($p < 0.001$), reported the highest training load and were all black African with a lower protein (% of total energy) and Vitamin C intake, and a higher carbohydrate intake (gram/kg/day) than hockey and netball players.

CONCLUSIONS
The prevalence of anaemia and iron deficiency in female university team sport athletes is a concern, especially in soccer players. Total carbohydrate intake – potentially at the expense of animal source protein and haem iron – as well as a low Vitamin C intake were associated with a poor iron status. A poor iron status was further associated with higher training loads, lower body weights and black African ethnicity. The consumption of a well-balanced diet, which meets daily energy and nutrient recommendations should be encouraged with an emphasis on Vitamin C intake to optimise non-heam iron absorption.

ROLE OF ULTRAPROCESSED FOODS IN MODULATING THE EFFECT OF MEDITERRANEAN DIET ON HUMAN AND PLANET HEALTH – THE PROMENADE STUDY: PRELIMINARY FINDINGS FROM THE HUMAN INTERVENTION STUDY

Daniela Martini[1]; Cristian Del Bo'[1]; Donato Angelino[2]; Beatrice Pellegrini; Vanessa Liuim[1]; Sofia Lotti[3]; Barbara Colombini[3]; Francesco Sofi[3]; Patrizia Riso[1]; Serafini Mauro[2]; Monica Dinu[3]
[1]Department of Food, Environmental and Nutritional Sciences (DeFENS), University of Milan, Milano, Italy; [2]Department of Bioscience and Technology for Food, Agriculture and Environment, University of Teramo, Teramo, Italy; [3]Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy

BACKGROUND AND OBJECTIVES
The Mediterranean diet (MD) is worldwide promoted as one of the healthiest and most sustainable dietary patterns. Despite MD includes the abundant consumption of plant-based foods typically consumed as raw or minimally processed, these products are increasingly replaced by ultra-processed foods (UPF) the which effect on human health is largely debated but poorly investigated. The present dietary intervention study aims at exploring for the first time whether the inclusion of UPF within a Mediterranean-based dietary pattern can impact on cardiometabolic markers, gut microbiota and other health markers in healthy Italian volunteers [1].

METHODS
A total of 50 clinically healthy adults will be recruited for a 7-month randomized, open, cross-over dietary intervention trial. Participants will be assigned to consume a 3-month MD high in UPF (intended as 5 UPF servings/day) or a low-UPF MD (intended as replacement with 5 unprocessed/minimally processed food serving/day), spaced by a 1-month wash-out period. Diets will be isocaloric and normalized for energy intake based on energy requirements. The primary endpoint will be the change in LDL-cholesterol levels from baseline. Blood, urine, and fecal samples will be collected from each participant before and after the dietary interventions, alongside food diaries and anthropometrics and body composition data.

RESULTS
So far, 23 participants have been recruited, 4 dropped out during the intervention so 19 have been enrolled in the intervention (13 men, 6 women; mean 27.3 BMI kg/m2; mean LDL cholesterol 224 mg/dL). Among them, 4 completed the entire trial by adhering to a MD-dietary pattern providing 15% and 35% energy from UPF in the low-UPF and high-UPF groups, respectively. Blood cholesterol significantly decreased after both interventions with no significant differences between the two groups. Preliminary findings revealed no significant changes in body weight nor in body composition.

CONCLUSIONS
The completion of the study is needed to better explore the degree to which the consumption of UPF influences the impact of the MD on human health, thus providing insights about a better understanding of the relationship between food processing and health.

DIETAI24: A NOVEL LLM-BASED DIETARY ASSESSMENT SOFTWARE FROM FOOD IMAGES

Runze Yan[1]; Hanqi Luo[2]; Jiaying Lu[1]; Darren Liu[1]; Terry Hartman[2]; Xiao Hu[1]
[1]Nell Hodgson Woodruff School of Nursing, Emory University, Atlanta, United States of America; [2]Rollins School of Public Health, Emory University, Atlanta, United States of America

BACKGROUND AND OBJECTIVES
We aimed to develop and validate innovative dietary assessment software that can accurately recognize foods, estimate portion sizes, and provide comprehensive nutrient estimations from food images, by combining large language models (LLMs) with nutrition databases.

METHODS
We developed DietAI24, combining LLM-based image analysis with a smart information retrieval system, to estimate up to 65 nutrients from food images collected by smartphone cameras. By integrating GPT-4 Turbo with the USDA Food and Nutrient Database for Dietary Studies (FNDDS), DietAI24 automatically matches food images to 5,624 standardized food items and over 23,000 portion sizes without requiring prior training data. We evaluated DietAI24 using two public data sources: ASA24 (17,000 dish images) and Nutrition5K (3,500 dish images), comparing its performance against three commercial apps (Calorie MAMA, Foodvisor, and SnapCalorie) and an advanced neural network model (ViT).

RESULTS
Using the ASA24 dataset, DietAI24 achieved mean absolute errors (MAE) per dish of 47.7 kcal for calories, 1.67g for fat, 6.95g for carbohydrates, 1.38g for protein, and 49.4g for dish mass, reducing errors by 76-83% for calories, 80-86% for fat, 71-78% for carbohydrates, and 67-88% for protein compared to commercial apps. Similar improvements were observed using the Nutrition5k dataset, with error reductions of 60-93% for calories, 51-72% for fat, 73-80% for carbohydrates, and 70-76% for protein. Expert evaluation by two dietitians confirmed DietAI24 achieved close to exact matches (scoring 3 or 4 on a 4-point scale, where 4 represents exact match) for both macro and micronutrients.

CONCLUSIONS
DietAI24 represents a substantial advancement in automated dietary assessment by enabling accurate, comprehensive nutrient estimation from smartphone images without manual entry, showing strong potential for large-scale dietary studies and clinical interventions.

COMPREHENSIVE ANALYSIS OF CIRCULATING HUMAN PROTEOME AND ITS ASSOCIATION WITH ADHERENCE TO THE MEDITERRANEAN DIET

Mirko Marino[1]; Cristian Del Bo'[1]; Simone Perna[1]; Massimiliano Tucci[1]; Iolanda Cioffi[1]; Daniela Martini[1]; Patrizia Riso[1]
[1]Department of Food, Environmental and Nutritional Sciences (DeFENS), University of Milan, Milano, Italy

BACKGROUND AND OBJECTIVES
The Mediterranean diet (MD) is widely recognized for its beneficial effects on health, particularly in preventing cardiovascular, metabolic, and inflammatory diseases. The Medi-Lite index is a validated tool to assess individual adherence to the MD, offering insights into its relationship with molecular biomarkers. This study aimed to investigate significant variations in the circulating proteome associated with adherence to the MD, using the Medi-Lite score, and to evaluate the potential of the Mediterranean dietary pattern in promoting metabolic health.

METHODS
A cohort of 61 healthy individuals (mean age 44.4 ± 12.3 years; 43 females and 18 males) was recruited as part of the INSTEAD project (www.onfoods.it). Participants were stratified into high and low adherence groups based on the median Medi-Lite score. Circulating proteins were analyzed using the SOMAscan platform, quantifying 7596 plasma proteins. Proteins with moderate-to-strong correlations ($r \geq 0.3$) with the Medi-Lite score and statistically significant differences ($p < 0.05$) between adherence groups were selected for further analysis.

RESULTS
Among the circulating proteome analyzed, 33 proteins were identified as significantly associated with adherence to the Mediterranean diet. These proteins are involved in diverse biological pathways. For instance, Transcobalamin-1, essential for vitamin B12 transport and DNA synthesis, reflects the role of micronutrient metabolism. Ephrin-B1, a key regulator of cell-cell communication and tissue development, underscores the impact of dietary habits on cellular organization and morphogenesis. Complement component C9, part of the terminal complement complex, highlights the influence of the diet on innate immune responses. These proteins cluster within specific biological pathways, including those related to immune regulation, protein folding, cellular structure, and metabolic homeostasis.

CONCLUSIONS
The findings underline the potential of the MD to modulate the circulating proteome, with significant implications for public health. Identified proteins reflect key biological pathways, suggesting that optimal adherence to the MD is associated with improved metabolic and immune homeostasis. Future dietary intervention studies are pivotal in order to investigate their impact on underlying molecular mechanisms in different target populations, also to develop personalized strategies able to promote optimal health.

GUT MICROBIOTA COMPOSITION DIFFERS BETWEEN EARLY AND LATE CHRONOTYPES IN HUMANS

Ana Velasco-Andonegui,[1, 2]; Sergio Esteban-Echeverría,[1]; Jose Ignacio Riezu-Boj,[1, 2, 3]; Marta Cuervo,[2, 3]; J. Alfredo Martinez[4, 5]; Maria J. Moreno-Aliaga[5, 3, 2]; Pedro González-Muniesa,[5, 3, 2, 1]; Fermín I. Milagro[1, 2, 3, 5]

BACKGROUND AND OBJECTIVES
Emerging evidence suggests that a bidirectional relationship between the circadian system and gut microbiota exists. Also, chronotype, the behavioral manifestation of circadian rhythms, influences metabolic health. In fact, late chronotypes have been linked to obesity, type 2 diabetes and unhealthier habits. However, the characterization of gut microbiota composition according to chronotype remains underexplored. Here, we investigated whether gut microbiota composition differs between chronotypes.

METHODS
Baseline data from 262 Spanish individuals from the OBEKIT study (NCT02737267) was analysed. Chronotype was determined using the Morningness-Eveningness Questionnaire, classifying participants into morning (upper tertile) and evening (lower tertile) chronotypes. Gut microbiota was profiled with 16S sequencing. Microbiota analyses were performed using the vegan package in R for diversity analysis and generalized lineal mixed models for differential analysis, all adjusted by age.

RESULTS
A total of 138 individuals were categorized as late chronotypes [70% female; mean (SD) age: 42 (11) years, BMI: 29.4 (4.8) kg/m²] and 124 as early chronotypes [70% female; age: 47 (10) years, BMI: 29.9 (5.4) kg/m²]. Alpha-diversity, according to Shannon and Pielou indexes, was significantly higher in early chronotypes (p=0.017 and p=0.028, respectively). Beta-diversity dissimilarity analysis (Aitchison index) confirmed differences in the overall taxonomic composition between chronotypes at species level (p= 0.05). In addition, two bacterial families that differed between chronotypes, namely, Borkfalkiaceae (pFDR = 0.026) and Candidatus Colimorpha enterica (pFDR = 0.048), both from the Clostridia class, were identified.

CONCLUSIONS
Our findings highlight differences in gut microbiota composition between chronotypes. Further research is needed to better understand this relationship and to guide the development of dietary strategies aimed at reducing the health risks associated with late chronotypes.

MEDITERRANEAN DIET ADHERENCE, TRIGLYCERIDE-GLUCOSE INDEX (TYG), AND ERYTHROCYTE MEMBRANE LIPIDOME IN CARDIOMETABOLIC RISK ASSESSMENT OF TESTICULAR GERM-CELL TUMOR SURVIVORS

Milica Zeković[1]; Marko ŽIvković,[2]; Uroš Bumbaširević,[2]; Nebojša Bojanić,[2]; Sanja Stanković,[3]; Aleksandar Janičić,[2]; Marija Takić,[1]
[1]Institute for Medical Research, National Institute of Republic of Serbia, University of Belgrade, Beograd, Serbia; [2]Clinic of Urology, University Clinical Centre of Serbia, Beograd, Serbia; [3]Center for Medical Biochemistry, University Clinical Centre of Serbia, Pasterova, Belgrade, Serbia, Belgrade, Serbia

BACKGROUND AND OBJECTIVES
Testicular germ-cell tumor (TGCT) survivors face increased risk of cardiometabolic complications due to chemotherapy-induced toxicities and potential gonadal dysfunction. The Mediterranean diet (Med Diet), with its cardioprotective and anti-inflammatory properties, represents a promising dietary intervention to mitigate such risks. This study aimed to explore the relationship between Mediterranean diet adherence, triglyceride-glucose index (TyG), and erythrocyte fatty acid (FA) profiles in TGCT survivors.

METHODS
TGCT survivors (n=92, mean age $\bar{x}$=35.89±8.67 years) were recruited for this cross-sectional study. Adherence to the Mediterranean diet was assessed using a validated dietary score (MedDietScore; range 0–55). TyG index was calculated using fasting triglycerides (TG) and glucose (GLU): TyG = ln[TG (mg/dL) × GLU (mg/dL)] / 2. Erythrocyte FA composition was determined using gas-liquid chromatography, and Omega-3 Index (O3I; sum of eicosapentaenoic acid and docosahexaenoic acid, %) was employed as a biomarker of cardiovascular health. Statistical analyses included correlation and multivariate regression to assess associations between MedDietScore, TyG, and erythrocyte FA profile.

RESULTS
Among study participants, 60.87% were classified as overweight or obese (Body Mass Index, BMI ≥25.0 kg/m²), and two-thirds displayed dyslipidemia. Participants demonstrated low-to-moderate adherence to the Mediterranean diet (MedDietScore $\bar{x}$=24.8±5.2). Two-thirds had O3I <4%, indicative of high cardiovascular risk. MedDietScore showed a moderate inverse correlation with TyG index ($r=-0.312$, $p<0.05$) and n-6/n-3 FA ratio ($r=-0.287$, $p<0.05$), while positively correlating with O3I ($r=0.428$, $p<0.01$) and delta-5 desaturase activity ($r=0.366$, $p<0.05$). Regression analysis confirmed that higher MedDietScore was associated with lower TyG values ($\beta=-0.221$, $p=0.047$) and improved FA profiles, even after adjusting for BMI and waist circumference.

CONCLUSIONS
This study highlights the potential role of Mediterranean diet adherence in reducing cardiometabolic risk among TGCT survivors. By synthesizing dietary, anthropometric, and biochemical parameters, it establishes a robust framework for personalized risk stratification and emphasizes the transformative potential of targeted dietary interventions in optimizing health outcomes within this vulnerable population.

EXAMINATION OF VITAMIN B1 NUTRITIONAL STATUS, ENERGY METABOLISM, AND PASTE FOODS FORTIFIED WITH VITAMIN B1 FOR FRAIL ELDERLY INDIVIDUALS

Ryoko Higuchi[1]; ikuko gomi[1]; Fukuoka Risa[1]; Yasuko Karibe[2]
[1]Department of Nutrition and Dietetics, Kanagawa University of Human Services, Yokosuka, Japan;
[2]Department of Nutrition and Dietetics, RihaparkMaioka, Yokohama, Japan

BACKGROUND AND OBJECTIVES

Japan, being a super-aged society, has advanced in elderly nutrition management. The fundamental approach to preventing malnutrition includes nutritional supplementation and dysphagia-adjusted diets. Among these, paste foods, which involve adding water and blending pre-cooked meals, may result in lower nutritional efficiency per unit weight or volume. Furthermore, water-soluble vitamins in paste foods are known to be prone to significant loss during heating. This study focuses on Vitamin B1, a coenzyme involved in energy metabolism and aims to report on the Vitamin B1 nutritional status of frail elderly individuals. The study also proposes a cooking method for paste foods that enhances energy density while fortifying Vitamin B1, which is essential for energy metabolism

METHODS

The study involved 87 frail elderly individuals, whose whole blood Vitamin B1 levels were tested. Individuals with levels of 0.2 μg/dL or lower were categorized as Vitamin B1 deficient. Multivariate logistic regression analysis was performed to explore related factors. Subsequently, the study examined the "zero-water cooking method," which is increasingly being adopted in Japanese facilities to enhance the energy density of paste foods. Vitamin B1 was added to rice jelly, and the retention of Vitamin B1 was evaluated. Additionally, the nutrient content of paste food made using Vitamin B1-fortified rice jelly was assessed

RESULTS

Of the 87 frail elderly individuals surveyed, 18 (20.7%) had Vitamin B1 deficiency. Seventeen individuals (19.5%) consumed paste food. The multivariate-adjusted odds ratio (95% confidence interval) for Vitamin B1 deficiency in those consuming paste food was 6.978 (1.038–49.924), $p = 0.046$, indicating a significantly higher risk compared to those consuming other types of food. Nutrient analysis of the rice jelly used in the zero-water cooking method showed approximately 70 kcal per 100g, with no detectable Vitamin B1. However, after fortifying the rice jelly with Vitamin B1, approximately 0.16 mg of Vitamin B1 remained. Without fortification, the energy intake from the paste food did not meet the estimated average required intake of Vitamin B1 (0.45 mg/1,000 kcal) as defined by the 2020 Japanese Dietary Reference Intakes.

CONCLUSIONS

Frail elderly individuals consuming paste food may be at risk of chronic Vitamin B1 deficiency. The zero-water cooking method using Vitamin B1-fortified rice jelly has the potential to both increase energy density and provide the necessary Vitamin B1 for energy metabolism.

THE RELATIONSHIP BETWEEN HOMOCYSTEINE AND URIC ACID IN CARDIOVASCULAR AND METABOLIC HEALTH

Natalia Samiilenko[1]; Mariia Saifullina[1, 2]; Sofiia Shpak[1]; Olena Zinchenko[1]; Yana Muzyra[1]; Tetiana Heorhytsa[1]; Nadiia Taras[1]
[1]-, LLC Samoilenko Clinic, Kyiv, Ukraine; [2]Educational and Scientific Center «Institute of Biology and Medicine», Taras Shevchenko National University of Kyiv, Kyiv, Ukraine

BACKGROUND AND OBJECTIVES
Homocysteine (Hcy) and uric acid (UA) are biomarkers involved in metabolic pathways and have been implicated in cardiovascular disease. Hcy is an amino acid produced from methionine metabolism, while UA is a product of purine breakdown. Elevated levels of both are associated with oxidative stress, endothelial dysfunction and inflammation, contributing to cardiometabolic syndrome [1, 2]. Recent studies suggest a positive correlation between Hcy and UA levels, indicating a shared impact on cardiovascular risk [3]. This study aims to investigate the relationship between Hcy and UA levels and their association with other cardiometabolic parameters, such as BMI, insulin level and HOMA-IR index.

METHODS
We studied 101 patients (pts): 64 women (63,4%) and 37 men (36,6%); mean age 39,3±11,1; mean BMI 29,6±5,7; 44 pts (44,4%) were with obesity. Statistical analysis was based on the chi-square (X^2) test, analysis of variance (ANOVA) and Pearson correlation coefficient.

RESULTS
Among pts with normal Hcy levels (< 11 μmol/l), the mean UA level was 329,5±83,5 μmol/l, while in pts with elevated level of Hcy it was significantly higher - 384.5±78,9 μmol/l (p=0.0104). In the group of pts with normal UA levels: 20% had a normal BMI, 42,5% were overweight and 37,5% had obesity; in the group with elevated UA: no pts had a normal BMI, 22,2% were overweight and 77,8% had obesity (p=0.019). Elevated insulin levels were more frequent in the group with elevated UA levels (27,78%) compared to those with normal UA levels (4,94%) (p=0.002). Statistically significant (p<0.05) moderate positive correlations were found between UA and BMI (r=0.448), insulin level (r=0.3584) and HOMA-IR index (r=0.389).

CONCLUSIONS
Our findings demonstrate an association between Hcy and UA levels. Significant differences in BMI and insulin levels were observed between groups with normal and elevated UA levels. Positive correlations of UA with BMI, insulin level and HOMA-IR index were detected. At the same time, the association between Hcy and other metabolic parameters was less pronounced. Understanding the interaction between Hcy and UA, and mechanisms underlying their association, may provide new strategies for preventing and managing cardiovascular and metabolic diseases.

EPO8_002

GLUTEN AND RICE PROTEIN HAVE POSITIVE EFFECTS ON PRESSURE INJURY PREVENTION BY THE SUPPRESSION OF COLLAGEN DEGRADATION

Takumi Yamane[1]; Atsuko Hayashi[1]; Mana Hayafuji[1]; Yuichi Oishi[1]
[1]Department of Nutritional Science and Food Safety, Tokyo University of Agriculture, Tokyo, Japan

BACKGROUND AND OBJECTIVES
Protein malnutrition has been shown to inhibit pressure injury healing in elderly people and hospitalized patients. Understanding the molecular mechanisms that protein nutrition affects pressure injury is known to be important for optimal pressure injury healing and prevention. However, the molecular mechanism underlying the alteration of pressure injury healing and prevention by dietary protein sources is not well understood. Therefore, in the present study, we examined the effects of dietary protein sources (casein, gluten and rice protein) on pressure injuries at the molecular level.

METHODS
After C57BL/6J mice were acclimated to a normal diet based on AIN-93G feed composition for 1 week, they were divided into the three following groups: casein, gluten, and rice protein and were fed for 1 week. Dorsal mouse skin was pulled up and trapped between two magnetic plates, and then plates were removed after 24 hours. The wounded skin tissues collected on 24 hours after reperfusion were used for the histopathological and gene expression analyses. Tissue sections were stained with hematoxylin and eosin and Masson's trichrome. We also investigated the effects of dietary casein, gluten and rice protein on the gene expression levels of the inflammatory markers in the wounded skin tissues by quantitative reverse transcription polymerase chain reaction.

RESULTS
The wound areas were significantly smaller in the gluten and rice protein group than those in the casein group at 24 h after reperfusion. The skin tissues of the gluten and rice protein group showed lower amounts of collagen deposition compared with that in the casein group. Interleukin-1β and tumor necrosis factor-α mRNA levels were significantly decreased in the wounded skin of the gluten and rice protein groups compared with that in the casein group.

CONCLUSIONS
It is likely that dietary gluten and rice protein have positive effects on pressure injury prevention by the suppression of collagen degradation and inflammation.

PALMITIC ACID DECREASES ADIPONECTIN ACTIVITY, PROMOTES OSTEOCLAST DIFFERENTIATION, AND INCREASES THE RISK OF OSTEOPOROSIS ONSET

Yuki Iwasaki[1]; Yoshiko Yokoyama[2]; Hirotaka Kubo[3]; Kazuhiko Kaji[4]; Hiromi Shiraishi[1]; Kazutaka Kano[2]
[1]Health and Nutrition, University of Human Arts & Sciences, Saitama, Japan; [2]Human Nutrition, Seitoku Univ. Grad. School, Matsudo, Japan; [3]Surgery, Sekishindo Clinic, Shibuya, Japan; [4]Research Adviser, KOSÉ Advanced Technology Research Institute, Kita, Japan

BACKGROUND AND OBJECTIVES
Osteoporosis, a major disease that significantly reduces quality of life (QOL) worldwide, also increases the risk of obesity, diabetes, metabolic syndrome, and non-alcoholic steatohepatitis (NASH). Concurrently, elevated blood levels of palmitic acid have been reported. This increase in palmitic acid associated with obesity, may interfere with the inhibition of osteoclast differentiation and activation with adiponectin, potentially exacerbating the onset of osteoporosis. However, the key intracellular signaling mechanisms involved in the disease progression remain unclear. Here, we aimed to elucidate the relationship and mechanisms underlying the effects of palmitic acid, adiponectin, and its receptor in the development of osteoporosis using an osteoclast differentiation model.

METHODS
We used murine macrophage-like RAW264.7 cells, which are known to differentiate into osteoclasts upon LPS stimulation. Adiponectin or AdipoRon and/or palmitic acid were added to the LPS-stimulated RAW264.7 cells, and after 24 hours, the mRNA expression of MCP-1 and AdipoR1 was analyzed using real-time PCR. As an alternative to adiponectin, AdipoRon, a small-molecule agonist of the adiponectin receptor, was employed for the experiments.

RESULTS
Adiponectin or AdipoRon significantly reduced LPS-induced MCP-1 mRNA expression. However, the suppressive effect of AdipoRon was completely abrogated in the presence of palmitic acid. Additionally, palmitic acid decreased the mRNA expression of the adiponectin receptor AdipoR1. Similarly, AdipoR1 mRNA expression was reduced by the TLR2 agonist. Notably, the effects of palmitic acid and the TLR2 agonist were reversed when treated with a TLR2 inhibitor, resulting in an increase in AdipoR1 mRNA expression.

CONCLUSIONS
These findings suggest that during the onset of osteoporosis, palmitic acid may contribute to the exacerbation of osteoporosis symptoms by suppressing adiponectin receptor expression and weakening adiponectin's activity. From a nutritional perspective, this study highlights the potential for developing preventive and therapeutic strategies for osteoporosis by modulating the types and quantities of dietary fatty acids.

THE EFFECTS OF 1-KESTOSE ON BLOOD CHOLESTEROL, ADIPOSE TISSUE INFLAMMATION, AND GUT MICROBIOTA IN RAT FED A HIGH-FAT DIET

Kento Kuramitsu[1]; Yoshihiro Kadota[2]; Kitaura Yasuyuki[3]
[1]Department of Applied Biosciences, Graduate School of Bioagricultural Sciences, Nagoya University, Nagoya, Japan; [2]Research and Development Center, B Food Science Co., Ltd., Chita, Japan; [3]Department of Applied Biosciences, Chubu University, Kasugai, Japan

BACKGROUND AND OBJECTIVES
The gut microbiota plays several crucial roles in health, such as maintaining intestinal homeostasis, regulating energy metabolism, protecting against pathogens, and modulating the immune system. Dysbiosis, an imbalance in the gut microbiota, is linked to various diseases, including inflammatory bowel disease and diabetes. To date, a high-fat diet (HFD) has been reported to cause dysbiosis, and suppressing dysbiosis may contribute to reducing some disease risk. 1-Kestose is a prebiotic consist of sucrose and fructose with a β-2,1 glycosidic bond, and we have previously reported that 1-kestose improves insulin resistance in rats with type 2 diabetes. This study aims to clarify the effects of 1-kestose on blood cholesterol level, adipose tissue inflammation and microbiota during the consumption of HFD.

METHODS
Male Sprague-Dawley rats were divided into two dietary groups: control diet (CD) or HFD. Each group was further subdivided to receive either tap water (–KES) or tap water supplemented with 1-kestose (+KES) throughout the study. The gut microbiota was evaluated using 16S rRNA amplicon sequencing, and mRNA gene expression in the liver and adipose tissue was assessed using RT-PCR. Gut bacterial metabolites in cecal contents were evaluated using LC-MS.

RESULTS
The HFD/–KES group showed a decrease in the cecum butyrate concentrations and an increase in mRNA gene expression of TNF alpha in adipose tissue; however, the intake of 1-kestose inhibited these changes as well increased *Butyricicoccus*, a butyrate-producing bacterium, in the cecum.
The HFD/+KES group also showed significantly reduced blood cholesterol level, and the mRNA gene expression of CYP7A1, a rate-limiting enzyme in bile acid synthesis, was significantly increased in the liver. Additionally, primary bile acids increased and bacteria with the genes encoded bile salt hydrolases, such as *Bifidobacterium*, were increased in the cecum of the rats in HFD/+KES group.

CONCLUSIONS
These RESULTS suggest that 1-kestose helps improve the increased blood cholesterol level and inflammation by feeding of HFD through modulation of the bile acid and short-chain fatty acid metabolism in the gut.

INTERACTION BETWEEN VITAMIN E HOMOLOGS AND VOLUNTARY EXERCISE ON THERMOGENESIS PROMOTION IN SKELETAL MUSCLE OF MICE

Haruka Takeuchi[1]; Hideki Inoue[2]; Miho Hanai[1]; Chie Takahashi-Muto[3]; Rieko Tanaka-Yachi[4]; Chikako Kiyose[1]
[1]Department of Nutrition and Life Science, Kanagawa Institute of Technology, Atsugi-shi, Kanagawa, Japan; [2]Department of Applied Chemistry and Bioscience, Kanagawa Institue of Technology, Atsugi-shi, Kanagawa, Japan; [3]Department of Medical Laboratory Science, Kitasato University School of Health Sciences, Kurotsuchishinden, Minamiuonuma-shi, Niigata, Japan; [4]Department of Pharmacology, National Research Institute for Child Health and Development, Setagaya-ku, Tokyo, Japan

BACKGROUND AND OBJECTIVES

Myokines (secreted from skeletal muscles) are bioactive molecules that regulate the systemic metabolism. The irisin myokine promotes the browning ("beiging") of white adipose tissue and improves thermogenesis. Therefore, factors that increase irisin expression are expected to have the anti-obesity effect. Previously, we showed that combining voluntary exercise with the intake of (the vitamin E homolog) δ-tocopherol tended to increase the thermogenesis-related gene expression in white adipose tissue. However, it remains unclear whether irisin expression is modulated by δ-tocopherol intake. Therefore, here, using mice we investigated if combining voluntary exercise with δ-tocopherol intake enhances irisin expression and promotes thermogenesis, especially in their skeletal muscles.

METHODS

Male C57BL/6J mice (3 weeks old) were divided into four groups as follows: (1) the control group (C-group); (2) the H-group, fed a high-fat/high-sucrose diet; (3) the HD-group, fed a high-fat/high-sucrose diet and δ-tocopherol; and (4) the voluntary exercising HED-group, fed a high-fat/high-sucrose diet and δ-tocopherol. δ-tocopherol was supplemented at a dose of 1,000mg per kilogram of the feed. The mice were fed in this pattern for 8 weeks. The "voluntary exercise" involved running in a rotary device, and the run-length was recorded during the feeding period using a rotary momentum measurement device. At the end of the study period, mice were subjected to overnight fasting before sampling their arterial blood and tissues for further analysis.

RESULTS

The mice in all the studied groups showed similar quadriceps femoris muscle weight. However, the transcription of the irisin gene (*FNDC5*), i.e., the *FNDC5* mRNA levels in the quadriceps femoris muscle tended to be higher in the HED-group than that in the H-group. Further, we measured the transcription of *PGC-1α* and *PPAR-δ* genes, as they regulate irisin expression. *PGC-1α* mRNA expression was significantly higher in the HED-group than that in the HD-group. Furthermore, the expression of *PGC-1α* and *PPAR-δ* mRNAs tended to be higher in the HED-group than that in the control, C-group.

CONCLUSIONS

Thus, we conclude that the interaction between voluntary exercise and δ-tocopherol intake can increase the expression of irisin. Further, we hypothesize that the observed promotion of thermogenesis in white adipose tissue, when voluntary exercise and δ-tocopherol intake are combined, is due to an increase in the expression of the irisin myokine.

TRANSGENERATIONAL EFFECTS OF LIFELONG SUCROSE CONSUMPTION IN MICE

Iris Ching Yee Yii[1]; Jimmy Chun Yu Louie[2]; Chi Bun Chan[1]
[1]School of Biological Sciences, The University of Hong Kong (HKU), Hong Kong, Hong Kong; [2]Department of Nursing and Allied Health, Swinburne University of Technology, Hawthorn, Australia

BACKGROUND AND OBJECTIVES
Chronic sucrose consumption induces metabolic disturbances, including hyperglycaemia, insulin resistance, hypertension, hyperlipidaemia, and weight gain in animal models. However, these findings have limited clinical applicability since most studies use supra-physiological sucrose dose, exceeding 50% of the total energy intake, while average human sugar consumption is around 20%. This study aims to investigate the effects of lifelong chronic sucrose consumption at human-relevant levels on the metabolic health of mice and their offspring.

METHODS
Initial generation (F0) mice, group-caged, were fed *ad libitum* on low (10% kcal, LSD) and high (25% kcal, HSD) sucrose-diet. Subsequent generations (F1 and F2) were produced by crossing LSD and HSD mice. Body composition, food intake, and glucose and insulin tolerance tests, were monitored trimonthly up to 90-week. Lipid profile were tested by ELISA and gene expression related to fatty acids and glucose metabolism was examined by qRT-PCR. Two-tailed t test or two-way ANOVA were used to compare between group differences, with significance set at $p < 0.05$.

RESULTS
There were no significant changes ($p > 0.05$) in the body compositions of F0 mice after 90 weeks on HSD. Both groups did not exhibit glucose intolerance or insulin insensitivity.
Furthermore, the offspring of these F0 mice demonstrated no noticeable metabolic differences at 48-week. This stability across generations raises questions about the potential resilience of both generations to dietary sugar.

CONCLUSIONS
This study suggests that chronic sugar consumption at the end of human relevant levels may not pose the same risks previously assumed, though inter- or multi-generational sugar effects remain inconclusive.

INTERACTIONS BETWEEN DELTA-TOCOPHEROL INTAKE AND EXERCISE ON ADIPOSE TISSUES OF MICE

Chikako Kiyose[1]; Haruka Takeuchi[1]; Hideki Inoue[2]; Miho Hanai[1]; Rieko Tanaka-Yachi[3]; Chie Takahashi-Muto[4]
[1]Department of Nutrition and Life Science, Kanagawa Institute of Technology, Atsugi-shi, Kanagawa-pref., Japan; [2]Department of Applied Chemistry and Bioscience, Kanagawa Institute of Technology, Atsugi-shi, Kanagawa-pref., Japan; [3]Department of Pharmacology, National Research Institute for Child Health and Development, Setagaya-ku, Tokyo, Japan; [4]Department of Medical Laboratory Science, Kitasato University School of Health Science, Kurotsuchishinden, Minamiuonuma, Niigata-pref., Japan

BACKGROUND AND OBJECTIVES

Vitamin E is a fat-soluble vitamin present in vegetable oils and nuts; it has eight naturally occurring forms: four tocopherols (α-, β-, γ-, and δ-tocopherol) and four tocotrienols (α-, β-, γ-, and δ-tocotrienol). Recently, vitamin E has been reported to have several novel functions, such as anti-obesity effects. Leptin, a hormone that depends on the adipose tissues, acts on leptin receptors in the hypothalamus to strongly suppress appetite. Vitamin E tends to accumulate in the adipose tissue; however, few studies have reported on its relationship with leptin. Therefore, this study aimed to evaluate the interactions between δ-tocopherol (-Toc) intake and exercise in the adipose tissues of mice.

METHODS

C57BL/6JJcl mice were divided into the control (C), exercise (CE), δ-Toc (CD), and exercise+δ-Toc (CED) groups. In this study, 50mg/kg of α-Toc was included in the diet of the mice in all groups. The CD and CED groups were further given 1,000mg/kg diet of δ-Toc. The mice were individually housed, and the cages for the CE and CED groups were equipped with a wheel and odometer to record exercise during experimental periods. The mice were provided feed and water *ad libitm* for 8 weeks. The mice fasted for 16 h and were then sacrificed under isoflurane anesthesia and their blood and tissue samples were taken for analysis.

RESULTS

The final body weights of the CE and CED groups were significantly lower than those of the C and CD groups. However, no significant difference was observed in the final body weight between the C and CE groups and the CD and CED groups. The fat masses were comparable to the final body weight. Therefore, exercise was found to significantly reduce body weight, and the result was dependent on the reduction in body fat mass. The concentration of leptin in the plasma of the CE and CED groups were significantly lower than those of C and CD groups. However, no effect of δ-Toc intake was observed.

CONCLUSIONS

The RESULTS revealed a significant positive correlation between body fat mass and plasma leptin concentration. However, δ-Toc intake did not affect plasma leptin levels. We plan to examine the gene expression of leptin in epididymal fat and discuss the RESULTS in the future.

NUTRITION KNOWLEDGE, SELF-EFFICACY AND DIETARY PRACTICE IN ARAB COUNTRIES

Abeer Alzaben[1]; Samira Mahboub[2]; Nahla Bawazeer[2]; Fatimah Almoayad[2]; Shahd Alabdulkader[2]; Alaa Al-Masud[3]; Huny Bakry[2]; Howeida Abusalih[2]; Yasir Hussein[4]; Laila Alkilani[5]; Nada Benajiba[6]
[1]Department of Health Sciences , Princess Nourah bint abdulrahman University, Riyadh, Saudi Arabia; [2]Department of Health Sciences, Princess Nourah bint abdulrahman University, Riyadh, Saudi Arabia; [3]Natural and Health Science Research Center, Princess Nourah bint abdulrahman University, Riyadh, Saudi Arabia; [4]Collage of Physical Education and Sport Sciences, University of Baghdad, Baghdad, Iraq; [5]College of Sport Sciences & Physical Activity, Princess Nourah bint abdulrahman University, Riyadh, Saudi Arabia; [6]Unité Mixte de Recherche en Nutrition et Alimentation, Université Ibn Tofaïl, Kénitra, Morocco

BACKGROUND AND OBJECTIVES
Nutrition are crucial factor contributing to the overall health in populations. The objective of the current study was to assess the nutritional knowledge, self-efficacy and practice (KSP) in younger adults across Arab countries.

METHODS
A cross-sectional study was conducted among Arab young aged between 18 and 25 years, living in the Arabian Peninsula, Africa or Eastern Mediterranean countries. A previously validated KSP questionnaire was distributed via online questionnaire. Sociodemographic data was collected.

RESULTS
A total of 2582 participants (1041 M; 1667 F) were included in the study. Knowledge score was significantly higher in Arabian Peninsula region (7.2 ± 1.9) than the Northern Africa region (5.4 ±2.3) and Eastern Mediterranean region (6.7 ± 1.9), ($p<0.01$, $F=173.2$). The Northern Africa region (1.4 ± 0.5) was significantly lower in the average self-efficacy scores than Arabian Peninsula (1.6 ± 0.4) and Eastern Mediterranean region (1.7 ± 0.4) ($p<0.01$, $F=132.3$). The Arabian Peninsula region (10.3 ± 3.9) was significantly lower in practice score than the Northern Africa region (11.4 ± 3.3) and Eastern Mediterranean region (11.8 ± 3.9) ($p<0.01$, $F=30.5$). Good, moderate and poor practice score was in 19%, 39% and 42%, respectively. High level of self-efficacy was associated with age, female, and high knowledge score in Northern Africa.

CONCLUSIONS
Although there is adequate knowledge score in Arab region, healthy nutritional practice needs to improve. Dietary patterns differed significantly across countries included in the study. Self-efficacy was lower in Northern Africa region. Different sociodemographic factors influencing nutritional knowledge, self-efficacy and practice among Arab regions. Nutrition awareness programs needs to be implemented in Arab region to improve nutritional knowledge and healthy dietary practice to improve overall health.

ASSESSING DIET QUALITY USING THE VALIDATED SHORT HEALTHY EATING INDEX (SHEI)

Abeer Alzaben[1]; Nahla Bawazeer[1]; Huny Bakry[1]
[1]Department of Health Sciences, Princess Nourah bint abdulrahman University, Riyadh, Saudi Arabia

BACKGROUND AND OBJECTIVES
The general health of populations is greatly influenced by nutritional considerations. This study aims to assess diet quality using short version of Healthy Eating Index (sHEI) and explore the relationship between sHEI and socio-demographic factors among young adults in Saudi Arabia.

METHODS
Face validity and content validity were computed as part of the validation process. Cronbach's alpha was performed to test the reliability. A cross-sectional study surveyed 605 young adults aged 18-25. Sociodemographic information and diet quality using sHEI were collected. Total sHEI score, adequacy and moderation score were calculated. The adequacy score reflects the foods that should be consumed in sufficient amounts. The moderation score reflects foods that should be consumed in limited amounts.

RESULTS
The mean content validity values for individual items were acceptable (range: 0.89–0.99) for all items. Cronbach's alpha of the sHEI nutrition scale was 0.81. The total sHEI score in this sample was 45 ± 9 (range 23-74), adequacy score 30 ± 8 (range 13-48), and moderation score 15 ± 5 (range 5-26). Whole fruit was the lowest item in the adequacy component 1.7 ± 1.9. Added sugar was the lowest item in the moderation component 3.3 ± 3.3. Factors influencing sHEI score (total, adequacy and moderation) among a sample of young adults were gender, body mass index, and region ($p<0.05$).

CONCLUSIONS
Diet quality is poor among young adults in Saudi Arabia. Awareness programs and nutrition education is important to focus on foods that need to be consumed in adequate and moderate amount, sustainable nutrition and eating behavior.

EPO8_015

THE EFFECTS OF BETAINE ON THE TRANSCRIPTION OF GENES INVOLVED IN LIPID METABOLISM IN PRIMARY RAT HEPATOCYTES

Grzegorz Nikrandt[1]; Agata Chmurzynska[1]
[1]Department of Human Nutrition and Dietetics, University of Life Sciences, Poznań, Poland

BACKGROUND AND OBJECTIVES
Betaine is a naturally occurring compound involved in crucial metabolic processes, such as methylation and hepatic lipid metabolism. Previous studies have shown that betaine may affect the expression of genes related to the synthesis, transport, and utilization of lipids. However, these studies were primarily conducted on specific cell lines, such as HepG2, which do not accurately reflect the metabolism of primary hepatocytes. This study aimed to assess the effects of betaine on the transcription of genes involved in lipid metabolism in primary hepatocytes derived from male Wistar rats.

METHODS
Primary hepatocytes from Wistar rats were cultured on collagen-coated twelve-well plates and treated overnight with 0, 5, or 20 mM of betaine. RNA was isolated using Trizol reagent, and reverse transcription was performed using a High-Capacity cDNA Reverse Transcription Kit (Thermo Fisher Scientific, USA). Real time PCR was carried out using a Roche LC480 Light Cycler with TaqMan assays. Statistical analysis was performed using Statistica 12 software.

RESULTS
We comprehensively assessed the effects of betaine on the transcription of the following genes: phosphoenolpyruvate carboxykinase 1 (*Pck1*), peroxisome proliferator-activated receptor gamma coactivator 1 alpha (*Ppargc1*), carnitine palmitoyltransferase 1a (*Cpt1a*), acyl-CoA synthetase long-chain family member 1 (*Acs*), fatty acid-binding protein 1 (*Fabp1*), peroxisome proliferator-activated receptor alpha (*Ppara*), peroxisome proliferator-activated receptor gamma (*Pparg*), and sterol regulatory element-binding transcription factor 1 (*Srebf1*).

CONCLUSIONS
The RESULTS of the study demonstrated that betaine affect the mRNA levels of genes involved in hepatic lipid metabolism, with these effects potentially being dose-dependent.

ACETIC ACID STIMULATES AMP-ACTIVATED PROTEIN KINASE AND EXPRESSION OF GENES IN HUMAN SKELETAL MUSCLE CELLS

Hitomi Maruta[1]; Hiromi Yamashita[2]
[1]nutritional science faculty of health and welfare science, kuboki 111, Soja, Japan; [2]Nutritional science, faculty of health and welfare science, kuboki 111, Soja, Japan

BACKGROUND AND OBJECTIVES
Previously, we found that acetic acid had effects on the activation of AMP-activated protein kinase (AMPK) and on the expression of GPR43 genes in skeletal muscles of rat. It was appeared that acetic acid functioned as an agent for improving lipid metabolism in the skeletal muscles. In this study, in order to investigate the effect of acetic acid on skeletal muscles of human, acetic acid on the activation of AMPK, GPR43, and the stimulation in expressions of genes and proteins in human skeletal muscle cells were analyzed.

METHODS
Human skeletal myoblasts (SKB-F) cells were differentiation and cultured for 7 days.
Total protein and total RNA were extracted from differentiated SKB-F cells. Protein and gene analyses were performed by Western blotting and quantitative real-time PCR, respectively.

RESULTS
The expression levels of genes (*GPR43*, *mef2a*, *mb*, *ppargc1a*, *cycs* and *sdha*) and proteins (pAMPK, MEF2A and PGC-1α) were elevated in the acetic acid-treated cells. On the other hand, the araA (AMPK inhibiter)-treated cells showed a declining trend in the expressions of some genes and proteins.

CONCLUSIONS
Acetic acid might improve skeletal muscle function in human via activations of GPR43 and AMPK.

SUPPLEMENT USE AND LABEL READING AMONG AMATEUR FITNESS ENTHUSIASTS AT A HIGH INTENSITY INTERVAL TRAINING (HIIT) FACILITY

Lindsay Reid[1]; Janicke Visser[1]; Nelene Koen[1]
[1]Department of Global Health, Division of Human Nutrition, Faculty of Medicine and Health Sciences, Stellenbosch University, Cape Town, South Africa

BACKGROUND AND OBJECTIVES
With increasing public interest in health and nutrition, supplements have become popular, particularly among recreational exercisers. While legislation exists to regulate dietary supplements, the industry is not monitored as it should be. Public knowledge of dietary supplements is limited, particularly the understanding of and ability to interpret supplement labels. This, together with the shortage of local data, poses a significant concern for public health. Against this backdrop, the study sought to determine the perceptions, beliefs, and practices of amateur fitness enthusiasts in relation to supplement use, label reading, and body composition.

METHODS
A cross-sectional descriptive study with an analytical component was conducted, involving amateur fitness enthusiasts (>18 years) with an active membership at a HIIT facility in Cape Town. Quantitative data were collected using an online, self-administered questionnaire (n=98), and a body composition analysis tool (InBody© 120)(n=32), and presented using descriptive statistics, supplemented with statistical analysis.

RESULTS
Forty-four percent of participants reported having a reasonable supplement knowledge. Only 5.1% used no supplements at all, citing lack of knowledge, perceived lack of necessity, or cost concerns. The remaining majority consumed a supplement in at least one of the four investigated categories: protein and energy- (81.6%), ergogenic- (40.8%), weight management- (25.8%), and multivitamin and mineral -supplements (74.7%). Protein and energy and multivitamin and mineral supplements were most frequently consumed (4–7 times per week) with 57.5% and 69.0% reporting these supplement groups as effective, respectively. Body composition data reflected a mean participant weight of 87.7 kg, skeletal mass of 35.8 kg, body fat percentage of 27.2%, and a body mass index of 28.8 kg/m2. While 51% reported that reading labels when choosing supplements is always important, the RESULTS varied regarding the specific supplement label elements considered when choosing supplements.

CONCLUSIONS
Supplement use was widespread, even among those with limited understanding. Many users demonstrated a fair understanding of supplements; however, clear disparities emerged regarding usage indications, supplement selection, and reliance on unreliable sources for advice. Extensive supplement label education and nutrition consultation are necessary to improve understanding of supplements and to enhance label-reading practices.

ANTIBIOTIC RESISTANCE IN SKIN MICROBIOTA IN TYPE 2 DIABETIC AND HEALTHY SUBJECTS

Monica Andrews[1]; Christine Kreindl[2]
[1]Facultad de la Salud, Universidad Autonoma de Chile, Santiago, Chile; [2]Facultad de la Salud, Autonomous University of Chile, Providencia, Chile

BACKGROUND AND OBJECTIVES

The use and misuse of antibiotics around te world has generated in recent years a rapid emergence in the sread of resistant bacteria and resistance genes, which is why the WHO characterized microbial resistance as a global public heath crisis that must be urgently resolved (WHO, 2015). The skin microbiota and the bacteria that compose it are the first to be exposed to different sources of these drugs (Jo, 2021), the extent of their resistance, and their impact on the health of the individuals are questions to be resolved. Objective: To evaluate antibiotic resistance in skin microbiota in compensated and decompensated subjects with type 2 diabetes and in healthy subjects.

METHODS

20 adults subjects with type 2 diabetes (T2D) with HbA1c greater than 7% considered as decompensated, HbA1c less than 7% considered as compensated and healthy subjects were evaluated. A sample for culture was obtained by scraping the skin with a swab from the plantar area (Timm, 2020), then a phenotypic determination was performed using Chromagar, performing antibiotic sensitivity test by applying sensidiscs for amoxicilin and clavulonic acid (AUG) and cefadroxil (Khan, 2023). FInally, the isolates were sequenced at SeqCenter.

RESULTS

A significant difference was observed in the age of the subjects, with the healthy ones being younger (ANOVA, p=0.01). Healthy subjetc were foud to have a skin microbiota with greater resistance to AUG (47.3%), also, compensated a decompensated T2D subjects were more sensitive to AUG than healthy individuals (57.1% and 61.0%, respectively, vs 27.3%). regarding Cefadroxil, it was also observed that compensated and decompensated T2D were more sensitive than healthy subjects (45.5% and 52.3%, respectively, vs 9.1%), about resistance of Cefadroxil, 47% of the healthy subjects were resistant. The species found differ according to the metabolic state whether they are resistant or not.

CONCLUSIONS

Healthy subjects without antibiotic consumption present resistance in their skin microbota and also the species differ according to the presence of sensitivity or resistance. In diabetic subjects, the resistance of bacteria is related to metabolic control as well as the species present. It is necessary to study what effect this finding has on the health of individuals.

EPO8_019

VITAMIN D3 IS MORE EFFECTIVE IN IMPROVING THE SKELETAL FUNCTIONS THAN VITAMIN D2 IN A RAT MODEL

Soumam Dutta[1]; Ayesha Ismail[1]
[1]Department of Endocrinology, ICMR - National Institute of Nutrition, Hyderabad, India

BACKGROUND AND OBJECTIVES

Vitamin D (VD) deficiency is widespread globally and VD fortification is being implemented in many countries. In certain countries, like India, VD2 is a more popular fortificant than VD3 owing to vegetarianism and cultural reasons. The structural differences in the side chains of VD2 and VD3 directly affect their metabolism, with VD3 showing a greater half-life than VD2. Therefore, the present study was designed to decipher the role of the two vitamers (VD2 vs VD3) when used independently or in combination at different levels in impacting the functions of the classical target organs (intestine, bone and kidney).

METHODS

Weanling male SD rats were fed either VD3 (400IU or 2000IU/kg) or VD2 (400IU or 2000IU/kg), or a combination of both vitamers (1000IU+1000IU/kg) or VD-deficient (0IU/kg) diets for 18-weeks. VD-depleted rats were rehabilitated with the same diets from 9th week, to assess reversal of effects. Serum parameters were analyzed using HPLC, ELISA and Atomic Absorption/UV-Vis-Spectrophotometry. 45Ca isotope was used to check fractional calcium absorption by Liquid Scintillation Counting. Bone quality was assessed by DEXA, Digital Force Tester, and histopathological analyses. Expression of genes involved in calcium absorption, reabsorption and VD metabolism were analyzed using RT-qPCR.

RESULTS

Serum 25(OH)D and calcium levels were significantly decreased, whereas PTH and ALP levels were significantly increased in the VD-deficient group compared to groups given either VD2 or VD3. A ~2-fold increase in 25(OH)D level was observed in VD3-fed groups than in VD2-fed groups, and concurrent supplementation of VD2 with VD3 had a declining effect on 25(OH)D. A trend of higher intestinal calcium absorption was observed in the groups fed VD3 than VD2-based diets (P<0.01). VD3 appeared to be more efficacious (P<0.01) than VD2 in improving bone mineral content, bone strength, articular cartilage thickness and collagen deposition, especially upon rehabilitation. Furthermore, VD3-fed groups exhibited a higher expression of *CaBP9k* and *Vdr* in the small intestine. Also, VD3 was more efficacious in improving *Trpv5*, *CaBP28k* and *Pmca1b* expression in kidney. A similar trend was observed in renal *Cubilin*, *Cyp27b1* and *Vdr* expression.

CONCLUSIONS

VD3 improved serum 25(OH)D levels and skeletal functions more efficiently than VD2, especially during the rehabilitation phase. VD3 could be a better alternative to VD2 for food fortification and supplementation programs.

EFFECTS OF CYSTINE ON THE REPRODUCTIVE ORGANS OF RATS WITH DISTURBED CIRCADIAN RHYTHMS

MIHO HANAI[1]; Amane Tamura[1]; Eri Nakamura,[1]
[1]Nutrition and Life Science, Kanagawa Institute of Technology, Atsugi, Japan

BACKGROUND AND OBJECTIVES
Men with disrupted circadian rhythms often exhibit reduced sperm counts and increased infertility risks. This study aims to clarify the effects of cystine supplementation on the reproductive organs of rats subjected to circadian rhythm disturbances

METHODS
Three-week-old male Fischer 344 strain rats were divided into four groups based on light–dark conditions and diet: normal light–dark cycle (light phase: 07:00–19:00) with a 9% casein diet (N9%), normal light–dark cycle with a cystine-supplemented diet (NCys), disturbed light–dark cycle with a 9% casein diet (D9%), and disturbed light–dark cycle with a cystine-supplemented diet (DCys). The disturbed light–dark cycle involved two protocols: in Experiment 1, the 24-h light–dark cycle was advanced by 8 h every 4 days; in Experiment 2, 8-h and 5-h light–dark cycles were alternated weekly. After 4 weeks, the rats were dissected between 13:00 and 15:00.

RESULTS
In Experiment 1, cystine supplementation increased body and reproductive organ weights, with no effects observed from the disturbed light–dark cycle. In Experiment 2, cystine supplementation raised body weight, whereas the disturbed light–dark cycle lowered this weight. Testis weight (g) in the D9% group was reduced compared to the DCys group. Serum testosterone levels remained unaffected by either cystine supplementation or the disturbed light–dark cycle. However, mRNA expression levels of Scarb1, Star, Cyp17a, and Hsd17b, key enzymes in testosterone synthesis, were significantly lower in the disturbed groups. Notably, Hsd17b mRNA expression significantly increased with cystine supplementation. Expression levels of Ldlr, Scp2, and Cyp11a mRNA were reduced in the D9% group compared with the N9% group, but no differences were observed between the DCys and NCys groups. The mRNA levels of Insl3, a marker of Leydig cell differentiation responsible for testosterone synthesis, were lower in the disturbed groups, with no detectable effect of cystine supplementation.

CONCLUSIONS
Weekly alternation between 8-h and 5-h light–dark cycles reduced mRNA expression levels of enzymes involved in testosterone synthesis. Cystine supplementation increased Hsd17b3 mRNA expression levels, promoting the conversion of androstenedione to testosterone. These RESULTS were observed 6–8 h and 0–2 h into the light phase for the normal and disturbed groups, respectively. Therefore, future research should consider the secretion rhythms of related hormones when interpreting these findings.

AMARANTH EXTRACTS REGULATE MITOCHONDRIAL BIOENERGETICS IN C2C12 MYOTUBES AND PRIMARY HEPATOCYTES

María del Sol Pacheco Gómez[1]; David Chavaro-Pérez[1]; Sandra Tobón-Cornejo[1]; Mariana Villegas-Romero[1]; Aneliz de Ita Zárate Ortiz[1]; Itzelly Ibarra Valdovinos[2]; Ana Arias; Israel García-Cano[3]; Natalia Vazquez Manjarrez[1]; Lilia Noriega[1]

[1]Fisiología de la Nutrición, Salvador Zubirán National Institute of Health Sciences and Nutrition, Ciudad de México, Mexico; [2]Vigilancia Epidemiológica, Salvador Zubirán National Institute of Health Sciences and Nutrition, Ciudad de México, Mexico; [3]Ciencia y Tecnología de los Alimentos, Salvador Zubirán National Institute of Health Sciences and Nutrition, Ciudad de México, Mexico

BACKGROUND AND OBJECTIVES

Amaranth, a pseudocereal native to Mexico, was a staple food of Mesoamerican civilizations (1). Supplementation with amaranth reduces hepatic cholesterol, triglycerides, and phospholipid levels in mice fed a high-fat diet (2), and its seed extracts improve glucose tolerance and insulin secretion in both type 2 diabetic (Goto-Kakizaki) and healthy Wistar rats (3). Despite these effects on lipid and glucose metabolism, the underlying mechanisms, particularly those involving mitochondrial function, remain unclear. This study aimed to evaluate the polyphenol content of four amaranth grain extracts and investigate their effects on mitochondrial function.

METHODS

Amaranth grains were obtained from two distinct sources: artisanal and commercial. Four extracts were prepared from each source: methanol extract (ME), 100% ethanol extract (EE100), 70% ethanol extract (EE70), and acetone extract (AE). The total polyphenol content was quantified using the Folin–Ciocalteu method. The effects of 2 nM gallic acid equivalents of each extract on mitochondrial bioenergetics were assessed in C2C12 myotubes and primary hepatocytes using an extracellular flux analyzer and a mitochondrial stress test.

RESULTS

The total polyphenol content was 117% and 77% higher in the ME and EE100 from artisanal amaranth compared to the commercial extracts. In contrast, the EE70 and AE from commercial amaranth contained 137% and 72.82% higher polyphenol levels than the artisanal extracts. In C2C12 myotubes, the ME, EE100, and AE from artisanal amaranth significantly enhanced maximal respiration and spare respiratory capacity. Similarly, EE100 and EE70 increased maximal respiration and spare respiratory capacity in primary hepatocytes. For commercial amaranth, ME and EE70 improved maximal respiration and spare respiratory capacity in primary hepatocytes, while EE100 and EE70 enhanced these parameters in C2C12 myotubes.

CONCLUSIONS

This study demonstrates that the source and extraction method significantly influence the polyphenol content and bioenergetic effects of amaranth grain extracts. Artisanal extracts showed greater potential in enhancing mitochondrial function in C2C12 myotubes, whereas commercial extracts were more effective in primary hepatocytes. The current work was supported by the Periodic Table of Food Initiative and the FOODEDU Good Food Fellows initiative through the American Heart Association.

ENERGY CONSUMPTION TIMING AND ITS ASSOCIATION WITH OVERWEIGHT AND OBESITY AMONG UNIVERSITY STUDENTS: A PILOT STUDY

Noura Alotibeو[1]; Deema Talic,[2]; Arwa Almutiri,[3]; Norah Alowaymir,[4]; Noha Almutiri,[3]; Nahla Bawazeer,[3]
[1]Nutrition Department, King Saud Medical City, Riyadh, Saudi Arabia; [2]Nutrition, Princess Nourah Bint Abdulrahman University -, Riyadh, Saudi Arabia; [3]Department of Health Sciences, Princess Nourah bint abdulrahman University, Riyadh, Saudi Arabia; [4]Nutrition, Nestle, Riyadh, Saudi Arabia

BACKGROUND AND OBJECTIVES
Food timing is a modifiable behavioral factor linked to overweight and obesity. This pilot study aimed to investigate the relationship between daily energy consumption timing and the prevalence of overweight and obesity among female university students.

METHODS
A pilot study was conducted involving female university students. Participants completed an online questionnaire to gather sociodemographic and lifestyle data. Anthropometric measurements were recorded, and dietary intake was assessed using 24-hour food recalls across three non-consecutive days. Statistical analyses, including ANOVA and T-tests, were employed to examine the relationship between energy consumption timing, body mass index and waist circumference.

RESULTS
A total of 47 participants were included in the analysis, categorized based on BMI and waist circumference. Obese and overweight participants had a higher total daily energy intake (1717 ± 721 kcal/day) compared to those with normal BMI (1529 ± 694 kcal/day). Additionally, obese and overweight individuals, as well as those with abdominal obesity, primarily consumed their daily energy intake at night. However, no statistically significant associations were observed between energy intake timing (day vs. night) and BMI or waist circumference.

CONCLUSIONS
The findings indicate that daily energy consumption timing is not significantly linked to overweight and obesity among female university students. The small sample size highlights the need for larger studies, and further exploration of food timing's relationship with overweight and obesity, particularly through randomized controlled trials, is recommended to establish causal links.

EPO8_024

THE EFFECT OF PROTEIN RESTRICTION ON THE GUT ENVIRONMENT IN HIGH-FAT DIET-FED MICE

Felicia Cindy[1]; Kitaura Yasuyuki[2]
[1]Dept. of Applied Biosciences, Graduate School of Bioagricultural Sciences, Nagoya University, Nagoya, Japan;
[2]Dept. of Applied Biosciences, Chubu University, Kasugai, Japan

BACKGROUND AND OBJECTIVES
Carbohydrates, proteins, and fats are essential macronutrients required for energy and physiological processes. There is growing evidence that the balance between protein and non-protein energy in the diet is more critical for health and aging than the individual effects of each macronutrient. Dietary protein restriction, in particular, has shown benefits for metabolic health and weight management, especially in comparison to high-fat diets. In addition, macronutrient balance also modulates the gut environment, which has been linked to host health and disease. This study thus aims to investigate how protein restriction affects the gut environment in mice fed a high-fat diet.

METHODS
C57BL/6N male mice were divided into three groups, each fed a different diet: control diet (CD), high-fat diet (HFD), or high-fat low-protein diet (HFLPD). After two weeks of rearing, tissues were collected, and microbiota composition and metabolites were analyzed using 16S rRNA amplicon sequencing, gas chromatography-mass spectrometry (GC-MS), and liquid chromatography-mass spectrometry (LC-MS).

RESULTS
Mice in the HFD group showed increased levels of potentially harmful cecal metabolites, including branched-chain amino acids (BCAAs) and aromatic amino acids (AAAs), as well as secondary bile acids (BAs), compared to the CD group. This was accompanied by a rise in *Lachnospiraceae*, a bacterial family known to produce secondary BAs. These metabolites were notably reduced with protein restriction in the HFLPD group, which also exhibited lower levels of cecal long-chain fatty acids compared to the HFD group.

CONCLUSIONS
These findings indicate that restricting protein during high fat intake modulates gut microbiota composition, reduces harmful metabolites, and may influence fat digestion or absorption. This highlights the potential of protein restriction as a dietary strategy, particularly in high-fat diets, to improve gut health and reduce the risk of diseases.

THE BENEFICIAL EFFECTS OF GABA-FERMENTED RICE BRAN ON CAFETERIA DIET-INDUCED NON-ALCOHOLIC FATTY LIVER DISEASE IN RATS

Chih-Hsien Wu[1]; Tsung-Yen Hsieh[1]; Yuh-Ting Huang[1]; Suh-Ching Yang[1]; Ya-Ling Chen[1]
[1]School of Nutrition and Health Sciences, Taipei Medical University, Taipei, Taiwan

BACKGROUND AND OBJECTIVES
Non-alcoholic fatty liver disease (NAFLD) is a common liver disorder strongly influenced by dietary factors. Functional foods like fermented rice bran, rich in bioactive compounds such as γ-aminobutyric acid (GABA), have shown potential in improving metabolic disorders. However, the effects of GABA-fermented rice bran on NAFLD remain unclear. Therefore, in this study, we aimed to investigate whether GABA-fermented rice bran exhibits beneficial effects on cafeteria diet induced NAFLD in rat model.

METHODS
40 male Wistar rats were divided into four groups: a normal diet group (C), a normal diet group supplemented with 300 mg/kg body weight GABA-fermented rice bran (CG), a cafeteria diet group (CAF), and a cafeteria diet group supplemented with 300 mg/kg body weight GABA-fermented rice bran (CAFG). After 16 weeks, rats were sacrificed to collect samples for further analysis.

RESULTS
After a 16-week cafeteria diet, the rats exhibited significantly higher body weight, perirenal and epididymal adipose tissue weight compared to the control group, whereas the GABA-fermented rice bran group showed significantly lower levels than the cafeteria group. The cafeteria diet significantly elevated blood glucose and HOMA-IR levels, but these were not notably reduced by GABA-fermented rice bran treatment. Additionally, plasma triglyceride levels, which were significantly increased by the cafeteria diet, were markedly reduced by GABA-fermented rice bran treatment. In contrast, the cafeteria diet significantly increased hepatic triglyceride levels, but GABA-fermented rice bran showed no significant effect.The cafeteria diet also increased plasma leptin and adiponectin levels compared to the control group, but these changes were reversed by GABA-fermented rice bran treatment. Regarding inflammatory response, the cafeteria diet significantly raised hepatic TNF-α levels, which were ameliorated by GABA-fermented rice bran. Histopathological liver analysis revealed that the cafeteria diet induced hepatic lipid accumulation and resulted in a significantly higher NAFLD score than the control group, whereas GABA-fermented rice bran reduced both lipid accumulation and NAFLD scores.

CONCLUSIONS
GABA-fermented rice bran alleviated the metabolic and inflammatory effects of cafeteria diet-induced NAFLD, by means of reducing body weight, adipose tissue weight, plasma triglycerides, and inflammation. These findings suggest that GABA-fermented rice bran can be a promising dietary intervention for NAFLD.

EARLY REGULATION OF INTESTINAL CALCIUM TRANSPORT IN RESPONSE TO FEEDING STIMULATION

Hinata Tanishige[1]; Hitoki Yamanaka[2]; Ritsuko Masuyama[1]
[1]Graduate School of Gastronomy Management, Ritsumeikan University Biwako Kusatsu Campus, Kusatsu, Japan; [2]Research Center for Advanced Science and Technology, Shinshu University, Matsumoto, Japan

BACKGROUND AND OBJECTIVES

Transcellular calcium transport in the small intestine is a predominant pathway to sustain calcium homeostasis when dietary calcium intake is insufficient. This pathway is initiated by increasing the expression of TRPV6, a calcium channel in intestinal epithelial cells, due to vitamin D action, and allows calcium entry into cells. While it has well been demonstrated that vitamin D action promotes calcium absorption in response to biological requirements, dietary calcium intake affects vitamin D action too. However, it is unclear whether this change is the result of endocrine regulation in response to the biological requirement or the consequence of changes in the luminal calcium content. In this study, we investigated the early response of intestinal calcium transport to dietary calcium intake.

METHODS

To elucidate the early response, wild-type (*Int Vdr+*) mice and mice lacking VDR activity in the intestine (*Int Vdr-*) mice at age 10-38 weeks were acclimated by repeating 24 hours fasting and 1 hour feeding with a control diet for 2 days. After a 2-day acclimation period, *Int Vdr+* and *Int Vdr-* mice fed a control diet that contained 0.5% calcium or a high-calcium diet that contained 1.0% calcium for 30 or 60 minutes. Blood and intestine samples were isolated before feeding, 30 and 60 minutes after feeding.

RESULTS

Serum glucose levels tended to increase 30 minutes after feeding, but serum calcium levels were not affected by feeding time and remained low compared to the levels of normal feeding status. TRPV6 protein expression in the small intestinal epithelium, assessed by western blot analysis, was increased in both *Int Vdr+* and *Int Vdr-* mice after 30 minutes of feeding. Besides, the signal of epithelial localization of TRPV6 was increased in *Int Vdr+* mice in a time-dependent manner, these signals were not abundantly detected in *Int Vdr-* mice, and no change with feeding time. Furthermore, the luminal calcium concentration in the small intestine did not change from before feeding till 60 minutes after feeding.

CONCLUSIONS

These RESULTS suggest that in the early phase after feeding, a mechanism that regulates calcium absorption by increasing TRPV6 expression in the intestinal epithelium responds to feeding, and this mechanism is promoted by vitamin D action.

EFFECT OF DIETARY CALCIUM DEFICIENCY ON ZINC LEVELS AND ZINC TRANSPORTERS ACROSS MULTIPLE TISSUES IN RATS

Takako Suzuki[1]; Yukio Nakamura[2]; Jun Takahashi[2]; Kazuharu Suzuki[3]
[1]Department of Human Nutrition, Faculty of Human Nutrition, Tokyo Kasei Gakuin University, 22 Sanban-cho, Chiyoda-ku, Japan; [2]Department of Orthopaedic Surgery, Shinshu University School of Medicine, 3-1-1 Asahi,Matsumoto, Nagano 390-8621, Japan; [3]Department of Nutritional Science, Faculty of Applied Bioscience, Tokyo University of Agriculture, 1-1-1 Sakuragaoka, Setagaya-ku, Tokyo 156-8502, Japan

BACKGROUND AND OBJECTIVES

Calcium is a vital mineral in the body, playing a critical role in numerous physiological processes. Its deficiency not only impairs skeletal integrity but also affects the metabolism and distribution of other essential minerals, such as magnesium and iron. Although our findings demonstrated that dietary zinc deficiency reduces serum calcium levels and impairs calcium utilization, leading to bone loss, limited research has addressed how dietary calcium deficiency affects zinc distribution in tissues.

In this study, we investigated the effects of dietary calcium deficiency on zinc concentrations and zinc transporter expression in the liver, kidney, and duodenum.

METHODS

After a 3-day adaptation to a control diet, four-week-old male Wistar rats were divided into two groups: a calcium-deficient group (CaD, 500 ppm) and a control group (C, 5000 ppm), pair-fed with the CaD group. Following two weeks of treatment, the rats were anesthetized, and blood, liver, duodenum, kidney, and femur samples were collected.

RESULTS

Our findings revealed that dietary calcium deficiency significantly increased zinc concentrations in the serum, liver, and femur, while reducing it in the kidney. Additionally, dietary calcium deficiency upregulated metallothioneins (Mt1, Mt2) and Zip1 in the liver but downregulated Mt1, Mt2, Zip1, Zip10, Zip13, and Zip14 in the kidney. In the duodenum, Mt1, Mt2, and ZnT1 expression increased, while Zip4 expression was significantly reduced.

CONCLUSIONS

These RESULTS indicated that dietary calcium deficiency altered zinc distribution across tissues by modulating the expression of zinc transporters, suggesting a complex interaction between calcium and zinc homeostasis in the body.

EFFECT OF ORAL INTAKE OF LINSEED OIL ON FATTY ACID METABOLISM-RELATED GENES IN THE SKIN OF OBESE MICE

Yoshiko Horie[1]; Akase Tomoko[1]
[1]Nursing, Yokohama City University School of Medicine, Yokohama, Japan

BACKGROUND AND OBJECTIVES

Obesity impairs skin barrier function and causes epidermal thickening (Mori et al., 2017; Horie et al., 2018). The impaired skin barrier function leads to a vicious cycle of itching and scratching, which further deteriorates skin barrier function and reduces quality of life. However, there are no established care methods for skin barrier dysfunction in obesity. We previously demonstrated that oral intake of linseed oil, which is rich in omega-3 fatty acids, inhibits skin barrier dysfunction in obesity (Horie et al., 2024). This study aims to elucidate, using molecular biological analysis, the effect of oral intake of linseed oil on fatty acid metabolism-related genes that are decreased in obese skin.

METHODS

Obese model mice (TSOD) were divided into Control and Omega groups. The Control group received sterile distilled water, and the Omega group received linseed oil orally for 8 weeks. After hair removal, UVB irradiation (40 mJ/cm2) was applied to the dorsal skin. Transepidermal water loss (TEWL) was measured, and skin samples were collected. Histological analysis was performed using hematoxylin-eosin (HE) staining, and mRNA expression levels of fatty acid metabolism-related genes were analyzed. This study was approved by the Yokohama City University Animal Experiment Committee (F-A-23-051).

RESULTS

The Omega group exhibited significantly lower TEWL values compared to the Control group. Histological analysis revealed that epidermal thickening was suppressed in the Omega group. Molecular biological analysis demonstrated that mRNA expression levels of *Acc1* and *CerS1*, *3*, and *6*, key enzymes involved in free fatty acids and ceramide synthesis, were significantly decreased in the Omega group compared to the Control group.

CONCLUSIONS

This study suggests that the suppression of skin barrier dysfunction in obese mice receiving linseed oil is associated with the modulation of fatty acid synthase enzymes. Compared to the Control group, in which the skin barrier function was impaired, gene expression of free fatty acids and ceramide synthase was decreased in the Omega group. This indicates that linseed oil suppressed the impaired barrier function in obese skin, as gene expression of the synthases was modulated in the Omega group. Further investigations into omega-3 fatty acid metabolites and other skin barrier-related factors are required to establish preventive care methods for obesity-related skin barrier dysfunction.

ETHYL P-METHOXYCINNAMATE SUPPRESSES EHRLICH ASCITES TUMOR CELL PROLIFERATION VIA ATP DEPLETION THROUGH INHIBITION OF FATTY ACID SYNTHESIS RATHER THAN GLYCOLYSIS

Yutaro Sasaki[1]; Niina Mizushima[1]; Isao Matsui-Yuasa[1]; Akiko Kojima-Yuasa[1]
[1]Department of Nutrition, Graduate School of Human Life and Ecology, Osaka Metropolitan University, Osaka, Japan

BACKGROUND AND OBJECTIVES
Cancer cells exhibit reprogrammed energy metabolism pathways, yet the primary mechanisms for meeting their energy demands remain poorly understood. Ethyl *p*-methoxycinnamate (EMC), a major component of the ginger plant *Kaempferia galanga* L., inhibits the proliferation of Ehrlich ascites tumor cells (EATCs) by inducing G1 phase arrest. This study aimed to examine the effects of EMC on energy metabolism pathways, particularly glycolysis and fatty acid metabolism, to gain deeper insights into the interactions between metabolic pathways in cancer cells.

METHODS
EATC were incubated with or without 100 μM EMC. Anti-cancer effects of EMC were evaluated by measuring glucose consumption, lactate release, ATP levels, mRNA and protein expression, intracellular triglyceride (TG) levels, DNA content, cell viability, and cell number.

RESULTS
EMC treatment significantly decreased ATP levels in EATCs, despite enhancing glycolytic activity, as evidenced by increased glucose consumption and lactate release in the culture medium. EMC inhibited the expression of fatty acid synthesis-related genes and decreased intracellular TG levels. Notably, the exogenous addition of palmitic acid reversed the EMC-induced decrease in ATP levels. These RESULTS demonstrate that EMC reduces ATP levels by inhibiting fatty acid synthesis. EMC-induced ATP depletion coincided with the inhibition of the G1/S phase transition. Furthermore, EMC reduced the number of EATCs, but this reduction was reversed by the addition of exogenous palmitic acid. These RESULTS suggest that the reduction in ATP production caused by the inhibition of fatty acid synthesis disrupts energy-dependent cell cycle progression, thereby suppressing EATC proliferation. Mechanistically, EMC suppressed the expression of SREBP1, a master regulator of fatty acid synthesis, and further inhibited the Ser62 phosphorylation of c-Myc, a transcriptional regulator of SREBP1. These findings indicate that EMC suppresses the expression of fatty acid synthesis-related genes through the inhibition of the c-Myc/SREBP1 pathway.

CONCLUSIONS
This study demonstrates that EMC suppresses ATP production in EATCs by inhibiting *de novo* fatty acid synthesis rather than glycolysis. These findings underscore the critical role of fatty acid metabolism in maintaining energy homeostasis in cancer cells and identify fatty acid synthesis as a promising therapeutic target for cancer treatment.

D-TOMATO ADVENTURE: CAN A BOWL OF SOUP BOOST YOUR VITAMIN D LEVELS?

Brenda Mionki[1]; Jie Li,[1]; Jennifer Ahn-Jarvis,[2]; Antonietta Hayhoe,[2]; Tracey Robertson,[3]; Sue Lanham-New,[3]; Martin Warren,[2]; Cathie Martin,[1]
[1]Biochemistry and Metabolism, John Innes Centre, Norwich, United Kingdom; [2]Human studies team, Quadram Institute, Norwich, United Kingdom; [3]Food and Nutrition, University of surrey, Surrey, United Kingdom

BACKGROUND AND OBJECTIVES
Vitamin D3 is essential for various cellular and bodily functions. While sunlight triggers its synthesis, dietary intake or supplementation is the most reliable way to meet recommended levels. Most plant-based foods are poor sources of vitamin D although they would play a crucial role in curbing deficiency as they are widely consumed and affordable. Recent research has developed tomato lines that accumulate pro-vitamin D3, which can convert to vitamin D3 through UV or sunlight exposure. By editing the cholesterogenesis pathway using CRISPR-Cas9 to knock out the *Sl7dr2* gene, these pro-vitamin D3 enriched tomatoes can achieve an average accumulation of 2 µg/g. This means that five biofortified tomatoes can meet the recommended daily intake of 10 µg of vitamin D.

METHODS
To investigate the bioavailability and efficacy of the biofortified tomatoes in maintaining plasma 25-OHD levels, tomato soups were made from the biofortified tomatoes to be consumed by healthy volunteers in a four arm, double blind study conducted in UK winter. For the food development, 200 tomato plants were grown to meet the required numbers for the study which yielded 300kgs of fresh weight tomatoes. Fresh and freeze dried tomatoes were exposed to UVB or UVC light for 2 hours to convert pro-vitamin D to vitamin D. The clinical study has just been approved and set to take place in January for a period of three weeks.

RESULTS
UVB was more effective than UVC in converting provitamin D to vitamin D in tomatoes. The levels of vitamin D can be increased by incubating the tomatoes at 50C overnight after UV irradiation. Fresh and freeze dried materials can be equally irradiated. Provitamin D and vitamin D are stable in storage at 4C and room temperature which is ideal for the participants during the study.

CONCLUSIONS
This study shows that biofortification of tomatoes with vitamin D could provide a route to curbing the prevalent vitamin D deficiency. The food development studies have shown that it is feasible to standardise the amounts of vitamin D provided by the tomatoes for a human study and UVB is more effective in conversion of provitamin D to vitamin D. The next steps are the recruitment for the human study.

MODULATION OF LIPID HOMEOSTASIS BY VITAMIN E ANALOGUES AND CANNABINOIDS IN HUMAN MACROPHAGES

Mengrui Li[1]; Sapna Deo[1, 2, 3]; Sylvia Daunert[1, 2, 3]; Jean-Marc Zingg[1, 2]
[1]Biochemistry and Molecular Biology, University of Miami, Miami, United States of America; [2]Dr. JT Macdonald Foundation Biomedical Nanotechnology Institute, University of Miami, Miami, United States of America; [3]Clinical and Translational Science Institute, University of Miami, Miami, United States of America

BACKGROUND AND OBJECTIVES

An imbalance of lipid homeostasis is considered as one of the factors of chronic inflammation. Excess lipid can activate CD36 scavenger receptor/fatty acid translocase (CD36/FAT) and Toll-like receptor (TLR2/TLR4) in macrophages resulting in accumulation of lipids and increased production of inflammatory cytokines such as IL6 and TNFα. Cannabinoids are known to modulate inflammation and lipid homeostasis in macrophages, by regulating cannabinoid receptors (CB1, CB2) but also other receptors such as transient receptor potential of vanilloid subtype 1 (TRPV1). Cannabinoid type 1 (CB1) receptor plays a role in lipid regulation and is considered as an important target in metabolic disease.

METHODS

To investigate the molecular mechanisms involved in modulation of lipid homeostasis and inflammation by cannabinoids, we analyzed the expression of lipid transport genes (CD36, SR-B1 ABCA1/G1 transporter) at mRNA (RT-qPCR) and protein (ELISA) levels. We tested whether vitamin E as a lipid-soluble antioxidant with anti-inflammatory and metabolic regulatory properties can modulate these events. By transfecting reporter plasmids for NFκB, PPARγ and Nrf2 into cell lines expressing CB1 or TRPV1 receptors, we assessed whether cannabinoids with/without vitamin E can change these signaling pathways. We tested both natural (αTAn) and synthetic forms (αTAr) of vitamin E acetate for their influence on ROS, toxicity, and cell proliferation.

RESULTS

The cannabinoid, Δ9-tetrahydrocannabinol (THC), increased the levels of lipids in THP-1 macrophages and increased the expression of IL6, IL1β, and TNFα genes at mRNA and protein level. THC also induced NFκB expression via CB1 receptor that could be inhibited by vitamin E. Treatment with the cannabinoid, cannabidiol (CBD), also showed upregulated PPARγ promoter activity via TRPV1 receptor. Our RESULTS suggest induction of genes involved in lipid uptake (CD36/FAT) after treatment with THC that can be prevented, albeit incompletely, by αTA or CBD. Interestingly, genes involved in cellular lipid export (SR-B1, ABCA1) were downregulated less by αTAn when compared to αTAr. Vitamin E has similar inhibitory effects on pro-inflammatory cytokines induced by THC via CB1 receptor as observed for lipid related gene modulation.

CONCLUSIONS

A detailed analysis of the molecular signaling mechanisms by which lipids accumulate in macrophages will not only be important to understand chronic inflammation but also for metabolic dysfunction in diseases such as atherosclerosis.

ASSOCIATIONS OF FOOD CHOICES, FOOD REWARD, AND EATING BEHAVIOR WITH MECHANICAL AND NERVOUS GASTRIC FUNCTIONS IN OBESITY AND BARIATRIC SURGERY: AN ARTIFICIAL INTELLIGENCE ASSISTED SCOPING REVIEW

Nina RITSCH[1, 2, 3]; Camille Bourque,[3]; Frédéric Bergeron,[4]; Julie-Anne Nazare[1]; Anestis Dougkas,[2]; Sylvain Iceta,[3, 5]

[1]CarMeN Laboratory, CRNH Rhône-Alpes, Oullins-Pierre-Bénite, France; [2]Research Center - Nutrition and Eating Behavior, Lyfe Institut, Écully, France; [3]Centre de Recherche, Institut Universitaire De Cardiologie Et De Pneumologie de Québec - Université Laval, Québec, Canada; [4]Library - Consulting Services, Laval University, Québec, Canada; [5]Département de Psychiatrie et Neurosciences, Faculté de Médecine, Université Laval, Québec, Canada

BACKGROUND AND OBJECTIVES

The hormonal causes of the alterations in dietary behaviour (e.g., food intake, food reward, gustation, olfaction, disordered eating such as binge eating or emotional eating) sometimes observed in the context of obesity and after bariatric surgery (BS) have been extensively studied. Yet, it remains poorly understood how alterations to the gastric structure may also contribute to these changes in dietary behaviour. The aims of this scoping review were (a) to explore the associations between mechanical and nervous gastric functions and parameters of dietary behaviour such as food intake, food reward, gustation, olfaction and disordered eating in people with obesity or those who had BS, and (b) to provide a comprehensive overview of the assessment tools used to explore mechanical and nervous gastric functions and parameters related to dietary behaviour.

METHODS

Using PRISMA guidelines, we performed a scoping review of studies that concurrently studied mechanical or nervous gastric functions and parameters of dietary behaviour. Studies of interest could include participants of all ages, with obesity or after BS. Both observational and interventional studies were considered. The search was undertaken in MEDLINE, Embase, PsycINFO, CINAHL, Web of Science, Google Scholar, and grey literature. The first screening based on abstracts and titles was conducted with an AI-assisted tool, ASReview.

RESULTS

Eighteen studies were selected, with only one study focusing on BS. An extensive array of methodologies was used to investigate a variety of gastric functions and dietary behaviours, with no study exploring gustation or olfaction. This considerable heterogeneity limits the ability to make firm CONCLUSIONS on the associations between gastric functions and dietary behaviour. However, in the context of obesity, gastric capacity, consumption to achieve satiation and gastric emptying speed were positively associated with binge eating or emotional eating, and with the consumption of carbohydrates. Gastric electrical activity was positively associated with fibre consumption. Interventions to re-educate gastric interoception (perception of hunger and satiety sensations), or to increase gastric electrical activity appeared to reduce overeating behaviours and food cravings.

CONCLUSIONS

Given the limited number and the heterogeneity of existing studies, certain associations between gastric mechanical and nervous functions and dietary behaviour in the context of obesity remain inconclusive. Our scoping review highlights the critical necessity for the development of novel studies in this field, particularly within the domain of BS.

THE PARTIAL REPLACEMENT OF ANIMAL-BASED PROTEINS WITH PLANT-BASED PROTEINS ALTERS AMINO ACID INTAKE AND SOURCES IN HEALTHY ADULTS: A RANDOMISED CONTROLLED TRIAL

Tiina Pellinen[1]; Tiina Sirkjärvi[1]; Essi Päivärinta[1]; Hanna Siren[1]; Suvi Itkonen[1]; Heli Reinivuo[2]; Liisa Valsta[2]; Anne-Maria Pajari[1]
[1]Department of food and nurtrition, University of Helsinki, Helsinki, Finland; [2]Nutrition, Thl - Finnish Institute for Health and Welfare, Mannerhemintie, Helsinki, Finland, Helsinki, Finland

BACKGROUND AND OBJECTIVES
The dietary shift towards more plant-based protein sources may change both the intake and the sources of amino acids. The aim of this study was to investigate the amino acid and protein intakes and their main sources in diets differing in plant/animal-based protein ratios.

METHODS
The study was a randomised controlled trial (RCT) including three intervention diets: ANIMAL, 50/50, and PLANT, with animal to plant protein ratios of 70:30; 50:50; 30:70. Altogether 136 healthy adult participants completed the 12-week RCT. In the 50/50 and PLANT groups, meat and dairy products were partially replaced with grains, nuts, seeds, and legumes. Amino acid and protein intakes (mg/kg body weight) and their sources were analysed based on 4-day food records. Eighteen different food categories were used to analyse amino acid sources in diet.

RESULTS
Intakes of protein, isoleucine, leucine, valine, histidine, and threonine were higher in the ANIMAL group than in the 50/50 and PLANT groups ($p<0.001$). Lysine and methionine intakes differed between all the diet groups with the highest intake in the ANIMAL group and lowest in the PLANT group, and tryptophan intake was higher in the ANIMAL group than in the PLANT group ($P<0.01$). The average requirements of the essential amino acids were met in all participants, apart from the methionine intake in two participants in the PLANT group. In the ANIMAL group, meat, milk, and cereals were the main sources of protein and amino acids. In the 50/50 group, in addition to the above-mentioned ones, legumes were also an important source of protein and amino acids. Nuts and seeds were also among the most important sources of protein and amino acids in the PLANT group. Unlike milk in the ANIMAL and 50:50 groups, plant-based dairy substitutes did not emerge as a significant protein source in the PLANT group.

CONCLUSIONS
When animal-based proteins were partially replaced by plant-based proteins, intakes of protein and essential amino acid were lower although the average requirements of the essential amino acid intakes were met in all diet groups when the protein intake was above the WHO/FAO reference intake (0.83 g/kg). Legumes in the 50/50 group, and in addition nuts and seeds in the PLANT group became an important source of protein and amino acids, besides the more traditional ones in ANIMAL group. However, plant-based dairy substitutes did not seem to replace milk as one of the most important sources of protein and amino acids.

EFFECTS OF A HIGH-FAT DIET LOAD ON THE FUNCTION OF INTRAPERITONEAL MACROPHAGES IN MICE

Hikono Sakata[1]; Misa Funaki[2]; Kanae Masuda[1]; Rio Kurihara[1]; Tomomi Komura[3]; Masaru Yoshida[3]
[1]Graduate School of Environmental Humanities, University of Hyogo, Himeji, Japan; [2]Faculty of Environmental Human Sciences, Department of Food, Environment and Nutrition, University of Hyogo, Himeji, Japan; [3]Center for Advanced Food Science Research, University of Hyogo, Himeji, Japan

BACKGROUND AND OBJECTIVES

In recent years, lifestyle-related diseases such as obesity, diabetes, and dyslipidemia have been recognized as problems, one of the causes of which is an excessive fatty diet. Obesity and other related diseases are known to be risk factors for the severity of infectious diseases such as sepsis and novel coronavirus infection, but their pathomechanisms have not been clarified. Therefore, we hypothesized that a diet high in fat might induce functional changes not only in adipocytes but also in macrophages, weakening the immune response and leading to aggravation of infectious diseases. Therefore, in this study, lipidomics, proteomics and RNA sequencing analyses were used to determine whether the fat composition of macrophages is altered by a high-fat diet load and what gene and protein expression is induced in macrophages by a high-fat diet load.

METHODS

Four-week-old mice were divided into normal diet (ND) and high-fat diet (HFD) groups and kept for four weeks. Macrophages were collected intraperitoneally from mice injected intraperitoneally with 2 mL of thioglycolic acid medium to promote macrophage proliferation one week before necropsy and cultured in Roswell Park Memorial Institute medium (RPMI) at 37°C in a 5% CO2 environment. After 2 hours of incubation in this environment, the floating cells were removed and the recovered macrophages were used for lipidomics, proteomics. In addition, RNA extracted from the macrophages was used for RNA sequencing analysis.

RESULTS

Lipidomics showed a marked increase in the proportion of TG (18:0_18:0_18:0) constituting oleic acid in macrophages in the high-fat diet. Proteomics identified more than 4000 proteins in each group. In the HFD group, compared to the ND group, decreased expression of proteins involved in phagocytosis, such as immunoglobulin and eosinophil peroxidase, was observed. In addition, RNA sequencing data analysis also showed a decrease in the expression levels of genes related to phagocytosis, which had been observed to decrease in proteomics.

CONCLUSIONS

From the above, the RESULTS show that a high-fat diet load not only alters the lipid composition within macrophages, but also alters gene and protein expression involved in various lipid metabolism and immune regulation. It was suggested that these changes in macrophage function may contribute to the development of infectious diseases and various disorders.

ADDITION OF EVOSORPTION ON WHEY PROTEIN PRODUCT INCREASE THE POST-PRANDIAL SERUM AMINO ACID

Lily Arsanti Lestari[1]; Christofora Hanny Wijaya[2]; Sri Raharjo[3]; Emy Huriyati[4]; Felisitas Mellania Ajeng Anggraeni[5]; Gisela Laras Anindiani[5]

[1]Nutrition and Health Department, Faculty of Medicine, Public Health and Nursing, Universitas Gadjah Mada, Yogyakarta, Indonesia; [2]Department of Food Science and Technology, Faculty of Agricultural Engineering and Technology, IPB University, Bogor, Indonesia; [3]Department of Food and Agricultural Product Technology, Faculty of Agricultural Technology, Universitas Gadjah Mada, Yogyakarta, Indonesia; [4]Nutrition and Health, Faculty of Medicine, Public Health and Nursing UGM, Yogyakarta, Indonesia; [5]Center for Food and Nutrition Studies, Universitas Gadjah Mada, Yogyakarta, Indonesia

BACKGROUND AND OBJECTIVES

A high-protein diet is needed for lean tissue-building. Some whey protein (WP) products suggest a high serving size of 50 g for WP. However, the amount of digested and absorbed WP may be limited due to a lack of endogenous digestive enzymes. The objective of this study was to evaluate the impact of Commercial Whey Protein (CWP) and Solid Food (SF) consumption compared to Evolene Whey Protein with the addition of Evosorption (EWPE) on postprandial amino acid levels, CRP, and nitrogen balance. Evosorption is a protease enzyme that contains 100,000 Units/g papain and 140 GDU/g bromelain.

METHODS

A single-blinded study was performed on healthy male subjects under fasting conditions. The study was carried out after approved by the Medical and Health Research Ethics Committee (MHREC), Universitas Gadjah Mada, Indonesia. The study involved nine healthy lean male subjects (age 20-36 years, BMI 20-24.9 kg/m2, and a normal CRP level <0.3 mg/L). All subjects were divided into three groups: EWPE, CWP, and SF from beef tenderloin. Each intervention product contains 50 grams of protein. Differences in protein absorption rate were determined by measuring serum postprandial amino acid levels. Urea levels in urine samples were used to determine total nitrogen. CRP levels were also measured.

RESULTS

The RESULTS showed that the %bioavailability of EWPE compared to SF shows significant differences ($p<0.05$) in each IAA. The EWPE group has a higher %bioavailability than the SF group, with the percentage increase varying among amino acids, ranging from 15% to 119%. The highest increase occurred in the amino acids threonine + glycine. The postprandial Branched Chain Amino Acids (BCAA) levels in the EWPE demonstrated a higher trend compared to the CWP and SF ($p<0.05$). The total AUC of all fourteen amino acids is considered the amino acid bioavailability of the EWPE, CWP, and the SF groups. The total TSAA AUC of the EWPE group was 22.4% higher than the CWP group ($p<0.05$). When compared to the SF group, the TSAA AUC of EWPE was 50.6% higher ($p<0.05$). The C-Reactive Protein (CRP) levels of EWPE group was not significantly different from the CWP and SF group ($p>0.05$), indicating that EWPE does not induce inflammation. The urinary nitrogen levels in the EWPE did not significantly differ compared to the CWP and SF ($p>0.05$).

CONCLUSIONS

The addition of Evosorption, a mixture of papain and bromelain, increased the bioavailability of WP. The EWPE has a higher bioavailability compared to CWP and SF from beef tenderloin, hence Evosorption can be added to WP to increase the digestion and absorption of WP.

LYSINE DEFICIENCY REDUCES HIPPOCAMPAL NEUROGENESIS AND IMPAIRS COGNITIVE-LIKE BEHAVIOR IN RATS

Rim Jaber[1]; Alaa El-Makkawi[1]; Batoul Darwish; Tamara Fahs[1]; Maram Chaaban[1]; Christina Mary Kouries[2]; Layal Jaafar[2]; Carla El-Mallah[2]; Wassim Abou-Kheir[1]; Omar Obeid[2]
[1]Anatomy, Cell Biology and Physiological Sciences, American University of Beirut, Beirut, Lebanon; [2]Nutrition and Food Sciences, American University of Beirut, Beirut, Lebanon

BACKGROUND AND OBJECTIVES
Increased consumption of cereal-based diets is known to reduce lysine availability. Previously, we demonstrated that lysine deficiency induced anxiety-like behavior in rats (1). However, its impact on hippocampal neurogenesis remains unclear. This study aimed to investigate the effects of lysine deficiency on hippocampal neurogenesis and its potential relationship with cognitive-like behavior in rats.

METHODS
Adult male Sprague-Dawley rats were randomized into three groups (n=8/group) and maintained on their respective diets for four weeks: a control group (adequate lysine) and two lysine-deficient groups (30% and 60% lysine-deficient diets). Neuro-proliferation and neuro-differentiation, early and late stages of neurogenesis, respectively, were assessed using Bromodeoxyuridine (BrdU) intraperitoneal injections. For proliferation, BrdU was administered 24 hours before euthanasia, while for neurogenesis, it was administered one month prior. Behavioral changes were evaluated biweekly using the Open Field Test (OFT) for spontaneous locomotion, Novel Object Recognition (NOR) for recognition memory, Y-maze for spatial memory, and Elevated Plus Maze (EPM) for anxiety-like behavior. Molecular analyses were performed post-experiment to evaluate neurogenesis activity, neurotrophic factor levels, and neurotransmitter receptor expression.

RESULTS
Behavioral assessments revealed that lysine deficiency significantly impaired spatial memory, novel object recognition, and exploratory behaviors, alongside increased anxiety-like behaviors. Both moderate and severe lysine-deficient diets significantly decreased neural stem cell proliferation and neurogenesis in the hippocampus. Molecular analysis showed reduced mRNA expression of neurotrophic factors and altered expression of neurotransmitter receptors in lysine-deficient rats

CONCLUSIONS
Moderate and severe lysine deficiency impaired hippocampal neurogenesis and cognitive-like behaviors in rats. These findings suggest that lysine deficiency may contribute to brain dysfunctions, with potential clinical implications for populations relying heavily on lysine-poor cereal diets.

IMPACT OF OBESITY ON DNA METHYLATION OF VITAMIN D PATHWAY GENES CYP2R1 AND VDR: A PILOT STUDY IN NORTHERN IRELAND

Kazi Lutfar Rahman[1]; Mary T. Mccann[1]; Mcknna Kevin[2]; Naimh Kearney[2]; Paul D. Thompson[1]
[1]Nutrition Innovation Centre for Food and Health (NICHE), Ulster University, Coleraine, United Kingdom; [2]Department of Dermatology, Belfast City Hospital, Belfast, United Kingdom

BACKGROUND AND OBJECTIVES
Background: Obesity is growing as a worldwide health epidemic, impacting a significant percentage of the population and resulting in millions of deaths each year. The rise in obesity rates is associated with perturbations within key metabolic pathways, influenced by both hereditary and epigenetic factors. This pilot study examines the correlation between obesity and DNA methylation patterns within genes pivotal to vitamin D status and response: CYP2R1 and VDR. **Objective:** The present study was undertaken to determine if body mass index (BMI) can serve a predictor for the regulation of these genes via changes in methylation, which could potentially impact vitamin D metabolism and inflammation.

METHODS
We examine DNA methylation by pyrosequencing at several CpG sites within the promoter and proximal enhancer regions of CYP2R1 and VDR genes using secondary blood samples from the MOVIT-D cohort (Maternal Obesity and baseline vitamin D insufficiency change the response to vitamin D supplementation: a double-blind, randomised trial in pregnant women), previously detailed by Alhomaid et al., 2021. From this cohort we selected consists of 65 women at 12th week of pregnancy; 34 having a normal BMI and 31 defined as obese.

RESULTS
Our research uncovered a correlation between obesity and increased levels of DNA methylation at locations within the VDR gene on chromosome 12, although the overall levels of methylation were low. We observed significant association between BMI and methylation at a cluster and two specific locations in the VDR gene. In addition, there is a correlation between higher methylation at a specific VDR site (Hg38-Chr12-47905640) and increased levels of TNF-α measured within cohort subjects.

CONCLUSIONS
The RESULTS suggest that alterations in the VDR gene due to BMI-related epigenetic modifications may contribute to inflammation and mediation of the vitamin D response. This sheds potential light on the molecular processes that link obesity, vitamin D insufficiency, and potential health consequences.

AMELIORATING EFFECTS OF VITAMIN K2 ON DEXTRAN SULFATE SODIUM-INDUCED ULCERATIVE COLITIS IN MICE

Shouna Hu[1]; Yan Ma[1]; Ke Xiong[1]; Aiguo Ma[1]
[1]School of Public Health, Qingdao university, Qingdao, China

BACKGROUND AND OBJECTIVES

Ulcerative colitis (UC) is a non-specific chronic inflammation of the gut, the pathogenesis of which is still unclear. Currently, there is no specific treatment for UC. Vitamin K (VK) deficiency is widespread in people with inflammatory bowel disease. Vitamin K (including Vitamin K1 and Vitamin K2) is a fat-soluble vitamin that helps to maintain the body's metabolism and health. Vitamin K2 (VK2) has higher biological activity than vitamin K1 (VK1). The roles of VK2 in inhibiting inflammation, oxidative stress, and suppressing immune response have been reported. The purpose of this study was to explore the alleviating effect of vitamin K2 (VK2) on UC, as well as its mechanism.

METHODS

C57BL/6J mice were given 3% DSS for seven days to establish UC, and they then received VK2 (15, 30, or 60 mg/kg·bw) and 5-aminosalicylic acid (100 mg/kg·bw) for two weeks. The clinical signs, body weights, colon lengths, and histological changes were recorded during the experiment. The serum MK-4/7, oxidative stress indexes, and inflammatory cytokines were analyzed. The expression of NF-κB pathway-related proteins and tight junction proteins was measured using western blot. The gut microbiota and short-chain fatty acids (SCFAs) were measured by 16S rRNA and targeted metabolomics.

RESULTS

According to the RESULTS, VK2 restored the colon lengths, improved the colonic histopathology, reduced the levels of proinflammatory cytokines (such as IL-1β, TNF-α, and IL-6), and boosted the level of the immunosuppressive cytokine IL-10 in the colon tissues of the colitis mice. Moreover, VK2 promoted the expression of mucin and tight junction proteins and significantly ameliorated the changes in NF-κB pathway-related proteins caused by DSS induction. Additionally, VK2 intervention had a significant ameliorative effect on intestinal flora alteration and increased the relative abundance of SCFA-producing bacteria, such as Eubacterium_ruminantium_group and Faecalibaculum.

CONCLUSIONS

In conclusion, VK2 alleviated the DSS-induced colitis in the mice, perhaps by boosting the dominant intestinal microflora, such as Faecalibaculum, by reducing intestinal microflora dysbiosis, and by modulating the expression of SCFAs, inflammatory factors, and intestinal barrier proteins.

INDIVIDUAL BRANCHED-CHAIN AMINO ACIDS DEFICIENCIES EXHIBIT DISTINCT EFFECT ON HEMATOLOGICAL PARAMETERS IN RATS

Layal Jaafar[1]; Nathalie Sous[1]; Hashem Shehade; Wassim Abou-Kheir[2]; Omar Obeid[1]
[1]Nutrition and Food Sciences, American University of Beirut, Beirut, Lebanon; [2]Anatomy, Cell Biology and Physiological Sciences, American University of Beirut, Beirut, Lebanon

BACKGROUND AND OBJECTIVES
Anemia, defined by low hemoglobin (Hb) levels, is a significant public health issue, particularly in low- and middle-income countries (LMICs), where diets are often of low protein quality and quantity. Recent findings showed a strong positive association between plasma levels of branched-chain amino acids (BCAAs); leucine (Leu), isoleucine (Ile), and valine (Val); and Hb [1]. However, the causal mechanism behind this observed correlation remains unclear. Notably, globin, the protein component of Hb, contains around 15% Leu and 10.6% Val, while ile is present in negligible amounts [2]. Accordingly, we aim to examine the effect of individual dietary BCAAs deficiency on hematological parameters in young male rats fed a low-protein diet.

METHODS
Four-week-old male Sprague Dawley rats were randomly divided into four groups based on their representative diets and monitored for six weeks (n=8/group). We utilized four different diets: an AA-defined low-protein diet (∼10 % of calories from protein, Low P) and three AA-defined low-individual BCAA diets (Low Leu, Low Val, Low Ile), in which the levels of leucine, valine, or isoleucine were reduced by 50% while maintaining ∼10% of calories from protein. At the end of the experiment, blood samples were collected from the superior vena cava for complete blood count (CBC) analysis.

RESULTS
The RESULTS showed no significant differences in Hb levels (p = 0.387) across the different dietary conditions. Despite no statistically significant difference (p=0.079), the lowest red blood cell (RBC) count was observed in the low-Val group (7.22 ± 0.40 million/cu.mm), indicating a trend towards reduced RBC levels compared to the other groups. Mean corpuscular volume (MCV) and mean corpuscular hemoglobin (MCH) were significantly higher in the individual BCAA deficiency groups, except for low-Leu, compared to the low-P group (p = 0.034 and p = 0.005, respectively). Furthermore, red cell distribution width (RDW) was markedly elevated in the low-Ile group (16.18 ± 0.56%) compared to all other groups (p = 0.026).

CONCLUSIONS
These data suggest that under a low-protein diet, individual BCAAs have distinct effects on hematological parameters. Further analysis is needed to clarify the exact causal mechanisms of these findings.

BACKGROUND AND OBJECTIVES
Phytosterols, which are abundant in soybeans, corn, rice bran, sesame seeds, etc., are a general term for the main sterols such as cholesterol and phytosterols, and their plant-derived components. Plant sterols are those with a different C-3 position in the steroid skeleton, and exist in the form of free sterols with a free hydroxyl group, sterol esters with an ester bond to a fatty acid, sterol glycosides, and acylated steryl β-glucosides (ASG) with an acyl group bonded to a sugar.
On the other hand, there have been few reports on the mechanisms by which plant sterols affect the accumulation of triglycerides in the body. Even in recent reviews of the functional characteristics of plant sterols, it has been shown that the mechanisms of action have not yet been fully elucidated. Therefore, the aim of this study was to investigate the effects of ASG, a highly purified plant sterol derivative, on lipid metabolism, including body fat and dyslipidemia, in obese mice fed a high-fat, high-sucrose diet (HFHSD).

METHODS
To investigate the mechanism of action of ASG on lipid metabolism, we compared the amount of body fat accumulation, plasma lipids, and gene expression in the liver of high-fat, high-sucrose diet-fed obese model mice and high-fat, high-sucrose diet-fed obese model mice that had been administered high-purity ASG for 55 days.

RESULTS
In the analysis of the mechanism, the lipid intake and the lipid excretion rate in the feces were the same in the HFHSD group and the ASG group, but the weight gain on day 55 of the ASG group was significantly lower (0.5% ASG: $P < 0.05$, 1.0% ASG: $P < 0.01$). Furthermore, plasma insulin, leptin and lipid concentrations were reduced, and adiponectin concentrations were increased in the ASG group. In addition, gene expression of adrenergic receptor β3 (ADRβ3), peroxisome proliferator-activated receptor α (PPARα), β-oxidation enzymes and uncoupling protein 3 (UCP3) was increased in the liver, and gene expression of fatty acid synthase (FAS) was decreased. Conversely, the amount of free fatty acids in the liver showed a significant positive correlation with the level of triglycerides, the weight of various adipose tissues, and FAS gene expression, but not with the intensity of β-oxidation-related gene expression.

CONCLUSIONS
These RESULTS suggest that ASG may reduce the accumulation of body fat by improving the secretion of adiponectin and increasing the β-oxidation of fatty acids in the liver, and suggest a possible anti-obesity mechanism of ASG.

DIRECT ANALYSIS OF ESTERIFIED DOCOSAHEXAENOIC ACID HYDROPEROXIDE ISOMERS IN BIOLOGICAL SYSTEMS WITH LIQUID CHROMATOGRAPHY-TANDEM MASS SPECTROMETRY

Ibuki Kusumoto[1]; Shunji Kato[1]; Kiyotaka Nakagawa[1]
[1]Graduate School of Agricultural Science, Tohoku University, Sendai, Miyagi, Japan

BACKGROUND AND OBJECTIVES

Docosahexaenoic acid (DHA), predominantly present in the brain, is crucial for brain function and health. Its high degree of unsaturation makes it highly susceptible to oxidation. In biological systems, lipids are oxidized either via non-enzymatic or enzymatic processes, producing different oxidation products (e.g., hydroperoxide). Oxidized lipid derivatives from the non-enzymatic process generally promote inflammation. In contrast, recent studies have identified numerous enzymatic oxidation products that function as lipid mediators, regulating inflammation in the body. Given the diverse implications and functionalities of oxidized lipids, understanding DHA oxidation pathways is essential for exploring the mechanisms behind DHA's physiological functions. To date, analytical challenges persist in directly analyzing DHA oxidation products in esterified forms, the major lipid pools in the brain. This study aimed to develop a liquid chromatography-mass spectrometry (LC-MS/MS) method for esterified DHA hydroperoxide (DHA;OOH) in biological systems.

METHODS

PC 16:0/22:6 was chosen as the target based on lipid composition in the whole brain (Igarashi *et al*, 2012). The target PC was prepared through esterification of DHA to 1-palmitoyl-lysophosphatidylcholine and subjected to photo-oxidation to obtain a hydroperoxide isomeric mixture. The multiple reaction monitoring conditions were optimized for each isomer with the prepared isomeric mixture. Optimized LC-MS/MS methods were applied to the phospholipid extract of the whole brain from a Sprague Dawley rat.

RESULTS

The product ion scan of sodium adduct of PC 16:0/22:6;OOH revealed products generated through the fragmentation near the OOH group, thereby allowing determination of OOH group position, as previously observed with free DHA;OOH (Kato *et al*, 2021). The LC-MS/MS chromatogram of the phospholipid fraction of the rat whole brain exhibited several isomer peaks, which included those generated via enzymatic and/or non-enzymatic processes (Derogis *et al*, 2013). Further refinement of the lipid extraction method is currently underway to enhance the sensitivity of the LC-MS/MS method.

CONCLUSIONS

The constructed LC-MS/MS method demonstrated potential applicability in exploring DHA oxidation processes in biological systems, possibly providing a closer understanding of DHA oxidation in the body.

EVALUATION OF AN ALTERNATIVE DIRECT AMINO ACID OXIDATION METHOD TO ESTIMATE THE TOLERABLE UPPER INTAKE LEVEL OF PROTEIN IN RATS

Aki Ogawa[1]; Yasuhiro Kido[2]
[1]Faculty of Clinical Nutrition and Dietetics, Kōnan Women's University, Kobe, Japan; [2]Faculty of Nutrition, Kanazawa Gakuin University, kanazawa, Japan

BACKGROUND AND OBJECTIVES
The use of protein supplements has become popular recently, but research is required on the health effects of excessive protein intake. The tolerable upper intake level of protein has not been established by the WHO/FAO/UNU (2007). The conventional method to measure the protein metabolism uses changes in expiratory 13CO2 levels after the oral administration of 13C-labelled amino acid. The present study was conducted to evaluate the tolerable upper intake level of protein in rats employing a direct amino acid oxidation (DAAO) technique using l-[1-13C]phenylalanine.

METHODS
Male rats (7-weeks old) were housed under controlled lighting conditions and fasted overnight. On the study day, in random order without repeats, eight rats received one of 4 levels of the casein diet (40, 50, 60, 70%), which contained 10% l-[1-13C]phenylalanine of the phenylalanine. The diet was consumed beginning at 09:00 and continued at 1-hour intervals until 18:00 for a total of 10 meals. Each meal accounted for 1/12 of the rats' total daily intake. Breath samples were collected, and the 13CO2 level in the breath was measured at 1-hour intervals from 09:00 to 19:00.

RESULTS
In all rats fed the 40~70% casein diets containing l-[1-13C]phenylalanine, the exhaled 13CO2 concentrations increased gradually until 16:00 and remained constant until 19:00. Although the 13CO2 in rats fed 40, 50 or 60% casein diets increased according to the increased protein intakes, the 13CO2 in the rats fed the 70% casein diet were similar to those of rats fed the 60% casein diet. As the protein intake increased, blood and urinary urea nitrogen increased steadily.

CONCLUSIONS
The RESULTS showed that the tolerable upper intake level of protein in rats was about a 60~70% casein diet, suggesting that the tolerable upper intake level of protein could be estimated using the alternative DAAO method.

THE NUTRIENT CONTENT, ANTIOXIDANT ACTIVITY, AND ORGANOLEPTIC PROPERTIES OF GELATO WITH THE ADDITION ON RED CABBAGE (BRASSICA OLERACEA L.) POWDER

Lily Arsanti Lestari[1]; Alya Safhira[2]; Ammar Muwahhid[2]
[1]Nutrition and Health Department, Faculty of Medicine, Public Health and Nursing, Universitas Gadjah Mada, Yogyakarta, Indonesia; [2]Nutrition and Health, Faculty of Medicine, Public Health and Nursing UGM, Yogyakarta, Indonesia

BACKGROUND AND OBJECTIVES
Recently, gelato become a very popular dessert in Indonesia. To improve the nutrient content and bioactive compounds in gelato, red cabbage (*Brassica oleracea* L.) powder is added. The objectives of this study were to evaluate the nutrient and anthocyanin content, antioxidant activity as well as organoleptic properties of gelato with the addition of red cabbage powder.

METHODS
As many as four levels of red cabbage addition namely 0%, 2%, 4%, and 6% was performed. The red cabbage powder was prepared with slicing 5-7 cm of red cabbage, the dried with food dehydrator at 55 oC for 20 hours, grinded and sieved with 80-mesh sieves. The gelato was made from UHT full cream milk, added with egg yolk, sugar powder, and guar gum as stabilizer. The mixture was then pasteurized at 80-85 oC for 30 seconds, cooled until 55 oC, added with red cabbage, cooled at 4 oC for 24 hours, agitated with ice cream maker for 25-30 minutes, kept at -14 until -18 oC until analysis. The moisture, ash, protein, fat, and crude fiber content was determined using AOAC method. The carbohydrate content was determined by difference. The anthocyanin content was determined with spectrophotometry method, while antioxidants activity was determined with DPPH (2,2-di(4-ert-octylphenyl)-1-picrylhydrazyl) colorimetry method. The organoleptic properties namely of colour, aroma, taste, and overall was determined using hedonic test.

RESULTS
The RESULTS showed that adding red cabbage powder to the gelato resulted in differences in moisture, ash, fat, crude fiber, anthocyanin content, and antioxidant activity, whereas the protein and carbohydrate content did not significantly differ. The hedonic test showed that the addition of red cabbage powder had a significant difference in the level of preference for organoleptic properties in color, aroma, taste, and overall parameters. The selected gelato product had good acceptability because 97% of panelists consumed the product more than 75% of serving size.

CONCLUSIONS
The addition of red cabbage to gelato affects the nutrient and anthocyanin content as well as antioxidant activity. Furthermore, it has good acceptability, so it can be consumed as a functional food rich in antioxidants.

QUANTITATIVE ANALYSIS OF SPHINGOLIPIDS IN FOOD INGREDIENTS FOR ESTIMATION OF AVERAGE INDIVIDUAL INTAKE

Tatsuya Sugawara[1]; Haruka Ogasawara[1]; Yuki Manabe[1]
[1]Graduate School of Agriculture, Kyoto University, Kyoto, Japan

BACKGROUND AND OBJECTIVES

Sphingolipids are a family of compounds that have a sphingoid base (long-chain base) with an amide-linked fatty acid and a polar head group, such as phosphorylcholine (for sphingomyelin) or carbohydrate (for cerebrosides, gangliosides, and other complex glycolipids), and are ubiquitous in a variety of food ingredients. Recent emerging evidence has implicated dietary sphingolipids in human health. On the other hand, highly polar sphingolipids (GIPCs) with complex sugar chain are present in higher plants, but are difficult to quantify and are not well known as food components. In this study, we attempted a comprehensive quantification of sphingolipids in foods by quantitative compositional analysis of the constituent sphingoid bases.

METHODS

Food materials derived from agricultural, livestock, and marine products were used as samples. The lyophilized samples were acid hydrolyzed directly, or fractionated into Folch's upper layer (including intermediate layer) and lower layer, and then acid hydrolyzed. The resulting sphingoid bases were fluorescently derivatized by an ortho-phthalaldehyde reagent and then quantitatively analyzed by HPLC with a fluorescence detector.

RESULTS

Based on the quantitative values obtained in this study, the sphingolipid contents in food ingredients were estimated. Compared to animal and fishery products, a considerable amount of highly polar sphingolipids was contained in agricultural products (10-85% of total sphingolipids), with trihydroxy types as the major sphingoid bases. Based on our RESULTS, it was newly estimated that each Japanese person consumes approximately 100 mg of highly polar sphingolipids per day, in addition to approximately 90 mg of general fat-soluble sphingolipids such as glucosylceramide and sphingomyelin.

CONCLUSIONS

In this study, quantitative analysis of sphingoid bases as degradation products of sphingolipids indicated that highly polar sphingolipids are daily consumed almost as much or more than regular simple fat-soluble sphingolipids.

UROLITHIN A IMPROVES VASCULAR ENDOTHELIAL FUNCTION BY INHIBITING ENDOTHELIN-1 PRODUCTION AND INCREASING ANTIOXIDANT ENZYME EXPRESSION

Yoshimi Kishimoto[1]; Masatake Kudoh[2]; Akiko Kohara[3]; Yuichi Ukawa[3]
[1]Department of Food Science and Human Nutrition, Setsunan University, Osaka, Japan; [2]Healthcare SBU, DAICEL CORPORATION, Niigata, Japan; [3]Healthcare SBU, DAICEL CORPORATION, Tokyo, Japan

BACKGROUND AND OBJECTIVES
Urolithins are microbiota-derived metabolites produced from ellagic acid present in certain foods, such as pomegranates, berries, and walnuts. We recently reported that Urolithin A (UA) intake tended to improve flow-mediated vasodilatation (FMD) score in non-UA producers. In this study, we investigated the effects of UA on vascular endothelial function, focusing on the anti-inflammatory and antioxidant mechanism.

METHODS
Human umbilical vein endothelial cells (HUVECs) were pre-treated with UA (~10 μM) for 24 h and then stimulated with TNF-α. The mRNA and protein analysis were performed by real time PCR and western blotting, respectively. Cell viability was evaluated by MTT assay.

RESULTS
UA significantly suppressed endothelin-1 (ET-1) mRNA expression and secreted protein levels, which were increased by TNF-α. UA also suppressed the mRNA expression of endothelin converting enzyme 1 (ECE1). Increased expressions of mRNA of inflammatory cytokines/chemokines (IL-6, IL-8 and MCP-1) by TNF-α were significantly suppressed by UA. Furthermore, UA significantly increased the mRNA expression of antioxidant enzymes, such as heme oxygenase 1 (HO-1), NAD(P)H quinone dehydrogenase 1 (NQO-1), and glutamate-cysteine ligase modifier subunit (GCLM). We found that UA stimulated Nrf2 translocation to the nucleus. In addition, pretreatment with UA significantly suppressed the decrease in cell viability caused by hydrogen peroxide.

CONCLUSIONS
These data suggest that UA inhibits the production of endothelin-1 and induces the expression of antioxidant enzymes, which may exert a protective effect against oxidative stress injury and contribute to improved vascular endothelial function.

GALACTO-OLIGOSACCHARIDES AMELIORATES THE DYSBIOSIS OF GUT MICROBIOTA AND ENHANCES RENAL URATE EXCRETION TO ALLEVIATE HYPERURICEMIA

Zhu Jiangyuan[1]; Xu Yingxi[2]; Yang Jialu[1]; Xia Min[2]; Liu Yan[2]
[1]school of public health, Sun Yat-sen University, Guang Zhou, China; [2]School of Public Health, Sun Yat-sen University, GuangZhou, China

BACKGROUND AND OBJECTIVES
Hyperuricemia (HUA) has become the second most common metabolic disease globally. In addition to gout, HUA has also been linked to the development of inflammatory arthritis, renal and cardiovascular diseases, posing a major threat to all societies. Recently, a growing body of evidence suggests that dysbiosis of gut microbiota plays an important role in the pathogenesis of HUA. Galacto-oligosaccharides (GOS) is a non-digestible carbohydrate, which has extensively demonstrated beneficial impact on intestinal health. However, its role in HUA remains unclear.

METHODS
Eight-week male mice on C57BL/6J background were fed with diet supplemented with 2% uric acid and 4% oxonic acid to induce HUA. 16s RNA sequencing was employed to examine the alterations of gut microbiota and mouse adeno-associated virus 9 delivery system was used to renal targeted knock down ABCG2 *in vivo*.

RESULTS
Gavage of GOS enhanced renal urate excretion by 75%, leading to 50% reduction in serum uric acid. Though no obvious difference in microbial diversity was observed, GOS treatment resulted in a notable increase in *Bacteroidia* but a remarkable reduction in *Gannaproteobacteria*. Moreover, mice receiving fecal microbial transplantation from donors fed with GOS demonstrated a 1.5-fold increase in fractional excretion of urate. Consistently, recombinant ATP binding cassette transporter G2 (ABCG2) in the kidney, a major transporter for urate, was found to be 1.8-fold higher at both transcriptional and protein levels in mice treated with GOS. Similarly, PDZ domain-containing 1 (PDZK1), a scaffold protein that bound to ABCG2 and mediated its subcellular localization was found to be 1.0-fold higher after GOS gavage. Notably, kidney-specific inhibition of ABCG2 largely abolished the uric acid-lowering effect of GOS. Mechanistically, GOS treatment suppressed the translocation of NF-κB to nucleus and led to a 30% reduction in the excretion of pro-inflammatory IL-1β, which in turn boosted kidney urate secretion.

CONCLUSIONS
Our findings indicated that GOS promoted kidney urate excretion and offered an alternative strategy for the prevention and treatment of HUA.

DELAYING THE ONSET OF DIABETES-RELATED SYMPTOMS BY 1,5-ANHYDRO-D-GLUCITOL THROUGH DISACCHARIDASE INHIBITION IN KKAY MICE

Kenichi Tanabe[1]; Sadako Nakamura[2]; Toshiyuki Nakayama[3]; Kazuhiro Yoshinaga[4]; Tsuneyuki Oku[2]
[1]Nutrition science, Nakamura Gakuen University, Fukuoka, Japan; [2]Food Science, Jumonji university, Saitama, Japan; [3]Anatomy, Hospital of University of Occupational and Environmental Health, Kitakyushu, Japan; [4]Food Science, SUNUS CO., LTD, Kagoshima, Japan

BACKGROUND AND OBJECTIVES
1,5-Anhydro-D-glucitol (1,5-AG) is a hexose polyol that is made from 1,5-anhydro-D-fructose (1,5-AF). Monosaccharides such as D-sorbose and L-arabinose strongly inhibit the activity of sucrase and maltase in the small intestine. Therefore, 1,5-AG also may be a candidate related for inhibition of disaccharidases. We investigated the inhibition to disaccharidases in rat intestine, and the delaying effect of feeding of 1,5-AG on the onset of diabetes through the antioxidant effect.

METHODS
Synthetic 1,5-AG (purity > 99 %) was provided by SUNUS Co., Ltd. (formerly Nihondenpun Kogyo, Co., Ltd., Kagoshima, Japan). The analysis of the hydrolyzing activity on disaccharides from rats was carried out following Oku's method using glucose oxidase. KKAy mice raised with AIN93G (control), 3% or 6% 1,5-AG and 6% erythritol (ERT, positive control) diet for 7 weeks.

RESULTS
1,5-AG inhibited about 50 % of sucrase and 30 % of maltase activity in rat small intestine. 1,5-AG strongly inhibited trehalase and lactase. Urinary glucose excretion in 6% 1,5-AG at 4, 6 weeks and that in 6% ERT at 4, 6, 7 weeks were significantly lower than that in control, respectively ($p<0.05$). After 7 weeks 8-hydroxy-2'-deoxyguanosine in urine, fasting plasma glucose, insulin, total cholesterol and triacylglycerol in 6% 1,5-AG were significantly lower than those in control ($p<0.05$), respectively.

CONCLUSIONS
These RESULTS demonstrate that the 1,5-AG may be useful a food ingredient which has antidiabetic effect. However, more research is required in terms of its mechanism of action in relation to its delaying effect on the onset of diabetes and antioxidant properties.

EFFECTS OF VITAMIN C DEFICIENCY AND REFEEDING ON ANXIETY-LIKE BEHAVIOR AND NEUROINFLAMMATION IN ODS RATS

Karin Masuda[1]; Akihito Ishigami[2]; Ayami Sato,[2]; Yoshitaka Kondo[2]; Asako Takenaka[3]
[1]Graduate School of Agriculture, Meiji University, Kanagawa, Japan; [2]Molecular Regulation of Aging, Tokyo Metropolitan Institute for Geriatrics and Gerontology, Tokyo, Japan; [3]School of Agriculture, Meiji University, Kawasaki, Japan

BACKGROUND AND OBJECTIVES
Vitamin C (VC) deficiency may increase anxiety-like behavior via oxidative stress in the brain. This study investigated the relationship between VC deficiency, anxiety-like behavior, and neuroinflammation, as well as the effects of VC refeeding, using ODS (ODS/ShiJcl od/od) rats, which lack the ability to synthesize VC.

METHODS
Five-week-old male ODS rats were fed either a VC-sufficient diet (0.3 g/100 g) or a VC-deficient diet. Half were used for anxiety behavior analysis and then dissected (C+ group, C- group). The remaining rats were provided with VC-supplemented water (2 g/L), maintained, and analyzed after behavior tests (C+/+ group, C-/+ group). Experiment 1 involved 17 days of VC deficiency followed by 9 days of supplementation, while Experiment 2 included 26 days of deficiency followed by 14 days of supplementation. Anxiety behavior was assessed using elevated plus maze (EPM) and open field (OF) tests. VC deficiency levels were evaluated through VC concentrations in tissues and plasma and hepatic Cytokine-induced neutrophil chemoattractant-1 (CINC-1) mRNA levels. Neuroinflammation and neuronal effects were assessed using hippocampal Interleukin-6 (IL-6) and Brain-derived neurotrophic factor (BDNF) mRNA levels.

RESULTS
In Experiment 1, OF tests showed significantly increased anxiety-like behavior in the C- group compared to the C+ group, restored to C+/+ levels in the C-/+ group. CINC-1 and IL-6 mRNA levels increased, while tissue and blood VC concentrations decreased in the C- group, all recovering to C+/+ levels in the C-/+ group.In Experiment 2, prolonged VC deficiency caused motor activity loss in EPM and OF tests in the C- group. Anxiety-like behavior in the C-/+ group remained higher than in the C+/+ group. CINC-1 and IL-6 mRNA increased, while tissue and plasma VC concentrations and BDNF mRNA decreased in the C- group, all recovering in the C-/+ group.

CONCLUSIONS
VC deficiency-induced anxiety-like behavior, reduced motor activity, and neuroinflammation were restored by VC refeeding. Severe VC deficiency increased neuroinflammation and reduced BDNF expression, both reversible with VC reintroduction. However, anxiety-like behavior caused by severe VC deficiency did not fully recover, even after refeeding.

CONFLICTS OF INTERESTS

METABOLISM OF SINENSETIN, A CITRUS PEEL COMPONENT, BY RAT AND GUINEA PIG LIVER MICROSOMES

Chiho Ohta[1]; Kana Sugimura[1]; Moe Kugimaru[1]; Nobuyuki Koga[1]
[1]Department of Nutritional Sciences, Nakamura Gakuen University, Fukuoka, Japan

BACKGROUND AND OBJECTIVES

Sinensetin (SNT) is a type of polymethoxyflavones (PMFs) distributed in citrus peel, and has attracted attention because it exhibits anti-cancer, anti-dementia and anti-inflammatory effects.1) It is important to clarify whether these effects currently are due to the parent compound or a metabolite. Recently, it has been reported that 5-demethylated (5-OH) PMFs derived from citrus peels have anti-cancer effects stronger than their parent compounds.2) Therefore, the metabolism of SNT was investigated using rat and guinea pig liver microsomes (Ms) and the effects of typical cytochrome P450 (CYP) inducers, phenobarbital (PB), 3-methylcholanthrene (MC) and dexamethazone (DEX) were also examined.

METHODS

Metabolic activity: SNT was incubated for 20 min at 37°C with animal liver Ms, NADPH-generating system, MgCl2, HEPES buffer (pH 7.4) under aerobic condition. Rat and guinea pig liver Ms were prepared from untreated (Con), PB-, MC- and DEX-treated animals. After incubation, an ice-cold methanol was added to stop the reaction and the incubation mixture was centrifuged to remove the denatured protein. The supernatants obtained were applied to reverse phase HPLC and LC-MS for analyses of the metabolites. Synthesis of metabolites: Three mono-demethylated SNT, 5-, 3'- and 4'-OH-SNT, were synthesized. 6-OH-SNT was estimated to be the other mono-demethylated form.

RESULTS

In rats: Con-Ms oxidized SNT to give six metabolites. Among them, M4, M3 and BM2 were major metabolites. LC-MS showed that M3 was a 1:1 mixture of 4'- and 3'-OH-SNT, and that BM2 was consistent with 5-OH-SNT. Also, M4 was presumed to be 6-OH-SNT. The product activities of 6-, 3'-, 4'- and 5-OH-SNT were 1.0, 0.4, 0.3 and 0.2 nmol/min/mg protein, respectively. PB-Ms increased 6-, 3'- and 5-OH-SNT 1.4- to 3-fold of Con-Ms. MC-Ms increased 3'- and 4'-OH-SNT 4-fold of Con-Ms. DEX-Ms also increased 6- and 5-OH-SNT 2-fold of Con-Ms. In guinea pigs: Con-Ms mainly produced 4'- and 6-OH-SNT at a rate of 1.0 and 0.6 nmol/min/mg protein, respectively. PB-Ms increased 6- and 5-OH-SNT, and MC-Ms significantly increased 4'-OH-SNT compared to Con-Ms. In contrast, DEX-Ms reduced 4'-OH-SNT to 58% of Con-Ms.

CONCLUSIONS

These RESULTS suggest that SNT metabolism Ms proceeds mainly via oxidative demethylation in rat and guinea pig liver, that DEX-inducible CYP3A and MC-inducible CYP1A enzymes were involved in the demethylation of A ring and B ring, respectively, and that PB-inducible CYP2B enzymes were involved in the demethylation of both A and B ring.

CONFLICTS OF INTERESTS

LIVER-SPLEEN AXIS IN GAN DIET-INDUCED MASH MODEL MICE

Yoshiko Yasuhara[1]; Yurika Tsuchiya[2]; Mika Kittaka[2]; Ken-Ichi Kobayashi[2]
[1]Department of Food and Nutrition, Notre Dame Seishin University, Okayama, Japan; [2]Notre Dame Seishin University, Department of Food and Nutrition, okayama, Japan

BACKGROUND AND OBJECTIVES

Nicotinamide adenine dinucleotide (NAD) is a redox coenzyme that is ubiquitously present in living organisms. In recent years, metabolic dysfunction associated steatohepatitis (MASH) induced by obesity has become a global problem, especially in developed countries. Against this background, a “Liver-Spleen axis" of MASH has been propounded, in which MASH affects not only the liver but also the splenic tissue in a linked manner, although the details of this linkage are often unclear.
We have previously found that gene expression related to NAD metabolism was reduced across the board in the liver of MASH model mice fed a Gubra Amylin NASH (GAN) diet for 14, 26, and 55 weeks. However, the effect of GAN diet intake on liver-spleen interaction remains unknown. In this study, we used obese MASH model mice to investigate the effect of diet intake on NAD metabolism in the liver and spleen.

METHODS

Seven-week-old male C57BL/6J mice were fed a GAN diet (high fat, high cholesterol, high fructose) for the GAN group and a control diet (10 kcal% fat) for the control group for 14, 26, and 55 weeks, respectively. Using the liver and spleen tissues obtained from these animals, the gene expression levels of each enzyme of NAD metabolism and inflammation/fibrosis-related factors were analyzed by quantitative PCR.

RESULTS

The RESULTS of measuring and comparing NAD metabolic enzyme gene expression levels in the liver using quantitative PCR showed that the expression levels of almost all NAD metabolic enzyme genes were lower in the groups that had been fed GAN feed for 14, 26, and 55 weeks compared to the control group. On the other hand, in the spleen, it was shown that the expression of most NAD metabolic enzyme genes was either lowered or unchanged. Interestingly, gene expression of IL-1b, TNF-a and MCP-1 was predominantly increased in the liver, whereas it was decreased in the spleen in the group fed the GAN diet for 26 weeks.

CONCLUSIONS

These findings suggest that NAD metabolism in obesity-induced MASH may be lower across the board in the liver, but lower or unchanged in the spleen. As for inflammation-related factors, the RESULTS suggest that there may be a relative relationship between gene expression variation in liver-derived and spleen-derived factors.

VITAMIN D DEFICIENCY INDUCES COGNITIVE IMPAIRMENT BY REGULATING SUMOYLATION MODIFICATION OF CYP27A1

Wang Tao[1]; Wang Lijing[1]; Feng Wenjing[1]; Guo Zhiting[1]; Yang Kexin[1]; Yu Huanling[1]; Rong Xiao[1]
[1]Department of Nutrition and Food Hygiene, Capital Medical University, Beijing, China

BACKGROUND AND OBJECTIVES
Our previous study has found that vitamin D (VD) deficiency plays an important role in the pathological progression of mild cognitive impairment (MCI). 27-hydroxycholesterol (27-OHC), one of the most abundant cholesterol-oxidized metabolites, is also a widely recognized risk factor for MCI. 27-OHC is synthesized by CYP27A1, which is a crucial enzyme in both oxysterols and VD metabolism. This study aims to explore whether VD deficiency induce cognitive decline by regulating CYP27A1 and its possible mechanism.

METHODS
Here, male C57BL/6J mice were fed a VD-deficient diet for 13 weeks to establish the VD-deficient (VDD) mice model. CYP27A1-short-hairpin RNA (CYP27A1-shRNA) and 2-D08 were used to inhibit the CYP27A1 expression and SUMOylation, respectively. Then, the neurobehavioral performance and brain pathological changes were evaluated. The gene and protein expression levels of SUMOylation related factors (SUMO1, Ubc9) in the brain were determined by qRT-PCR and western blot. The interaction between CYP27A1 and SUMO1 protein was assessed with Co-immunoprecipitation (Co-IP) and immunofluorescence.

RESULTS
Our RESULTS showed that the serum level of 25(OH)D in the VDD group was significantly decreased when compared with the Control group and lower than 20 ng/mL, indicating a successful modeling of VDD mice. The levels of 27-OHC in both serum and brain in the 27-OHC-treated group were remarkably higher than that of the Control mice; and the levels of which in VDD+27-OHC group were higher than that in the single treatment of VDD or 27-OHC. The learning and memory performance, as well as the Aβ deposition and brain histopathological lesions also support this phenotype. However, by using CYP27A1-shRNA, the VDD mice showed decreased serum 27-OHC level. As for the SUMOylation related factors, upregulated expression of SUMO1 gene, and Ubc9 gene and protein were observed in VDD and 27-OHC group. Moreover, significant co-localization of CYP27A1 and SUMO1 in the brain was found, and the Co-IP RESULTS showed that there was interaction between the two proteins. But by inhibiting the SUMOylation, the VDD mice showed the opposite RESULTS.

CONCLUSIONS
This study suggests that VD deficiency induces learning and memory decline by regulating CYP27A1, increasing 27-OHC load in the circulation and brain, exacerbating brain pathological injury and Aβ deposition. The SUMOylation modification of CYP27A1 might be a critical mechanism by which VD deficiency modulates cognitive impairment, but its molecular targets and modification sites are worthy of further investigation.

EFFECTS OF GUBRA AMYLIN NASH (GAN) INDUCED OBESITY ON THE DEVELOPMENT OF NON-ALCOHOLIC FATTY PANCREATIC DISEASE (NAFPD) AND PANCREATIC NAD METABOLISM

Mika Kittaka[1]; Mayuka Takahashi[2]; Yoshiko Yasuhara[3]; Ken-Ichi Kobayashi[3]
[1]Graduate School of Human Life Sciences, Notre Dame Seishin University, Okayama, Japan; [2]Health and Nutrition, Sanyo Gakuen College, Okayama, Japan; [3]Department of Food and Nutrition, Notre Dame Seishin University, Okayama, Japan

BACKGROUND AND OBJECTIVES
Metabolic dysfunction associated steatotic liver disease (MASLD), previously called non-alcoholic fatty liver disease (NAFLD), has recently gained attention as a major global health problem. Recently, non-alcoholic fatty liver disease (NAFLD) caused by obesity has become a worldwide problem. Recently, a pathology similar to NAFLD has been shown to occur in the pancreas and is referred to as non-alcoholic fatty pancreatic disease (NAFPD). NAFPD is gaining attention with the increasing number of pancreatic cancer patients, but its pathogenetic mechanism is still an enigma.Recently, it has been shown that a pathogenesis similar to NAFLD occurs in the pancreas, and the concept of non-alcoholic fatty pancreatic disease (NAFPD) has been attracting attention, but there are many unknowns. On the other hand, nicotinamide adenine dinucleotide (NAD) is a major redox cofactor and plays important roles in various aspects of metabolism, inflammation and aging. In this study, we aimed to clarify the effects of obesity on the development of NAFPD and on pancreatic NAD metabolism using GAN-induced obesity model mice.

METHODS
Seven-week-old male C57BL/6J mice were fed a Gubra Amylin NASH (GAN) diet containing high fat (40%), high fructose (22%) and high cholesterol (2%) ,samples for 14 weeks (GAN-14), 26 weeks (GAN-26) or 55 weeks (GAN-55). SerumSera from these samples were used for biochemical analysis of aAmylase. For pancreas, Hematoxylin-eosin (HE) and Sirius Red staining was performed on paraffin sections of the pancreas. Aand gene expression levels of fibrosis-related factors, enzymes of NAD biosynthesismetabolic enzyme were examined by gene expression levels quantitative PCR was performed.

RESULTS
GAN-14 and GAN-55 showed a significant increase in Col1a1 gene expression in the pancreas, while GAN-26 showed a significant increase in α-SMA gene expression. In addition, positive Sirius Red staining was observed in all groups. In addition, GAN-55 showed areas of inflammation on HE staining. Thus, it was concluded that pancreatic fibrosis had occurred and progressed in all groups. The expression levels of NAD metabolism-related enzyme genes in GAN-14 and GAN-55 were increased, while there was no overall change in the GAN-26.

CONCLUSIONS
These RESULTS indicate that not only NAFLD but also NAFPD develops and progresses due to GAN-induced obesity, and that NAFLD and NAFPD have different patterns of NAD metabolic changes.

IDENTIFICATION OF RECEPTORS INVOLVED IN THE PROCESS OF QUINOLINIC ACID-INDUCED RENAL FIBROSIS

Mamiko Ishikawa[1]; Yoshiko Yasuhara[2]; Shin-Ichi Fukuoka[3]; Ken-Ichi Kobayashi[2]
[1]Graduate School of Human Life Sciences, Notre Dame Seishin University, Okayama, Japan; [2]Department of Food and Nutrition, Notre Dame Seishin University, Okayama, Japan; [3]School of Cultural and Creative Studies, Aoyama Gakuin University, Tokyo, Japan

BACKGROUND AND OBJECTIVES
Recently, the rapid increase in the number of patients with chronic kidney disease (CKD) has led to an increase in the number of dialysis and kidney transplants, which in turn has put pressure on the government financial. Therefore, although it is important to understand the pathogenesis of renal fibrosis, many details remain unclear. Quinolinic acid (QA), an intermediate metabolite of tryptophan, is neurotoxin and uremic toxin. We have shown that QA may be an inducer of renal fibrosis using QPRT knockout mice. However, the detailed mechanisms, in particular the receptive mechanisms of QA in renal tissue, are unknown. Therefore, the present study aimed to identify QA receptors in the kidney.

METHODS
We focused on three QA receptor candidates, aryl hydrocarbon receptor (AhR), receptor for advanced glycation end product (RAGE) and *N*-methyl-*D*-aspartate (NMDA) receptor. The following studies were performed using renal tissue from QPRT knockout mice and human kidney-2 (HK-2) cells. Using renal tissue of QPRT knockout mice (Homo and WT) and human kidney-2 (HK-2) cells, quantitative PCR for above target gene of receptors was performed. And immunohistology analysis (IHC) using antibodies of above target gene of receptors was performed from animal renal tissue.

RESULTS
As a result of real-time PCR, renal tissue of mice (14-week-old), gene expression level of NR2C was significant increase in Homo relative to the WT. In 60-week-old, there was a significant decrease in NR2C, 3A, and RAGE gene expression of Homo compared to WT. IHC of renal tissue showed that NR1 and 2A were markedly decreased in the distal tubules of Homo of 60-week-old, and markedly positive images in the distal and proximal tubules of Homo of 14-week-old. And, there was a significant decrease in AhR and its target genes, RAGE, NR1, NR2B, NR2C, and NR2D in HK-2 cells treated with QA.

CONCLUSIONS
These RESULTS suggested that these changes in the expression and localization of NMDA receptors may be associated with QA inducible renal fibrogenesis. In HK-2 cells, gene expression of almost all receptors was decreased in a concentration-dependent manner, suggesting that QA may involve three receptors in human proximal tubular cells. Therefore, we concluded that renal injury may be caused by a novel mechanism other than the known mechanism of urotoxic-induced renal injury.

HYPOPHYSECTOMY ABOLISHES SEX DIFFERENCES AND PROTEIN DEFICIENCY-INDUCED INCREASE IN HEPATIC VLDLR IN MICE

Jiuxiang Cao[1]; Asako Takenaka[2]
[1]Graduate School of Agriculture, Meiji University, Kawasaki, Japan; [2]School of Agriculture, Meiji University, Kawasaki, Japan

BACKGROUND AND OBJECTIVES
The very-low-density lipoprotein receptor (VLDLR) facilitates the uptake of VLDL and its increased expression in the liver has been implicated in hepatic fat accumulation. Previously, we reported that protein deficiency elevates hepatic VLDLR mRNA and protein levels, with female mice showing higher VLDLR expression than males. It is known that protein deficiency induces growth hormone (GH) resistance, and that GH secretion patterns regulate sex-specific gene expression. Additionally, the GH signaling factor STAT5 suppresses VLDLR expression. This study aimed to investigate whether changes in VLDLR expression due to protein deficiency and sex differences are caused by GH.

METHODS
Seven-week-old male and female C57BL/6J mice (10 per group) underwent either hypophysectomy or a sham operation. They were then fed either a control diet containing 20% casein or a low-protein diet with 1% casein for 16 days. Hepatic VLDLR mRNA and protein levels were measured, along with fibroblast growth factor 21 (FGF21) mRNA, a hormone that responds to protein deficiency and regulates lipid metabolism. Serum and hepatic triglyceride (TG) levels were also evaluated.

RESULTS
In sham-operated mice, hepatic VLDLR mRNA and protein levels increased on a low-protein diet, but in hypophysectomized mice, this increase in VLDLR protein was abolished and VLDLR mRNA levels were decreased. In the control diet group, females exhibited higher VLDLR mRNA and protein levels than males, a sex difference that was eliminated by hypophysectomy. Additionally, FGF21 mRNA levels and hepatic TG levels showed sex-specific differences and increased in response to protein deficiency, but these changes were also abolished by hypophysectomy.

CONCLUSIONS
The protein deficiency-induced increase in hepatic VLDLR levels and the sex differences were abolished after hypophysectomy, suggesting that these changes are regulated by GH. Likewise, the changes in hepatic lipids and FGF21 mRNA levels caused by protein deficiency and sex differences were eliminated by hypophysectomy, indicating that GH may also play a key role in regulating these lipid metabolism-related alterations.

THE PROTECTIVE EFFECT OF QUERCETIN ON OXIDATIVE DAMAGE TO PC12 CELL

Hung-Chang Hung[1]; Cheng-yang Hsieh[2]; Po-Wei Tsai[3]; Shu Ming Huang[4]
[1]Internal Medicine, Nantou Hospital Ministry of Health and Welfare, Nantou City, Nantou County, Taiwan, Taiwan; [2]Department of Chemical and Materials Engineering, National Ilan University, Yilan, Taiwan; [3]Department of Food Science, National taiwan ocean, keelung, Taiwan; [4]Department of Clinical Nurition, Nantou Hospital Ministry of Health and Welfare, Nantou City, Nantou County, Taiwan, Taiwan

BACKGROUND AND OBJECTIVES
Oxidative stress-induced neuroinflammation or neurodegeneration may cause to brain cell damage, leading to chronic diseases such as memory decline and cognitive dysfunction. For example Alzheimer's , Huntington's and Parkinson's disease. Quercetin, a phytochemical and a type of flavonoid, has been shown in many studies to possess antioxidant properties and the ability to scavenge free radicals, It is anti-tumor, improves cardiovascular disease, blood sugar, and neuroprotective functions. Quercetin is found in many natural fruits and vegetables, with particularly high concentrations in onions, apples, broccoli, and tea .

METHODS
In this study, we will use quercetin to treat PC-12 cells as a model, and induce oxidative damage in the PC-12 cells with hydrogen peroxide (H2O2).

RESULTS
The RESULTS show that quercetin concentration between 0-30 μM does is non-toxic. According to pharmacology analysis, quercetin was found to exert its effects by influencing the mechanisms of AKT1, HSPB1, HSPD1, and PRNP, activating the PI3K/AKT pathway, promoting neuronal survival, and inhibiting apoptosis. It induces the expression of heat shock proteins (HSPB1 and HSPD1), stabilizes protein folding, reduces the toxicity of misfolded proteins, improves mitochondrial function, decreases oxidative stress, and prevents mitochondria-induced apoptosis. Additionally, it maintains the normal function of PRNP, reducing neurotoxicity and protein aggregation.

CONCLUSIONS
These effects are particularly applicable to the treatment research of Parkinson's disease and Alzheimer's disease, highlighting the potential therapeutic efficacy of quercetin in neurodegenerative diseases.

EFFECTS OF SOY ISOFLAVONE ON MRNA EXPRESSION PROFILE OF MICE FED A HIGH-FAT DIET

So Min Shin[1]; Young Hye Kwon[1]
[1]Food and Nutrition, Seoul National University (SNU), Gwanak Campus, Seoul, Korea, Republic of

BACKGROUND AND OBJECTIVES
Soy protein, rich in isoflavones and bioactive peptides, has been shown to mitigate metabolic dysfunction-associated fatty liver disease (MAFLD). However, the primary active components and underlying mechanisms remain unclear. Previously, we reported distinct effects of soy protein components on adiposity and circulating microRNA (miRNA) profiles in obese mice. In this study, we compared the effects of soy protein with low and high isoflavone content on hepatic gene expression profiles in mice fed a high-fat (HF) diet. Regulatory networks between circulating miRNAs and hepatic target genes were also investigated.

METHODS
Male C57BL/6J mice were divided into four dietary groups: control (C), high-fat (HF), HF with low-isoflavone soy protein (HF/S), and HF with high-isoflavone soy protein (HF/SI). The experimental diets were administered for 16 weeks. Hepatic transcriptomes were analyzed using microarray technology.

RESULTS
Mice fed an HF/SI diet showed a significant reduction in hepatic steatosis compared to those on the HF diet. Transcriptome analysis identified two distinct clusters (cluster 1: HF and HF/S groups; cluster 2: HF/SI group) among HF-fed mice. Between the HF and C groups, a total of 956 genes showed significant differences (adjusted P-value < 0.05, |fold change| ≥ 1.5). The HF/S diet altered the expression of 129 genes associated with 9 Kyoto Encyclopedia of Genes and Genomes (KEGG) pathways, while the HF/SI diet significantly influenced 624 genes enriched in 86 KEGG pathways. Functional analysis of differentially expressed genes (DEGs) indicated that several of top 10 KEGG and Gene Ontology Cellular Component (GO:CC) terms were related to the endoplasmic reticulum and phagosome in the HF vs. C comparison. Notably, the HF/SI diet reversed the expression of most of these genes, unlike the HF/S diet. In the HF vs. C comparison, half of twelve differentially expressed miRNAs (DEMs) in the serum, including miR-6931-5p and miR-7002-5p, had target genes among hepatic DEGs. All identified two down-regulated DEMs in the HF/SI vs. HF comparison had 8 up-regulated target genes, which were associated with RNA translation and exocytosis.

CONCLUSIONS
HF feeding altered hepatic gene expression, which was more effectively reversed by an HF/SI diet compared to an HF/S diet. These data suggest that soy isoflavones play a key role in alleviating MAFLD in mice. Further studies are warranted to investigate gene expression profiles in other tissues and identify the role of serum miRNAs regulated by soy protein.

CONFLICTS OF INTERESTS

HIGH GLUCOSE INHIBITS THE UPTAKE OF LDL CHOLESTEROL BY ENDOCYTOSIS

Makoto Hagiwara[1]; Nagano Tadasato[1]; Matsushita Kenji[2, 3]
[1]Department of Health and Nutrition, University of Niigata Prefecture, Niigata, Japan; [2]Department of Oral Disease Research, National Center for Geriatrics and Gerontology, Obu, Japan; [3]Department of Dental Hygiene, Ogaki Women's college, Gifu, Japan

BACKGROUND AND OBJECTIVES
Glucose is the primary energy source for cells and is essential for sustaining life activities. However, excessive daily intake of carbohydrates can lead to insulin resistance, increasing the risk of diabetes. Moreover, chronic hyperglycemia promotes atherosclerosis, thereby raising the risks of heart disease, cerebrovascular disorders, and even mortality. On the other hand, small GTP-binding protein Rab5 is a key protein involved in endocytosis, including the uptake of LDL cholesterol. However, the molecular mechanisms through which hyperglycemia affects endocytosis remain largely unclear. Therefore, in the present study, we analyzed the dynamic changes in endocytosis under hyperglycemic conditions using cells cultured in a high-glucose medium.

METHODS
For the following experiments, A549 cells cultured in normal glucose concentration medium and high glucose concentration medium were used as samples. Co-localization of Rab5 and EEA1 was observed by fluorescence microscopy after immunostaining with specific antibodies for each protein. Co-localization was quantified by calculating the Pearson coefficient using ImageJ. The activity of Rab5 was analyzed by the GST-R5BD pulldown method reported by Hagiwara et al. LDL-cholesterol uptake was measured by adding pH-rode LDL to cells and measuring it with a fluorescent macroplate reader. Phosphorylation of MAPK and inflammation-related factors were analyzed by Western blotting.

RESULTS
The colocalization of Rab5 with the early endosome marker EEA1 was significantly reduced in cells cultured in high-glucose medium compared to those cultured in normal-glucose medium. Additionally, Rab5 activity was found to be decreased in high-glucose medium-cultured cells relative to normal-glucose medium-cultured cells. Furthermore, LDL cholesterol endocytosis was significantly reduced in high-glucose medium-cultured cells compared to normal-glucose medium-cultured cells. Furthermore, it was revealed that high glucose promotes inflammation via MAPK signaling.

CONCLUSIONS
It is clear that hyperglycemia reduces Rab5 activity and inhibits endocytosis of LDL cholesterol. High glucose may accumulate cholesterol in the blood by inhibiting endocytosis via inflammation-related factors.

THE IMPACT OF MULTIPLE MICRONUTRIENT SUPPLEMENTATION ON BREASTMILK MICRONUTRIENT CONCENTRATIONS

Cecillia Wechessa[1, 2]; Godwin Agyemang[3]; Jacqueline Waeni[4]; James Berkley,[4, 5]; Sophie Moore[3]; Martha Mwangome[4]

[1]Training Department, KEMRI-Wellcome Trust, Kilifi, Kenya; [2]Science, Technology, Engineering and Mathematics, Open University, Milton Keynes, United Kingdom; [3]Women & Children's Health, King's College London Guy's Campus, London, United Kingdom; [4]Clinical research, KEMRI-Wellcome Trust Research Programme, Kilifi, Kenya; [5]Centre for Tropical Medicine and Global Health, University of Oxford, Oxford, United Kingdom

BACKGROUND AND OBJECTIVES

Supplementation with multiple micronutrients (MMS) during pregnancy compared to Iron and folic acid alone has been shown to improve birth outcomes. However, little is known of whether MMS during pregnancy additionally impacts breastmilk micronutrient concentrations. Breastmilk is the most suitable food for infants and for an exclusively breastfed child, their micronutrient intake is dependent on the breastmilk micronutrient concentrations. Therefore, we sought to systematically review literature to determine the impact of MMS on breastmilk micronutrient concentrations.

METHODS

PubMed, Embase, Scopus and Cochrane databases were searched using relevant key words from the year 1990 to September 2023. We included articles written in English which investigated breastmilk micronutrient concentrations after MMS. Articles that reported supplementation with multiple micronutrients during lactation period only were excluded.

RESULTS

We found 1558 records from the electronic databases. After removing duplicates and irrelevant articles, 818 records were screened according to the title and abstract. Subsequently, 174 records were critically screened, and 22 records were included in this review. Micronutrients studied included Vitamins A, B, D and E, iodine, zinc, calcium, copper, magnesium, manganese, phosphorus, potassium, selenium, and sodium. From the included studies, 16 studies reported increased breastmilk micronutrients levels of Vitamins A, B1, B9, B12 and E, iodine and zinc among the intervention arm compared to the comparator while 6 studies reported no significant differences in breastmilk Vitamins A and B12, iodine, iron, copper, magnesium, manganese, phosphorus, potassium, selenium and sodium.

CONCLUSIONS

There are conflicting findings on the effect of multiple micronutrient supplementation during pregnancy on breastmilk micronutrient levels. These differences may arise from variations in the supplementation, the specific micronutrient biomarkers measured in breastmilk, the analytical methods used to analyze these biomarkers and dietary composition. Further research is needed to determine the optimal dosing and composition of supplements during pregnancy to maximize its impact on breastmilk micronutrient levels. Additionally, harmonization of methods used in breastmilk analysis is needed to facilitate comparisons across studies.

THE ESTABLISHMENT OF A NOVEL DIABETIC RETINOPATHY-LIKE ANIMAL MODEL

Wen-Ning Su[1]; Chun-Jung Lin[1]; Ting-Hua Lai[1]; Jing-Ting Su[1]; Wei-Chun Chang[1]; Zhi-Mei Huang[1]; Yi-Ling Lin[2, 1]; Yi-Chen Chen[2]; Chung-Tien Lin[3]; Szu-Chuan Shen[1]
[1]Graduated Program of Nutrition Science, National Taiwan Normal University Gongguan Campus, Taipei, Taiwan; [2]Department of Animal Science and Technology, National Taiwan University, Taipei, Taiwan; [3]Department of Veterinary Medicine, National Taiwan University, Taipei, Taiwan

BACKGROUND AND OBJECTIVES
Type 2 diabetes mellitus (T2DM) is a metabolic disease characterized by hyperglycemia and hyperinsulinemia. Poor long-term glycemic control leads to both microvascular and macrovascular complications, with approximately 20% of diabetic patients developing diabetic retinopathy (DR). DR may progress to complications such as macular edema, neovascular glaucoma, or even retinal detachment, potentially resulting in blindness once without early intervention. The aim of this study is to establish an DR-like animal model by inducing T2DM through streptozotocin (STZ) injection and a high-fat diet (HFD), and subsequently inducing retinal damage with sodium iodate (SI).

METHODS
Sprague-Dawley (SD) rats were fed a high-fat diet (54% of calories from fat) for 4 weeks. Subsequently, STZ was administered intraperitoneally at a dose of 35 mg/kg body weight (b.w.) for two consecutive days. After successful induction of hyperglycemia, SI (30 mg/kg b.w.) was then administered intraperitoneally to induce retinal damage. Upon confirmation of retinal function abnormalities, metformin (MET) was administered as a positive control at a dose of 200 mg/kg b.w. once daily for 4 weeks. Retinal function was assessed using electroretinography (ERG) at week 0th and 4th to diagnose the induction of retinopathy. Blood biochemical analysis and the oxidative status of retinal tissue were evaluated after the rats were sacrificed.

RESULTS
The ERG RESULTS at the 4th week showed that the a- and b-wave amplitudes were significantly decreased in DR-like rats compared to control rats ($p<0.05$). However, the b-wave amplitudes were significantly increased in metformin-treated DR-like rats compared to the DR-like rats ($p<0.05$). Fasting blood sugar analysis revealed that the rats in the DR and MET groups were hyperglycemic (>200 mg/dL) after 6 weeks of STZ injection and HFD feeding. The oxidative status of the retinal tissue showed that malondialdehyde levels were significantly increased in DR-like rats compared to control rats ($p<0.05$), and decreased in MET-treated DR-like rats compared to DR-like rats.

CONCLUSIONS
In conclusion, the RESULTS demonstrate that the combination of STZ and SI injection can rapidly induce retinopathy syndrome via hyperglycemia, and metformin may suppress the progression of retinopathy by reducing oxidative stress in DR-like rats.

MEASURING COMMUNICATION IN MICROBIAL BIOFILMS IN RESPONSE TO ANTIBIOTICS, PHYTOCHEMICALS AND STRESSORS

Jean-Marc Zingg[1, 2]; Pratibha Joshi[1]; Michael Moraskie[3]; Mengrui Li[1]; Sherwin Reyes[1, 2]; Md Harun Or Roshid[1, 2, 4]; Sapna Deo[1, 2, 3]; Sylvia Daunert[1, 2, 3]

BACKGROUND AND OBJECTIVES

In their natural environment, bacteria can grow in biofilms that are often resistant to antibiotics and disinfectants in wounds, infectious diseases and implantable devices. The communication mechanisms between the bacteria are also different in biofilms compared to planktonic cultures. However, it has been challenging to develop assays that can measure changes in signaling and communication within the biofilm in response to antibiotics, disinfectants and phytochemicals and to assign a physiological function to these changes.

METHODS

A high-throughput assay system is developed for measuring communication in microbial biofilms in a 96-well microtiter plate format. In this assay, bioluminescent microbial whole cell biosensor systems (MWCBs) embedded into the biofilm were exposed to gradients of quorum sensing molecules (QSMs) such as N-acetyl-homoserine lactones (AHLs), or 3,5-dimethylpyrazin-2-ol (DPO), and the response pattern monitored. Increasing concentrations of phytochemicals that can act as natural quorum sensing inhibitors (QSIs) such as curcumin (from *Curcuma longa*), or 3,3'-diindolylmethane (DIM) (from cruciferous vegetables) were tested for their ability to modulate communication in response to QSMs. Further, the regulatory role of disinfectants (e.g., H2O2) or antibiotics (e.g., ciprofloxacin, trimethoprim/sulfamethoxazole)) on the communication responses were assessed.

RESULTS

Curcumin and DIM at higher concentrations lead to inhibition of quorum sensing in biofilms after 4h and 24h and is not followed by biofilm disintegration. H2O2 above 0.002% efficiently inhibited the activity of the biosensors and was leading to biofilm disintegration. At lower concentrations of H2O2 we observed induction of the MWCBs. The antibiotics inhibited the MWCBs activity at concentration above their minimal inhibitory concentration (MIC), but this did not necessarily lead to the disintegration of the biofilm. Interestingly, similar to low concentrations of H2O2, the antibiotics activated the MWCBs at concentrations close to their MIC, possibly as result of H2O2 generated during their bactericidal action.

CONCLUSIONS

We hypothesize that the observed response to stressors reflects increased communication in the bacterial biofilm. A detailed analysis of the molecular signaling mechanisms by which phytonutrients and stressors modulate communication in biofilms will not only be important to understand chronic infection but also for identifying novel mechanisms involved in developing antibiotic tolerance and resistance.

IDENTIFICATION OF NEW PEPTIDES FROM PEA PROTEIN ISOLATE IMPLICATED IN GLUCOSE METABOLISM AND FOOD INTAKE REGULATION

Lefranc-Millot Catherine[1]; Hairati Aboubacar[2]; Barbara Deracinois[2]; Caroline Perreau,[1]; Rozenn Ravallec,[2]; Christophe Flahaut,[2]; Benoit Cudennec,[2]
[1]Life Sciences R&D, Nutrition Department, 62136 Lestrem, France, Lestrem, France; [2]UMR Transfrontalière BioEcoAgro-INRAe 1158, Univ. Lille, INRAE, Univ. Liège, UPJV, JUNIA, Univ., Université de Lille, Villeneuve d'Ascq, France

BACKGROUND AND OBJECTIVES
Dietary proteins, mainly from animal sources, and their digestates, through peptides and amino acids generated during digestion, exhibit numerous biological functions beneficial to prevent or treat pathological conditions. Proteins stimulate intestinal hormones like glucagon-like peptide 1 (GLP-1) and cholecystokinin (CCK), influencing short-term food intake via enteroendocrine cells (EECs). GLP-1 promotes insulin secretion, inhibits glucagon release, and, like CCK, signals satiety. However, GLP-1's rapid inactivation by dipeptidyl peptidase IV (DPP-IV) limits its efficacy. Protein-rich diets, including plant-based proteins ones, have been linked to reduced obesity risk, improved glucose regulation, and type 2 diabetes prevention. This study aimed to identify new bioactive peptides, generated during simulated gastrointestinal digestion of pea protein isolate NUTRALYS® S85F from Roquette (PPI), that stimulate CCK and GLP-1 secretion in EECs and inhibit DPP-IV activity after intestinal barrier (IB) passage.

METHODS
In vitro digestion followed the INFOGEST protocol, modified to include brush border peptidases and duodenal absorption using a Caco-2/HT29-MTX IB model. DPP-IV inhibitory activity was evaluated in human plasma using a specific fluorescent substrate, and IC50 values were determined. CCK and GLP-1 secretion by STC-1 EECs were quantified via ELISA after incubation with digested samples. Fractionation of digested PPI was performed using strong cation exchange chromatography and reversed-phase HPLC. Bioactive fractions were analyzed by peptidomics to identify novel peptides. Selected peptides were synthesized and tested for hormone secretion and DPP-IV inhibition. Peptides capable of crossing the IB were identified using the Caco-2/HT29-MTX model.

RESULTS
Several novel peptides derived from pea protein were identified, exhibiting dual bioactivity by stimulating CCK secretion, GLP-1 secretion, or both. Additionally, peptides capable of crossing the intestinal barrier demonstrated significant DPP-IV inhibitory activity in human plasma, with promising low IC50 values.

CONCLUSIONS
The findings highlight the potential of pea protein-derived peptides in preventing and managing obesity and type 2 diabetes. These RESULTS support the development of plant-based functional foods tailored for personalized nutrition and would deserve further studies in humans.

EFFECT OF EGG CONSUMPTION ON COGNITION IN HEALTHY OLDER ADULTS: FINDINGS FROM A RANDOMISED CONTROLLED TRIAL

Nessmah Sultan[1]; Nicole Kellow,[1]; Clare Macmahon,[2]; Markus Raab,[3]; Caroline Tuck,[4]; Jessica Biesiekierski[5]
[1]Nutrition, Dietetics and Food, Monash University Clayton Campus, Clayton, Australia; [2]School of Allied Health, Human Services, and Sport, La Trobe University, Bundoora, Australia; [3]Institute of Psychology, German Sport University Cologne, Köln, Germany; [4]Department of Nursing and Allied Health, Swinburne University of Technology, Hawthorn, Australia; [5]School of Agriculture, Food and Ecosystem Sciences, The University of Melbourne, Parkville, Australia

BACKGROUND AND OBJECTIVES
Eggs are rich in nutrients beneficial for cognitive function, such as phospholipids, choline, and tryptophan. However, most research on egg consumption and cognition has been observational, mainly addressing cognitive decline with aging. Few studies have investigated the effects of egg intake on cognition in healthy older adults, with a lack of high-quality study designs.

METHODS
This 6-week long, parallel-arm randomized controlled trial (RCT) aimed to examine the impact of egg consumption on cognition, including interoception, risk-taking, decision-making and reaction-time in healthy older adults. Forty-eight healthy adults aged over 65 were randomised to either the intervention group (n=24) who consumed 2 whole eggs/day, or the control group (n=24) who avoided eating eggs. Participants completed 4 computer-based validated cognitive tests at week 0 and week 6. The Schandry task measured interoception (heartbeat perception (Hb) in 25s, 35s and 55s rounds), the balloon analogue risk task (BART) measured risk-taking, the Iowa Gambling Task (IGT) assessed decision-making, and the Deary-Liewald test measured simple reaction time (SRT) and choice reaction time (CRT). Changes in cognitive task RESULTS within and between groups were analysed via linear mixed models analysis using SPSS, with RESULTS controlled for sleepiness (measured by Karolinska Sleepiness Scale) and gender. Continuous data is presented as mean ± SD where parametric, or median (IQR) where non-parametric.

RESULTS
Of the n = 48 participants enrolled, n = 45 completed the 6-week program and were included in data analysis (egg n=23, control n=22). Participants were 70% female, aged 69.0 (5) years and exhibited BMI of 25.2 ± 3.2 kg/m2 . At week 0, cognitive task RESULTS between intervention and control groups were not significantly different. At week 6 interoception was not impacted by egg consumption (Hb: 25s p = 0.242; 35s p = 0.273; 55s p = 0.341), nor was risk-taking (BART p = 0.235), decision making (IGT p = 0.529), or reaction-time (SRT p = 0.627, CRT p = 0.831).

CONCLUSIONS
Consuming 2 eggs/day for 6-weeks did not affect cognitive test RESULTS in healthy older adults when compared to those who avoided eggs, indicating no negative impact from regular egg consumption. This is the first RCT to examine the effects of egg intake on these cognitive parameters. Future studies should consider longer interventions or different cognitive tests to fully understand the potential cognitive effects of egg consumption.

EFFECT OF PUPALIA LAPPACEA, IRESINE HERBSTII, FICUS CAPENSIS AND MORINDA LUCIDA LEAF EXTRACTS ON PHENYLHYDRAZIN-INDUCED ANAEMIC ADULT MALE ALBINO WISTER RATS

Ngozi Mercy Nnam[1]; Okosis R. Oji[1]; Peace Ani[1]
[1]Department of Nutrition and Dietetics, University of Nigeria, UNN Nsukka, Nsukka, Nigeria, Federal Republic of

BACKGROUND AND OBJECTIVES
Anemia remains a major public health issue worldwide, with an estimated 40% of children under five and one-third of women of reproductive age affected. While conventional treatments are available, there is growing interest in the potential of medicinal plants as safer, alternatives for managing anemia. The study determined the effect of *Pupalia lappacea, Ipomoea herbstii, Ficus capensis and Morinda lucida leaf extracts* on phenylhydrazin-induced anaemic rats.

METHODS
The wild leaves (*Pupalia lappacea, Ipomoea herbstii, Ficus capensis and Morinda lucida*) were collected from the bush and fallow lands in villages. The leaves were cleaned and shade-dried at room temperature for seven days. The dried samples were milled separately into homogeneous powders of 60 µm using a laboratory hammer mill. Methanol extracts of the powdered samples were separately prepared by cold maceration. Acute toxicity test (LD50) was conducted to determine safe levels of the extracts. Adult male Wistar rats (n=120) were acclimatized and randomly assigned into five groups of six rats for each leaf extract. Anaemia was induced using phenylhydrazine and confirmed before treatment commenced. Based on that the established safe levels, three doses of the extracts (10, 100, 1000 mg/kg body weight) were administered orally to Groups C, D, and E, respectively for 14 days. Groups A served as the untreated control, while Group B received a standard drug for anaemia. Blood samples were collected via retro-orbital puncture under ether anesthesia and analyzed for packed cell volume (PCV), red blood cell count (RBC), and hemoglobin (Hb). Data were analyzed using SPSS (version 23), and statistical significance was set at $p < 0.05$.

RESULTS
A significant increase ($p < 0.05$) in PCV, RBC and Hb levels was observed from baseline and end-line values in all groups treated with different doses of the leaf extracts. These increases were comparable to those observed in rats treated with the standard drug for anaemia.

CONCLUSIONS
The study revealed that the leaf extracts of *Pupalia lappacea, Ipomoea herbstii, Ficus capensis and Morinda lucida* significantly improved the hematological parameters, particularly PCV, RBC count, and Hb levels in phenylhydrazine-induced anemic adult male albino Wistar rats. These findings suggest that the plant extracts have potential therapeutic effects on anemia and could be further explored as natural remedies, especially in regions with limited access to conventional treatments.

BARRIERS AND ENABLERS OF SELECTED NUTRITION AND AGRICULTURAL PRACTICES AMONG WOMEN AND CHILDREN IN SIX SUB-REGIONS AND REFUGEE SETTLEMENTS OF UGANDA

Joweria Nambooze[1]; Elisha Nangosha[1]; Shirley Kansabe[1]; Tracy Lukiya Birungi[1]; Edward Linton Onekalit[1]; Muniirah Mbabazi[2]; Wilson Kirabira[2]; Zakaria Fusheini[3]; Mary Nabisere[3]; Immaculate Daisy Yossa[4]; Peterson Kikomeko Kato[1]

[1]Nutritional Sciences and Dietetics, Kyambogo University, Kampala, Uganda; [2]Nutrition, Africa Innovations Institute, Kampala, Uganda; [3]Nutrition, UNICEF, Kampala, Uganda; [4]CASCADE Project, CARE International in Uganda, Kampala, Uganda

BACKGROUND AND OBJECTIVES

Women play a crucial role in ensuring that nutritious foods are available and consumed by children. However, their effectiveness is shaped by a complex interaction of barriers, enablers, and motivators unique to each community and region. This study examines the barriers and enablers related to key nutritional and behavioral practices in six sub-regions of Uganda. The aim was to understand the factors that influence optimal food production, access, and consumption practices among women and children.

METHODS

The Barrier Analysis methodology was used in the current study. Data were analyzed with Excel for tabulation and Atlas.ti for qualitative insights. Ethical clearance for this study was obtained from the Clarke International University Research Ethics Committee and the Uganda National Council for Science and Technology

RESULTS

RESULTS showed that doers in Karamoja and Acholi were more likely to meet MMF, benefiting from better access to food and community support, while non-doers in Kamuli were 12.5 times more likely to perceive negative consequences from missing MMF (p=0.007). Regarding dietary diversity, doers in Tooro and Lango consistently reported better access to diverse food groups, while non-doers, especially in refugee settlements, struggled with food rationing (p=0.002). Women's dietary diversity also followed a similar pattern, with doers in Acholi and Tooro benefiting from better access to agricultural resources (p=0.024).

Other enablers identified include savings and loan associations, which were key to improving dietary diversity, particularly in Lango and West Nile, where households participating in savings programs were more likely to invest in nutrient-dense foods (p=0.014).

In refugee settlements, non-doers struggled with food rations (3.7 times, $p = 0.040$), financial constraints (4.1 times, $p = 0.002$), and limited resources, while doers benefited from cultivation and livestock (33% facilitation, $p < 0.01$) and greater confidence (26% more, $p = 0.001$). Key interventions include improving food access, financial aid, and agricultural support.

CONCLUSIONS

Optimal nutrition was significantly influenced by access to resources such as land, agriculture, and financial stability. Non-doers encountered substantial barriers, including financial constraints, land scarcity, and farming difficulties, particularly in areas like Karamoja, Tooro, and West Nile.

THE NUTRITIONAL CONTRIBUTION AND RELATIONSHIP WITH HEALTH OF BREAD CONSUMPTION

Léa Ribet[1]; Amira Kassis[2]; Jacquier Emma[2]; Céline Monnet[1]; Bosco Nabil[1]; Mickael Durand-Dubief[1]
[1]Lesaffre Institute of Science & Technology, Lesaffre, Marcq-en-Barœul, France; [2]Nutrition & Health, Neat Science, Châtel-Saint-Denis, Switzerland

BACKGROUND AND OBJECTIVES
Bread is one of the most widely consumed staple foods globally, with a long history and strong cultural associations. However, the perception of bread as a nutritious and health-promoting food remains unclear. The objective of this comprehensive review is to critically evaluate the epidemiological and clinical evidence on the nutritional contribution of bread and its relationship with various health outcomes.

METHODS
We conducted a broad search using PubMed, the MeSH database, and Google Scholar, with keywords including "bread", "overweight", "obesity", "cardiometabolic disease", "cardiovascular disease", "type 2 diabetes", "digestive health", and "risk factors" (e.g., blood lipids, glucose, insulin, BMI). The included studies were epidemiological, observational, and clinical trials investigating the relationship between bread, assessed either alone or as part of a dietary pattern, and health. Additionally, we searched for official reports from global Nutrition and Health Authorities, as well as publications on the nutritional composition of bread.

RESULTS
Our review confirmed that bread makes a significant contribution to the intake of key nutrients in various regions of the world. However, the evidence on the health effects of bread is complex. We did not observe clear evidence that bread intake, as a broad category, is linked to the risk of obesity, cardiometabolic disease, or digestive health issues. Importantly, the review highlighted the proven benefits of whole grain bread on metabolic and digestive health, in addition to its favorable nutrient profile. Emerging evidence also suggests potential health benefits associated with breads made from other whole grains, such as oat, barley, and rye.

CONCLUSIONS
This comprehensive review critically appraised the available evidence to address the question of whether bread consumption is related to health and disease. From a nutritional standpoint, bread, especially whole grain varieties, makes a significant contribution to energy and key nutrient intakes. The association between bread and health is complex, and no strong evidence establishes a causal relationship between bread consumption and disease. However, whole grain bread has shown benefits over refined breads and other staple foods, such as improved body weight regulation, cardiometabolic health, and digestive health.

CONFLICTS OF INTERESTS

EFFECT OF A WORKPLACE HEALTH PROMOTING ACTIVITIES ON EMPLOYEE'S EATING BEHAVIOR IN HOSPITAL

CHIA-TZU Lin[1]; Wan-Chin Chen[2]
[1]Department of Nutrition and Dietetics, Changhua Christian Hospital, Changhua, Taiwan; [2]Department of Family Medicine, Changhua Christian Hospital, Changhua, Taiwan

BACKGROUND AND OBJECTIVES
According to the reported data of WHO, noncommunicable diseases (NCDs) kill 41 million people each year. Health promotion strategies that encourage healthy eating are critical in preventing NCDs. Developing and implementing worksite health promotion program in hospital can create a health-supporting workplace for healthcare worker. As this reason, the aim of the study was to implement a health promoting activities in the hospital canteen, and examine the effect on employee's eating behavior.

METHODS
A 9-month workplace health promotion program was implemented in the hospital canteen. We recruit 100 subjects from employees who always buying dining in the canteen. This study intend to encourage healthy eating through a series of interventions, which include " the meal with red, yellow and green color-coded calorie labeling ", " real food of my balance plates exhibition and video education", "purchase of unrefined whole grains can be discounted on meal expenses" . A questionnaire survey on "Healthy Eating Knowledge and Behavior" was conducted before and after the study, and the total times of purchases of unrefined whole grains during the program was also collected to investigate the changing of eating behavior.

RESULTS
A total of 75 adult participants (males = 7, female = 68; mean age 43.6y) who had completed pre- and post-surveys were included in the analysis. The scores of healthy eating behaviors (HEB) stage ranged from 1 to 5 with a mean of 2.88 and 3.45 before and after the study respectively. (1=precontemplation, 2=contemplation, 3=preparation, 4=action, 5=maintenance). The percentage of all participants in the HEB action and maintenance stages was 33 % before and increased to 60 % after the study. The healthy eating consciousness measured by three questions with five-point Likert Scales had a mean of 4.0 in pre and 4.36 in post study. The total times of purchases of unrefined whole grains increased by 2,521 for all participants in the study, and intake of unrefined whole grains increased by an average of 19% compared to pre-study.

CONCLUSIONS
Although healthcare workers are relatively well aware of healthy eating, the RESULTS of this study suggest that multi-strategy interventions are effective in advancing the stage of healthy eating behaviors and increasing their willingness to purchase unrefined whole grains. Research suggests that this may be an effective intervention strategy to achieve behaviour change.

NEUROPROTECTIVE POTENTIAL OF ECKLONIA CAVA POLYPHENOLS FOR PARKINSON'S DISEASE PREVENTION: ACTIVATION OF THE NRF2-ARE PATHWAY

Akiko Kojima-Yuasa[1]; Yuri Yasuda[1]; Manami Sakai[1]; Tamakii Tokumatsu[1]; Chiharu Ueda[1]; Isao Matsui-Yuasa[1]
[1]Department of Nutrition, Graduate School of Human Life and Ecology, Osaka Metropolitan University, Osaka, Japan

BACKGROUND AND OBJECTIVES
Parkinson's disease (PD) is a progressive neurodegenerative disorder characterized by the degeneration of dopamine-producing neurons in the substantia nigra, leading to motor impairments, cognitive decline, and non-motor symptoms. Oxidative stress plays a pivotal role in PD pathogenesis, highlighting the need for novel preventive and therapeutic strategies. This study explores the potential of *Ecklonia cava* polyphenols (ECPs**)**, rich in the antioxidant phlorotannin, to mitigate oxidative damage and protect neurons via activation of the Nrf2–antioxidant response element (ARE) pathway.

METHODS
For *in vitro* experiments, SH-SY5Y human neuroblastoma cells were cultured in Dulbecco's Modified Eagle's Medium supplemented with 10% fetal bovine serum. For *in vivo* studies, a PD mouse model was created by administering rotenone (10 mg/kg body weight) orally for 30 days. Motor functions were assessed using the pole test (to measure movement slowness) and the wire hang test (to evaluate grip strength).

RESULTS
In vitro, ECP treatment enhanced the activity and expression of NAD(P)H quinone oxidoreductase-1 (NQO1), promoted nuclear translocation of Nrf2, and increased p62 expression, sustaining Nrf2 activation via a positive feedback loop. These effects were attenuated by Compound C, an AMPK inhibitor, indicating an AMPK-dependent mechanism of Nrf2 activation.
In vivo, ECPs significantly improved motor performance in rotenone-treated mice, restored intestinal motility, preserved colonic tissue integrity, and increased tyrosine hydroxylase (TH) expression in the substantia nigra, demonstrating protection of dopaminergic neurons.

CONCLUSIONS
This study reveals that ECPs exert neuroprotective effects by activating the Nrf2–ARE pathway, alleviating neuronal damage, and improving motor and gastrointestinal dysfunction in a PD mouse model. These findings suggest that ECPs hold promise as a natural, innovative approach to preventing PD. Further research is warranted to elucidate the detailed mechanisms of ECP action and its potential clinical applications.

NUTRITIONAL INTAKE IN A MILITARY CONTEXT: IN THE FIELD, ON BASE AND AT HOME

Minke Geerts[1]; Leanne Van Der Hout[1]; Lotte Peters,[2]; Pim Scheiberlich[1]; Iris Maria De Hoogh[1]
[1]Human Performance, TNO - Locatie Soesterberg, Soesterberg, Netherlands; [2]Biomedical Signals and Systems, University of Twente, Enschede, Netherlands

BACKGROUND AND OBJECTIVES
Adequate and sufficient nutrition is a necessity for military personnel to perform at their best. Inadequate nutrition can lead to reduced health and performance, and an increased risk of injuries and dropouts. Little is known about the nutritional intake within the Dutch military. Therefore, the current study focusses on energy, nutrient and fluid intake of Dutch soldiers in the field, on base and at home.

METHODS
72 soldiers from the Dutch light armoured brigade were included in this study. In the field, where soldiers use rations, a food intake/waste method was used. Participants were asked to hand in their packaging waste and fill out questionnaires to assess their energy, nutrient and fluid intake. On base and at home, participants recorded their dietary intake using online food diaries. Nutritional intake was compared to reference guidelines. Energy intake on base and at home was also compared to energy expenditure which was measured using online questionnaires. Energy expenditure data in the field was not available for this study.

RESULTS
Carbohydrate and fibre intake were below the reference values in all three settings, while protein and fluid intake met the recommended levels. (Saturated) fat intake was higher than the reference values in all three settings. Sodium intake was above recommended levels at home and on base, but adequate in the field. Energy intake was below the reference intake in all three settings and below energy expenditure on base. At home, energy intake and expenditure were approximately comparable.

CONCLUSIONS
Despite known risks of over- and underreporting in dietary and physical activity assessment, the findings suggest that participants in this study consumed insufficient energy in the field and on base. Since carbohydrate and fibre intake were below the reference values in all three settings, increasing fibre-rich carbohydrate consumption would be the most effective strategy to address the energy shortfall. Enhancing energy intake, particularly in the field, is expected to improve military performance.

CHENOPODIUM FORMOSANUM EXTRACT INHIBITS TNFA-INDUCED ROS PRODUCTION AND ROS-MEDIATED ENDOTHELIAL TO MESENCHYMAL TRANSITION AND INFLAMMATION VIA INDUCTION OF ANTIOXIDANT ENZYMES IN HUMAN ENDOTHELIAL CELLS

En-Ling Yeh,[1]; Yu-Syuan Houng[2, 3]; Tzu-Huan Hung[4]; Chien-Chun Li[2]
[1]Department of Nutrition, Hungkuang University, Taichung, Taiwan; [2]Department of Nutrition, Chung Shan Medical University, Taichung, Taiwan; [3]Department of Dietetics, Ministry of Health and Welfare Shuang-Ho Hospital, Taipei, Taiwan; [4]Crop Genetic Resources and Biotechnology Division, Agricultural Research Institute, Taichung, Taiwan

BACKGROUND AND OBJECTIVES
Tumor necrosis factor-α (TNF-α), a proinflammatory cytokine, has been shown to induce the production of reactive oxygen species and lead to endothelial dysfunction. *Chenopodium formosanum*, also known as Djulis, is an amaranthaceae chenopodioideae chenopodium plant. The extract of *Chenopodium formosanum* (CFE) contains several flavonoid compounds exerting antioxidative, anti-inflammatory, and antiadipogenic properties. However, the mechanism of CFE in protecting the endothelial function has not been clarified. Tumor necrosis factor-α (TNF-α), a proinflammatory cytokine, has been shown to induce the production of reactive oxygen species and lead to endothelial dysfunction. *Chenopodium formosanum*, also known as Djulis, is an amaranthaceae chenopodioideae chenopodium plant. The extract of *Chenopodium formosanum* (CFE) contains several flavonoid compounds exerting antioxidative, anti-inflammatory, and antiadipogenic properties. However, the mechanism of CFE in protecting the endothelial function has not been clarified.

METHODS
In this study, EA.hy926 human vascular endothelial cells were used to investigate the effect of CFE on TNF-α-induced inflammation, adhesion, Endothelial-to-mesenchymal transition (EndMT), and oxidative stress.

RESULTS
The RESULTS showed that treatment with 10 ng/mL TNF-α did not affect cell viability, but significantly increased reactive oxygen species (ROS) production, and the phosphorylation of JNK, ERK, p38 mitogen-activated protein kinases (MAPKs), protein kinase B (PKB/Akt) and signal transducer and activator of transcription 3 (STAT3). Moreover, the nuclear translocation of nuclear factor kappa-B (NF-κB) and the protein level of vascular cell adhesion protein-1 (VCAM-1), intercellular adhesion molecule-1 (ICAM-1), interleukin-1 beta (IL-1β), interleukin-6 (IL-6) as well as EndMT-relate protein such as vimentin, but VE-cadherin were increased by TNF-α. Pretreatment with 150 μg/mL CFE significantly increased superoxide dismutase 1 (SOD1), superoxide dismutase 2 (SOD2), glutathione reductase (GR), catalase as well as heme oxygenase-1 (HO-1), and decreased TNF-α mediated ROS production, p-ERK, p-Akt, p-JNK, VCAM-1, ICAM-1, IL-1β, IL-6, vimentin, and VE-cadherin.

CONCLUSIONS
In conclusion, CFE can inhibit TNF-α induced ROS production, ERK/NF-κB, JNK/NF-κB, Akt/NF-κB as well as STAT3, and decrease inflammation, adhesion, EndMT by upregulating antioxidant enzymes in EA.hy926 cell to improving vascular endothelial dysfunction.

IMPACT OF DAIRY GALACTO-OLIGOSACCHARIDE ON THE ELDERLY MICROBIOME : AN IN VITRO STUDY

Antoine Cauchoix[1]; Marion Lemaire[1]; Prodigest Bv[2]; Pourprix Julie[3]; Benjamin Choque[1]
[1]Research and Innovation Center, Sodiaal, Rennes, France; [2]ProDigest BV, Technologiepark 73, Gent, Belgium; [3]Research and development, Euroserum, PORT SUR SAONE, France

BACKGROUND AND OBJECTIVES
Prebiotics are substrates selectively utilized by host microorganisms conferring a health benefit. If the prebiotic effect of galactooligosaccharides (GOS) is well-known, only few studies investigated their effects in elderly population which is concerned by a microbiota shift around 55 years old. The aim of the study was to investigate in vitro the prebiotic effect of a long-term repeated exposure to dairy GOS (SICAGOS) in a healthy elderly donor.

METHODS
The faecal inocula of ten healthy elderly donors were tested in a pre-screening experiment to identify a representative donor. The SHIME® experiment consisting in three bioreactors mimicking the human digestive system: one for the stomach and small intestine, one for the proximal colon and the last one for the distal colon was realised with repeated administration of 4 g/d of SIGAGOS for 3 weeks. This first stage of digestion mimics the alterations that SICAGOS undergoes before reaching the microbiota in humans. We investigated the effects of SICAGOS on the metabolic activity and composition of the gut microbiota (lactate, ammonium, SCFA and branched SCFA), quantitative 16S targeted sequencing and on gut barrier integrity and inflammation using a Caco-2/THP-1 co-culture cell model, in comparison with a negative control, without treatment.

RESULTS
The decrease in pH and SCFA productions observed in all tested elderly donors indicated that the SICAGOS was efficiently fermented by the gut microbiota. During the long-term SHIME® experiment, the microbial fermentation was increased. Indeed, all SCFA rose, in both colonic regions. It was especially true for acetate that represented approximately 60% of the increase and for butyrate that reach 10.7mM in control but 12.8mM with treatment, in proximal colon, and, respectively, 12.2 mM against 15.8mM in distal colon. Also, *Bifidobacteria* were much more numerous with the SICAGOS consumption. Indeed, they represent around 0.49% of abundances in control, but rose to 6.1% with SICAGOS. Finally, SICAGOS had no effect on the gut barrier integrity, but the secretion of IL-10 and NF-kB activity were significantly higher in the distal colon.

CONCLUSIONS
Repeated exposure of dairy GOS (SICAGOS) showed interesting effects by boosting SCFA production, IL-10 secretion, NF-κB activity and upregulating *Bifidobacterium.*, might be associated to an enhance of anti-inflammatory properties. These RESULTS pointed out the potential prebiotic effect of SICAGOS in elderly which could be studied more precisely through a clinical investigation.

COMPARISON OF PROTEIN DIGESTION KINETICS: IMPLICATIONS FOR NUTRITIONAL APPLICATIONS

Blanca Edelia González Martínez[1]; Lizy Daniela Padilla Buentello[2]; Ana Sofia Ortega Villarreal[2]; Manuel Lopez Cabanillas Lomeli[2]; Abad Arturo Lopez Hernandez[2]
[1]Facultad de Salud Pública y Nutrición, Universidad Autónoma de Nuevo León , Monterrey, Mexico; [2]Facultad de Salud Pública y Nutrición, Universidad Autónoma de Nuevo León, Monterrey, Mexico

BACKGROUND AND OBJECTIVES
Depending on digestion and hydrolysis rates, proteins can be classified as "fast" or "slow." The use of "fast" digesting proteins helps overcome "anabolic resistance" (reduction in skeletal muscle sensitivity/response to anabolic stimuli) by stimulating protein synthesis and improving muscle function. The objective of this study was to evaluate the release kinetics of plant-based proteins using an in vitro gastrointestinal digestion protocol.

METHODS
Six protein isolates were analyzed: tepary bean (TB), fava bean (FB), rice (RC), soybean (SB), corn (CN), and pea (PE). Digestibility, bioaccessibility, and release rates were determined and compared to whey protein isolate (WP) and casein (CA) using an in vitro gastrointestinal digestion protocol (INFOGEST). Digestion rates were measured every 30 minutes, and protein bioaccessibility was simulated using a 10 kDa dialysis membrane. Protein concentration was quantified by the Dumas and Lowry methods for all samples, and kinetic parameters were analyzed.

RESULTS
Animal-derived proteins WPI and CA achieved the highest digestibility percentages (99% and 96%, respectively) compared to plant-based proteins (ranging from 82% to 71%) in the following order: CN, PE, FB, SB, TB, and RC. Regarding bioaccessibility, RC showed the highest value, comparable to WPI, while TB, SB, and CA exhibited the lowest values. Statistical analysis of release rates grouped TB and FB with CA, categorizing them as “slow” proteins. None of the plant-based proteins demonstrated a release rate comparable to the "fast" WPI. Therefore, protein isolates from PE, CN, RC, and SB can be categorized as “intermediate-digesting” proteins.

CONCLUSIONS
Among plant-based proteins, there are promising options for various metabolic applications. Proteins from PE, CN, and RC exhibit intermediate digestibility profiles, making them suitable for contexts requiring early amino acid availability, such as pre-workout scenarios. On the other hand, FB and TB exhibit characteristics of slow-digesting proteins, suitable for applications requiring sustained amino acid release. None of the plant-based proteins matched the release rates of WPI, highlighting the need to optimize production processes and formulations for these isolates. This study reinforces the value of plant-based proteins for specific applications and promotes their integration into sustainable and personalized nutritional strategies.

ESTABLISHMENT OF A CELLULAR SENESCENT MODEL OF HUMAN IPS CELL-DERIVED INTESTINAL ORGANOIDS: A NOVEL RESEARCH TOOL FOR NUTRITION IN THE ELDERLY

Tatsuhiro Ayabe[1]; Yu Takahashi[2]; I-Ting Lee[2]; Takeshi Kokubo[1]; Yoshio Yamauchi[2]; Ryuichiro Sato[2]
[1]Institute of Health Sciences, Kirin Holdings Company, Limited, Fujisawa, Japan; [2]Graduate School of Agricultural and Life Sciences, The University of Tokyo, Tokyo, Japan

BACKGROUND AND OBJECTIVES

In the elderly, intestinal functions such as barrier integrity and nutrient absorption tend to decline, and intestinal aging is linked to systemic aging. However, the direct assessment of human intestinal aging is challenging; thus, detailed mechanisms and effective prevention methods are not well established. In this study, we developed a cellular senescence model by using human iPS cell (iPSC)-derived intestinal organoids as an in vitro evaluation system that mimics human intestinal aging.

METHODS

iPSC-derived intestinal organoids cultured in a monolayer were treated with cisplatin, an anticancer drug, or butyrate, a compound with HDAC inhibitory activity, for 3–5 days. Cellular senescence was evaluated by gene expression analysis of p16 and p21, markers of cell cycle arrest, and IL8 and TNFα, components of the senescence-associated secretory phenotype, using qPCR. Cellular senescence was also examined by staining the cells with SA β-gal. Transepithelial electrical resistance (TEER) was measured as an indicator of intestinal barrier function. RNA-seq analysis, followed by differential gene expression and KEGG pathway analyses, was performed.

RESULTS

Treatment with cisplatin (10–20 μM) and butyrate (20–30 mM) increased the gene expression of p16 and p21, as well as IL8 and TNFα, and increased the number of SA β-gal-positive cells, indicating the induction of cellular senescence. Additionally, in the cisplatin-treated model, the TEER values decreased. KEGG pathway analysis revealed that the *p53 signaling pathway* was upregulated after treatment with 20 μM cisplatin for five days, consistent with the induction of cellular senescence. Furthermore, several pathways related to nutrient absorption and metabolism were downregulated by cisplatin treatment, partially simulating age-related decline in nutrient absorption. Finally, we explored food components that suppress intestinal cellular senescence using the cisplatin-treated model and identified certain food components that attenuate cisplatin-induced changes.

CONCLUSIONS

This study is the first to evaluate the efficacy of food components in a cellular senescent iPSC-derived intestinal organoids that exhibit a decline in intestinal barrier function and nutrient metabolism. This model could serve as an effective research tool for establishing preventive methods against human intestinal aging and nutritional disruption in the elderly.

ACA EXHIBITS ANTI-OBESITY EFFECTS BY ACTIVATING AMPK AND INHIBITING CREB TRANSCRIPTIONAL ACTIVITY

Masako Barnes[1]; Haru Hashimoto[2]; Isao Matsui-Yuasa[2]; Akiko Kojima-Yuasa[2]
[1]Research and Development Headquarters, Sakata INX Corporation, Itami, Japan; [2]Department of Nutrition, Graduate School of Human Life and Ecology, Osaka Metropolitan University, Osaka, Japan

BACKGROUND AND OBJECTIVES
Obesity, affecting over one billion people worldwide, arises from an imbalance between energy intake and expenditure, leading to excessive fat accumulation and an elevated risk of chronic conditions such as type 2 diabetes and metabolic disorders. Despite the potential benefits of lifestyle modifications, sustainable weight loss remains challenging, and concerns about the safety of anti-obesity drugs have driven interest in natural compounds. 1'-acetoxychavicol acetate (ACA), a bioactive compound derived from the wild ginger *Alpinia galanga*, has demonstrated anti-obesity effects in both in vitro and in vivo studies. However, the precise mechanisms underlying these effects are not fully understood. This study investigates the molecular mechanisms by which ACA inhibits adipogenesis in 3T3-L1 preadipocytes.

METHODS
3T3-L1 preadipocytes were cultured in differentiation-inducing medium for 8 days in the presence or absence of ACA. Lipid accumulation was assessed via Oil Red O staining, while cell viability was evaluated using the MTT assay. Gene and protein expression levels of adipogenic and lipogenic markers were analyzed using real-time PCR and Western blotting.

RESULTS
ACA significantly reduced lipid accumulation in 3T3-L1 cells without notable cytotoxicity. It downregulated the expression of key fatty acid synthesis-related genes (*srebp1c*, *acc*, *fas*, *fabp4*) and adipogenic transcription factors (C/EBPβ, PPARγ, C/EBPα). Notably, ACA increased CREB phosphorylation at serine 133, a transcription factor for C/EBPβ, via a PKA-dependent pathway. Additionally, ACA enhanced AMPK phosphorylation, which inhibits CBP/p300, a co-activator of CREB, further suppressing adipogenic signaling.

CONCLUSIONS
These findings suggest that ACA exerts anti-adipogenic effects by modulating AMPK activation and suppressing CREB transcriptional activity. This study provides insights into the potential of ACA as a natural compound for obesity management.

IMPACT OF MODERATE MATERNAL RIBOFLAVIN DEFICIENCY ON THE GROWTH AND DEVELOPMENT OF OFFSPRING RATS

S Gomathi[1]; H Radha[1]; G Bhanuprakash Reddy,[1]; S Sreenivasa Reddy,[1]
[1]BIOCHEMISTRY, ICMR - National Institute of Nutrition, Hyderabad, India

BACKGROUND AND OBJECTIVES
Riboflavin (vitamin B2) is crucial for energy metabolism and physiological processes. Pregnant women have a greater chance of being riboflavin deficient. However, there is limited research on how maternal riboflavin deficiency impacts offspring's growth, development, and anthropometric measurements. This study investigated the effects of maternal riboflavin (moderate) deficiency on offspring growth and development in a rat model.

METHODS
Two-month-old female Wistar (WNIN) rats were randomly divided into three groups: control (AIN-93G diet with 5 mg/kg of riboflavin), pair-fed, and riboflavin-deficient (0.5 mg/kg). After six weeks riboflavin deficiency was confirmed in the riboflavin deficient group and was allowed to mate with male littermates followed by pregnancy and lactation. The pups stayed with their mothers during lactation and received a diet similar to the mothers during weaning. The experiment included four groups of pups: control, pair-fed, deficient, and replenishment. Pups were maintained for 6 weeks before sacrificing them.

RESULTS
Female rats were fed a riboflavin-deficient diet, resulting in decreased body weight. While maternal fertility and pregnancy indices were unaffected, litter size was reduced in the deficient group of dams. Offspring of riboflavin-deficient dams exhibited delayed developmental milestones, including pinna unfolding, eye slit formation, and fur growth. Furthermore, they showed significantly lower anthropometric measurements of body weight, length, and abdominal circumference. Post-weaning mortality was higher in the deficient group, likely due to hypoglycemia. Replenishment with a riboflavin-sufficient diet partially reversed these adverse effects.

CONCLUSIONS
These findings emphasize the critical role of adequate maternal riboflavin intake for optimal fetal and postnatal growth and development in offspring.

METHYL DEFICIENCY FUELS HEPATOCELLULAR CARCINOMA STEMNESS AND METABOLIC SHIFTS

Wan-Jing Chen[1]; Ya-Ting Jhuang[1]; Wen-Yu Lan[1]; Ya-Chun Hu[2]; Kai-Wen Huang[3, 4, 5]
[1]Medical Research Center, Cardinal Tien Hospital, New Taipei, Taiwan; [2]Department of Nutrition, Cardinal Tien Hospital, New Taipei, Taiwan; [3]Department of Surgery, National Taiwan University Hospital, Taipei, Taiwan; [4]Hepatitis Research Center, National Taiwan University Hospital, Taipei, Taiwan; [5]Graduate Institute of Clinical Medicine, National Taiwan University College of Medicine, Taipei, Taiwan

BACKGROUND AND OBJECTIVES
Hepatocellular carcinoma (HCC) is a common primary malignant cancer with a high mortality rate. Folate deficiency has been identified as a potential stress factor in the tumor microenvironment. However, the relationship between overall methyl nutrients and the malignant progression of HCC remains unclear. The objective was to examine how methyl nutrient deficiency reshapes the metabolic microenvironment and drives the progression of hepatocellular carcinoma.

METHODS
This study cultured human liver cancer cells (HepG2) in a low-methyl-nutrient microenvironment and subsequently performed intrahepatic xenotransplantation into C57BL/6 mice to establish a liver cancer animal model.

RESULTS
The RESULTS showed that folate and choline insufficiency, compared to the control group, significantly promoted *in vitro* HCC stemness, as indicated by (1) an increased wound healing area, (2) a 2-3-fold increase in tumor sphere volume and number, and (3) upregulation of cancer stem cell surface markers. Furthermore, the *in vivo* model revealed that methyl-nutrient insufficiency elevated serum LDH activity, caused disturbances in NADPH redox balance, and increased DNMT1 expression. Folate and choline deficiency exhibited Warburg effect characteristics and a decrease in methylation-related metabolites, such as acetylcholine and sarcosine.

CONCLUSIONS
In summary, methyl nutrient insufficiency drives the acquisition of HCC stem cell properties, reshapes the metabolic microenvironment, and exacerbates the risk of DNA hypomethylation.

ANTI-OBESITY EFFECTS OF CITRUS JABARA EXTRACT: MECHANISMS OF ADIPOCYTE DIFFERENTIATION INHIBITION AND LIPOLYSIS PROMOTION

Tomoyo Minamizono[1]; Isao Matsui-Yuasa[1]; Akiko Kojima-Yuasa[1]
[1]Department of Nutrition, Graduate School of Human Life and Ecology, Osaka Metropolitan University, Osaka, Japan

BACKGROUND AND OBJECTIVES
Obesity is a major risk factor for lifestyle-related diseases, including diabetes, hypertension, and dyslipidemia, which can progress to severe conditions such as myocardial infarction and stroke. With the global prevalence of obesity on the rise, effective prevention and intervention strategies are critically needed. *Citrus jabara*, a citrus fruit native to Kitayama Village, Wakayama Prefecture, Japan, has gained attention for its potential health benefits. Rich in vitamins A and C, carotene, and flavonoids, its peel contains narirutin, a flavonoid known for anti-allergic properties. However, its potential anti-obesity effects remain unexplored. This study aims to evaluate the anti-obesity effects of *jabara* extract and elucidate its underlying mechanisms.

METHODS
3T3-L1 preadipocytes were induced to differentiate into adipocytes over 8 days in the presence of various concentrations of *jabara* extract. Intracellular triglyceride accumulation was assessed via Oil Red O staining, while cell viability was determined using the MTT assay. Gene and protein expression levels of key factors in adipocyte differentiation and fatty acid synthesis were analyzed using real-time PCR and Western blotting.

RESULTS
Jabara extract did not affect cell viability but significantly reduced intracellular fat accumulation in a concentration-dependent manner, as demonstrated by Oil Red O staining. Stage-specific assays revealed that *jabara* extract inhibited fat accumulation during both early and late differentiation phases, suggesting effects on differentiation and lipolysis. Additionally, *jabara* extract reduced the expression of C/EBPα and PPARγ, critical transcriptional regulators of adipocyte differentiation, at both the gene and protein levels.

CONCLUSIONS
Jabara extract exhibits promising anti-obesity effects by inhibiting adipocyte differentiation and promoting lipolysis. These findings suggest that *jabara* may serve as a functional food ingredient for obesity prevention and management. Further studies are warranted to isolate and characterize its active components.

SEARCH FOR SIPHONAXANTHIN DEHYDROGENASE MODULATORS

Yuki Manabe[1]; Tatsuya Sugawara[1]
[1]Graduate School of Agriculture, Kyoto University, Kyoto, Japan

BACKGROUND AND OBJECTIVES

Siphonaxanthin is a carotenoid found in some edible green algae with potent anti-inflammatory effects. We previously showed that most of the orally administered siphonaxanthin is metabolized to three different dehydrometabolites, which exhibit stronger anti-inflammatory activities than siphonaxanthin itself. However, enzymes responsible for dehydrogenation of siphonaxanthin has not been identified. In addition, there is little information about the factors that regulate dehydrogenation of siphonaxanthin. In this study, we tried to elucidate them using cultured cell models.

METHODS

Cells were incubated with siphonaxanthin with or without various chemicals for 24 h. Accumulated dehydrometabolites of siphonaxanthin were extracted by Bligh-Dyer's method and quantified using HPLC-PDA.

RESULTS

We evaluated the dehydrogenase activity of human liver-derived HepG2, Huh7, and HepaRG cells, rat liver-derived McA-RH7777 cells, and human intestine-derived Caco-2 and HT29-MTX-E12 cells towards siphonaxanthin. HepG2 cells exhibited the stronger activity; hence, we used this cell line afterwards. We incubated HepG2 cells with siphonaxanthin in the presence or absence of various chemicals and found that itraconazole increased the dehydrogenase activity. On the other hand, α-naphthoflavone decreased the dehydrogenase activity of HepG2 cells. Since itraconazole and α-naphthoflavone are reported to activate and inhibit aryl-hydrocarbon receptor (AhR), respectively, we treated the cells with both itraconazole and α-naphthoflavone. The increase in the dehydrogenase activity by itraconazole was cancelled by α-naphthoflavone.

CONCLUSIONS

AhR activation would result in the increase the dehydrogenase activity towards siphonaxanthin. Food ingredients with AhR agonist activity could increase anti-inflammatory effects of siphonaxanthin via upregulation of siphonaxanthin dehydrogenase.

THE EFFECT OF CHEDDAR CHEESE CONSUMPTION ON THE GUT MICROBIOME: EXPLORING THE ROLE OF THE DAIRY MATRIX

Clíona Ní Chonnacháin[1]; Emma Feeney[2]; Martina Rooney[3]; Eileen Gibney[2]; Jamie A Fitzgerald[4]
[1]Institute of Food and Health, University College Dublin, Dublin, Ireland; [2]Institute for Food and Health, University College Dublin, Dublin, Ireland; [3]Co-Centre for Sustainable Food Systems, University College Dublin, Dublin, Ireland; [4]ADAPT Centre, Munster Technological University, Cork, Ireland

BACKGROUND AND OBJECTIVES

Cheddar cheese is a nutritionally dense food matrix containing nutrients and bioactives with the potential to influence the gut microbiome (1). Food matrices (physical structures wherein nutrients are situated) influence nutrient absorption and digestibility (2). Thus, the dairy matrix may affect gut microbial responses to dairy foods. This research aims to identify gut microbial responses to cheddar cheese consumption, considering aspects of the dairy matrix.

METHODS

Secondary analysis was conducted on a subset (n=69) of data from a 6-week parallel dietary intervention study (3). Interventions were: (A) 120g unmelted cheddar cheese (n=30); (B) 120g melted cheddar cheese (n=18); (C) butter (49g), calcium caseinate powder (30g), and Ca supplement (500mg) (n=21). Anthropometry, dietary intake data and fecal samples were collected at week 0 and 6 (W0, W6). Fecal samples underwent 16S rRNA gene sequencing (Illumina NextSeq2000), followed by bioinformatic and statistical analysis determining the impact of the intervention on the gut microbiome. This involved differential abundance testing (ALDEx2 with Wilcoxon), alpha diversity (Shannon, Simpson with Wilcoxon) and beta diversity analysis (PCoA on Bray-Curtis dissimilarity (BC) with PERMANOVA).

RESULTS

At baseline, 52% were female, mean age was 58.2±5.4 years and mean BMI was 28.3±3.4kg/m², with no significant differences between groups or timepoints. Following 16S rRNA sequencing, 12098 unique bacterial taxa were identified across the total cohort. Under a false discovery rate cutoff of 0.1, Dorea ($W=0.568$, $p=0.079$) and Erysipelotrichaceae UCG-003 ($W=0.887$, $p=0.097$) were significantly increased at W6 in the unmelted cheese group. Bacteroides was differentially abundant in the unmelted group, relative to the melted group at W6 ($W=0.587$, $p=0.034$). Bacterial alpha diversity (Shannon, Simpson) significantly increased from W0 to W6 in the unmelted group ($p<0.05$). Beta diversity (PERMANOVA on BC) showed a significant group effect considering all groups and timepoints ($F=1.505$, $p<0.01$), although there was no significant effect considering W6 only.

CONCLUSIONS

The unmelted cheese group showed an increase in overall gut bacterial diversity, with further increases seen in the fermenting bacteria Dorea and Erysipelotrichaceae UCG-003. Unmelted cheddar cheese may positively modulate the gut microbiome by increasing species richness and evenness, potentially conferring benefits to the host. Heating and altering physical cheese structure disrupts the dairy matrix, potentially influencing downstream gut-nutrient interactions and subsequent gut microbial response. This effect warrants further exploration.

EPO8_099

A NOVEL POSTBIOTIC FORM OF LACTIPLANTIBACILLUS PLANTARUM AMELIORATES EXCESSIVE FAT ACCUMULATION IN OBESE MICE

Fermín I. Milagro[1, 2, 3]; Ignacio Goyache[1]; Miguel López-Yoldi[1]; Lorena Valdés[4]; Ana Lucía Rodas[4]; Raquel Virto[4]; Paula Aranaz[1]
[1]Center for Nutrition Research, University of Navarra, Pamplona, Spain; [2]CIBEROBN, Carlos III Health Institute, Madrid, Spain; [3]A406, Idisna, Pamplona, Spain; [4]Microbiología, CNTA, San Adrián, Spain

BACKGROUND AND OBJECTIVES
Obesity is a multifactorial disease characterized by an excessive accumulation of adipose tissue. This excess of adiposity contributes to the development of other obesity-related metabolic disturbances, such as chronic inflammation and insulin resistance. Different strategies can contribute to reduce excess adiposity, including the improvement of the microbiota–gut–adipose axis. This is the case of new probiotics with anti-obesity properties (i.e, some strains of *Lactiplantibacillus plantarum*). However, postbiotics, defined as bacteria-free extracts and non-viable microorganisms, may be even more effective to the host and are being preferred as potential therapeutic tools. Here, we evaluate the fat-reducing activity of a novel postbiotic form of a strain of *Lactiplantibacillus plantarum* in a diet-induced obesity mouse model

METHODS
22 male C56BL/6 mice were fed a high-fat-high sugar (HFS) diet and 10% of fructose in the water to induce obesity, and were divided into two groups: HFS group (n=11, HFS diet without supplement) and POSTBIOTIC group (n=11, HFS diet supplemented with 2 x 10E9 *Lactiplantibacillus plantarum* dead cells/day during 10 weeks). An additional group of mice (CNT group, n=8) was fed a rodent maintenance diet (14% protein) during the whole experiment, as non-obese control mice. Body composition, body weight, adiposity and biochemical parameters were analysed in all groups. Finally, microbiota was analysed by 16S rRNA sequencing in the faecal samples of the three groups

RESULTS
All HFS-fed mice exhibited a significant increase in body weight and fat mass in comparison with the control diet-fed animals. However, despite no differences in total body weight, mice supplemented with the postbiotic form of *L. plantarum* showed a significant reduction in the proportion of retroperitoneal, mesenteric and subcutaneous fat depots. Metagenomic analyses revealed differences in the gut microbiota of treated and untreated-HFS groups at family, genus and species level

CONCLUSIONS
Our RESULTS suggest that the novel postbiotic form of *Lactiplantibacillus plantarum* has potential activity against excessive fat accumulation and can target the obesity-related dysbiosis, emphasizing the positive impacts of postbiotics on obesity and its comorbidities

CONFLICTS OF INTERESTS

KAEMPFEROL-3-O-RUTINOSIDE ISOLATED FROM GYNURA BICOLOR (국문명: 금시초): ANTIOXIDANT AND FUNCTIONAL TEA DEVELOPMENT

Hae Ju Moon[1]; Jun Hyeong Kim[1]; Suk Heung Oh[1]
[1]Department of Food and Biotechnology, Woosuk University, Wanju-gun, Jeonbuk State, South Korea, Korea, Republic of

BACKGROUND AND OBJECTIVES
Kaempferol-3-O-rutinoside (K-3-O) is a flavonoid with strong antioxidant activity, making it a promising compound for functional foods and materials. *Gynura bicolor* has been traditionally consumed in Southeast Asia, particularly in Taiwan, China, and Japan, and is known for its bioactive compounds such as flavonoids and anthocyanins. These properties suggest its potential as a functional ingredient. However, research on *Gynura bicolor* cultivated in Korea is limited, highlighting the need for systematic studies. This study aims to isolate, identify, and quantify K-3-O from the BuOH fraction of *Gynura bicolor*, establish data on its antioxidant activity, and assess its potential as a functional material.

METHODS
The extract of *Gynura bicolor* was fractionated stepwise to obtain the BuOH fraction, from which K-3-O was isolated using open column chromatography. Structural validation was performed via NMR spectroscopy with methanol-d_4 as the solvent, confirming the 1H and 13C signals characteristic of the kaempferol skeleton and rutinoside moiety. LC-MS analysis used multiple reaction monitoring (MRM) mode to track ion transitions from m/z 594.39 to 286.22. A calibration curve using a Sigma-Aldrich standard (10–500 ppb) ensured accurate detection.

RESULTS
K-3-O was identified in LC-MS analysis with a retention time (RT) of 2.38 minutes, and its concentration in the BuOH fraction was 217.9 ppb. NMR analysis confirmed its structure through 1H signals (6.4–7.8 ppm) and 13C signals (60–105 ppm). The BuOH fraction showed DPPH radical scavenging activity of 82.3%, surpassing the EtOAc fraction (75.2%). LC-MS analysis established detection (LOD, 10 ppb) and quantification limits (LOQ, 30 ppb) for K-3-O, with a high calibration curve linearity ($R^2 = 0.999827$).

CONCLUSIONS
This study successfully isolated, identified, and quantified Kaempferol-3-O-rutinoside (K-3-O) from the BuOH fraction of *Gynura bicolor* cultivated in Korea. The findings confirm the potential of *Gynura bicolor* as a functional material with antioxidant properties. Future research will focus on K-3-O's antioxidant mechanisms and effects on reactive oxygen species (ROS) using *Caenorhabditis elegans* as a model.

THE EFFECT OF A SLUSH PUPPY-GLYCEROL COMBINATION ON THERMOREGULATION AND FLUID BALANCE DURING A MILITARILY RELEVANT PHYSICAL EXERCISE

Leanne Van Der Hout[1]; Mila Kuller[1]; Minke Geerts[1]; Kristel Kamstra[2]; Lisa Klous[1]; Iris Maria De Hoogh[1]; Sam Ballak[1]
[1]Human Performance, TNO - Locatie Soesterberg, Soesterberg, Netherlands; [2]Healthy Living and Work, TNO Leiden, Leiden, Netherlands

BACKGROUND AND OBJECTIVES
Military personnel often face high levels of heat stress due to heavy gear and intense activity in combination with high ambient temperatures, increasing the risk of heat illness. Nutritional mitigating strategies can enable soldiers to work effectively in the heat. It is known that a slush puppy drink can lower core temperature, while adding glycerol can help to retain fluid (Lee, Kenefick & Cheuvront, 2015, Goulet et al., 2018). This study aims to determine if the combined ingestion of a glycerol-slush drink can reduce thermal strain and improve fluid balance, potentially enhancing safety and performance in hot environments in a military relevant protocol.

METHODS
In this crossover study with three conditions, during each visit 12 healthy male participants will perform a 50-minute march, followed by a 10-minute break, conducted in a climate chamber set to 33°C with 50% relative humidity. The three conditions are: an isotonic sports drink at 33°C, a slush puppy drink at 0°C, and a combined slush puppy glycerol drink at 0°C. Participants will consume one of the three test drinks 30 minutes before starting each march. During the march, several continuous measurements will be performed, including heart rate and core and skin temperature. In addition, blood plasma volume, total urine production, total sweat loss, and local sweat production and concentration will be measured at multiple times. Also, subjective responses, such as perceived exertion and thermal sensation will be collected. A two-way repeated measures ANOVA will be used to compare the effects of the drink conditions.

RESULTS
It is anticipated that the slush puppy drink will lower core temperature, reduce sweat rate, decrease thermal sensation, and improve thermal comfort compared to the isotonic drink alone. Glycerol is expected to enhance fluid retention, resulting in increased blood plasma volume and reduced urine output. The combination of slush and glycerol is anticipated to outperform the other conditions, specifically concerning core temperature and fluid balance.

CONCLUSIONS
This study is expected to offer valuable insights into the effects of a combined slush puppy-glycerol drink on thermoregulation and fluid balance during a military relevant task. The RESULTS of this study can contribute to heat mitigation strategies for military personnel, with the combined approach of slush and glycerol providing a practical solution for managing both thermal load and dehydration for performing in hot conditions.

FACTORS INFLUENCING THE IMPLEMENTATION OF THE NUTRITION COMPACT AGREEMENT AMONG MEMBERS OF THE MULTISECTORAL STEERING COMMITTEE ON NUTRITION IN TANZANIA

Rayman Mwangosi[1]; Mruma Henry[2]; Panras Godwin[2]
[1]Health and Nutrition, Save the Children International Tanzania Programme, Dar es Salaam, Tanzania, United Republic of; [2]School of public Health and Social Science, Muhimbili University of Health and Allied Sciences, Dar es Salaam, Tanzania, United Republic of

BACKGROUND AND OBJECTIVES
Malnutrition remains a pressing challenge in Tanzania, necessitating multisectoral efforts to address its complex causes. The Nutrition Compact Agreement was introduced to enhance accountability and foster collaboration among stakeholders. This study explored the factors influencing its implementation, focusing on facilitating factors, challenges, and perceptions of its complexity.

METHODS
A qualitative approach was employed, utilizing 20 key informant interviews with members of the Multisectoral Steering Committee on Nutrition from different Nutrition sensitive departments. Data were thematically analysed to identify key enablers, challenges, and perceptions related to the Nutrition compact agreement.

RESULTS
Facilitating Factors: Government commitment, effective coordination mechanisms, and active participation of NGOs were crucial. Availability of signed agreements, budget allocations, and availability of guidelines such as School feeding guidelines and Village Health and Nutrition(VHND) guideline further enhanced implementation of Nutrition Compact in the Region.
Challenges: Limited financial resources, shortages of skilled personnel, outdated policies, and inadequate tools hindered progress. Poor supervision and gaps in training also constrained effective implementation.
Perceptions of Complexity: Stakeholders found the compact well-structured, with clearly defined roles, but emphasized the need for continuous capacity-building due to staff turnover.

CONCLUSIONS
The Nutrition Compact Agreement is a promising framework for addressing malnutrition through multisectoral collaboration. However, addressing resource gaps, updating policies, and strengthening capacity-building are critical for sustained success. These findings underscore the need for coordinated, resource-driven strategies to achieve nutrition goals.

SOCIODEMOGRAPHIC, NUTRITIONAL, AND CLINICAL PROFILE OF CHILDHOOD STUNTING IN SOUTHERN PHILIPPINES: DATA FROM MOTHER-CHILD DYADS

Genevieve Tupas[1, 2, 3]; John Lennon Calorio,[1]; Cecile Melisse Derecho[2]; Arian Blanch Maraon[2]; Lovelle Mae Marasigan[2]; Gerard Bryan Gonzales[3, 1]
[1]Center for Research and Development, Davao Medical School Foundation Inc, Davao City, Philippines; [2]Research and Development Center for Maternal and Child Health, Davao Medical School Foundation Inc., Davao, Philippines; [3]Department of Public Health and Primary Care, Faculty of Medicine and Health Sciences, Ghent University, Ghent, Belgium

BACKGROUND AND OBJECTIVES
In the Philippines, one in every four children under five years old is stunted (1), with the highest prevalence observed in the southern region, where up to 45% of children under five are affected (2). This study aimed to determine the sociodemographic, nutritional, and health-related profiles of stunted children in southern Philippines by analyzing mother-child dyads.

METHODS
A case-control study was conducted among children under five years old in selected regions of southern Philippines. Cases included stunted children and their mothers, while controls were non-stunted children and their mothers matched for age, sex and residence. Physical examinations and anthropometric measurements were performed, and mothers were interviewed regarding sociodemographic factors and health practices. Data were analyzed using Logistic Regression.

RESULTS
A total of 408 mother-child dyads were included, comprising 203 stunted children and their mothers, and 205 non-stunted counterparts. A majority of stunted children were aged 0–5 months (112; 56.6%). The male-to-female ratio was similar across groups. Most stunted children were also underweight (197; 96.1%), a finding mirrored among non-stunted children (196; 96.6%). Both groups predominantly completed the primary series of immunizations. Maternal factors significantly associated with childhood stunting included being underweight, married, religion, residing in rural areas, using open-pit toilets, and reliance on well water.

CONCLUSIONS
Childhood stunting in southern Philippines is influenced by a combination of sociodemographic, nutritional, and environmental factors. These findings highlight the need for integrated interventions focusing on maternal nutrition, access to safe water, and improved sanitation to reduce stunting prevalence in this region. Addressing these determinants is crucial to improve child growth and development outcomes.

COVERAGE SURVEY OF INTEGRATED MANAGEMENT OF ACUTE MALNUTRITION PROGRAM USING SLEAC METHODOLOGY

Ranjan Kapali[1]; Lila Bikram Thapa[2]; Ojaswi Acharya[3]; Kusum Wagle[4]
[1]Nutrition and Health, Action Against Hunger | ACTION CONTRE LA FAIM (ACF), Lalitpur, Nepal; [2]Family Welfare Division, Department of Health Services, Kathmandu, Nepal; [3]Country Director, Action Against Hunger | ACTION CONTRE LA FAIM (ACF), Lalitpur, Nepal; [4]Nutrition, Nepali Technical Assistance Group (NTAG) Office, Kathmandu, Nepal

BACKGROUND AND OBJECTIVES

Acute malnutrition, or wasting, is a leading cause of child morbidity and mortality. To address this, Nepal's government implements the Integrated Management of Acute Malnutrition (IMAM) program across all 77 districts. Despite these efforts, 8% of children aged 6–59 months remain wasted, with some provinces exceeding the WHO emergency threshold. This survey aimed to evaluate IMAM program coverage in three districts and identify barriers and facilitators to improving access and coverage nationwide.

METHODS

This coverage survey utilized the Simplified Lot Quality Assurance Sampling Evaluation of Access and Coverage (SLEAC) methodology across three districts: Rautahat (Madhesh Province), Dolakha (Bagmati Province), and Mugu (Karnali Province) representing the three ecological regions of the nation. Districts were selected based on screening, admission, cured, and defaulter rates for wasting. Using two-stage cluster sampling, trained enumerators visited households with children aged 6–59 months from August to October 2024. Mid-upper arm circumference (MUAC) measurements classified children as SAM or normal per WHO cut-offs, while caregivers were interviewed to identify barriers and boosters to program utilization.

RESULTS

A total of 14,175 children were screened using MUAC across Rautahat (6,347), Dolakha (4,471), and Mugu (3,357). IMAM program coverage for SAM treatment was classified as "low" (below 20%) in Rautahat and Dolakha but "high" (above 50%) in Mugu. Barriers included caregiver unawareness of malnutrition, the IMAM program, and treatment options, lack of accompanying persons, family illness, low household decision-making power for women, therapeutic food shortages, skepticism about program effectiveness, and insufficient information. Boosters included malnutrition diagnosis by health personnel and caregiver satisfaction with services.

CONCLUSIONS

Improvements and adaptations in the IMAM program are necessary to enhance coverage across all districts. Key to this effort will be increasing awareness of malnutrition and the availability of the program, as well as enhancing the quality of IMAM treatment at the health facility level. Proper monitoring of the implementation and well managed supply chain can help enhance coverage and access of the program.

THE AVAILABILITY, ACCESSIBILITY AND CONSISTENCY OF ALLERGEN INFORMATION OF FOODSTUFFS ACROSS ONLINE RESTAURANT AND DELIVERY APPLICATION PLATFORMS USED IN SOUTH AFRICA.

Yolande Smit[1]; Evette Van Niekerk[1]
[1]Department of Global Health, Division of Human Nutrition, Faculty of Medicine and Health Sciences, Stellenbosch University, Cape Town, South Africa

BACKGROUND AND OBJECTIVES
The acceleration of digitalization has led to significant growth in online retail. Consumers with food allergies remain at risk due to the absence of standardized allergen labelling on online platforms, as current legislation and practices are inadequate for the digital food marketplace. This study aimed to investigate the availability and accessibility of allergen information on online platforms.

METHODS
Observational checklists were used to collect data for two online platforms: restaurants and delivery applications. Data collection took place over two weeks, in March 2024 by standardised researchers. Descriptive statistics, Pearson Chi-Squared, and Fisher Exact tests were used for data analysis.

RESULTS
Among the 17 applications, 88.2% (n=15) had a search bar. Only 23.5% (n=4) included an interactive communication feature, and 17.6% (n=3) had an allergen filter. Applications were significantly more likely to feature a search bar function (p=0.05). Only 50% (n=8) of menu item platforms and 55.6% (n=5) of grocery item applications displayed ingredients. Allergen presence was declared for 30.2% (n=86) of all products (n=285). Information was available only in English. For products containing allergen information 59.3% (n=51) displayed an allergen heading. The number of clicks to reach allergen information was 2.5. Customization options were available for 78.4% (n=80) of meal items. Only 10% (n=8) offered allergen-friendly alternatives, 46.3% (n=37) allowed item removal, and 67.5% (n=54) accepted special instructions.

CONCLUSIONS
There is significant room for improvement in enhancing consumers with food allergies' ability to make informed online food choices. It is recommended that legislation on food labelling be extended to online platforms, ensuring a standardized format for allergen information to protect consumers with food allergies.

DEVELOPING A NATIONAL FOOD COMPOSITION DATABASE: THE PROCESS OF FOOD SELECTION

María Serena De Vecchi Pellati Vayra[1]; Antonella Vacani,[1]; Fernanda Risso,[1]; Marina Moirano,[1]; Laura Raggio[1]
[1]School of Nutrition, Universidad de la República, Montevideo, Uruguay

BACKGROUND AND OBJECTIVES
The absence of an updated and methodologically sound food composition database represents a significant limitation for health professionals, researchers, and institutions in our country. Currently, foreign food composition tables are used, which do not accurately reflect the characteristics of foods consumed at the national level. The objective of this study is to document the process of prioritizing nutrients and identifying priority foods in our country, which will be analyzed to finalize a national food composition database.

METHODS
A team of national experts in the field secured funding to implement a project focused on a limited number of foods. Following international guidelines adapted to the national context from Infoods-FAO, the project began with the selection of priority nutrients and advanced towards identifying foods for sampling. This selection was based on data analysis from the latest household food consumption survey, given the lack of information on food consumption frequency among adults in our country.

RESULTS
Despite economic and material constraints, significant progress was made in selecting foods to be analyzed at the laboratory level.

CONCLUSIONS
This project not only faces technical and logistical challenges but also presents an opportunity to strengthen national capacities and establish strategic partnerships. In this way, the project lays the foundation for the development of a national food composition database to support decision-making in health, nutrition, and food research.

MOLECULAR FOOTPRINT & METABOLIC ROLE OF ADIPOSE TISSUE-DERIVED EXTRACELLULAR VESICLES IN EARLY-STAGE OBESITY AS POTENTIAL BIOMARKERS OF INSULIN RESISTANCE

Humberto Astiazaran-Garcia[1]; Jaime Delgadillo-Velázquez,[2]; Elizabeth Carvajal-Millan,[3]; Magdalena Aguirre-García,[4]; Efraín Alday-Noriega,[5]; Esaú Bojórquez-Velázquez,[6]; José ÁNgel Huerta-Ocampo,[7]
[1]DCQB-Nutrition, Universidad de Sonora, Hermosillo, Mexico; [2]Nutrition, CIAD, Hermosillo, Mexico; [3]CTAOA, CIAD, Hermosillo, Mexico; [4]Laboratorio de Inmunobioquímica Molecular y Cardiopatías, National Institute of Cardiology Ignacio Chavez, Ciudad de México, Mexico; [5]DCQB, Universidad de Sonora, Hermosillo, Mexico; [6]Advanced Molecular Studies Network, Instituto de Ecología, Xalapa, Mexico; [7]Ciencia de los Alimentos, CIAD, Hermosillo, Mexico

BACKGROUND AND OBJECTIVES
Extracellular Vesicles (EVs) are nanoparticles relased and used by cells for intercellular communication. In this context, EVs and their content could serve as potential biomarkers of insulin resistance (IR). Obesity is a risk factor affecting adipose tissue (AT) function and, consequently, insulin sensitivity. The aim was to analyze the metabolic role of the EV content of AT in the early stages of obesity.

METHODS
In the first step, a rat model of diet-induced obesity was established for 10 weeks. In a second step, the proteome of adipose tissue-derived EVs (ADEVs) was analyzed to determine a molecular fingerprint thatdistinguishes the obesity/IR group.

RESULTS
In the first phase, the obese group showed higher levels of both the triacylglyceride-glucose index (T&G) and the triacylglyceride/HDL-c ratio, both used to estimate IR, compared to the control group. For ADEVs, size was related to T&G ($r=0.63$; $p<0.02$) and with multiple linear regression models, we were able to predict the T&G value from the diameter of the ADEVs ($p<0.05$). In the second phase, through label-free quantitative proteomic analysis, potential biomarkers of proteins involved in metabolic processes of the insulin signaling pathway, regulation of triacylglyceride synthesis in adipocytes, and higher abundance of proteins involved in glycolysis were found in the control group.On the other hand,in the obesity/IR group, we found molecular fingerprints of proteins involved in catabolic processes, increased secretion of EVs, and proteins involved in the development of IR. In addition, a first exploratory phosphoproteomic approach found phosphoproteins involved in the regulation of inflammation, oxidative stress, and the assembly of proteins related to the insulin signaling pathway. However, only the obese/IR group presented GLUT 4 transporter protein and protein phosphatase 1 as characteristic molecular signatures.

CONCLUSIONS
Our RESULTS suggest that the lager the size of the ADEV, the higher the degree of systemic IR as assessed by T&G. Together with size, the molecular content of proteins and phosphoproteins of the ADEV could be used to identify early IR and monitor it in people who consume high-fat diets, or increase their waist circumference as consequence of weight gain.

BALANCING NUTRITION AND ACCEPTABILITY: ENRICHED KUNUN ZAKI FORMULATIONS FOR MALNUTRITION INTERVENTION

Aisha Gadanya[1]
[1]Biochemistry, Bayero University, Kano, Kano, Nigeria, Federal Republic of

BACKGROUND AND OBJECTIVES
Abstract
Kunun zaki is a traditional, non-alcoholic beverage in Northern Nigeria, typically made from fermented millet. This study aimed to enhance the nutritional profile of *kunun zaki* by incorporating whole millet, sprouted millet and sesame seeds, targeting increased protein, vitamins, essential fatty acids and minerals beneficial for maternal nutrition.

METHODS
Five formulations with varying ingredients' proportions were developed and analysed for proximate composition, vitamin and mineral content, amino acid profile and anti-nutritional factors. Sensory evaluation was also conducted with 20 panellists assessing taste, colour, aroma, sweetness, appearance, solubility and general acceptability on a 9-point hedonic scale.

RESULTS
The enriched formulations showed significant increase ($P<0.05$) in protein, essential fatty acids, B vitamins, and minerals like calcium, iron, and zinc. Additionally, fermentation and sprouting reduced anti-nutritional factors such as phytates and tannins, enhancing mineral bioavailability. However, sensory evaluation reveals that nutritionally inferior but traditional formulation (containing 100% unsprouted millet) are prepared in taste, aroma and overall acceptability over the innovative, nutritionally-superior formulations (containing varying proportions of sprouted millet and sesame seeds) among the panellists, probably due to latter stronger and less familiar flavour profiles. Incorporating whole and sprouted millet with sesame in the beverage significantly improves its nutritional quality, supporting its potential as a functional beverage with health benefits, particularly for maternal nutrition. However, the acceptability of the formulations toward the consumers need to be re-evaluated due to the poor acceptability of nutrient-dense formulations. This study highlights the potential of nutrient-enriched *kunun zaki* as a functional beverage for maternal nutrition, emphasizing the need to optimize sensory attributes to balance nutritional enhancement with consumer preferences.

CONCLUSIONS
The findings provide a foundation for developing culturally relevant, nutrient-rich foods to address malnutrition in at-risk populations.

DEVELOPMENT AND VALIDATION OF A KUWAITI FOOD FREQUENCY QUESTIONNAIRE FOR DIETARY FIBRE INTAKE IN OLDER ADULTS

Aljazi Alajmi[1]; Ada Lizbeth Garcia,[1]; Christine Edwards[1]
[1]Human Nutrition, School of Medicine, Dentistry and Nursing, University of Glasgow, Glasgow, Unit, University of Glasgow, Glasgow, United Kingdom

BACKGROUND AND OBJECTIVES
Dietary fibre (DF) intake is little understood in older adults. Very few dietary studies include those over 60y and, even if included, they are not separated from other adults. Low intake may be related to increased constipation but to establish DF intake validated assessment tools based on locally relevant foods are needed. This study developed and validated a Kuwaiti- DF specific FFQ (KWFFQ-DF) for those over 60y.

METHODS
Sixty participants (>60y) (healthy and those with diabetes and/or hypertension) were recruited from ten geriatric clinics in six governorates of Kuwait (June to September 2022). The KWFFQ-DF was developed by adapting and updating existing validated FFQs for Arab populations(1-6). Pre-testing reduced a long list of 190 items from eleven food groups to seven fibre-rich groups. The KWFFQ-DF was validated against 24-hour multiple-pass recall (24H-MPR) and 3-day weighed diaries (3DWD). Methods were compared after testing for Shapiro-Wilk normality. Pearson correlation, Bland-Altman plots, and Weighted Kappa analysis were applied.

RESULTS
Participants (44 females, 16 males) aged 61-85y had a mean BMI of 30 kg/m2 (range: 21-50). The average total dietary fibre (TDF) intake was 23.5g/day (6g soluble dietary fibre [SDF], 17.5g insoluble dietary fibre [IDF]) in the KWFFQ-DF validation, 23.4g/day (6g SDF, 18g IDF) in 3DWD, and 23.1g/day (6g SDF, 17g IDF) in 24H-MPR. Common high-fibre food sources included fresh dates palm, watermelon, local breads, vegetables, chickpeas, and various types of wheat and rice-based dishes. There was a similar range of TDF intake (11.0-34.0g/day) SD 5.79g in KWFFQ-DF, 6.08g in 3DWD, and 6.54g in 24H-MPR. KWFFQ-DF intakes correlated well with 3DWD ($r=0.871$, $p < 0.01$) and 24H-MPR ($r=0.851$, $p < 0.01$). Weighted Kappa indicated moderate agreement (0.66 for 3DWD, 0.63 for 24H-MPR). Sensitivity to DF intake ≥25 g/day was 67%, with a specificity of 93%.

CONCLUSIONS
The KWFFQ-DF is a valid tool for assessing DF intake in older Kuwaiti adults and supports further development of nutrient-specific FFQs for the region.

IMPROVING THE SCHOOL FOOD ENVIRONMENT IN SOUTH AFRICA: REGULATION AND MONITORING OF FOOD AND BEVERAGE SALES AT SCHOOL TUCKSHOPS

Ashika Naicker[1]; Pal Imana[2]
[1]Food and Nutrition , Durban University of Technology, Durban, South Africa; [2]Food and Nutrition, Durban University of Technology, Durban, South Africa

BACKGROUND AND OBJECTIVES
As part of UNICEF's initiative to improve the school food environment (SFE) in South Africa and promote better health outcomes for learners, seven multi-stakeholder co-developed interventions were piloted in six public schools for the purpose of scaling up nationwide. The SFE in South Africa primarily consists of meal provisioning through the National School Nutrition Programme (NSNP), the sale of food and beverages at tuckshops and external vendors, and packed lunches brought by learners. The first intervention focused on regulating and monitoring food and beverage sales at school tuckshops, with the primary objective of introducing healthier options while addressing challenges to their adoption and long-term sustainability.

METHODS
A participatory approach was adopted, with each school co-developing a list of healthy food items to be sold at tuckshops in collaboration with the research team. Schools implemented one of two strategies depending on tuckshop ownership: a phased introduction of healthy foods or a complete transition to a healthy tuckshop with the sale of no competitive foods. Accountability and communication plans were co-developed, and tuckshop vendors received training alongside support for procuring healthy items. The intervention, rolled out over three months, was supported by promotional materials and choice architecture tools. Monitoring and evaluation included sales data and feedback from all stakeholders.

RESULTS
Two schools successfully implemented a full-on healthy tuckshop, while four schools with contracted external vendors adopted a phased approach. Key barriers included the presence of competitive foods, resistance from tuckshop owners, limited availability of affordable healthy items, competition from external vendors, and challenges associated with large learner populations. Facilitators included strong support from school leadership, the gradual introduction of healthy items, and the popularity of affordable, healthy snacks.

CONCLUSIONS
The pilot highlighted critical considerations for scaling the intervention, such as the dependency of schools on tuckshop revenue, the sustainability of healthy tuckshops, affordability and access to healthy items, and the need for partnerships with reliable suppliers. To address these challenges, a National Healthy Tuckshop Policy is proposed with clear nutritional standards. Further, integration with health-promoting school policy, robust monitoring and accountability mechanisms, and capacity building through training for tuckshop operators and educational campaigns for learners and parents are recommended.

NEUROPROTECTIVE EFFECTS OF STRAWBERRY LEAF EXTRACT ON PARKINSON'S DISEASE: MECHANISMS AND POTENTIAL APPLICATIONS

Chiharu Ueda[1]; Tamakii Tokumatsu[1]; Manami Sakai[1]; Isao Matsui-Yuasa[1]; Akiko Kojima-Yuasa[1]
[1]Department of Nutrition, Graduate School of Human Life and Ecology, Osaka Metropolitan University, Osaka, Japan

BACKGROUND AND OBJECTIVES
Parkinson's disease (PD) is a neurodegenerative disorder characterized by the degeneration of dopamine-producing neurons in the substantia nigra, leading to motor impairments and non-motor symptoms. With the increasing incidence of PD due to global population aging, the number of patients is expected to rise. Currently, no established treatments exist to halt the progression of PD, and available therapies focus solely on symptom management. Therefore, there is a pressing need to develop fundamental treatments and preventive measures for PD. Strawberry (*Fragaria x ananassa* Duch.), a perennial plant of the Rosaceae family, contains leaves rich in polyphenols, surpassing those found in the fruit. Strawberry leaves exhibit physiological effects such as antioxidant activity, but they are largely treated as agricultural waste. Exploring their potential application may contribute to waste utilization and health advancements. This study aims to investigate the preventive effects of strawberry leaf extract (SLE) on PD.

METHODS
Human neuroblastoma SH-SY5Y cells, widely used in PD-related studies, were cultured in Dulbecco's Modified Eagle's Medium with 10% fetal bovine serum. Neuronal damage was induced using rotenone, a mitochondrial electron transport chain inhibitor. SLE was added concurrently with rotenone at the start of the main culture. Analyses included cell viability, intracellular reactive oxygen species (ROS) production, nuclear Nrf2 expression, and apoptotic markers. Gene expression levels were assessed using real-time PCR.

RESULTS
SLE restored cell viability reduced by rotenone. Elevated ROS levels induced by rotenone were decreased to control levels following SLE treatment. SLE promoted Nrf2 translocation into the nucleus, an effect inhibited by an AMPK inhibitor. Furthermore, SLE significantly increased the expression of p62, which facilitates Nrf2 nuclear translocation. Additionally, SLE reduced PINK1 expression levels elevated by rotenone and suppressed apoptotic cell death

CONCLUSIONS
These findings suggest that strawberry leaf extract exerts neuroprotective effects by reducing ROS production and promoting Nrf2 nuclear translocation via the AMPK signaling pathway. The use of strawberry leaf extract offers potential as both a preventive measure for PD and an innovative approach to agricultural waste utilization.

ANTI-OBESITY EFFECTS OF STRAWBERRY LEAF EXTRACT: MECHANISTIC INSIGHTS AND POTENTIAL FOR SUSTAINABLE UTILIZATION

Yuka Minamizono[1]; Isao Matsui-Yuasa[1]; Akiko Kojima-Yuasa[1]
[1]Department of Nutrition, Graduate School of Human Life and Ecology, Osaka Metropolitan University, Osaka, Japan

BACKGROUND AND OBJECTIVES
Diabetes and dyslipidemia, both of which are lifestyle-related diseases, are closely associated with obesity and significantly increase the risk of mortality from conditions such as myocardial infarction. Dietary interventions play a critical role in their prevention. Recently, the potential of food functionality in obesity prevention has garnered attention, leading to advancements in the development of functional foods. Strawberry (*Fragaria x ananassa* Duch.), a perennial herb of the Rosaceae family, has been reported in previous studies to possess anti-inflammatory and antioxidant properties in its leaves. However, the anti-obesity effects of strawberry leaf extract (SLE) remain unclear. This study aims to elucidate the anti-obesity effects of SLE and its underlying mechanisms. Additionally, by exploring the potential utilization of strawberry leaves -currently discarded in large quantities as industrial waste- this research contributes to sustainable societal practices.

METHODS
Using 3T3-L1 preadipocytes, the effects of SLE on cell viability were evaluated using the MTT assay. Adipocytes were cultured in differentiation-inducing medium for 8 days, and intracellular fat accumulation was assessed via Oil Red O staining. The activity of glycerol-3-phosphate dehydrogenase (GPDH), a rate-limiting enzyme in triglyceride synthesis, was measured through absorbance changes. Furthermore, the expression levels of genes and proteins involved in adipocyte differentiation and fatty acid synthesis were analyzed by real-time PCR and Western blotting, respectively.

RESULTS
SLE did not affect cell viability but significantly reduced fat accumulation and GPDH activity. The expression of *C/EBPα* and *PPARγ*, key regulators of adipocyte differentiation, was suppressed at both the gene and protein levels. Additionally, the expression of *SREBP-1c* and *ACC1*, involved in fatty acid synthesis, was significantly decreased. Furthermore, SLE was found to promote AMPK phosphorylation, a key regulator of energy metabolism, while inhibiting ERK phosphorylation, which is closely linked to insulin signaling.

CONCLUSIONS
These findings suggest that SLE suppresses fatty acid synthesis by promoting AMPK phosphorylation and exerts anti-obesity effects by inhibiting ERK phosphorylation. The potential use of SLE not only offers a novel approach to obesity management but also aligns with efforts toward sustainable resource utilization.

STAKEHOLDER PERCEPTIONS OF THE SOUTH AFRICAN SCHOOL FOOD ENVIRONMENT: BASELINE FINDINGS

Imana Pal[1, 2]; Ashika Naicker[1]; Evonne Shanita Singh[1]
[1]Food and Nutrition Consumer Sciences, Durban University of Technology, Durban, South Africa; [2]School of Health Sciences and Technology, UPES, Dehradun, India

BACKGROUND AND OBJECTIVES
South Africa is experiencing a growing prevalence of overweight and obesity, affecting young children and adolescents. Agents of change play a crucial role in improving the school food environment (SFE), directly or indirectly, and they wield the ability to promote behavioural change, improving health outcomes. This study set out to determine stakeholders' perceptions of the South African public SFE to gain a deeper understanding of their perspectives and identify barriers and facilitators to fostering a healthy SFE.

METHODS
Six public schools representing a combination of an urban and rural mix, including three primary and three secondary schools, were preselected by the Department of Basic Education as pilot schools to improve the SFE in South Africa. Data were collected through focus group discussions (FGDs) with learners, parents, teachers, volunteer food handlers, and school governing bodies, alongside key informant interviews with principals, formal food vendors, and informal food vendors to determine stakeholders' perceptions and capacity to improve the SFE. Qualitative data was analysed through thematic analysis.

RESULTS
Thirty FGDs were done collectively, six for each stakeholder and 18 key informant interviews were conducted among the principals, and formal and informal vendors, six for each stakeholder. The FGDs and key informant interviews yielded several themes, including policy implementation gap and governance, barriers and facilitators of accessing healthy foods at schools, exposure to marketing and advertising, individual-level considerations to food choice, and operational challenges in food provisioning.

CONCLUSIONS
The barriers and facilitators identified in the themes and sub-themes through this multi-stakeholder approach in SFE serve as a valuable framework for the development of intervention strategies for establishing a sustainable, healthy SFE in South Africa.

ERO1A DNA METHYLATION MEDIATES THE TRANSGENERATIONAL EFFECTS OF ZINC, SELENIUM AND CHROMIUM ON ER STRESS AND GLUCOSE HOMEOSTASIS IN FEMALE OFFSPRING OF GESTATIONAL DIABETES RATS

Xueqiong Yao[1]; Xuefeng Yang,[2]
[1]School of Public Health, University of South China, Heng Yang Shi, China; [2]Department of Nutrition and Food Hygiene, School of Public Health, Huazhong University of Science and Technology, Wuhan, China

BACKGROUND AND OBJECTIVES
Zinc, selenium and chromium supplementation improved hepatic endoplasmic reticulum (ER) stress in GDM rats and had beneficial transgenerational effects on glucose homeostasis in female offspring. However, whether the epigenetic molecular mechanism is involved in the transgenerational effects of zinc, selenium and chromium is relatively unknown. Therefore, this study aims to explore the potential epigenetic mechanisms involved.

METHODS
Female Sprague Dawley rats were fed with either an HFS (to induce the GDM model) or LF diet for three consecutive generations (F0, F1, and F2), and supplemented with zinc (10 mg/kg.BW), selenium (20 μg/kg.BW) chromium (20 μg/kg.BW) daily by gavage. Global DNA methylation levels and methylation status of promoter regions of ER stress-related genes were investigated in the liver of F1 and F2 female neonates. GDM caused glucose intolerance, insulin resistance, hepatic ER stress, and increased global DNA methylation in F1 and F2 female neonates.

RESULTS
GDM caused glucose intolerance, insulin resistance, hepatic ER stress, and increased global DNA methylation in F1 and F2 female neonates. Pyrosequencing identified a hypermethylated promoter region in ERO1α that regulated ER stress, which was associated with reduced gene expression and activation of ER stress. Efficient zinc, selenium and chromium supplementation with GDM conferred significant protection against the hypermethylation status of the ERO1α gene promoter region in F1 and F2 female neonates, thus alleviating the ER stress and insulin resistance.

CONCLUSIONS
GDM caused glucose intolerance, insulin resistance, hepatic ER stress, and increased global DNA methylation in F1 and F2 female neonates. Pyrosequencing identified a hypermethylated promoter region in ERO1α that regulated ER stress, which was associated with reduced gene expression and activation of ER stress. Efficient zinc, selenium and chromium supplementation with GDM conferred significant protection against the hypermethylation status of the ERO1α gene promoter region in F1 and F2 female neonates, thus alleviating the ER stress and insulin resistance.

ROLE OF PHOSPHATE HOMEOSTASIS IN LOCAL ENERGY METABOLISM MAINTAINED BY ENPP1 ACTIVITY

Keito Matsubayashi[1]; Hitoki Yamanaka[2]; Ritsuko Masuyama[1]
[1]Graduate School of Gastronomy Management, Ritsumeikan University Biwako Kusatsu Campus, Kusatsu, Japan; [2]Research Center for Advanced Science and Technology, Shinshu University, Matsumoto, Japan

BACKGROUND AND OBJECTIVES
Phosphate insufficiency affect bone development due to compensating mechanisms in homeostasis. As locomotor organ, muscle function alters correspondingly to bone tissue, however, the direct effects of phosphate homeostasis on muscle function have not yet been revealed. In animal study, administration of high phosphate diet impaired energy metabolism and caused the reduction in muscle functions that was accompanied by hyperphosphatemia. We therefore investigate the role of phosphate homeostasis on muscle function by in vitro study with muscle cells.

METHODS
C2C12 muscle cells were cultured, and cells maturations were initiated. Alteration of phosphate homeostasis was recreated in culture medium containing different levels of phosphate. In addition, since active form of vitamin D [1,25(OH)2D3] and cell surface located enzyme, ectonucleotide pyrophosphatase/phosphodiesterase 1 (Enpp1) play an important role in phosphate metabolism in the body, we assessed the role of these factors on muscle cells function with several phosphate conditions in culture. To this aim, concentration of 1,25(OH)2D and Enpp1 specific inhibitor were adjusted to 10-9M to 10-11M and 10-5M to 10-6 M respectively in medium and supplied to culture for 48 hours. At the end, medium and cultured cells were separatory collected for protein expression and glucose assay.

RESULTS
As a result, the protein levels of Glucose transporter and ATP synthase revealed with western blot analysis was decreased by blockade of ENPP1 activity in cultured cells. These RESULTS suggested that the altering phosphate dynamics depend on Enpp1 function at cell membrane affect glucose-ATP metabolism. Next, the amount of bone marrow fat tissue was assessed in femur of Enpp1 asj mice as a parameters of nutrition sufficiency. These mice show low blood phosphate from a young age; thus, we use these mice to investigate the effect of organ phosphate metabolism. The values of the amount of fat tissue in bone marrow cavity were higher than those of WT mice.

CONCLUSIONS
Taken together, the phosphate dynamics directly changed local energy metabolism in muscle cells. Phosphate sufficiency is considered as an important factor to maintain utilization of nutrition based on energy metabolism.

STUDY ON THE GLUCOSE RELEASING RATE (GR) METHOD: GR VALUES OF CARBOHYDRATE-RICH FOODS

Takako Ikeda[1, 2]; Hiroko Nakamura[2]; Yukiko Nakanishi[2, 3]; Mika Kimura[3]; Hajime Sasaki[3]
[1]Faculty of Food and Health Science, Showa Women's University, Tokyo, Japan; [2]Institute for Women's Health Science, Showa Women's University, Tokyo, Japan; [3]GR Project, International Life Sciences Insitute Japan, Tokyo, Japan

BACKGROUND AND OBJECTIVES

The Glycemic Index (GI) predicts postprandial blood glucose levels but requires invasive blood sampling, posing challenges such as psychological stress, costs, and time consumption. A simpler screening method is needed for developing low-glycemic foods. The Glucose Releasing Rate (GR) method, developed by the ILSI Japan GR Project, measures glucose release from foods to predict glycemic responses. This study assessed the validity of the GR method by comparing GR values with GI values for carbohydrate-rich foods.

METHODS

The GR method involves in vitro simulation of mastication, gastric digestion, pancreatic enzyme treatment, and disaccharide breakdown in the small intestine. GR is expressed as the ratio of glucose concentration at 20 minutes relative to that at 16 hours. GR values of 11 carbohydrate-dominant foods (e.g., rice, bread, noodles, and standard meals) were measured. The available carbohydrate content of these foods ranged from 81 g/100 g (cornflakes) to 14 g/100 g (standard meal). Additionally, low-carbohydrate foods (apples, milk, soybeans) were tested for GR values.

RESULTS

No correlation was found between the available carbohydrate content and GR values ($R^2 = 0.0448$). GR and GI values exhibited a positive correlation ($y = 0.9052x + 8.0098$, $R^2 = 0.6755$). Low-carbohydrate foods showed high GR values. The correlation between 20-minute glucose release and GI values was moderate ($y = 27.394x + 29.112$, $R^2 = 0.6331$).

CONCLUSIONS

The study suggests that GR values reflect the digestibility rather than the quantity of carbohydrates in foods. A strong correlation between GR and GI values for carbohydrate-dominant foods supports the potential of GR as an alternative to GI measurement. Additionally, 20-minute glucose release may serve as an indicator for glycemic response, including for low-carbohydrate foods. Further data accumulation for diverse foods and recipes is necessary.

PROTECTIVE EFFECTS OF ECHINOCHROME A ON HEPATIC STEATOSIS

Jimin Hong[1, 2]; Hyobeen Park[1, 2]; Bohkyung Kim[1, 2]
[1]Department of Food Science and Nutrition, Pusan National University, Busan, Korea, Republic of; [2]BK21 FOUR Program : Precision Nutrition Program for Future Global Leaders, Pusan National University, Busan, Korea, Republic of

BACKGROUND AND OBJECTIVES
Disrupted glucose and lipid metabolisms, along with oxidative stress and inflammation are highly associated with the progression of metabolic dysfunction-associated steatotic liver disease (MASLD). Echinochrome A, a common pigment found in sea urchin (*Echinoidea*), has been reported to exhibit effects on metabolic regulation, inflammation and oxidative stress. However, its effects on hepatic steatosis remain largely unknown. In the present study, we investigated the protective effects and its underlying mechanisms of EchA against hepatic steatosis.

METHODS
HepG2 cells were treated with palmate to induce hepatic steatosis, followed by EchA treatment. The expression of genes involved in hepatic lipid metabolism, oxidative stress, and inflammation were measured using quantitative RT-PCR and western blot analysis. Cellular triglyceride contents and reactive oxygen species (ROS) levels were measured by oil red O staining and 2′,7′-dichlorofluorescein, respectively. The energy metabolism of steatotic HepG2 cells was analyzed by an extracellular flux analyzer.

RESULTS
EchA attenuated the increased the mRNA and protein expressions of the genes involved in lipogenesis and cholesterol metabolisms, i.e. sterol regulatory element-binding protein 1, acetyl-coenzyme A carboxylases, fatty acid synthase and 3-hydroxy-3-methylglutaryl-CoA reductase, in PA-induced steatotic HepG2 cells. In contrast, the expressions of carnitine palmitoyltransferase 1α, acyl-CoA oxidase and peroxisome proliferator-activated receptor alpha were significantly reduced by EchA treatment in hepatic steatosis. EchA decreased cellular ROS levels, accompanied by changes in the expression of antioxidant enzymes. The inflammatory genes including interleukin 1β (Il-1β) and IL-6 were significantly suppressed by EchA in steatotic cell. The effects of EchA on inflammatory genes were attributed to the inhibition of nuclear translocation of nuclear factor-κB. Furthermore, EchA treatment led to alterations in mitochondrial function in hepatic steatosis.

CONCLUSIONS
EchA attenuated lipid accumulation, oxidative stress, and inflammation in hepatic steatosis. Therefore, EchA may have the potential to be developed as a therapeutic agent for the prevention of MASLD.

STUDY ON THE MECHANISM OF DIVISION OF LABOR AND COOPERATION IN GUT MICROBIOTA INDUCED BY POLYSACCHARIDE ALTERNATION

Qiannan Wang[1]; Xiaoya Wang[1]
[1]College of Food Science and Nutritional Engineering, China Agricultural University, Beijing, China

BACKGROUND AND OBJECTIVES
Polysaccharides, as a type of complex carbohydrate, are widely present in nature and daily diet, playing an important role in maintaining intestinal health, regulating immune function, and other aspects of the body. However, the mechanism by which polysaccharides induce division of labor and cooperation among gut microbiota is currently not fully understood. The aim of this study is to comprehensively analyze metagenomics, transcriptomics, and metabolomics, combined with animal experiments, to explore the mechanism of polysaccharide alternation induced division of labor and cooperation in gut microbiota, in order to provide theoretical basis for regulating gut microbiota balance and promoting overall health.

METHODS
To test the effects of different types of polysaccharides on gut microbiota in an in vitro simulated intestinal environment, high-throughput sequencing technology was used to analyze the gene expression and diversity changes of gut microbiota under the action of polysaccharides, detect the regulatory effect of polysaccharides on gut metabolites, and verify the effects of alternating intake of polysaccharides on gut microbiota structure, gut health, and immune function through animal models. Finally, the comprehensive experimental RESULTS were used to explore the division of labor and cooperation mechanism of gut microbiota induced by polysaccharides.

RESULTS
In vitro simulation experiments and metagenomic analysis have shown that different types of polysaccharides can significantly affect the diversity and abundance of gut microbiota, selectively promoting the proliferation of beneficial bacteria and inhibiting harmful bacteria. Transcriptomics further revealed the precise regulatory mechanism of polysaccharides on gene transcription in microbial communities, while metabolomics found that polysaccharides significantly alter intestinal metabolites and regulate microbial metabolic activity. Animal experiments have ultimately confirmed that alternating intake of polysaccharides can optimize the structure and function of the gut microbiota, enhance the intestinal barrier and immune function of the body.

CONCLUSIONS
This study suggests that alternating intake of polysaccharides can maintain a good balance of gut microbiota by inducing division of labor and cooperation among the microbiota. Reasonably combining the intake types of polysaccharides can more effectively regulate the balance of gut microbiota.

EVALUATION OF THE NUTRITIONAL STATUS AND EATING HABITS OF HOSPITAL EMPLOYEES BASED ON THEIR WORKING SHIFTS

Gülsüm Şahin Bodur[1]; Alev Keser[2]
[1]Nutrition and Dietetics, Çankırı karatekin university, Ankara, Türkiye; [2]Nutrition and Dietetics, Ankara University, Ankara, Türkiye

BACKGROUND AND OBJECTIVES
The shift-based schedules of hospital employees can significantly impact their nutritional habits and overall health status. In this study, it is aimed to evaluate the nutritional status and eating habits of hospital employees based on their shift-based working conditions.

METHODS
The study was conducted between November 2017-March 2018 on a total of 200 individuals aged 21-50 years, working at a hospital. Individuals who volunteered to participate in the study were included. Data were collected face-to-face. The questionnaire, included parameters such as age, gender, marital status, and nutritional status. The analyses were conducted at a 95% confidence level ($p<0.05$).

RESULTS
Of the shift-working participants included in this study, 62.3% were women($p<0.05$). While the average age of non-shift workers was 30.8±7.98 years, the average age of shift workers was found to be 29.7±6.43 years($p<0.05$). Half of the participants were nurses($p<0.05$). Among shift workers, 7% used dietary supplements, whereas this rate was 10.1% among non-shift workers($p>0.05$). Among female shift workers, 51.8% stated that they gained weight after starting the shift system, and 25.9% reported weight loss($p<0.05$). Additionally, 63.8% of shift-working individuals stated that their food consumption had increased($p>0.05$). The proportion of shift workers who skip main meals due to irregular working hours was 58.5%($p>0.05$).

CONCLUSIONS
In conclusion, this study highlights the significant impact of shift-based work on employees' nutritional habits, emphasizing the importance of implementing targeted interventions to support their health and improve workplace conditions.

EVALUATING THE PHYSICAL ENVIRONMENT AND MEAL SERVED IN SCHOOL FEEDING PROGRAMS: AN OBSERVATIONAL STUDY IN THE HOHOE, GHANA

Phyllis Addo[1]; Jessica Akpene Seworh Fanah[1]; Felix Teyko[1]; Mercy Adjei Adumatta[1]; Christabel Seyram Agbley[1]; Ophelia Afua Kotoku[1]; Stephanie Salomey Dzidzornu[1]; Ernestina Adzim[1]; Matilda Agbanyo[1]; Marina Sewornu[1]; Beverlyn Asheley Mensah[1]; Amadea Larbi[1]
[1]Family and Community Health Department, Fred N. Binka School of Public Health, University of Health and Allied Sciences, Ho, Ghana

BACKGROUND AND OBJECTIVES
The Ghana School Feeding Program (GSFP) has improved school attendance, enrollment, and academic performance but faces challenges related to unsupportive food environments, hygiene, and sanitation practices. This study aimed to assess the physical environment where school meals are served and consumed to inform actionable improvements.

METHODS
An observational study was conducted in 11 schools in Hohoe Township participating in the GSFP. Between February and March 2023, a checklist adapted from the MEALS4NCDs project was employed to evaluate the physical environment and promote healthy eating. Frequencies and percentages were calculated using Microsoft Excel. Ethical standards and permissions were adhered to.

RESULTS
The assessment revealed deficiencies in infrastructure, hygiene, and program implementation. Ten of the 11 schools used open or partially covered spaces for serving meals, with only two providing proper seating arrangements. Over 90% of students did not have their bowls or cutlery, frequently sharing unwashed items. Hand washing facilities were inadequate; only 18% of schools provided water and soap, while 27% had no water available. None of the schools implemented basic food hygiene measures, such as protecting meals from contamination. Waste management was also poor, with only 45% of schools having rubbish bins, and just 20% being covered. Teacher and head teacher participation in supervising the program was minimal, leading to compromised oversight of food distribution and cleanliness. Additionally, no school displayed materials promoting healthy eating, while nearby shops selling unhealthy snacks further influenced students' dietary habits.

CONCLUSIONS
The GSFP in Hohoe Township faces infrastructure, hygiene, and oversight challenges that limit its effectiveness. Addressing these issues requires investment in designated eating areas, improved hygiene facilities, enforcement of food safety measures, and initiatives promoting healthy eating. Enhancing teacher involvement and stakeholder engagement is critical to improving program supervision and maximizing student benefits.

EPO8_133

ASSESSMENT OF THE EFFECT OF HEME IRON CONTENT IN MEAT ON STRUCTURAL CHANGES IN DIETARY NUCLEIC ACIDS CAUSED BY HIGH-TEMPERATURE TREATMENT

Anna Kościelak[1]; Agnieszka Bartoszek[1]
[1]Department of Chemistry, Technology and Biotechnology of Food, Gdańsk University of Technology, Gdańsk, Poland

BACKGROUND AND OBJECTIVES
Heme iron in red meat promotes the oxidation of lipids and proteins, contributing to the carcinogenic properties of processed red meat [1]. Most food products are the source of dietary nucleic acids (dietNA) which are prone to oxidation and may also undergo oxidation in the presence of heme iron during thermal processing. This study aimed to assess how thermal processing influences the integrity and oxidation level of dietNA in selected meat samples with varying heme iron levels.

METHODS
Beef, pork, and poultry samples were thermally treated (fried or grilled) under controlled conditions. Microscopic imaging was used to visualize the abundance and distribution of dietNA in the studied samples. DNA was isolated from the samples and heat-induced changes affecting meat DNA integrity were assessed using electrophoresis and comet assay modified to suit the food sample research. Next, to measure levels of oxidatively damaged DNA in tested meat samples, the comet assay was combined with digestion by 8-oxo-2'-deoxyguanosine excision enzyme, formamidopyrimidine DNA glycosylase (Fpg).

RESULTS
Nuclei containing dietNA visible in raw meat structures were preserved after processing. Electrophoresis revealed that both frying and grilling caused dietNA fragmentation in all meat samples. However, comet assay RESULTS showed 70% of nuclear DNA in the comet tail for raw beef samples, indicating the highest fragmentation by nucleases still active in unprocessed meat. Grilling and frying reduced fragmentation to 12% and 3.5%, respectively, probably due to inactivation of endogenous nucleases. A similar trend of decreasing % of DNA in the comet tail after thermal treatment was observed in pork and poultry. Application of Fpg enzyme significantly increased the % of DNA in the comet tail for grilled and fried beef only.

CONCLUSIONS
DNA fragmentation observed in processed and raw meat samples may result from both thermal treatment and hydrolysis by endogenous nucleases present in the examined tissue. Thermal processing of meat leads to inactivation of nucleases, but when intensive, may also lead to degradation of DNA and changes in the appearance of comet tails. The increased % of DNA in the comet tail for grilled and fried beef after Fpg enzyme treatment suggests higher oxidation level in meat with the highest heme iron content.

EPO8_134

IMPACT OF STRUCTURAL CHANGES UPON GASTROINTESTINAL DIGESTION OF DIFFERENT CEREALS ON PROTEIN DEGRADATION

Guillermo Santos Sanchez[1]; Cristina Gómez-Marín[1]; Beatriz Miralles[1]; Ibtissam Kaikat[2]; Isidra Recio[1]; Marta Martinez Sanz[1]
[1]CIAL, Institute of Food Science Research, CSIC-UAM, Madrid, Spain; [2]Ciència Animal i dels Aliments, SNiBA., Facultat de Veterinària Campus de la UAB, Barcelona, Spain

BACKGROUND AND OBJECTIVES
Exploring alternative protein sources of non-animal origin has led to increased interest in utilizing grain cereals as substitutes for food applications. The present study was conducted to determine the impact of the composition and cell wall structure of different cereals on their *in vivo* gastrointestinal protein digestibility, carrying out an in-depth characterization of the structural changes taking place along the digestion process.

METHODS
The digestion of starch and protein was studied in 5-week-old piglets fed six diets: starch-casein, oat, extruded oat, wheat, corn, and rice, plus an N-free control.After four hours, piglets were slaughtered, and digesta samples were collected. A comprehensive analysis and characterization of the liquid/solid fractions of the digests, including nitrogen measurements, SDS-PAGE, particle size, confocal microscopy, nanostructural characterization by small angle X-ray scattering (SAXS) and bile salts quantification, was carried out.

RESULTS
Protein degradation varied at the stomach and jejunum levels depending on the ingredient. Faster protein digestion occurred with rice and wheat, while oat, extruded oat, and corn showed slower degradation. Jejunum digests of rice and starch-casein had smaller particles compared to oats or corn. Images obtained by confocal microscopy showed starch granules still visible in gastric digesta, whose size was related to the structure of the native grains and their susceptibility to be digested. Once in the jejunum, small polysaccharide fragments were observed in the wheat and corn digests, which could be related to a higher content of resistant starch in these substrates. Regarding proteins, these were detected in the jejunum digests in all ingredients except for starch casein and N-free diets. Finally, the RESULTS obtained by SAXS showed more soluble components found in the gastric digests from starch-casein and rice, which may be explained by a greater extent of digestion of these two substrates at the stomach. Regarding the jejunum digests, differences were observed in the scattering patterns of corn and wheat compared to the rest of the ingredients, with soluble particle sizes of 80 nm, which could correspond to partially digested starch or resistant starch fractions.

CONCLUSIONS
The present investigation provides a complete characterization of the gastric and intestinal digests of cereal versus dairy-based diets and clarifies the structural changes at the micro and nanomolecular level of proteins and starch during gastrointestinal digestion. This provides digestion evidence for selecting cereal sources for human consumption.

VIOLA CANESCENS EXTRACT AND ITS BIOACTIVE COMPOUND MITIGATE MUSCLE ATROPHY IN DEXAMETHASONE-INDUCED C2C12 CELLS

Sin-Hye Park[1]; Yulong Zheng[1]; Noreen Saba[1]; Il-Jun Kang[1]; Soon Sung Lim[1]; Young-Hee Kang[1]
[1]Department of Food Science and Nutrition, Korean Nutrition Institute, Hallym University, Chuncheon-si, Korea, Republic of

BACKGROUND AND OBJECTIVES
Skeletal muscle atrophy, characterized by the loss of muscle mass and strength, is a hallmark of sarcopenia and related conditions. Violanthin, a flavone glycoside found in *Viola canescens*, exhibits diverse bioactivities; however, its effects on skeletal muscle atrophy have not been investigated. This study aimed to investigate the protective effects of *Viola canescens* extract and violanthin against dexamethasone-induced skeletal muscle atrophy in C2C12 myotubes.

METHODS
C2C12 myoblasts were cultured in differentiation media containing 2% horse serum for 6 days to induce myotube formation. Differentiated myotubes were subsequently treated with 0.2 mM dexamethasone and either 10-100 μg/mL *Viola canescens* extract or 1-20 μM violanthin for 24 h.

RESULTS
Viola canescens extract and its bioactive compound, violanthin, significantly enhanced the cell viability of myotubes exposed to dexamethasone, indicating their protective effects against glucocorticoid-induced muscle atrophy. Both *Viola canescens* extract and violanthin significantly downregulated the transcriptional level of muscle atrophy-related genes, including Trim63 (Murf1) and Fbxo32 (Mafbx), which are key mediators of muscle protein degradation pathways. Additionally, *Viola canescens* extract and violanthin also reduced the induction of Foxo3a transcription factor, a critical upstream regulator of these atrophy-related genes. Furthermore, *Viola canescens* extract and violanthin suppressed apoptotic marker expression, such as Casp3, a gene associated with programmed cell death, by modulating the balance between pro-apoptotic Bax and anti-apoptotic Bcl2l.

CONCLUSIONS
Viola canescens extract and its bioactive compound, violanthin, demonstrate protective effects against dexamethasone-induced skeletal muscle atrophy by enhancing cell viability, suppressing muscle atrophy-related gene expression, and modulating apoptotic pathways.

QUALITY OF POST-OPERATIVE FEEDING FOR VISCERAL SURGERY PATIENTS IN TWO HOSPITAL

Oceane Danmadou[1]; Lorenzo Guede[1]; Carmelle Mizehoun Adissoda[1]
[1]Nutrition and dietetics, Faculty of health Science - Cotonou, Cotonou, Benin

BACKGROUND AND OBJECTIVES
Malnutrition in hospitals, particularly within surgical departments, is a significant yet under recognized issue. It often stems from inadequate nutrition due to poor dietary management during hospitalization. This study investigated the quality of postoperative nutrition provided in visceral surgery departments at two hospitals. The objectives were twofold: first, to compare patients' nutritional intake with established recommendations, and second, to explore the relationship between diet quality and postoperative nutritional status.

METHODS
This cross-sectional study was conducted over four months and included 90 patients who had undergone visceral surgery. The primary variables were assessed by evaluating the extent to which patients' nutritional needs were met, including energy, protein, vitamins A, C, and D, zinc, and iron intake. Additionally, an overall diet quality score was calculated. Ethical approval for the study was obtained in advance, and data were analyzed using appropriate statistical software.

RESULTS
Postoperative malnutrition was observed in 60% of patients. A considerable proportion had inadequate intake of energy (57.8%), protein (56.7%), Zinc (62,2%),vitamin A (58.9%), and iron (65.5%). over time, more than half of the patients had normal vitamin C (58,9%) and vitamin D (51,1%). Overall, 62.2% of patients equivalent to roughly three out of five were found to have poor-quality diets postoperatively. A statistically significant relationship ($p < 0.01$) was identified between diet quality and postoperative nutritional status. Among patients discharged with malnutrition, 81.48% (44 out of 54) had been provided with diets of poor quality.

CONCLUSIONS
The quality of postoperative nutrition in visceral surgery departments was largely insufficient and failed to meet patients' nutritional requirements. Systematic evaluation of nutritional status and dedicated postoperative dietary management should be prioritized as integral components of care for surgical patients.

EVALUATION OF NUTRITIONAL QUALITY OF COMPLEMENTARY FOODS FORMULATED FROM BLENDS OF NIGERIAN YELLOW MAIZE (ZEA MAYS), SOYBEAN (GLYCINE MAX) AND CRAYFISH (PROCAMBARUS CLARKII)

Halid Sheriff Adegbusi[1]
[1]Department of Biological Sciences/Teaching, Nigeria Police Academy CBT Center, Wudil, Nigeria, Federal Republic of

BACKGROUND AND OBJECTIVES
Plant-based complementary foods (CFs) generally supply insufficient amount of nutrients to meet recommended nutrient intakes for 6–23 months old children. This study determined the nutritional quality of CFs formulated from blends of Nigerian yellow maize (*Zea mays*), soybean (*Glycine max*) and crayfish (*Procambarus clarkii*).

METHODS
Three CFs were formulated, namely; maize flour (MF, 100 g), blends of maize and soybean flour (MSF, 72:28 g) and maize, soybean and crayfish flour (MSCF, 80:10:10 g). Nutritional quality was evaluated using analyses of chemical composition of CFs, and biology quality of complementary food diets (CFDs) fed to weaned Sprague Dawley rats fed. Data were compared by Multivariate Analysis of Variance and significantly differentiated at $P \leq 0.05$. Nine selected nutritional criteria were used to determine CF that possessed optimal nutritional characteristic on comparison with MF and fortified wheat flour (FWMF).

RESULTS
Total scores obtained from selected nutritional criteria ranked MSCF, having total score of 22, the lowest and thus considered to possess the most desirable nutritional characteristics compared to MF, MSF and commercial CF (FWMF) that had the respective total score of 54, 39 and 33.

CONCLUSIONS
Conclusively, MSCF may serve as a better alternative CF for MF and MSC, which compared favourably with FWMF. This study has produced a potential alternative cost-effective and adequate CF, formulated from crayfish (*Procambarus clarkii*) supplementation of locally available blend of yellow maize (*Zea mays*) and soybean (*Glycine max*), for the poor human population, in order to encourage the consumption of animal-sourced CF for alleviating the prevalence of childhood undernutrition.

IMPACT OF A SWITCH DIET AFTER HIGH-FAT DIET INDUCED OBESITY COMBINED WITH AGING ON CARDIAC FUNCTION

Thaïs Delmont[1]; Sandrine Luce[1]; Alissa Tarraf[1]; Carole Henique[1]; Stéphanie Bayol[1]; Geneviève Derumeaux[1]; Laurianne Bonnet[1]
[1]U955, Institute National De La Santé Et De La Recherche Médicale, Créteil, France

BACKGROUND AND OBJECTIVES
Aging and obesity both contribute to the onset of metabolic disorders and cardiovascular disease. Whether aging worsens high-fat diet (HFD)-induced obesity cardiac alterations in a murine model is not yet demonstrated. Furthermore, the beneficial effect of a weight loss induced by switch diet (SD), from HFD to control diet (CD) has been demonstrated on cardiac remodelling and function in young mice but not in aged mice.
Our aim was first to assess the impact of HFD in old mice and to evaluate the reversibility of HFD-induced cardiac alterations by SD in young and aged mice.

METHODS
We performed a study in young (5-month-old) and old (12-month-old) mice, fed with HFD (60% fat + 5% sucrose) for 20 weeks or switched to CD for 8 weeks (SD group) after 12 weeks of HFD. We performed metabolic tests (GTT, ITT) and echocardiography [cardiac function assessed by left ventricular ejection fraction (LVEF) and systolic strain rate (SR)].

RESULTS
The comparison between young and old mice in CD groups shows that aging increases the body weight, adiposity index and cardiac hypertrophy and impairs myocardial function (SR but not LVEF). HFD regimen increases similarly body weight and adiposity index in both young and old mice, whilst cardiac function is impaired with a similar decrease of systolic SR in young and old mice. SD induces a similar weight loss and decrease of the adiposity index in young and old mice. However, SD improves systolic function assessed by SR in young but not aged mice. Interestingly, this improvement in SR was associated with an amelioration of glucose tolerance in young mice.

CONCLUSIONS
Our data demonstrate that HFD-induced obesity and SD-induced weight loss modulate cardiac function differently with aging. Thus, the improvement of cardiac function by SD in young mice is not found in old mice.

HEALTH BENEFITS OF CHEESE: A REVIEW OF CURRENT LITERATURE

Emmeline Salameh[1]; Océane Savary[2]; Mathilde Guerville[1]; Romane Troadec[1]; Charlotte Magnant[1]; Amandine Ligneul[1]
[1]Nutrition Department, Lactalis Research & Development, Retiers, France, Retiers, France; [2]Microbiology Department, Lactalis Research & Development, Retiers, France, Retiers, France

BACKGROUND AND OBJECTIVES
Cheese is a widely consumed dairy product with a rich nutritional profile. This review aims to summarize the current literature on the health benefits of cheese, focusing on its impact on cardiovascular disease (CVD) and type 2 diabetes (T2D).

METHODS
A comprehensive literature search was conducted using databases such as PubMed and Google Scholar. Studies included in this review were published between 2010 and 2023 and examined the effects of cheese consumption on CVD and T2D risk.

RESULTS
The literature indicates that moderate cheese consumption is associated with several health benefits, including a notably lower risk of developing CVD (moderate evidence) and T2D (low evidence). It is important to note that studies often vary between examining cheese as a broad category and focusing on specific products. Multiple studies report a reduction in LDL cholesterol levels compared to butter and no increase in blood triglyceride levels after consumption. Regarding glycemia, there is no alteration in basal glycemia, potential benefits in reducing postprandial glycemia, and no modification of glycated haemoglobin levels. Data on the Homeostatic Model Assessment (HOMA) and insulin are currently contradictory. Cheese consumption has also been shown to positively influence gut microbiota, promoting the growth of beneficial bacteria. Other biological markers, such as inflammation, have been explored, but the data remain contradictory. There are no data on the effects of cheese consumption on oxidative stress and arterial pressure.

CONCLUSIONS
The reviewed studies suggest that cheese can be a beneficial addition to a balanced diet, contributing to improved cardiovascular health, diabetes and gut microbiota. Further research is needed to fully understand the long-term health impacts and underlying mechanisms.

MODELING OF THE EFFECTS OF SLOW DIGESTIBLE STARCH (SDS) CONTENT IN CEREAL PRODUCTS ON GLUCOSE METABOLISM

Séverine Olivier[1]; Olivier Brack[2]; Alexandra Meynier[1]; Sophie Vinoy[1]
[1]Nutrition Research, Mondelez R&D, Paris Saclay Tech Centre, Saclay, France; [2]Société K.S.I.C, Statistique Industrielle-Kh2 Consulting, Esches, France

BACKGROUND AND OBJECTIVES

Starch is a major source of carbohydrates in cereal products. Starch digestibility mainly depends on technological processes. The preservation of Slowly Digestible Starch (SDS) levels in cereal products has beneficial effects on postprandial glucose absorption kinetics and glucose metabolism. Understanding the range of SDS content associated with positive physiological effects is of high interest to develop starchy foods that contribute to improved glycemic control and insulin sensitivity.In this study, we analyzed the relationship between SDS in cereal products and parameters of glucose metabolism, such as the appearance rate of exogenous glucose (RaE) and postprandial glycemic and insulinemic responses.

METHODS

We conducted a statistical meta-analysis on ten randomized controlled clinical trials studying the effects of consuming cereal products (biscuits and extruded products) with a wide range of SDS contents on glucose metabolism in healthy and overweight individuals (190 subjects). SDS content in biscuits varied from 8g to 21g per portion while SDS content in extruded products was less than 1g per portion. We built prediction models to simulate the contribution of SDS to RaE kinetics and glycemic response parameters such as delta peak of glycemia (Δ peak) and maximum concentration of blood glucose (*C*max g), and we expressed SDS as g per portion or as a percentage of available starch (%SDS/avStarch).

RESULTS

We found that for cereal products with SDS content higher than 7g per portion and higher than 35%/avStarch the predicted contribution to the RaE kinetics between 125 and 240 minutes was more important (increased up to 2-fold) compared to cereal products with low SDS content (less than 1g per portion and 3%/avStarch). Regarding glycemic response parameters, we found that the predicted Δ peak was reduced by 1,4-fold in cereals products with SDS content higher than 7g per portion and higher than 35% SDS/avStarch compared to low SDS condition. Similar RESULTS were obtained with *C*max g parameter.

CONCLUSIONS

SDS modeling in cereal products and the predicted effects on glucose metabolism helps to identify the range of SDS and available starch needed to induce beneficial metabolic response during postprandial phase. Indeed, formulation of cereal products with high SDS content is an important nutritional parameter to build healthier diets. Recently, it has been demonstrated that high SDS diet improved glycemic control in type 2 diabetes patients.

VITAMIN D STATUS AND ITS DETERMINANTS IN YOUNG ADULTS IN SELECTED RURAL AREA IN SRI LANKA

Thilanka Ranathunga[1]; Abinajah Vartharasa,[2]; Askar Shereen[3]; Thakshila Adikari[3]
[1]Dept of Applied Nutrition , Wayamba University of Sri Lanka Makandura Premises, Kurunegala, Sri Lanka; [2]Applied Nutrition, Wayamba University of Sri Lanka, Kurunegala, Sri Lanka; [3]Dept of Applied Nutrition, Wayamba University of Sri Lanka, Kurunegala, Sri Lanka

BACKGROUND AND OBJECTIVES
Vitamin D is a fat-soluble vitamin that is essential in musculoskeletal health. However, no recent studies have been conducted in Sri Lanka to identify the vitamin D status and its determinants in young adults in Sri Lanka. This study aimed to identify vitamin D status and factors associated with vitamin D status among young adults in a selected rural area in Sri Lanka.

METHODS
A cross-sectional study was conducted in selected 3 villages located in North Central Province in Sri Lanka, recruiting 75 young adults. General questionnaire was used to identify the socio-demographic and economic information of the participants. Sun exposure questionnaire was used to identify the sun exposure determinants. Diet diaries were used to determine the vitamin D intake using a computer software. Weight and height were also measured. Serum 25(OH)D concentration was measured in blood samples using the ELISA technique. SPSS software was used for the statistical analysis of data.

RESULTS
Mean serum 25(OH)D concentration of the participants was 19.87 ± 7.27ng/mL. Prevalence of vitamin D sufficiency, insufficiency and deficiency were 39% (n=29), 53% (n=40) and 8% (n=6), respectively. Vitamin D status was associated with gender (p=0.01), where the mean serum 25(OH)D for males (22.19 ± 8.42ng/mL) was significantly higher than for females (17.61 ± 5.09 ng/mL). Age (p=0.013) and vitamin D intake (p=0.032) showed significant positive associations with serum 25(OH)D concentration. Nature of the occupation (p=0.021), duration of sun exposure (p =0.003), sun avoidance (p=0.050) and skin exposure area during weekdays (p=0.019) and weekend days (p =0.043) were significantly associated with serum 25(OH) D concentration. Body Mass Index (BMI), ethnicity, religion, monthly income, education level, alcohol and tobacco use were not significantly associated with serum 25(OH)D concentration

CONCLUSIONS
Nearly half of the population was vitamin D deficient and insufficient. The findings of this study can be used to educate the general public about the importance of sun exposure in order to improve vitamin D status. Further studies are required to identify the vitamin D status in a representative sample of young adults in Sri Lanka.

IRON ABSORPTION AND VARIATIONS OF IRON STATUS PARAMETERS, HEPCIDIN, INFLAMMATORY MARKERS AND SEX HORMONES DURING THE MENSTRUAL CYCLE

Kesso Gabrielle van Zutphen-Küffer[1]; Verhoef Hans[2]; Alida Melse-Boonstra[3]; Isabelle Herter-Aeberli[4]
[1]Science, Sight and Life, Basel, Switzerland; [2]Human Nutrition and Health, Wageningen University & Research, Wageningen, Netherlands; [3]Division of Human Nutrition and Health, Wageningen University & Research, Wageningen, Netherlands; [4]Departement of Health Sciences and Technology, ETH Zürich, Zürich, Switzerland

BACKGROUND AND OBJECTIVES
Menstruation and the menstrual cycle, despite being primary factors in iron deficiency and anemia, have not been extensively researched as focal points for combating anemia. Data on fluctuations in iron status markers, hepcidin, and sex hormones throughout the menstrual cycle—and their impact on iron absorption—remain limited and ambiguous. This exploratory study aimed to measure and compare changes in iron absorption, iron status, hepcidin, inflammatory markers, and the hormones estrogen and progesterone at various points in the menstrual cycle. The long-term goal was to identify the best timing for iron supplementation. Our hypotheses were: (1) changes in iron absorption would correlate with phases of the menstrual cycle, enabling identification of optimal timing for supplementation; (2) the investigation of iron status and related parameters would reveal insights into the underlying mechanisms affecting iron absorption.

METHODS
In this single-blind, randomized crossover trial, 10 female students aged 18-30 with normal BMI and low iron stores started bi-daily blood sampling on the second day of their menstrual cycle, continuing through day 28 of a 40-day study. Iron absorption was measured from six isotopically labeled meals, administered in two blocks, using different iron isotopes. The study monitored hemoglobin, iron biomarkers, hepcidin, inflammatory markers, and sex hormones, and iron absorption using red blood cell incorporation of stable isotopes 14 days after administration.

RESULTS
Preliminary RESULTS suggest that menstruation may significantly impact iron deficiency and anemia, with inflammatory processes, particularly IL-6, potentially affecting iron absorption during hormonal shifts in the menstrual cycle. Unexpectedly, higher hepcidin levels were observed in the early follicular phase, differing from previous studies. This discrepancy may relate to variations in inflammation and iron status markers, requiring further investigation. Early findings indicate that IL-6, alongside hormones such as estrogen and progesterone, may regulate hepcidin, highlighting complex interactions between inflammation and hormone-driven iron metabolism.

CONCLUSIONS
Our preliminary findings point to the luteal phase as a potentially better time for iron supplementation, although additional research is needed. The study's gender-sensitive approach highlights the importance of tailored intervention strategies for addressing iron deficiency in menstruating women.

ECO-FRIENDLY EXTRACTION OF LEMON BALM: HARNESSING NADES FOR ENHANCED BIOACTIVE COMPOUND RECOVERY

Branislava Teofilović[1]; Zorana Nikić[1]; Kristina Stanišić[1]; Nevena Grujić Letić[1]; Snežana Papović[2]; Emilia Gligorić[1]; Milan Vraneš[2]
[1]Pharmacy, Medical Faculty in Novi Sad, Novi Sad, Serbia; [2]Analytical chemistry, Faculty of Science, Novi Sad, Serbia

BACKGROUND AND OBJECTIVES
Lemon balm (*Melissa officinalis*, Lamiaceae) is a medicinal herb rich in bioactive compounds, often extracted using techniques like NADES (Natural Deep Eutectic Solvents) to enhance yield and preserve stability. This eco-friendly extraction method offers a sustainable approach to obtaining antioxidants, polyphenols, and other valuable phytochemicals.

METHODS
This study focused on evaluating the extraction of phenolic compounds, including phenolic acids and flavonoids, from lemon balm cultivated at the Institute for Medicinal Plant Research. Two natural deep eutectic solvents, choline chloride/glucose (1:2) and choline chloride/urea (1:1), were employed for the extraction. The phenolic compound content in the extracts was analyzed using high-performance liquid chromatography (HPLC).

RESULTS
The choline chloride/glucose mixture proved to be more effective for the extraction of phenolic acids and flavonoids from lemon balm. Using this solvent, gallic, chlorogenic, p-hydroxybenzoic, caffeic, coumaric, and ferulic acids were extracted, as well as epicatechin, quercetin, and naringenin. The concentrations of the extracted compounds ranged from 15.02 to 196.04 mg/g of crude drug, with caffeic acid being the dominant component. The choline chloride/urea solvent was effective only for the extraction of gallic acid.

CONCLUSIONS
Choline chloride/glucose NADES demonstrated considerable potential as eco-friendly solvents for extracting phenolic acids and flavonoids from lemon balm. The findings underscore the effectiveness of choline chloride/glucose for caffeic acid extraction and suggest broader applications of NADES in cosmetic and pharmaceutical industries.

FOOD COMPLEXITY: EFFECTS ON EATING RATE AND ORAL PROCESSING BEHAVIOURS

Saenz-Pardo-Reyes Erika[1]; Antonio López-Espinoza[2]; Alma Gabriela Martínez Moreno[3]; Maria Del Rocio Padilla Galindo[3]
[1]Mexicali Medical School, Autonomous University of Baja California, Mexicali, Mexico; [2]RIICAN, Red Internacional de Investigaciones en Comportamiento Alimentario y Nutrición (RIICAN), Ciudad Guzmán, Mexico; [3]Instituto de Investigaciones en Comportamiento Alimentario y Nutrición (IICAN), University of Guadalajara, Ciudad Guzmán, Mexico

BACKGROUND AND OBJECTIVES
The complexity of food is characterized by the number of sensory components and the sensations they elicit. Studies have explored the complexity of taste, aroma, appearance, and texture in food. It has been proposed that meals with high sensory complexity can modify oral processing behaviors, decrease eating speed and energy intake, and enhance satiation and satiety responses. This study aims to analyze the effect of food texture complexity on eating rate and oral processing behaviors.

METHODS
The study involved 30 young adults aged between 18 and 35, 15 men and 15 women with a healthy BMI and fat percentage. Various measurements were conducted, including (a) body composition and basal metabolism using the Inbody 370 and SECA stadiometer; (b) eating rate in kcal/min; and (c) components of oral processing behavior (duration, number of bites, and chewing) through videotaping and observation during meal sessions. The participants were served two types of sandwich rolls: low complexity (BC) and high textural complexity (AC). Statistical analysis was carried out using STATA version 12.0, employing repeated measures ANOVA, Fridman, T-Student, Wilcoxon, Ramsey, Pearson, and Cochran-Mantel-Hanzel tests.

RESULTS
The primary findings indicated that participants exhibited a greater number of bites ($F: 5.27$; $p < 0.05$) and a decreased eating rate in kcal per minute ($F: 4.90$; $p < 0.05$) when consuming the AC sandwich roll compared to the texturally simpler BC roll. Furthermore, males demonstrated a higher eating rate than females (1071 vs 759; $p<0.05$, $n=60$). Additionally, a positive correlation was observed between skeletal muscle mass ($r: 0.2649$; $p < 0.05$) and basal metabolic rate with eating speed ($r = 0.2636$; $p < 0.05$; $n = 60$).

CONCLUSIONS
Biological factors such as skeletal muscle mass, basal metabolic rate, and sex play a role in mediating elements of eating behavior. However, sensory attributes, such as food complexity, effectively modulate aspects such as eating rate and oral processing behaviors.

EVALUATION OF FOOD LITERACY, SUSTAINABLE AND HEALTHY EATING BEHAVIORS IN FOOD SERVICE SYSTEMS EMPLOYEES

Nasminel Tekin[1]; Feride Ayyıldız[1]
[1]Nutrition and Dietetics, Gazi University Faculty of Health Sciences, Ankara, Türkiye

BACKGROUND AND OBJECTIVES
The environmental impacts of Food Service Systems (FSS) are assessed across production, distribution, preparation, service, and waste management stages. Individuals employed in this domain should be incorporated into developing practices and strategies for sustainable and healthy eating (SHE) behaviors. Food literacy (FL) can be the foundation for adopting SHE behaviors and diet quality. This study aimed to assess the correlation among FL, diet quality and SHE behaviors among FSS employees.

METHODS
The research involved 173 FSS employees, comprising 100 males (57.8%) and 73 females (42.2%), aged 18 to 64 years, employed in university kitchens and dining halls. The socio-demographic characteristics of the individuals participating in the study were questioned. The SHE behaviors scale, self-perceived food literacy (SPFL) scale and a questionnaire including 24-hour dietary recalls were administered face-to-face. Healthy Eating Index-2020 (HEI) was used to evaluate diet quality. Data were analyzed using the SPSS 24.0 program, with a significance level set at $p<0.05$.

RESULTS
The mean age of the study participants was 42.5±9.45 years for males and 40.2±10.26 years for females, respectively**.** The present study included FSS staff; 24.9% were chefs, 5.2% were sous chefs, 53.8% were waiters, and 16.2% were dishwashers. A statistically significant positive moderate correlation was found between the total score of the SHE behaviors scale and the total score of SPFL (r: 0.593, $p<0.001$). A statistically significant positive correlation existed between the SPFL total score and the HEI total score (r:0.160, $p<0.05$). A statistically significant difference in SPFL total scores was found among occupational categories ($p<0.05$).

CONCLUSIONS
Improving food literacy among FSS employees is believed to influence SHE behaviors and diet quality positively. This is important for improving individual health and raising awareness of sustainable food systems.

COMBINED INFLUENCE OF PHENOLIC ACIDS AND Ω-3 FATTY ACIDS ON INFLAMMATORY PROCESSES: INHIBITION OF PROSTAGLANDIN E2 AND THROMBOXANE A2 PRODUCTION IN VITRO

Ivana Beara[1]; Tatjana Majkić[1]; Ljiljana Milovanović[1]
[1]Department of chemistry, biochemistry and environmental protection, Faculty of Sciences, University of Novi Sad, Novi Sad, Serbia

BACKGROUND AND OBJECTIVES

Inflammation is an immune response to injurious stimuli (microbiological, chemical, or mechanical), that triggers pro-inflammatory mediators like prostaglandins, cytokines, and leukotrienes, contributing to the pathogenesis of several diseases, including cardiovascular disorders, autoimmune diseases, and cancer. Dietary compounds, such as phenolic acids and ω-3 fatty acids, are recognized as potential anti-inflammatory agents. Based on this premise, the aim of this study was to evaluate the anti-inflammatory potential of three phenolic acids (caffeic, *p*-coumaric, and ferulic acid) and ω-3 fatty acids: eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), both individually and in combination.

METHODS

Anti-inflammatory activity was assessed using an *in vitro* cell-based model system with human leukemic monocytes (U937 cell line), in which inflammation was induced by lipopolysaccharide (LPS). The levels of pro-inflammatory mediators, prostaglandin E2 (PGE2) and thromboxane A2 (TXA2), were quantified using the LC-MS/MS technique. RESULTS are expressed as percentages of PGE2 and TXA2 production relative to the control.

RESULTS

The RESULTS demonstrated that combinations of EPA and DHA with *p*-coumaric acid were the only ones to significantly inhibited PGE2 production, with reductions of 10 and 11%, respectively. Notably, the synergistic effects of the individual components were most pronounced in these combinations. Conversely, all tested combinations of phenolic acids and ω-3 fatty acids significantly reduced TXA2 production under inflammatory conditions, from 17 to 33%. Synergistic effects were observed for EPA combined with caffeic acid, as well as for DHA in mixtures with caffeic or ferulic acids. In contrast, the other components in the remaining combinations exhibited antagonistic interactions.

CONCLUSIONS

These findings highlight the substantial anti-inflammatory effects of specific combinations and contribute to ongoing research into the therapeutic potential of phenolic acids and ω-3 fatty acids in inflammation.

NUTRIENT INTAKE INADEQUACY CORRELATES WITH POOR COGNITIVE FUNCTION OF ATHLETES IN THREE MAJOR SPORTING REGIONS IN GHANA

Divine Eli-Cophie[1]; Reginald Adjetey Annan[2]; Charles Apprey,[3]
[1]Sports and Exercise Nutrition, University of Health and Allied Sciences, Ho, Ghana; [2]Department of Biochemistry and Biotechnology, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana; [3]Biochemistry and Biotechnology, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana

BACKGROUND AND OBJECTIVES
Nutrition is central to the performance optimization of athletes. However, nutrient intake, and its association with cognitive functions of performance such as reaction time and concentration of athletes has been scarcely studied. The study sought to evaluate the nutrient intake and their association with the indicators of cognitive function of athletes from three major sporting disciplines in Ghana.

METHODS
This was a cross-sectional study where participants' dietary intake was determined using multiple 24hr recall, and anthropometric parameters were also measured. All study participants were made to take a concentration grid test and ruler drop reaction time test to measure their concentration and reaction time respectively. The data were analyzed using SPSS to establish associations at a 95% confidence interval

RESULTS
The mean reaction time, and concentration, scores of athletes with an average weight of 59.3 ± 12.6kg were 193.8 ± 21.6 ms, and 33.3 ± 12.6 respectively. Dietary carbohydrate (4.3 ± 1.7 g/kg.day-1) and protein intake (0.9 ± 0.5 g/kg.day-1) were below recommendation. More than half of them had inadequate dietary calcium (99.6%), iron (60.5%), zinc (82.4%), folate (76.1%), riboflavin (80.9%), vitamin C (83.2%), and B12. (100%) Most athletes (79.7%) had inadequate energy intake with an average energy deficit of 1377.6 kcal. The calorie intake, reaction time and concentration were respectively more improved among the track athletes (2253.5 kcal, 187.4ms, 40.20) than the boxers (1656.9kcal, 203.0ms, 25.44) and football players (1387.2kcal, 194.0ms, 31.76). Folate, Vitamin C and B6 correlated ($p < 0.05$) with reaction time. Energy intake ($p = 0.016$) could account for about 2.0 and 2.7% of the variation in reaction time and concentration respectively.

CONCLUSIONS
Most athletes did not meet the requirements for energy and micronutrients. Calories predicted a very small but significant variation in concentration and reaction time, measured as indicators of cognitive function.

EXPLORING THE LINK BETWEEN NUTRITIONAL STATUS, ANTHROPOMETRIC PROFILES AND DIETARY ANTIOXIDANT IN HEMODIALYSIS PATIENTS

ÖZLEM PÖLENT[1]; Adviye Gülçin Sağdiçoğlu Celep[2]
[1]Nutrition and Dietetic, Kırklareli University Faculy of Health Science, Kırklareli, Türkiye; [2]Nutrition and Dietetic, Gazi University Faculty of Health Science, Ankara, Türkiye

BACKGROUND AND OBJECTIVES
In patients with Chronic Renal Failure (CRF), complications are based on increased oxidative stress. CRF patients, often facing negative clinical and nutritional status caused by persistent oxidative stress and chronic inflammation. This study investigated that evaluation of the relationship between nutritional status, anthropometric measurement, and dietary antioxidant capacity in hemodialysis (HD) patients.

METHODS
This case-control study included 44 (female n=12, male n=32) HD patients (mean age=56,89±15,94), and 44 (female n=12, male n=32) healthy individuals (mean age=57,66±10,89). General characteristics were assessed through a questionnaire, while nutritional and inflammatory status were evaluated using the Subjective Global Assessment-7P (SGA-7P) and Malnutrition Inflammation Score (MIS). Anthropometric measurements, including body weight (post-hemodialysis, kg), height (cm), Body Mass Index (BMI), calf circumference (cm), triceps skinfold thickness (mm), and handgrip strength (kg), were obtained using standardized methods and calibrated instruments. Dietary antioxidant capacity was analyzed via an antioxidant food frequency questionnaire. Statistical analyses were performed using the Pearson correlation for normally distributed data and, Mann-Whitney U test for non-normally distributed data with SPSS (version 27).

RESULTS
HD patients had significantly lower SGD-7P ($Z=-4.509$, $p<0.001$) and MIS ($Z=-7.059$, $p<0.001$) scores than healthy participants. Similarly, the case group had significantly lower values for weight ($t=2.249$, $p=0.027$), calf circumference ($t=-3.615$, $p<0.001$), and hand grip strength ($Z=3.981$, $p<0.001$). Furthermore, the dietary antioxidant capacity of the case group was significantly lower compared to the control group ($t=-12.588$, $p<0.001$). In the case group, significant positive correlation was identified between dietary antioxidant capacity and hand grip strength ($r=0.385$, $p=0.010$), suggesting that an increase in hand grip strength may be associated with a rise in dietary antioxidant capacity. In the control group, a weak but significant positive correlation was found between dietary antioxidant capacity and both calf circumference ($r=0.447$, $p<0.002$), and triceps skinfold thickness ($r=0.355$, $p<0.018$). However, no significant correlation was observed between dietary antioxidant capacity and SGD-7P or MIS scores in both groups.

CONCLUSIONS
In HD patients, nutritional deficiencies and decreased antioxidant intake may reduce body resistance and increase inflammation compared to healthy individuals.

FUNCTIONAL ANALYSIS OF AFRICAN-CENTRIC POLYMORPHISMS OF THE ZINC TRANSPORTER GENE SLC39A10

Jee-Oo Song[1]; Moon-Suhn Ryu[1]
[1]Department of Food and Nutrition, Yonsei University, Seoul, Korea, Republic of

BACKGROUND AND OBJECTIVES

Zinc is an essential nutrient involved in numerous biological functions. Its homeostasis is tightly controlled through the coordinated action of two transporter families: SLC30A (ZnT), mediating efflux, and SLC39A (ZIP), facilitating influx. ZIP10 (encoded by *SLC39A10*) plays an integral role in maintaining cytosolic zinc levels. This study investigates the functional impact of population-specific missense mutations in *SLC39A10*, focusing on variants prevalent in African populations.

METHODS

Through gnomAD human genome database screening, three single nucleotide polymorphisms (SNPs) in *SLC39A10* with the highest global allele frequencies were identified to be prevalent in African populations. *In silico* analyses (e.g., SIFT, AlphaFold) were performed to predict the potential impact of the variants, and *SLC39A10* open reading frame (ORF) constructs containing the respective mutations were transfected into 293T cells for further investigation of their functional consequences.

RESULTS

Overexpression of wild-type and mutant *SLC39A10* ORFs was confirmed at both mRNA and protein levels. No apparent differences were observed among the mutations in the expression of ZIP10 and biomarker genes (*MT1X* and *MT2A*). However, two SNPs demonstrated a significant decrease in the metallothionein induction by supplemental zinc treatment, suggesting impaired zinc import activity. Notably, these two SNPs reside within histidine-rich domains, previously identified to play a vital role in the zinc transport function of ZIP proteins. Ongoing studies include detailed characterization of zinc transport kinetics and subcellular localization analyses.

CONCLUSIONS

We identified functionally significant ZIP10 variants specific to African populations, potentially representing genetic adaptations in zinc metabolism. These findings have implications for population-specific approaches to addressing zinc deficiency and underscore the importance of investigating the systemic health impacts of these genetic variations.

EFFECTS OF FUNCTIONAL LIPIDS ON LIPID METABOLISM ALTERATIONS INDUCED BY A CAF DIET IN A MURINE MODEL

Candela Suppo[1]; Ana Fariña[1]; Gisela Kuhn[1]; Jimena Lavandera[1]; Emilse Negro[1]; Claudio A. Bernal[1]
[1]Food Science and Nutrition, Universidad Nacional del Litoral, Santa Fe, Argentina

BACKGROUND AND OBJECTIVES
The cafeteria diet (CAF), high in saturated fats and simple carbohydrates, leads to metabolic disorders associated with chronic non-communicable diseases (NCDs). Functional lipids (FL), such as those present in virgin flaxseed oil (FO), as well as the conjugated linoleic acid (CLA), may regulate lipid metabolism. The aim was to study the effect of FO and CLA, alone or combined (FLc), on the alterations on lipid metabolism of rats fed CAF diet.

METHODS
Male Wistar rats (~300g) were divided into 5 groups (n=6) and fed for 10 weeks with: control (C): 4% soybean oil; CAF: 35% lipids; CAF+FO: 26% lipids + 9% FO; CAF+CLA: 34% lipids + 1% CLA; CAF+FLc: 25% lipids + 9% FO + 1% CLA. Energy intake, body weight (BW) gain, and adipose tissue (AT) weight, were assessed. Hepatic TAG levels, in vivo TAG secretion rate (TAG-SR), expression of genes and activity of enzymes related to fatty acid lipogenesis and β-oxidation in liver and AT were analysed. Data were evaluated using One-Way ANOVA, followed by Tukey's test, or by T-test ($p<0.05$).

RESULTS
The CAF vs C group increased energy intake (+50%), BW gain (+45%), adiposity (+13%), and hepatic TAG levels (+21%). The CAF+FLc vs CAF group reduced BW gain (-15%), AT weight (-19%), and hepatic TAG levels (-16%). The attenuation of hepatic steatosis observed in the CAF+FLc group could be linked to an increased TAG-SR (+26%) and upregulation of MTTP expression (+18%). Additionally, higher hepatic PPARα expression (+94%) enhanced peroxisomal oxidation through increased ACOX1 mRNA levels (+40%). In AT, reduced SREBP-1c expression (-85%) decreased lipogenesis, as evidenced by lower FAS activity (-41%). Individual effects of functional lipids were also observed. Compared to the CAF group, FO supplementation improved hepatic CPT-1a activity (CAF+FO: +40%; CAF+FLc: +26%), while CLA supplementation increased PPARα mRNA levels in AT (CAF+CLA: +1912%; CAF+FLc: +4729%), promoting oxidative genes like UCP2 (CAF+CLA: +171%; CAF+FLc: +90%), and enhancing CPT-1b expression and activity (CAF+CLA: +237% and +41%; CAF+FLc: +163% and +33%).

CONCLUSIONS
The combination of FO and CLA mitigates the metabolic alterations induced by a CAF diet, as evidenced by reductions in adiposity and hepatic TAG levels. These effects are linked to enhanced TAG-SR and β-oxidation processes. These findings suggest that FL can mitigate CAF diet-induced dysregulations, providing potential strategies for dietary management of lipid metabolism disorders.

INVESTIGATING SCHWANN CELL DAMAGE MECHANISMS IN DIABETIC PERIPHERAL NEUROPATHY UNDER LOW CHOLESTEROL CONDITIONS

Sing-Hua Tsou[1]; Pai-Yi Chiu[2]; Chien-Ning Huang[3]; Chih-Li Lin[3]
[1]Translational Medicine Center, Chung Shan Medical University Hospital, Taichung, Taiwan; [2]Department of Neurology, Show Chwan Memorial Hospital, Taichung, Taiwan; [3]Institute of Medicine, Chung Shan Medical University, Taichung, Taiwan

BACKGROUND AND OBJECTIVES
Diabetic peripheral neuropathy (DPN) is a common complication of diabetes characterized by nerve damage and microvascular dysfunction. Cholesterol is vital for myelin integrity, with Schwann cells playing a key role in nerve repair. Both high and low cholesterol levels are linked to severe neuropathy, raising concerns about the risks of aggressive cholesterol-lowering strategies. Given the role of nutrition in lipid metabolism and neural health, this study investigates how dietary factors influence Schwann cell function and explores the potential benefits of mono- and polyunsaturated fatty acids (MUFA and PUFA) in managing DPN.

METHODS
RSC96 Schwann cells were treated with high-glucose and low-cholesterol conditions using methyl-β-cyclodextrin (MβCD) to simulate cholesterol depletion. Cell viability, oxidative stress, and survival were assessed, with MUFA and PUFA supplementation evaluated for protective effects. Diabetic mouse models were used to study the impact of low cholesterol on neuropathy symptoms and the therapeutic potential of dietary PUFA. Clinical data were analyzed to explore associations between lipid profiles, dietary habits, and neuropathy severity.

RESULTS
Aging and diabetic nephropathy were associated with severe neuropathy, while glycemic control showed no significant correlation. Abnormalities in LDL and HDL cholesterol levels strongly correlated with neuropathy severity. Cholesterol depletion in Schwann cells reduced viability and increased oxidative stress under high-glucose conditions. Dietary MUFA and PUFA mitigated these effects, with PUFA showing superior protective effects by reducing oxidative damage and enhancing cell survival. In diabetic mouse models, low cholesterol worsened neuropathy symptoms, while PUFA supplementation improved nerve function, reduced oxidative stress, and supported myelin repair. Clinical data showed a U-shaped relationship between cholesterol levels and neuropathy severity, underscoring the importance of balanced lipid intake.

CONCLUSIONS
Cholesterol is critical for Schwann cell function and neural repair, but excessive cholesterol reduction can impair these processes. Dietary PUFA demonstrated significant neuroprotective effects, reducing oxidative damage and supporting nerve repair in both cellular and animal models. These findings emphasize the importance of nutritional strategies in managing DPN, particularly through lipid profile optimization and PUFA supplementation. Targeted dietary interventions should be integrated into diabetes care to balance cardiovascular health and neural protection. Further studies are needed to refine dietary guidelines and therapeutic approaches for DPN.

EFFECTS OF GLP-1 RA SEMAGLUTIDE AND ADIPORON ON LIPID DROPLET ACCUMULATION AND OXIDATIVE STRESS IN PANCREATIC B CELLS

Chih-Li Lin[1]; Tsou Sing-Hua[2]; Wang Chin-Kun[3]; Huang Chien-Ning[1]
[1]Institute of Medicine, Chung Shan Medical University, Taichung, South District, Taiwan; [2]Department of Medical Research, Chung Shan Medical University Hospital, Taichung, South District, Taiwan; [3]School of Nutrition, Chung Shan Medical University, Taichung, South District, Taiwan

BACKGROUND AND OBJECTIVES
Non-alcoholic fatty pancreas disease (NAFPD) is a metabolic disorder characterized by ectopic lipid deposition in the pancreas, impairing β-cell function and increasing the risk of type 2 diabetes (T2D). Dietary patterns and nutrient excess, particularly high-fat and high-carbohydrate intake, are critical contributors to its progression. This study examines the potential of the GLP-1 receptor agonist (GLP-1 RA) Semaglutide and the adiponectin receptor agonist AdipoRon to mitigate the adverse effects of nutrient overload on pancreatic β-cells, focusing on lipid droplet (LD) accumulation, oxidative stress, and cellular functionality.

METHODS
Human β-cells (1.4E7 cell line) were treated with free fatty acids (FFA) under high-glucose conditions for 24 hours. Interventions included Semaglutide, AdipoRon, or a combination of both. LD accumulation was assessed using Nile Red staining, oxidative stress was measured with DCFH-DA fluorescence, and high-content analysis quantified LD size and number. Mitochondrial membrane potential was evaluated using JC-1 staining, and apoptosis markers were analyzed via Western blotting. β-cell functionality was assessed through insulin secretion assays and preproinsulin mRNA expression.

RESULTS
High-glucose and FFA exposure significantly increased LD accumulation, oxidative stress, and apoptosis, while reducing mitochondrial function and β-cell viability. Semaglutide treatment reduced LD accumulation, oxidative stress, and apoptosis while preserving mitochondrial membrane potential. The combination of Semaglutide and AdipoRon demonstrated enhanced effects, further reducing LD size and number, restoring mitochondrial integrity, and improving insulin secretion and preproinsulin mRNA expression.

CONCLUSIONS
Semaglutide and AdipoRon provide synergistic protection against nutrient-induced β-cell dysfunction by reducing oxidative stress, modulating lipid metabolism, and preserving mitochondrial function. These findings suggest that targeting lipid metabolism and oxidative stress could offer an effective therapeutic approach for managing NAFPD. Moreover, modifying nutritional strategies to enhance adiponectin signaling may further potentiate the efficacy of Semaglutide in combating NAFPD. Further studies are warranted to explore the clinical applicability of these interventions in addressing nutrient-driven metabolic disorders.

MACRONUTRIENT BALANCE CONTRIBUTES TO HUMAN GUT MICROBIOME DIVERSITY: IN VITRO DIGESTION AND GUT FERMENTATION OF PULSES AND VEGETABLES

INSEON HWANG[1]
[1]Agrofood Resources, National Institute of Agricultural Sciences, Wanju-gun, Korea, Republic of

BACKGROUND AND OBJECTIVES
An in vitro digestion and fermentation model, designed to simulate human food digestion and colonic fermentation, enables the efficient prediction of the health effects of food consumption on the human body. Using this model, the impact of pulse and vegetable digestion on the human microbiome was assessed, and the implications of plant-based diets were examined from a microbiome perspective.

METHODS
The interactions between macronutrients (free sugars, free amino acids, and free fatty acids), the human gut microbial genus, and their metabolites (short-chain fatty acids) were comprehensively investigated for eight pulse and five vegetable species. The complete food digesta fermented for up to 24 h were anaylzed by 16S rRNA sequencing method for taxonomic profiling. Microbial diversity was measured by the calculation of α-diversity (Shannon index) and β-diversity (Bray-Curtis distance). Statistical methods including network analysis and linear regression analysis were employed to investigate the correlations between variables.

RESULTS
The relative abundance of gut health-detrimental genera represented by Escherichia-Shigella increased in kidney bean, soybean, cowpea, chickpea, and black bean samples. In contrast, the relative abundance of health-positive genera were elevated in red bean, mung bean, and Heunguseul, with the proportion of the pathogenic Escherichia-Shigella decreased. Concurrently, microbial diversity exclusively increased in these three species. In addition, despite the lower nutrient contents in the three pulses, network analysis revealed that the nutrient contents in the pulse digesta possess rich positive or negative correlations with a variety of bacteria, as well as their metabolites. The linear regression analysis demonstrated that the ratio of carbohydrates to fatty acids and amino acids to fatty acids displayed negative correlations with the diversity increase. When the model was applied using only vegetables, which contained minimal nutrients aside from a limited amount of free sugars, an increase in certain beneficial bacteria associated with dietary fiber was observed for some species. However, the overall microbial diversity decreased across all samples.

CONCLUSIONS
It is noteworthy that a diet comprising foods with a balanced nutritional profile supports the growth of beneficial gut microbes, thereby promoting microbial eubiosis. For a plant-based diet to be sustainable in terms of human health, it is suggested that a combination of dietary patterns that ensures nutritional balance is necessary.

ANTIOXIDANT AND CHEMOPREVENTIVE ACTIVITY OF HYDRODISTILLATION WATER RESIDUES FROM CLOVE

CHIN-CHUNG WU[1]; Lin Yu-Chun[1]
[1]Graduate Institute of Natural Products, Kaohsiung Medical University, Sanmin District, Kaohsiung City, Taiwan, Taiwan

BACKGROUND AND OBJECTIVES
Clove is a spice used as a flavor in foods and a natural medicine mainly due to its rich essential oil. However, the potential beneficial effects of the clove aqueous extract are less noticeable. This study aims to investigate the antioxidant and chemopreventive effects of the water residues obtained after the clove essential oil hydrodistillation (WRHC).

METHODS
The total phenol and flavonoid contents were determined using the colorimetric method. The chemical profile was analyzed using liquid chromatography-tandem mass spectrometry (LC-MS/MS). Antioxidant activity was determined using DPPH radical scavenging assay. Cell migration and invasion were determined using wound healing and transwell assays. Protein disulfide isomerase (PDI) activity was determined using di-eosin-glutathione reduction assay.

RESULTS
Chemical analysis revealed that WRHC contained high levels of phenolic compounds and flavonoids that were correlated with its antioxidant activity. Pretreatment of human lung cancer A549 cells with low concentrations of WRHC (≤ 1 μg/mL) led to significant inhibition of cell migration and invasion. A mechanistic study revealed that WRHC inhibited the activity of PDI located on the cell surface that regulates functions of the integrins and, thus, the migration and invasion of cancer cells. In contrast, clove essential oil and eugenol, its major component, were ineffective in inhibiting PDI.

CONCLUSIONS
The antioxidant and chemopreventive effects of the hydrodistillation water residues from cloves may be beneficial in preventing lung cancer.

UMBELLIFERONE MITIGATES DIABETIC MUSCLE ATROPHY BY REGULATING MITOCHONDRIAL DYNAMICS AND THE UBIQUITIN-PROTEASOME SYSTEM

Dongyeon Kim[1]; Young-Hee Kang[2]; Min-Kyung Kang[3]
[1]Food Science and Nutirition, Andong National University, Andong, Korea, Republic of; [2]Department of Food Science and Nutrition, Korean Nutrition Institute, Hallym University, Chuncheon-si, Korea, Republic of; [3]Food Science and Nutrition, Andong National University, Andong, Korea, Republic of

BACKGROUND AND OBJECTIVES
Diabetes mellitus is a prevalent metabolic disorder often associated with complications like diabetic sarcopenia, characterized by reduced muscle mass, strength, and function. A key feature of diabetic sarcopenia is mitochondrial dysfunction, disrupting cellular energy metabolism and quality control. Additionally, diabetes accelerates muscle protein degradation via the ubiquitin-proteasome system, leading to muscle atrophy. This study evaluated the potential of umbelliferone, a natural compound, to mitigate muscle atrophy in high-glucose-treated muscle cells and diabetic muscle tissues.

METHODS
C2C12 myoblasts were cultured in DMEM with 10% FBS and differentiated using 2% horse serum. Cells were exposed to high-glucose medium with 10–20 μM umbelliferone for 4 days. In parallel, db/db diabetic mice were administered 10 mg/kg umbelliferone orally for 8 weeks. Western blot analyses assessed muscle-related factors (MyoD, myogenin, MYH, SMM), mitochondrial biogenesis markers (SIRT1, AMPK, PGC-1α, FIS1, DRP1, MFN1, OPA1), and atrophy-related proteins (MuRF1, Atrogin-1). Muscle function was evaluated via grip strength tests.

RESULTS
High glucose reduced myogenesis-related factor expression in C2C12 cells and diabetic mouse muscles, which was restored by umbelliferone, along with improved grip strength. Umbelliferone increased mitochondrial biogenesis and fusion (MFN1, OPA1) while decreasing fission (FIS1, DRP1). It also downregulated atrophy-inducing proteins (MuRF1, Atrogin-1) and suppressed ubiquitin-proteasome activity.

CONCLUSIONS
Umbelliferone mitigated diabetic muscle dysfunction by enhancing myogenesis-related factors, regulating mitochondrial dynamics, and suppressing the ubiquitin-proteasome system, demonstrating its potential to alleviate diabetic sarcopenia.

FLAVONOID PROFILING AND ANTIOXIDANT POTENTIAL OF OKRA (ABELMOSCHUS ESCULENTUS) GERMPLASM

Yoon-Jung Lee[1]; Bum-Soo Hahn[1]; Young-Wang Na[1]; Soomuk Cho[1]; Seong-Hoon Kim[1]; Ae-Jin Hwang[1]; Hyeonseok Oh[1]
[1]National Agrobiodiversity Center(NAC), National Institute of Agricultural Sciences, Wanju-gun, Korea, Republic of

BACKGROUND AND OBJECTIVES
Okra (*Abelmoschus esculentus*), valued for its nutrition and climate adaptability, is a versatile vegetable crop. This study evaluated 220 okra germplasm accessions conserved by the National Agrobiodiversity Center of South Korea, focusing on flavonoid profiling, antioxidant potential, and agricultural traits. By quantifying two key flavonoid, quercetin-3-gentiobioside and isoquercetin, and analyzing their correlation with antioxidant activities, we aimed to explore okra's potential applications in food and nutrition sciences.

METHODS
Okra germplasm was cultivated under uniform conditions, and agricultural traits, including pod length, width, and weight, were measured. Flavonoids quercetin-3-gentiobioside and isoquercetin were quantified using ultra-performance liquid chromatography (UPLC). Antioxidant properties, including total phenolic content (TPC, mg gallic acid equivalents), total flavonoid content (TFC, mg quercetin equivalents), ABTS and DPPH radical scavenging activity (mg Trolox equivalents), and reducing power (mg L-ascorbic acid equivalents), were assessed on a dry weight (DW) basis.

RESULTS
Significant variability was observed in agricultural traits, with pod length ranging from 6.10 to 30.00 cm (mean: 14.30 ± 3.54 cm) and pod weight from 5.60 to 91.70 g (mean: 30.22 ± 12.79 g). Flavonoid quantification revealed that quercetin-3-gentiobioside and isoquercetin levels averaged 2.13 ± 0.879 mg/g DW and 0.86 ± 0.387 mg/g DW, respectively. TPC ranged from 0.57 to 6.49 mg GAE/g DW (mean: 3.25 ± 1.22 mg/g DW), while TFC ranged from 0.25 to 2.24 mg QE/g DW (mean: 0.94 ± 0.36 mg/g DW). Among antioxidant assays, ABTS demonstrated the highest activity (mean: 4.23 ± 0.87 mg TE/g DW), followed by DPPH (mean: 4.14 ± 1.95 mg TE/g DW) and reducing power (mean: 1.70 ± 0.69 mg L-AAE/g DW). Quercetin-3-gentiobioside and isoquercetin exhibited a strong correlation (r = 0.74) and were moderately correlated with TFC (r = 0.70, 0.67) and ABTS (r = 0.60, 0.60). These RESULTS suggest that quercetin-3-gentiobioside and isoquercetin significantly contribute to the antioxidant properties of okra.

CONCLUSIONS
The findings underscore the genetic and functional diversity of okra germplasm, emphasizing the pivotal role of quercetin glycosides in antioxidant potential. These RESULTS offer insights into okra's applications in breeding programs, functional food development, and food science, highlighting its dual value as an agricultural and nutritional resource.

THE ANTI-OBESITY EFFECTS OF STICKY FOODS IN MICE FED WITH A HIGH FAT DIET

Yi-Hsiu Chen[1]; Yu-An Wei[1]; Jiun-Rong Chen[1]; Suh-Ching Yang[1]
[1]School of Nutrition and Health Sciences, Taipei Medical University, Taipei, Taiwan

BACKGROUND AND OBJECTIVES
It is well-known that obesity has a high prevalence worldwide, and also in Taiwan. In contrast, Japan has a low obesity rate, which may be linked to traditional dishes rich in soluble dietary fiber, such as seaweed and mushrooms with a sticky texture. In Taiwan, there are many local food ingredients with a sticky texture, similar to those in Japan. Therefore, the aim of this study was to investigate the anti-obesity effects of these local sticky foods (SF) in mice fed a high-fat diet.

METHODS
Twenty-eight 8-week-old C57BL/6 mice were used in this study. The mice were divided into four groups and fed different diets: control diet (AIN-93M) (C), 90% control diet and 10% SF (CSF), high-fat diet (60% of calories from fat) (H), or 90% high-fat diet and 10% SF (HSF). The SF was a mixture of various sticky ingredients, including seaweed, mushrooms, okra, and yam.

RESULTS
After 8 weeks of feeding, H group exhibited significantly higher body weight gain, food efficiency, relative adipose tissue weight, and alanine aminotransferase (ALT) activity compared to C group. The relative small intestine and colon lengths were significantly shorter in H group than in C group. However, HSF group showed significantly lower body weight gain, food efficiency, relative adipose tissue weight, and ALT activity compared to H group, while the relative small intestine and colon lengths were significantly longer.

CONCLUSIONS
In conclusion, the sticky food mixture demonstrated beneficial effects in reducing adipose tissue weight and body weight gain, as well as in prolonging the digestive tract.

CONFLICTS OF INTERESTS

BACKGROUND AND OBJECTIVES

Georgia has a rich agricultural tradition, with 43.4% of its land used for agriculture. Wheat, an ancient crop in Georgia, includes 14 species and over 150 varieties. This research initiates Georgia's first database, "Chemical Content of Georgian Wheat Varieties," analyzing the nutrient content of 12 local wheat varieties. The findings will support nutrition studies, determine nutrient profiles, and contribute to dietary strategies based on actual data from Georgian wheat varieties.

METHODS

Wheat, a polyploid crop, is rich in carbohydrates, proteins, minerals, vitamins, and fiber, with local factors influencing its nutrient content. This study evaluated the chemical content of 139 nutrients across 12 Georgian wheat varieties, analyzing over 1,529 chemical indicators. The wheat samples were tested in internationally accredited laboratories, and the RESULTS were calculated considering EFSA Intake Reference Values and the coefficient of nutrient transition into food. The assessment focuses on diet balance, highlighting the role of Georgian wheat in providing essential nutrients like proteins, amino acids, carbohydrates, fats, vitamins, and minerals for health and well-being.

RESULTS

In this study, Georgian wheat samples were examined for crude protein and 19 amino acids, providing insights into their nutritional composition. The RESULTS showed that the crude protein content was high, with several samples exhibiting significantly elevated levels of essential amino acids compared to other varieties. Additionally, the levels of conditionally essential amino acids were notably higher. Gluten index and wet gluten content were on the lower end. However, dietary fiber content was found to be higher than in many other wheat varieties, indicating potential benefits for digestive health. Regarding fatty acids, the Georgian wheat samples contained higher levels of monounsaturated and polyunsaturated fatty acids (MUFAs and PUFAs), while saturated fatty acids were lower. Several wheat varieties were also rich in vitamins and minerals, including vitamin B9, niacin, vitamin E, copper, zinc, and iron, contributing significantly to daily nutritional requirements and highlighting their potential role in supporting a balanced diet.

CONCLUSIONS

Wheat and wheat-based products play a crucial role in providing essential nutrients and energy in a balanced diet. This study highlights the significant potential of Georgian wheat endemic varieties in providing essential nutrients. As a pioneering effort, it underscores the need for further research to assess nutrient content in flour and baked products.

POLYPHENOL-MEDIATED EPIGENETIC REMODELLING IN LIPOTOXICITY-CHALLENGED HUMAN MAMMARY EPITHELIAL CELLS

Huiying Amelie Zhang[1]; Barbara Stefanska[1]
[1]Food Nutrition and Health, The University of British Columbia, Vancouver, Canada

BACKGROUND AND OBJECTIVES

Adiposity and dysregulation of lipid metabolism, signified by elevated plasma free fatty acids, are known risk factors for breast diseases, including breast cancer (1). Epigenetics plays important regulatory roles in breast health (2), which refers to transcriptional regulations of gene expression without altering the DNA sequence, e.g., DNA methylation and histone modifications (3). Our previous studies show that pterostilbene (PTS), a dietary polyphenol from berries, impacts histone methylation (H3K36me3) at specific gene loci in breast cancer cells, regulating expression of oncogenes (4). However, the epigenetic effects of PTS on preventing disruptions of homeostasis in the healthy mammary epithelial cells remain to be investigated. Considering *in vivo* relevance of microbial metabolism, pinostilbene (PNS), the major colonic metabolite of PTS (5), is of high interest. PNS exhibits similar antioxidant and anti-inflammatory activities as PTS (6), however its epigenetic effects remain unknown. This study aims to explore PTS and PNS effects on the fatty acids (FA)-challenged mammary epithelial cells, focusing on epigenetic regulation of gene expression.

METHODS

Human mammary epithelial cells (MCF10A) were treated with FA for 48 h to induce lipotoxicity, followed by a 72h treatment with PTS or PNS. Cell growth and viability were analyzed with Acridine Orange/Propidium Iodine (AO/PI) staining, and cellular fatty acid accumulation with Oil Red O (ORO) staining. Genome-wide H3K36me3 occupancy and gene expression are being determined with chromatin immunoprecipitation sequencing (ChIP-seq) and RNA sequencing (RNA-seq), respectively.

RESULTS

FA treatment inhibited cell growth and viability dose-dependently, and the concentration that reduced the viable cell number to 50% of non-FA treated control cells (IC50) was established at 380 μM, with 2:1 molarity ratio of oleic and palmitic acids. Cellular uptake of FA, as indicated by intracellular lipid accumulation with ORO staining, was positively correlated with FA concentration. The IC50 of PTS was established at 5 μM in FA-challenged MCF10A cells, which was comparable to the IC50 of 6 μM in non-FA treated control cells. PTS treatment at 5 μM had no cytotoxic effects and significantly reduced intracellular lipid accumulation in FA-challenged cells. The dose-response of PNS is under investigation.

CONCLUSIONS

PTS effectively mitigated FA-induced intracellular lipid accumulation to protect the cells against lipotoxicity. The PTS-mediated epigenetic dynamics underlying the protective effect will be revealed with ongoing ChIP-seq and RNA-seq analyses.

IDENTIFICATION OF A-SYNUCLEIN AMYLOID FORMATION INHIBITORS IN MAITAKE EXTRACTS

MISAKI ONO[1]
[1]Faculty of Nutritional Sciences, Department of Nutritional Sciences, Nakamura Gakuen University, FUKUOKA, Japan

BACKGROUND AND OBJECTIVES

Parkinson's disease is caused by the aggregation and accumulation of α-synuclein (α-SN) in neuronal cells. Since maitake hot water extract (MHW) exhibits strong inhibitory effects on α-SN amyloid formation, this study aimed to identify the inhibitory substances within maitake extracts.

METHODS

MHW Preparation: Hot water extraction was performed using freeze-dried and ground maitake (M).Molecular Weight Fractionation (MWCO): MHW was fractionated using a 106–104 MWCO membrane. Maitake Ethanol Extraction (ME): Ethanol extraction was performed using M.Maitake Crude Polysaccharide Extraction (MCP): M was mixed with water, heated at 121°C, and precipitated using ethanol.To assess α-SN amyloid formation inhibition, each of the extracts (1–4) was added to non-amyloidized α-SN at a $1/10^3$ (v/v) dilution. After shaking at 37°C for 72 hours, Thioflavin T (ThT) fluorescence was measured. The α-SN fibrillization rate (AR) was calculated by normalizing the fluorescence intensity of untreated samples at 72 hours to 100%.

RESULTS

MHW: AR was 0%, indicating complete inhibition of amyloid formation. MWCO: Fractions above 106 MWCO showed an AR of 90%, demonstrating weak inhibition of amyloid formation. Fractions below 106 MWCO showed AR values comparable to MHW, effectively inhibiting amyloid formation. ME: AR values for ME with ethanol concentrations of 0–50% were similar to MHW, indicating inhibition of amyloid formation. However, AR increased in an ethanol concentration-dependent manner for ME with ethanol concentrations ≥60%. MCP: AR was 50%, significantly lower than untreated samples but significantly higher than MHW.

CONCLUSIONS

The inhibitory substances in maitake for α-SN amyloid formation are estimated to have a molecular weight below 106 MWCO and are not extracted under high ethanol conditions. Adding crude polysaccharides from maitake resulted in a 50% inhibition of amyloid formation, suggesting that polysaccharides are one of the inhibitory substances. However, the substances responsible for the remaining 50% inhibition have yet to be identified.

MATCHA GREEN TEA IMPROVES LIPID METABOLISM DISORDER AND GUT DYSBIOSIS IN CAFETERIA DIET-INDUCED NAFLD IN A RAT MODEL

Hsieh Tsung-Yen,[1]; Ho-Ching Chong,[1]; Suh-Ching Yang[1]; Watanabe Yasuo[2]; Yamada Shizuo[3]; Kazuteru Ohashi[4]; Ya-Ling Chen[1]
[1]School of Nutrition and Health Sciences, Taipei Medical University, Taipei, Taiwan; [2]Pharmacy, Yokohama College, Yokohama, Japan; [3]Pharmaceutical Sciences, University of Shizuoka, Shizuoka, Japan; [4]President and CEO, KAWANE MATCHA CO.,LTD, Shizuoka, Japan

BACKGROUND AND OBJECTIVES
Non-alcoholic fatty liver disease (NAFLD) becomes the most common chronic liver condition in the world. In animal model, cafeteria diet used to induce NAFLD by adding high-fat, high- sugar, and high-salt human snacks and processed foods to the animal-based feeds. Matcha is a processed green tea that contains higher levels of caffeine and catechins. Research about the effects of matcha on lipid metabolism and gut microbiota in NAFLD still limited. Therefore, this study aims to investigate the effects of matcha on lipid metabolism and gut microbiota in NAFLD by cafeteria diet fed rats.

METHODS
Forty-eight 7-week-old male Wistar rats were divided into six groups (n = 8), including a control group (C)(normal diet, LabDiet 5001), C+0.2% matcha group (C+0.2%), C+1% matcha group (C+1%), cafeteria group (Caf)(including cheese sandwich crackers, milk puffs, chips, sausages and LabDiet 5001), Caf+0.2% matcha group (Caf+0.2%), and Caf+1% matcha group (Caf+1%). All rats were sacrificed after 12 weeks.

RESULTS
The RESULTS indicated that liver total cholesterol (TC) and liver triglycerides (TG) concentrations had significantly increased in the Caf group when compared to C group, and the 0.2% matcha intervention improved this phenomenon. Hepatic H&E staining showed that matcha improved the steatosis and inflammation under cafeteria diet feeding. The steatosis score, inflammation score, and NAFLD score of the Caf group had significantly increased compared to those of the C group. On the other hand, steatosis scores of the Caf+0.2% and Caf+1% groups had significantly decreased compared to that of the Caf group. Besides, 12-week cafeteria diet feeding disrupted gut microbiota composition while a significant increase in *Akkermansiaceae* and *Akkermansia* (AKK) in the Caf+0.2% group was found. Additionally, in the Caf+1% group, a significant increase of *Parabacteroides* and *Faecalibacterium* were observed.

CONCLUSIONS
In conclusion, matcha showed the potential for improving lipid metabolism disorder and gut dysbiosis in cafeteria diet-induced NAFLD model.

THE IMPACT OF SUPPLEMENTATION WITH KRILL OIL DURING DIET-INDUCED BODY MASS LOSS AND BODY WEIGHT MAINTENANCE PHASES ON BODY COMPOSITION AND SUBJECTIVE APPETITE

Mansour Alblaji[1]; Stuart Gray[2]; Ada L. Garcia[1]; Dalia Malkova[1]
[1]Human Nutrition, School of Medicine, Dentistry and Nursing, University of Glasgow, Glasgow, United Kingdom; [2]School of Cardiovascular and Metabolic Health, University of Glasgow, Glasgow, United Kingdom

BACKGROUND AND OBJECTIVES
Supplementation with long-chain n-3 polyunsaturated fatty acids (LCn-3 PUFA) is associated with appetite reduction [1, 2]. We investigated the impact of krill oil (KO), as a source of LCn-3 PUFA supplement, on changes in body composition, subjective appetite, and gastrointestinal appetite hormones during body weight loss and weight maintenance phases.

METHODS
Twenty-eight adults (mean age: 39.4±11.7 years; BMI: 27.9±3.2 kg/m²) participated in a double-blind, randomised, placebo-controlled trial. Participants consumed either 4g/day of KO or 4 g/day of vegetable oil (placebo) during the 4-week preparation phase, the 8-week alternate-day fasting phase, and the subsequent 8-week body weight maintenance phase. Body mass, body fat and fat-free mass were measured before, and after weight loss and weight maintenance phases. Fasting and postprandial subjective appetite scores and plasma concentrations of acylated ghrelin, GLP-1, and PYY were measured before and after the weight loss phase. A two-way ANOVA with repeated measures assessed the impact of time, group, and time*group interaction effects.

RESULTS
Body weight was reduced by -4.6±1.4 kg and -4.5±1.9 kg in the KO and placebo groups, respectively. The ANOVA revealed a significant time ($p<0.05$), but not group ($p>0.05$) or time*group interaction ($p>0.05$) effects for body mass, fat mass or FFM during the weight loss phase. During the weight maintenance phase, no significant time, group, or time*group interaction effects were found for body mass and FFM (all $p>0.05$), while for fat mass, the time*group interaction effect was significant ($p<0.05$). During the maintenance phase, in the KO group fat mass remained unchanged (+0.1±0.3 kg, $p>0.05$), but increased significantly in the placebo group (+0.4±0.3 kg, $p< 0.05$). This coincided with a significant reduction in the composite appetite score (CAS) in the KO group (-6.6 ±7.4 mm, $p<0.05$) but not in the placebo group (-3.7 ±8.3 mm, $p> 0.05$) during the body weight loss phase. There were no significant time, group, or time*group interaction effects for acylated ghrelin, GLP-1, and PYY during the weight loss phase (all $p > 0.05$).

CONCLUSIONS
KO supplementation during diet-induced weight loss may induce favourable changes in subjective appetite and prevent short-term fat mass regain.

CLASSIFICATION OF SCHOOL MENUS IN BRAZIL USING GENERATIVE AI

Matheus Ferreira dos Santos[1]; Prado Martins Isabela[2]; Rafaella Camargo[3]; Evandro Ribeiro[4]; Semíramis Martins Álvares Domene[5]

[1]Department of Administration, School of Economics, Administration and Accounting of Ribeirão Pr, USP Campus de Ribeirão Preto, Pirassununga, Brazil; [2]Postgraduate Program in Nutrition, Federal University of São Paulo Unifesp, São Paulo, Brazil, USP Campus de Ribeirão Preto, Ribeirao Preto, Brazil; [3]Interdisciplinary Postgraduate Program in Health Sciences, Universidade Federal de São Paulo - Campus Baixada Santista - Edifício Acadêmico I, Santos, Brazil; [4]Department of Administration, School of Economics, Administration and Accounting of Ribeirão Pr, USP Campus de Ribeirão Preto, Ribeirao Preto, Brazil; [5]Department of Public Policies and Collective Health, Institute of Health and Society, Universidade Federal de São Paulo - Campus Baixada Santista - Edifício Acadêmico I, Santos, Brazil

BACKGROUND AND OBJECTIVES

The Revised Quality Index for School Meal Menus (IQCAE-R) is one of the few existing frameworks designed to assess the nutritional quality of school meal menus [1]. It assigns positive scores to healthy foods such as fruits and vegetables and negative scores to sweets and ultra-processed foods. It also takes regional ingredients and healthy practices into account. Developing an application that automatically calculates the IQCAE-R offers several benefits. By utilizing generative artificial intelligence based on Large Language Models (LLMs) [2], and advanced techniques, including GraphRAG [3] and Hybrid Retrieval [4], it is possible to perform a contextualized and efficient analysis of menus and classify them according to the IQCAE-R.

METHODS

A Knowledge Graph [5] is developed in Neo4j, encompassing entities such as foods and food groups, along with their attributes (e.g., name, category, and embeddings [6]. Python integration facilitates the use of the Neo4j-Graphrag library for communication with the LLM and hybrid data retrieval. The Extract-Transform-Load (ETL) process [7], organizes data for analysis, leveraging embeddings from OpenAI's text-embedding-3-large model to ensure precise identification and classification. By accurately recognizing and classifying food items in daily school menus, the system calculates the IQCAE-R for weekly menus.

RESULTS

The project introduces an innovative system that processes weekly school menus to identify food items and evaluate their nutritional dimensions, enabling automated IQCAE-R calculation. By integrating GraphRAG and Hybrid Retrieval techniques with Neo4j, the system uncovers complex relationships between food items and nutritional components. This automation improves classification accuracy and ensures compliance with IQCAE-R guidelines, fostering healthier eating practices in Brazil’s public schools.

CONCLUSIONS

This project proposes a groundbreaking, automated approach to calculate the IQCAE-R for school meal menus, addressing the current gap in systematic nutritional analysis. By employing GraphRAG techniques, Hybrid Retrieval, and the Neo4j graph database, the system utilizes generative artificial intelligence to identify, classify, and score food items according to IQCAE-R criteria. This solution enhances efficiency in index generation and represents a technological leap forward in optimizing school food management.

CAGRISEMA IMPROVES INSULIN SENSITIVITY IN DIET-INDUCED OBESE RATS

Vanessa Folope Leborgne[1]; Anna Secher[2]; Christian L Brand[3]; Kirsten Raun[2]
[1]Medical, Novo Nordisk, Puteaux, France; [2]Global drug discovery, Novo Nordisk, Søborg, Denmark; [3]Global drug discovery, Novo Nordisk A/S - site Måløv, Måløv, Denmark

BACKGROUND AND OBJECTIVES
CagriSema (CS), a combination of the long-acting analogues of amylin (cagrilintide) and glucagon-like peptide-1 (semaglutide), is in clinical development for treatment of obesity. It is unknown whether CS leads to improvement of insulin sensitivity. The aim of this study was to investigate changes in insulin sensitivity with CS in diet-induced obese (DIO) rats.

METHODS
DIO male rats were allocated to three groups (n=6 per group): vehicle control (VC), CS and a vehicle group that was weight-matched (WM) to CS by calorie restriction. The groups were stratified by body weight (BW), fat mass and fat-free mass. The rats received daily s.c. doses of either 2 nmol/kg CS or vehicle, and food availability in the WM group was adjusted daily to achieve similar weight loss as in the CS group. After 21 days of treatment, rats were instrumented under general anaesthesia (isoflurane) with carotid and jugular catheters for sampling and infusions, respectively. After 9–11 days of recovery, rats were subjected to a 180-minute hyperinsulinaemic (15 pmol/kg/min) and euglycaemic (~5.7 mM) clamp. 3H-glucose and 14C-2-deoxy-glucose (2DG) were used to measure hepatic glucose production (HGP), glucose uptake (GU) and tissue-specific 2DG uptake.

RESULTS
CS-treated rats and WM treated rats lost ~10% BW (baseline-adjusted). Inducing a comparable BW loss between WM rats and CS rats required a supply of ~10% less food (accumulated) to the WM rats, suggesting an additional effect by CS in metabolic adaptation. FI in CS and WM groups returned to baseline levels at the end of treatment without an increase in BW. No change in fasting plasma glucose was observed between groups, but baseline plasma insulin decreased by 40% with CS compared with VC ($p<0.03$) suggesting an increase in insulin sensitivity. Compared with the VC group, clamp glucose infusion rates (GIR) increased by 4.2- and 2.6-fold in the CS ($p<0.001$) and WM ($p=0.097$) groups, respectively. No significant differences in HGP between groups, but compared with VC group, GU increased by 3.3- and 1.6-fold in CS ($p=0.002$) and WM (NS) groups, respectively. To further explore the GU in specific tissues, 2DG uptake in muscle and fat was evaluated and found to be higher in muscle (but not in fat) in CS group compared to VC group.

CONCLUSIONS
Treatment with CS increased insulin sensitivity and improved glucose metabolism compared with VC in DIO rats. This improvement in insulin sensitivity could only partly be explained by weight loss as the GIR was numerically, but not significantly (65%, $p=0.079$), larger in the CS group compared to the WM group.

EPO8_185

EFFECT OF MANGANESE OVERLOAD ON ZIP8 EXPRESSION IN NEONATAL MOUSE LIVER

Ningning Zhao[1]
[1]Nutritional Sciences and Wellness, The University of Arizona, Tucson, United States of America

BACKGROUND AND OBJECTIVES
ZIP8 (SLC39A8) is a membrane metal transporter that mediates the transport of divalent cations, especially manganese (Mn), essential for various enzymatic activities in metabolic processes. This study investigates the effects of maternal dietary manganese content on ZIP8 expression in liver, lung, kidney, and spleen of neonatal mice, aiming to understand how manganese overload affects ZIP8-mediated homeostasis and tissue distribution.

METHODS
Neonatal mice models were generated from 8-9 week old wild-type breeding pairs, divided into two dietary groups: a control group fed with a 20 ppm Mn diet and a Mn-overload group fed with a 2000 ppm Mn diet. The breeding pairs were maintained on these diets throughout breeding and lactation to modify maternal breast milk Mn content. ZIP8 expression in the liver, lung, kidney, and spleen of the offspring was quantified using Western blot analysis.

RESULTS
Significant decreases in hepatic ZIP8 expression were observed in both male and female neonates from the Mn-overload diet group, suggesting reduced Mn reabsorption from bile and potentially increased Mn excretion. In contrast, ZIP8 expression in the lung, kidney, and spleen showed no significant differences between the dietary groups, indicating a tissue-specific response to dietary manganese overload.

CONCLUSIONS
The findings highlight the liver as a critical site for ZIP8 regulation in response to dietary Mn changes. The decreased expression of ZIP8 in the liver under Mn overload conditions suggests a protective mechanism against Mn toxicity, possibly by reducing Mn reabsorption and increasing excretion. This study underscores the importance of ZIP8 in maintaining Mn homeostasis and suggests potential implications for managing conditions associated with Mn dysregulation. Further research is needed to explore the mechanisms of ZIP8 regulation in other tissues and under different dietary conditions.

ASSESSING THE EVIDENCE: A CRITICAL REVIEW OF NUTRITIONAL REQUIREMENTS VALUES AND INTAKE RECOMMENDATIONS

Sumati Bajaj[1]; Marco Springmann[1]
[1]Institute for Global Health, University College London, London, United Kingdom

BACKGROUND AND OBJECTIVES
Nutrient requirement values established by large-scale committees like WHO1, EFSA2 and IOM3 provide the foundation for nutrient intake recommendations, global assessments of inadequate nutrient intake, and public health strategies to address nutrient deficiencies. However, the reliability and generalisability of these requirement values have not been systematically examined. To address this gap, we critically reviewed the quality of evidence base used to establish requirements by these committees.

METHODS
We examined the methodological approaches used by EFSA and IOM to set average requirements (AR) and adequate intakes (AI) for 20 micronutrients across various life stages: adults, infants, children, and pregnant and lactating women. For each nutrient and age group, we reviewed the characteristics of evidence used by these committees, including the number of studies, study demographics, and publication timelines.

RESULTS
For adults, ARs for 10 nutrients were based on experimental studies establishing clear relationships between intake and health endpoints. Fewer than 5 experimental studies, typically published between the 1950s-2000s and featuring small sample sizes (7 to 50 participants), were used for most of these nutrients. For other nutrients, ARs or AIs were derived from less robust alternative approaches, including short-term balance studies, factorial analyses, and observed intakes from healthy populations in national dietary surveys, none of which clearly reflect the effect of nutrients on health. For infants and lactating women, ARs or AIs for most nutrients were based on breastmilk nutrient concentrations typically derived from fewer than 10 observational studies involving a range of participants (7 to 600 postpartum women), which were published between the 1970s-2010s. For children and pregnant women, ARs or AIs were often extrapolated from other age groups.

CONCLUSIONS
Evidence used by EFSA and IOM to derive nutrient requirements is limited and outdated for nearly all micronutrients. Urgent efforts are needed for more robust, and contemporary evidence to ensure nutrient requirement values are reliable, equitable, and reflective of global health needs.

CORRELATION OF NUTRITIONAL STATUS AND HEMOGLOBIN LEVEL AMONG ADOLESCENT-SCHOOL GIRLS IN SUB-URBAN OF WEST JAVA, INDONESIA

Lestari Octavia[1]; S Hayuningsih,[2]; F. Fitrianingsih[3]; W Rahardjo,[4]
[1]Research Unit, Universitas Gunadarma Kampus D, Depok, Indonesia; [2]Midwifery, Universitas Gunadarma Kampus D, Depok, Indonesia; [3]Computer Science, Universitas Gunadarma Kampus D, Depok, Indonesia; [4]Psychology, Universitas Gunadarma Kampus D, Depok, Indonesia

BACKGROUND AND OBJECTIVES
Anemia, a condition characterized by a reduced number of red blood cells or hemoglobin, is a significant public health concern, particularly among adolescent girls. Adolescence is a crucial developmental phase, and anemia during this time can have severe consequences, including increased risk of foetal morbidity and mortality in the future..The current study aims to investigate the correlation between nutritional status and hemoglobin levels among adolescent-school girls in West Java, Indonesia. The research will enrich the study of public health problems in low- and middle-income countries.

METHODS
This cross-sectional study was conducted among 311 adolescent-school girls in West Java, Indonesia. Data on demographic characteristics, nutritional status, and hemoglobin levels were collected through a structured questionnaire and laboratory analysis. Nutritional status was assessed using body mass index, and hemoglobin levels were measured using a standard hemoglobin testing method. Pearson correlation analysis was used to examine the relationship between nutritional status and hemoglobin levels.

RESULTS
The study included 311 adolescent-school girls with a median age ± SE of 17 ± 0.04 years. The prevalence of moederate anemia was 24.4%, while the prevalence of mild anemia was 16.4% for a hemoglobin level between 11 and 11.9 g/dL rather than 12 g/dL. The prevalence of underweight, normal, and overweight was 29.6%, 54%, and 16.4%, respectively. There is no significant correlation observed between nutritional status and hemoglobin levels ($r = 0.038$, $p > 0.05$), indicating that nutritional status is not correlated with hemoglobin level for this particular population. Further study is required to investigate the possible factors affecting the hemoglobin level of the adolescent-school girls in the sub-urban area.

CONCLUSIONS
Targeted interventions aimed at improving the nutritional status of this population may be an effective approach to reducing the burden of anemia.

BETA-CRYPTOXANTHINE AND VITAMIN C CONTENT IN MOMORDICA CHARANTIA L

Kayoko Uezu[1]; Eiko Uezu,[2]
[1]Okinawa office , Quest-Computer Co., Ltd., Tokyo, Japan; [2]Emeritus Professor, University of the Ryukyus, Okinawa, Japan

BACKGROUND AND OBJECTIVES

Momordica charantia has been used as a vegetable in Okinawa, a southern region of Japan, Southeast Asia, and the Pacific islands. With global warming, it is also being cultivated in Hokkaido, a northern region of Japan. Vitamin C and β-carotene have been focused of attention as nutritional components of Momordica charantia[1],[2]. In this study, we report on β-cryptoxanthin contained in ripe Momordica charantia fruits.

METHODS

A single seedling of Momordica charantia was planted in a planter filled with soil on the balcony of an apartment building. Samples were considered fully ripe when more than half of the fruit had turned yellow and was about to split, or when the fruit had started to split at the time of harvest. Samples that were more than half green at the time of harvest were considered semi-ripe. As a control, fruits that were entirely green three weeks after flowering (pollination) were considered mature-green fruit. We requested the Japan Food Research Center to measure the β-cryptoxanthin and Vitamin C content in the same samples.

RESULTS

The β-cryptoxanthin content of mature-green fruit of Momordica charantia was 6μg/100g. The β-cryptoxanthin content of semi-ripe fruit was 154-267μg/100g, while that of fully ripe fruit was 950-2230μg/100g. The Vitamin C content of semi-ripe and fully ripe were lower level than mature-green fruit.

CONCLUSIONS

The β-cryptoxanthin content of Momordica charantia, which was 6μg/100g in mature-green fruit, was observed to increase with ripeness. When approximately 50% or more of the fruit had turned yellow, no difference was observed between approximately 50% turned yellow fruit and almost 100% turned yellow fruit. The Vitamin C content was decreased as days pass after pollination, and it showed a similar result as the other reports[1],[2]. It is said that fully ripe fruit has low nutritional value and is not tasty, but considering the high β-cryptoxanthin content, it cannot be said that it has low nutritional value.

Role of methylxanthines in the modulation of age-associated intestinal barrier dysfunction: RESULTS from an in vitro study

Marco Rendine[1]; Marco Gellera[1]; Mirko Marino[1]; Daniela Martini[1]; Cristian Del Bo'[1]; Patrizia Riso[1]
[1]Department of Food, Environmental and Nutritional Sciences (DeFENS), University of Milan, Milano, Italy

BACKGROUND AND OBJECTIVES

We recently documented that an 8-week intervention with a (poly)phenol-rich diet reduced serum zonulin and calprotectin levels, as markers of intestinal permeability (IP) and inflammation, in older adults (1-2). In addition, we found an inverse association between serum methylxanthines (MX), derivatives from cocoa and/or green tea intake, with serum zonulin levels (3). The aim of this study was to test the hypothesis that MX may play a role in the modulation of barrier function in an in vitro model of intestinal epithelial cells. This study was carried out in parallel with the activities of the OnFoods project (https://onfoods.it/).

METHODS

Colorectal adenocarcinoma cells (Caco-2) were differentiated into polarized monolayers, pre-treated with D-galactose (30 g/L) for 24 h, in order to induce age-associated intestinal barrier dysfunction, and incubated with 3-Methylxanthine and 7-Methylxanthine (1.25-20 µM) for additional 24 h. The transepithelial electrical resistance (TEER) and fluorescein isothiocyanate-dextran (FITC-D) efflux assays were used to measure the integrity of the intestinal monolayer. Additionally, the regulation of intestinal barrier markers including occludin, zonulin and p53 was evaluated by ELISA kits.

RESULTS

D-Gal treatment significantly elevated zonulin levels (at about +140% fold change compared to the control, $p<0.05$) but not p53 levels (+19% fold change, $p>0.05$). The administration of physiological concentrations of MX mitigated D-Gal-induced intestinal barrier dysfunction, as documented by a significant increase in TEER and a significant reduction in FITC-d values and zonulin production. No effect on p53 and occludin levels was observed.

CONCLUSIONS

The findings suggest a potential contribution of MX in the modulation of IP thus, supporting the correlation found within the human trial. These RESULTS could represent an important starting point for in vivo studies focused on the demonstration of a beneficial effect of MX and/or related food sources in the context of IP conditions.

IDENTIFICATION OF NOVEL ANTI-TUMOR PEPTIDES FROM SOY-BASED TEMPEH AND THEIR MECHANISM IN PANCREATIC AND COLORECTAL CANCER CELLS

Happy Kurnia Permatasari[1]; Fahrul Nurkolis[2]
[1]Biochemistry and Biomolecular, Universitas Brawijaya, Malang, Indonesia; [2]Master of Basic Medical Science, Faculty of Medicine Airlangga University, Surabaya, Indonesia

BACKGROUND AND OBJECTIVES
Pancreatic and colorectal cancers are among the most aggressive and prevalent cancers worldwide, with limited treatment efficacy and severe side effects. Functional foods, such as soy-based tempeh, have shown potential anticancer properties. This study aimed to identify bioactive peptides from soy-based tempeh hydrolysate (SBTE) and evaluate their antitumor potential through bioinformatics and in vitro analysis.

METHODS
SBTE was prepared by enzymatic hydrolysis using trypsin, followed by untargeted metabolomic profiling via liquid chromatography-mass spectrometry (LC-MS/MS) to identify peptide sequences. Bioinformatic analysis, including network pharmacology and molecular docking, was conducted to determine interactions with cancer-related receptors such as EGFR, iNOS, BIRC2, ANPEP, and PARP1. In vitro studies using HT-29 (colorectal) and PANC-1 (pancreatic) cancer cell lines assessed the cytotoxic effects and downregulation of cancer-related receptor expressions.

RESULTS
A novel peptide, P1 (GENEEEDSGAIVTVK), and four dipeptides (Ile-Arg, Lys-Pro, Gly-Leu, Lys-Leu) were identified from SBTE. Molecular docking analysis revealed strong binding affinities to cancer receptors, with the highest affinity observed for PARP1 (-6.5 kcal/mol) and EGFR (-6.2 kcal/mol). In vitro experiments demonstrated a significant reduction in the expression of cancer-related receptors, with a 10-fold downregulation in PANC-1 and HT-29 cells. The SBTE and its peptides exhibited selective cytotoxicity, with LD50 values significantly lower in cancer cells compared to normal cells.

CONCLUSIONS
SBTE and its bioactive peptides demonstrate promising anticancer potential through targeted receptor downregulation and selective cytotoxicity, making them potential candidates for functional food development or novel anticancer therapies against pancreatic and colorectal cancers.

COMPARATIVE STUDY OF NUTRITIONAL STATUS IN PRESCHOOL CHILDREN: A CASE STUDY OF MONGOLIA AND SWITZERLAND

Nomin Bayarsukh[1]
[1]School of Industrial Technology, Mongolian University of Science and Technology, Ulaanbaatar, Mongolia

BACKGROUND AND OBJECTIVES
Proper nutrition plays a fundamental role in children's growth and health, particularly during the preschool years, a critical period for establishing dietary habits. This study aims to compare the nutritional quality of preschool meals, dietary patterns, and food supply systems between Mongolia and Switzerland to identify key factors influencing child nutrition and health outcomes.

METHODS
The study was conducted between November 2022 and April 2023, involving 306 children aged 3–6 years from preschools in Ulaanbaatar, Mongolia, and Lausanne, Switzerland. Data were collected using food frequency questionnaires, 24-hour dietary recall methods, and on-site analysis of preschool meal production and food supply systems. Nutrient intake was assessed using national and international dietary guidelines. Statistical analyses were performed using SPSS and NutriSurvey software.

RESULTS
Significant differences in nutritional intake and dietary practices were observed. Mongolian preschool meals contained excessive protein (+16.3%) but insufficient fat (-20.5%), while Swiss meals showed excess fat (+36.8%) and inadequate protein (-16.9%) and carbohydrates (-29.2%). Mongolian children consumed less fruits and vegetables but more sugary snacks and beverages compared to Swiss children. Additionally, the absence of nutritionists in meal planning and systemic differences in food supply practices were identified as contributing factors.

CONCLUSIONS
The study highlights the need for tailored interventions to improve preschool nutrition programs, including employing nutritionists, enhancing parent education, and implementing sustainable food policies. Lessons from Switzerland's standardized food regulations and environmental sustainability approaches could serve as a model for Mongolia to address its nutritional challenges and promote healthier childhood development.

ESTABLISHING A COMMUNITY ADVISORY BOARD FOR A NUTRITION CLINICAL TRIAL; STRATEGY AND PROCESS

Sophie Chabeda[1]; Alison Talbert[1]; Fredrick Opel[1]; Hassan Alphan[1]; Martha Mwangome[1]
[1]Clinical Research, KEMRI-Wellcome Trust Research Programme, Kilifi, Kenya

BACKGROUND AND OBJECTIVES

Community advisory boards (CABs) are crucial organs for involving communities in research. Although CABs have been commonly used in HIV-related clinical trials, their use in other fields, such as nutrition, is less well-documented. Prior to implementation of a nutrition trial within the community to establish optimal dosage of multiple micronutrient supplementation (MMS) for women of reproductive age (WRA), the trial team established a CAB. The CAB was set up to foster trust and address potential challenges or rumors that could potentially arise from implementation of a nutrition clinical trial within the community

METHODS

The process of setting up a CAB began with stakeholder consultations with the local administrative leaders, research institution's community representatives and leaders from organized community groups. Additionally, the research institution's community engagement team were also consulted. The consultation process aimed to gather diverse views on the process of setting up the CAB. The CAB was to include representation from women, men, youth, people with disabilities, health leaders and local administrative leaders from the study community. Potential CAB members were to be identified and endorsed by the community members in an open-air community gathering organized by the local administration. Finally, a 5-day training was to be conducted to equip the CAB members with knowledge on the research institution activities, research ethics, trial processes and their roles as CAB members.

RESULTS

The diverse consultation resulted in a document outlining a standard operating procedure (SOP) for setting up a CAB within a research institution. Two separate CABs were set up at the two trial sites each with 12 members, totaling 24 members across both sites. The composition of the CABs ensured gender balance (12 males; 12 females) and included various community leaders and representatives from different groupings within the community.

CONCLUSIONS

The successful establishment of the CAB corresponded to an integrated approach that involved engaging multiple stakeholders, such as local administrative leaders, existing community groups, and the research institution's community representatives. The experience gained by the community engagement team was essential to the process, helping to ensure the CAB's effective setup and functioning. The standard operating procedures are an institutional resource for future use.

BASIL ESSENTIAL OIL AND ABIETIC ACID: SYNERGISTIC ANTIBACTERIAL AND ANTIBIOFILM EFFECTS AGAINST VAGINAL PATHOGENS

Jumin Park[1, 2]; Minkyoung Park[1]; Bohkyung Kim[1, 2]; Heeseob Lee[1]
[1]Department of Food Science and Nutrition, Pusan National University, Busan, Korea, Republic of; [2]BK21 FOUR Program : Precision Nutrition Program for Future Global Leaders, Pusan National University, Busan, Korea, Republic of

BACKGROUND AND OBJECTIVES
Vaginitis is a common gynecological condition caused by bacterial infections. The vagina's environment is susceptible to microbial overgrowth, leading to various types of vaginitis. Basil (*Ocimum basilicum* L.) essential oil and abietic acid have demonstrated antibacterial and antiinflammatory effects. Combining these two natural compounds presents a promising synergistic approach to inhibit vaginal pathogens. This study evaluated their combined antibacterial effects using the Checkerboard dilution method to determine the fractional inhibitory concentration index (FICI). This research aims to contribute to the development of novel feminine hygiene products for the prevention and treatment of vaginitis.

METHODS
Basil essential oil was extracted via steam distillation. Abietic acid was purified from rosin. The Checkerboard dilution method was employed to analyze the combined antibacterial effects of these compounds against vaginal pathogens and to determine the FICI. Antibacterial activity was evaluated through broth microdilution assays. Biofilm formation was assessed using crystal violet staining, and the expression of virulence factor genes was analyzed via quantitative PCR. Additionally, the effects of the optimal mixture on the growth of *lactobacilli* were examined.

RESULTS
Both basil essential oil and abietic acid exhibited potent antibacterial activity against four vaginal pathogens at low concentrations. Their combination demonstrated significant synergistic effects against all tested pathogens, with the strongest effect observed against *Candida albicans*. This synergy effectively inhibited biofilm formation and modulated virulence factor genes expression. Importantly, this combination did not adversely affect the growth of *lactobacilli*, supporting its potential safety in vaginal applications.

CONCLUSIONS
This study highlights the potent synergistic antibacterial and antibiofilm effects of basil essential oil and abietic acid against vaginal pathogens, especially *C. albicans*. These findings suggest a promising natural alternative for preventing and treating vaginitis.

INTESTINAL ABSORPTION OF C- AND O-GLUCOSIDES OF APIGENIN AND LUTEOLIN IN THORACIC-LYMPH CANNULATED RATS

Mika Kawamoto[1]; Toshiyuki Nakamura[2]; Kaeko Murota[1]
[1]Faculty of Life and Environmental Sciences, Shimane University (Matsue campus), Matsue, Japan; [2]Graduate School of Environmental and Life Science, Okayama University Tsushima Campus, Okayama, Japan

BACKGROUND AND OBJECTIVES
Flavonoids are major functional components and found mainly in various glycosidic forms in plant foods. The type of sugar moieties bound to one or more hydroxy groups or carbons (*O*-glycoside or *C*-glycoside) strongly affect their bioavailability. In this study, we compared the intestinal absorption of major flavones, apigenin and luteolin, focusing on the chemical forms of their aglycones and monoglucosides.

METHODS
Apigenin and luteolin were administered intraduodenally as their aglycones or monoglucosides (*O*- and *C*-linkages) to rats with thoracic lymph duct cannulation. Lymph fluid, peripheral blood, urine, and feces were collected for 6 h (aglycones and *O*-glucosides) or 12 h (C-glucosides). The samples were treated with β-glucuronidase/sulfatase and subjected to quantitative analysis by HPLC-PDA. The untreated samples were partly analyzed by LC-MS/MS to identify their metabolites.

RESULTS
When apigenin was administered to lymph-cannulated rats, the plasma and lymphatic levels after *O*-glucoside administration were significantly higher than those of aglycone administration. In the case of luteolin, its aglycone and *O*-glucoside showed similar absorbability. Interestingly, luteolin was transported to the lymphatic system at higher levels than apigenin. After administration of *C*-glucosides of apigenin and luteolin, their aglycones were not detected either with or without deconjugation in the plasma and lymph at an early phase, indicating that *C*-glycosidic linkage cannot be cleaved at the intestinal mucosa. Instead, the intact C-glucosides were detected at lower levels both in the plasma and lymph to a similar extent. In the urine, apigenin *C*-glucoside were detected at a higher level than luteolin *C*-glucoside. LC-MS/MS analysis indicated that the part of *C*-glucosides appeared in the plasma, lymph and urine as their sulfates. On the other hand, the conjugated aglycones and their derivatives were detected in the feces with the parent *C*-glucosides. These observations suggest the degradation of *C*-glucosides by intestinal microbiota.

CONCLUSIONS
The modification of *O*-monoglucoside did not change the lymphatic transport ratio of flavones but enhanced the apigenin absorption. Also, *C*-monoglucosides can be absorbed intact as well as their conjugated forms and the corresponding aglycone at a late phase. These RESULTS will be helpful to understand the distinguished benefits in various plant foods.

CONFLICTS OF INTERESTS
The authors have no conflict of interest.

PREVENTION OF INTESTINAL INFLAMMATION BY HUMAN BREAST MILK-DERIVED EXTRACELLULAR VESICLES IN A DSS-INDUCED MOUSE MODEL OF INFLAMMATORY BOWEL DISEASE

Jae-Hee Kwon,[1]; Do-Kyun Kim,[2]; Young-Eun Cho[1]
[1]Food and Nutrition, Andong National University, Andong, Korea, Republic of; [2]Korea Zoonosis Research Institute, Jeonbuk National University Museum, Iksan, Korea, Republic of

BACKGROUND AND OBJECTIVES
Inflammatory bowel disease (IBD) is a chronic condition characterized by persistent inflammation of the intestines. Current treatments, including immunosuppressants and biologics, often come with side effects and limited long-term efficacy. Consequently, there is an urgent need for innovative therapeutic strategies. Extracellular vesicles (EVs), small vesicles crucial for intercellular communication, have shown potential in treating various diseases. Notably, EVs derived from human breast milk modulate immune responses, reduce inflammation, and promote tissue repair, positioning them as a promising candidate for restoring gut homeostasis in IBD.

METHODS
Sample collection was approved by the Bioethics Committee of the Human-derived Materials Research Institute. EVs derived from human breast milk were isolated and characterized using ultracentrifugation. IBD was induced in mice using dextran sulfate sodium (DSS), followed by oral administration of these EVs for treatment. The effects on intestinal damage and inflammation were evaluated by analyzing blood, small intestine, large intestine, and liver samples, focusing on the impact of EV treatment on intestinal injury and inflammation.

RESULTS
EVs derived from human breast milk significantly reduced inflammation and facilitated tissue repair in both the small and large intestines of IBD model mice. These EVs also contained immunoglobulins that suppressed pro-inflammatory cytokine production and regulated intestinal immune responses, aiding in the resolution of inflammation.

CONCLUSIONS
This study demonstrates that EVs derived from human breast milk play a crucial role in IBD treatment, with immunoglobulins significantly contributing to the mechanisms of inflammation reduction. These findings suggest that EV-based therapies could provide an effective immunological approach to IBD treatment.

PROTECTIVE EFFECTS OF EDIBLE GINSENG-DERIVED EXTRACELLULAR VESICLES ON LIVER FIBROSIS: REGULATION OF TIMP2/MMPS PATHWAYS AND GUT MICROBIOTA MODULATION

Ji-Su Kim,[1]; Do-Kyun Kim,[2]; Young-Eun Cho[1]
[1]Food and Nutrition, Andong National University, Andong, Korea, Republic of; [2]Korea Zoonosis Research Institute, Jeonbuk National University Museum, Iksan, Korea, Republic of

BACKGROUND AND OBJECTIVES
Metabolic dysfunction-associated fatty liver disease (MASLD) and alcohol-associated liver disease (ALD) represent chronic liver diseases that can progress to steatohepatitis (inflammation), liver fibrosis/cirrhosis, liver failure, and death. Unfortunately, there are few medicines approved for treating liver fibrosis/cirrhosis. Therefore, in this study, we investigated the protective effects of ginseng-derived extracellular vesicles (GDEVs) administration on liver fibrosis.

METHODS
We administered GDEVs to mouse and cell models of liver fibrosis. The effects were assessed through histological analysis and biomarker measurements to evaluate fibrosis mitigation.

RESULTS
GDEVs successfully reached the gut or liver in both *in vitro* and *in vivo* models without much degradation or cytotoxicity. GDEVs administration decreased serum endotoxin levels and restored intestinal barrier proteins with gut microbiome changes in both MASLD and ALD mouse models. Additionally, GDEVs administration reduced oxidative stress and fibrosis maker proteins to baseline levels in both models of MASLD and ALD mice. GDEVs also ameliorated liver fibrosis through regulating TIMP2/MMPs pathways in LX-2 human stellate cells and MASLD mice.

CONCLUSIONS
These RESULTS demonstrate for the first time that GDEVs can prevent MASLD- and ALD-mediated intestinal hyperpermeability and liver fibrosis through the gut-liver axis via restoration of gut microbiome and attenuating oxidative stress and fibrosis marker proteins.

INTEGRATIVE TRANSCRIPTOMIC AND BIOINFORMATIC ANALYSIS OF CINNAMOMUM ZEYLANICUM ESSENTIAL OIL'S CYTOTOXIC EFFECTS ON CERVICAL CANCER CELL LINES

Rubén Piña-Cruz[1]; Andrea Molina-Pineda[2]; Laura Vanessa Herrera-Ayala[2]; Pablo C Ortiz-Lazareno[2]; Luis Felipe Jave-Suárez[2]; Adriana Aguilar-Lemarroy[2]
[1]Doctorado en Ciencias en Biología Molecular en Medicina, University of Guadalajara, Guadalajara, Mexico; [2]División de Inmunología, CIBO, Guadalajara, Mexico

BACKGROUND AND OBJECTIVES
Cinnamomum zeylanicum (cinnamon) is a plant widely used in culinary applications, with essential oil rich in volatile compounds that exhibit biological activities, including anticancer properties. However, its effects and mechanisms of action in cervical cancer are not well understood. This study aimed to perform an integrative transcriptomic and bioinformatic analysis to evaluate the cytotoxic effects of cinnamon essential oil (CEO) on cervical cancer cell lines, focusing on its molecular mechanisms and pathways involved in its anticancer activity.

METHODS
Experiments were conducted on two tumorigenic cell lines, HeLa and SiHa, and one non-tumorigenic cell line, HaCaT. Cell viability was assessed using the WST-1 assay, apoptosis and cell death through Annexin-V and propidium iodide staining, and caspase activation by flow cytometry. RNA sequencing was employed followed by an integrative bioinformatic analysis.

RESULTS
CEO significantly reduced cell viability, increased apoptosis, and activated caspase 9 in HeLa and SiHa cells. Transcriptomic analysis revealed upregulation of genes involved in cellular stress, DNA damage, and protein synthesis. Differentially expressed genes were enriched in apoptosis, cell cycle, and p53 signaling pathways. CEO also suppressed genes related to oxidative phosphorylation and the cell cycle, with HeLa cells showing the highest sensitivity. Weighted gene co-expression network analysis identified key genes regulated by CEO, including *MT-CO1, MT-CO2, PPP1R15A, HSPA6, ATF3, DDIT3, DEDD2, HMOX1, CXCL8, FOSB, and CDKN1A.*

CONCLUSIONS
These RESULTS demonstrate that CEO has potent antiproliferative and proapoptotic effects on cervical cancer cells, suggesting its potential as an anticancer agent. Further research is needed to validate these findings and evaluate its safety and efficacy in *in vivo* models.

ASSESSING THE IMPACT OF A DIVERSE FIBER MIX ON GASTROINTESTINAL TOLERANCE AND MICROBIOTA COMPOSITION IN HEALTHY ADULTS

Lotte Dopheide[1, 2]; Marta Kozior[1]; Sebastian Tims[1]; Jeroen Van Bergenhenegouwen[1]; Johan De Vogel-Van Den Bosch[1]; Amra Buco[1]; Louise Harvey[1]; Ardy Van Helvoort[1, 3]
[1]Research & Innovation, Danone Research & Innovation, Utrecht, Netherlands; [2]Department of Gastroenterology-Hepatology, NUTRIM, Maastricht University, Maastricht, Netherlands; [3]Department of Respiratory Medicine, NUTRIM, Maastricht University, Maastricht, Netherlands

BACKGROUND AND OBJECTIVES

Fibers are inherently present in a wide range of naturally occurring foods, predominantly grains, fruits, vegetables and legumes, and each fiber source has specific physicochemical and chemical properties. The average fiber recommendation in a Western diet is approximately 25 g/day. In the Western diet the fiber recommendation is often not met, resulting in a so-called “fiber-gap”. Adequate fiber intake is associated with several health benefits and reduced disease risk. These benefits often originate from the gut, where fibers undergo microbial fermentation and microbial metabolites are produced. As with consuming a diverse, healthy diet, we hypothesize that consuming a variety of fiber sources and types could support a diverse collection of gut bacteria which may help to maintain a balanced and resilient microbiome. However, this diverse fiber mix should be well tolerated. Thus, we aimed to assess gastrointestinal (GI) tolerance of a novel diverse gluten-free fiber mix and its impact on the microbiota and microbial metabolites in healthy adults.

METHODS

We conducted an open label, single arm, single-centre study in 45-69-year-old healthy male and female participants consuming 2x 3 g/day of a diverse gluten-free fiber mix for 4 weeks, in addition to their habitual diet. GI symptoms were assessed weekly using the validated Gastrointestinal Symptom Rating Scale (GSRS). Additionally, fecal form type (Bristol Stool Chart), defecation frequency, digestion-related quality of life (Digestion-associated Quality of Life Questionnaire, DQLQ), compliance, stool samples and dietary intake were evaluated.

RESULTS

Of the 43 recruited participants, 41 were included in the full analysis set. No increase in any of the GSRS dimensions was observed during the intervention compared to baseline, nor in fecal form type at week 1 and week 4 compared to baseline. The majority of participants reported normal fecal form type. We observed a significant increase in mean defecation frequency at week 1 compared to baseline, there was no difference after 4 weeks. The increase in DQLQ score from baseline to week 4 reached statistical significance but both scores were close to the minimum of 0, hence the change was not considered meaningful. Study product intake compliance was ~96-99% for both quantity and number of servings. Analysis of dietary intake, microbiota and microbial metabolite is presently ongoing.

CONCLUSIONS

Consuming 6g of a diverse gluten-free fiber mix in addition to the habitual diet was well tolerated. Having access to a variety of gluten-free fiber sources would benefit those individuals unable to meet the recommended daily take due to dietary habits or restrictions.

THE EFFECTS OF ORAL IRON SUPPLEMENTATION ON SERUM HEPCIDIN AND GLUCOSE METABOLISM DURING PREGNANCY

Giulia Pironaci[1]; Katharina Quack-Loetscher,[2]; Michael Zimmermann,[1]; Nicole Stoffel,[3]
[1]RDM Investigative Medicine, MRC Weatherall Institute of Molecular Medicine (Oxford University & John Radcliffe Hospital), Oxford, United Kingdom; [2]Klinik für Geburtshilfe, Frauenklinik UZH, Zürich, Switzerland; [3]Health Science and Technologies Department, ETH LFV, Zürich, Switzerland

BACKGROUND AND OBJECTIVES
Gestational diabetes mellitus (GDM) and iron deficiency (ID) are common during pregnancy, both increasing the risk of complications. High circulating hepcidin may contribute to iron loading in hepatic and adipose tissue, reducing insulin sensitivity and causing metabolic dysfunction. In young women with ID, high oral iron doses trigger an acute hepcidin increase. Whether this occurs during pregnancy and impacts insulin sensitivity remains unclear. This study aims to determine whether high iron doses during pregnancy acutely increase hepcidin levels and affect glucose metabolism by decreasing insulin sensitivity.

METHODS
Pregnant women at 24th-28th weeks of gestation were divided into two groups: the ‘high iron’ group, received 200 mg of oral iron on study days 3-6, and the ‘low iron’ group, which received 15 mg oral iron on days 0-14. Oral glucose tolerance test (OGTT) were performed on days 0 and 7, and a final blood sample was collected on day 14.

RESULTS
Data from twenty-five women (‘high iron’ group: n=14; ‘low iron’ group: n=11) were analysed. High-dose iron supplementation significantly increased serum hepcidin on day 7 ($p=0.011$), compared to day 0 and day 14 ($p<0.05$). No changes were observed in haemoglobin, iron status and inflammatory parameters. Iron supplementation had no effect on fasting blood glucose or fasting insulin. However, the rise in blood glucose during the OGTT was significantly greater on day 7 compared to day 0 in the ‘high iron’ group ($p = 0.022$). No such difference was observed in the ‘low iron’ group, ($p = 0.214$).

CONCLUSIONS
Preliminary data indicate that high oral iron doses during pregnancy increase serum hepcidin levels at 24 hours and elevate glucose levels following an OGTT. Additionally, there is a trend suggesting an increase in fasting insulin and a greater insulin response during the OGTT after high iron supplementation compared to baseline.

EVALUATION OF THE BIOLOGICAL POTENTIAL OF ELDERBERRY (SAMBUCUS NIGRA L.) FROM MONTENEGRO: POLYPHENOLIC PROFILE, MODULATION OF ICAM-1 EXPRESSION AND 12-HETE, PGE2 AND TXA2 PRODUCTION

Tatjana Majkić[1]; Ivana Beara[1]; Ljiljana Milovanović[1]; Jörg Heilmann[2]; Anna Unterholzner[2]; Guido Jürgenliemk,[2]; Ljilja Torović[3]; Jelena Bajac; Milena Terzić
[1]Department of chemistry, biochemistry and environmental protection, Faculty of Sciences, University of Novi Sad, Novi Sad, Serbia; [2]Department for Pharmaceutical Biology, University of Regensburg, Regensburg, Germany; [3]Department of Pharmacy, Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia

BACKGROUND AND OBJECTIVES
Elderberry (*Sambucus nigra* L.) is recognized for its high concentration of bioactive polyphenolic compounds, which offer considerable nutritional and therapeutic benefits. Therefore, interest in food supplements made from this fruits is steadily increasing. Northern Montenegro, a region abundant in wild-growing elderberries, offers favorable environmental conditions for their healthy growth, yet the exploitation of elderberries from this area remains minimal. This study aimed to investigate the polyphenolic profile and biological potential of elderberries from this region, focusing on their anti-inflammatory effects.

METHODS
Elderberry fruits were lyophilized, and water extracts were prepared by microwave-assisted extraction. The polyphenolic profiles were quantified by HPLC-UV/VIS, while total phenols, tannins, flavonoids, and anthocyanins were analyzed spectrophotometrically. The ability of the extract to modulate ICAM-1 expression was evaluated in HMEC-1 endothelial cells treated with the extract (50–500 µg/mL). ICAM-1 expression was induced with TNF-α and analyzed by fluorescence-activated cell sorting. Additionally, the extract's impact on arachidonic acid metabolism was examined *ex vivo* using platelets. Inflammation was induced with calcimycin (Calcium Ionophore A23187) and CaCl2, while quantification of 12-HETE, PGE2, and TXA2 in the cell lysate was performed by LC-MS/MS.

RESULTS
The quantitative analysis of 40 polyphenolic compounds resulted in the detection of 13 compounds, with cyanidin-3-*O*-glucoside and rutin as the most abundant. The extract demonstrated a dose-dependent inhibition of ICAM-1 expression (12-26%). Regarding arachidonic acid metabolism, the extract (c=1.5 mg/mL) exhibited the most significant inhibition of PGE2 (71%), followed by 12-HETE (38%) and modest inhibition of TXA2 (11%).

CONCLUSIONS
These findings highlight the potential of elderberries from Montenegro as a promising source of bioactive compounds with broad applications in the food and pharmaceutical industries, particularly for products aimed at inflammation prevention.

SLEEP DISORDERS (SD) AND ASSOCIATED FACTORS IN SEVERELY MALNOURISHED ADULT PATIENTS WITH ANOREXIA NERVOSA (AN)

Axel Fortel[1]; Mouna Hanachi[2]
[1]Nutrition, Hôpital Paul-Brousse Ap-Hp, Villejuif, France; [2]Micalis team FInE, Inrae Ile-De-France, Jouy-en-Josas, France

BACKGROUND AND OBJECTIVES
Severely malnourished patients with AN may present SD. The aim of this study was to characterize these SD and to investigate the possible link between severe undernutrition, and sleep disorders in a cohort of malnourished patients with AN.

METHODS
We conducted an observational study including adult inpatients in a intensive care clinical nutrition department in Paul Brousse university hospital for nutritional rehabilitation. Nutritional status (BMI (kg/m²), plasma albumin (g/L), transthyretin (in g/L) and Triiodothyronin (in pmol/L)); quality and quantity sleep (Epworth Sleepiness Scale, Pittsburgh Sleep Quality Index (PSQI) and Insomnia Severity Index (ISI)) and psychiatric symptoms (Beck scale, Eating Disorder Inventory 2nd edition and the Godin Leisure-Time Exercise) were assessed at admission.

RESULTS
Thirty-seven patients were included: age: 32.6 +/-15.3, sex ratio : 2M/35F, BMI : 12.4 +/-2.1; 78.4% have poor sleep quality, 59.5% suffer from insomnia and 37.8% have a sleep debt. there was no daytime sleepiness on the Epworth scale (7.08+/-4.5), but insomnia on the ISI scale (10.19+/-6.36). The most pathological components on the PSQI were subjective sleep quality (1.65+/-0.86), sleep disturbance (1.57+/-0.5), poor daytime form (1.38+/-0.92) and sleep latency (1.35+/-0.98). In bivariate analysis, quality of sleep waw significantly correlated with the depressive symptoms (Beck) and AN specific symptom (EDI): the higher the Beck scales, the higher the scales on the three sleep questionnaires ($p<0,01$ for Epworth and ISI scales; $p = 0,02$ for PSQI scale). The RESULTS are similar with the EDI score ($p<0,016$ for the three scales). there was no link between nutritional status and sleep disorders.

CONCLUSIONS
All patients with AN have sleep disorders with sleep onset and / or sleep quality disorders, associated with the severity of AN symptoms but not with the nutritional status. Larger longitudinal studies are needs to confirm the role of nutritional status in steep disturbances.

EFFECTS OF DIETARY OMEGA-3 FATTY ACIDS ON SYNAPTIC STRUCTURE AND FUNCTION

Dinia Saraj[1]; Mariam Wehbe[2]; Paula Terroba[2]; Kjetil Retterstøl[1]; Svend Davanger[2]
[1]Nutrition, University of Oslo, Oslo, Norway; [2]Molecular Medicine, University of Oslo, Oslo, Norway

BACKGROUND AND OBJECTIVES
Ageing is associated with a decrease in omega-3 fatty acid concentrations, and low intake of omega-3 fatty acids has been linked to neurodevelopmental and neurodegenerative disorders. Yet, there is a lack of understanding of the molecular mechanisms underlying the effects of omega-3 fatty acids in the development and function of synapses in the central nervous system.
The objectives are to investigate the possible role of omega 3 fatty acids in sustaining synaptic structure and function in young adult mice.

METHODS
We use omega-3 fatty acids as anti-neuroinflammatory agents. We have fed young mice (C57BL/6) with a diet with or without the omega-3 fatty acids docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA) for 5 months after weaning. The methods used are: Western blot, Golgi staining, Morris water maze and whole blood testing.

RESULTS
The dietary intervention led to an 1100 % increase in the concentration of DHA when measuring area percentage of fatty acid methyl ester (FAME) in whole blood compared to negative controls, while the corresponding increase in EPA was even higher (4000 %). In the brain, we found significantly increased dendritic spine density in the hippocampus in the omega 3-group. Furthermore, we observed significantly increased concentrations of the synaptic glutamate receptor subunits GluA1, GluA2, GluN2B, and a reduction in microglia marker Iba1, in brain hippocampal homogenate in the omega-3 group, compared to negative controls. In the corresponding homogenate of cerebral cortex we observed increased GluA2, GluN2B and synaptic protein synaptotagmin 1, while reduction of Iba1, and neuronal growth factors mBDNF and ProBDNF. When tested in a Morris water maze for learning abilities, there was a trend towards quicker learning in the omega 3 fatty acid enrichment group.

CONCLUSIONS
Dietary supplementation of omega-3 fatty acids increases their concentrations in whole blood. In the brain, we observed increased dendritic spine density. In addition, the concentrations of brain synaptic glutamate receptors are increased in the omega-3 diet group while it interestingly reduces the microglial inflammatory marker Iba1 in the hippocampus. The omega-3 enriched diet also improved learning measures in the Morris water maze.

EPO8_219

IMPACT OF PHENOLIC ACIDS ON PROSTAGLANDIN E2 AND THROMBOXANE A2 PRODUCTION IN INFLAMMATORY PROCESSES

Ljiljana Milovanović[1]; Tatjana Majkić[1]; Ivana Beara[1]
[1]Department of chemistry, biochemistry and environmental protection, Faculty of Sciences, University of Novi Sad, Novi Sad, Serbia

BACKGROUND AND OBJECTIVES

Phenolic acids are secondary plant metabolites, but they can also be formed by the metabolism of polyphenols in the human body. These compounds may exhibit different bioactivities, including antioxidant and anti-inflammatory. Inflammation can lead to numerous disease, such as cardiovascular and neurodegenerative diseases, cancer etc. The overproduction of pro-inflammatory mediators such as prostaglandin E2 (PGE2) and thromboxane A2 (TXA2) through the cyclooxygenase (COX) pathway of arachidonic acid metabolism, has important role in inflammation.
The aim of this study was to determine the anti-inflammatory potential of 7 selected phenolic acids (gallic acid; 3-*O*-methyl gallic acid; 4-*O*-methyl gallic acid; 3-(3-hydroxyphenyl)propionic acid; 3-(4-hydroxyphenyl)propionic acid; 3-hydroxyhippuric acid; 4-hydroxyhippuric acid) and their ability to inhibit production of PGE2 and TXA2 in an *in vitro* cell-based model (human monocytes, U937 cell line).

METHODS

The anti-inflammatory potential of phenolic acids was tested at five different concentrations, ranging from 1 to 25 μM. Inflammation was induced by lipopolysaccharide (LPS). The content of PGE2 and TXA2 in cell lysate was evaluated using LC-MS/MS technique. RESULTS are presented as percentages of production relative to control.

RESULTS

Only 4-*O*-methylgallic acid inhibited the production of PGE2 at all tested concentrations (up to 15%), with no dose-dependent effect observed. On the other hand, several phenolic acids inhibited the production of TXA2 at all applied concentrations, while the others reduced production of the pro-inflammatory mediator TXA2 only at concentrations higher than physiological levels (greater than 5 μM).

CONCLUSIONS

The RESULTS suggest that not all phenolic acids have considerable effects on PGE2 and TXA2 production at physiological concentrations. There is need for futhere investigation about different mechanisam of anti-inflammatory actions of phenolic acids or their potential synergistic effect at physiological concentrations.

PERCEPTIONS OF AFRICAN MIGRANT WOMEN REGARDING HEALTHY AND UNHEALTHY FOODS DURING PREGNANCY AND THE POSTPARTUM PERIOD IN AUSTRALIA: A QUALITATIVE STUDY

Bolanle Olajide[1]; Paige Van Der Pligt[2]; Vidanka Vasilevski[3]; Fiona Mckay[1]
[1]School of Health and Social Development, Deakin University, Melbourne, Australia; [2]School of Exercise and Nutrition Sciences, Deakin University, Melbourne, Australia; [3]School of Nursing & Midwifery, Deakin University, Melbourne, Australia

BACKGROUND AND OBJECTIVES
Women face challenges choosing and identifying healthy foods during pregnancy and the postpartum period. For African migrant women, these challenges may be heightened by immigration, as navigating between different cultural values can complicate food decision-making. Understanding African women's perceptions of healthy and unhealthy foods after migrating to Australia is essential to offering effective nutritional support during pregnancy. This study aimed to explore African migrant women's perceptions of healthy and unhealthy foods during pregnancy and the postpartum period in Australia.

METHODS
Participants were recruited through purposive, convenience, and snowball sampling methods. This study used the photovoice method. Participants were asked to take photos representing foods they considered to be healthy and unhealthy during these periods. Semi-structured, photo-assisted interviews were conducted with eleven participants, all of whom were either currently pregnant or had been pregnant within the past five years while living in Australia. A qualitative descriptive approach to analysis was undertaken.

RESULTS
Two key themes were identified: 'perceptions of healthy foods during pregnancy and the postpartum period' and 'perceptions of unhealthy foods during pregnancy and the postpartum period'. Healthy foods during pregnancy were described as balanced, energy-providing, nutrient-restorative, whole, and typically homemade. Similarly, healthy foods were considered to be balanced and filling in the postpartum period. Unhealthy foods during both periods were identified as those high in calories or fat.

CONCLUSIONS
While African migrant women identified clear perceptions of healthy and unhealthy foods during these periods, it remains uncertain to the extent that these perceptions translate into consistent dietary practices. Further research is needed to explore participants' actual food intake and diet quality during these critical periods. These findings underscore the importance of integrating cultural flexibility and adaptability into dietary guidance for migrant women.
