Yaka Mah. Yeni Meram Cad. Kasım Halife Sok. B Blok No: 11 Meram/KONYA/TÜRKİYE
0332 221 0 575 - www. neupress.org
Certificate No: 48888
Publication Type: Book-Academic Publications
Publication Date: October 2026
Place of Publication: Konya, Türkiye
Language: English
Dimensions: 21x29. 7 cm
Edition: 1
Page Count: XXIV+1525
Category: Social, Humanities, and Administrative Sciences
SDG Category: 9 - Industry, Innovation, and Infrastructure
Keywords: Computer Science, Artificial Intelligence, Machine Learning, Cybersecurity.

Conference Committee

General Chairman
Dr. Adem Tekerek
General Chair | Gazi University, Ankara, Türkiye

Co-Chairmen
Dr. Jana Žiljak Gršić
Organizing Committee Member | Zagreb University of Applied Sciences (TVZ), Zagreb, Croatia

Dr. Diana Bratić
Organizing Committee Member | University of Zagreb, Zagreb, Croatia

Organizing Committee
Dr. Erol Kurt
Organizing Committee Member | Gazi University, Ankara, Türkiye

Dr. Mehmet Tekerek
Organizing Committee Member | Ankara University, Ankara, Türkiye

International Technical Committee

- **Dr. Abzetdin Adamov**, ADA University, Azerbaijan
- **Dr. Ahmet Artu Yıldırım**, Advanced Micro Devices, United States
- **Dr. Ali Safaa Sadiq**, Nottingham Trent University, United Kingdom
- **Dr. Amit Bhagat Maulana**, Azad National Institute of Technology, Bhopal, India
- **Dr. Amir Pourabdollah**, Nottingham Trent University, United Kingdom
- **Dr. Ayhan Erdem** , Gazi University, Türkiye
- **Dr. Bünyamin Ciylan** , Gazi University, Türkiye
- **Dr. Burak Küçükgöz**, Newcastle University, United Kingdom
- **Dr. Cemal Gemci**, Cyberverse, Türkiye
- **Dr. Cemal Koçak** , Gazi University, Türkiye
- **Dr. Daan Van Den Berg** , Vrije Universiteit Amsterdam, Netherlands
- **Dr. David Joseph Brown**, Nottingham Trent University, United Kingdom
- **Dr. Davor Cafuta**, Zagreb University of Applied Sciences (TVZ), Croatia
- **Dr. Dharmendra Singh Rajput**, Vellore Institute of Technology, Vellore, India
- **Dr. Eda Akman Aydın** , Gazi University, Türkiye
- **Dr. Elviz Ismayilov**, Azerbaijan State Oil and Industry University, Azerbaijan
- **Dr. Fecir Duran**, Gazi University, Ankara, Türkiye
- **Dr. Fakhranda Alimardanova**, Khazar University, Azerbaijan
- **Dr. Hasan Tınmaz**, Woosong University, South Korea
- **Dr. Hüseyin Çakır** , Gazi University, Türkiye
- **Dr. Hüseyin Polat** , Gazi University, Ankara, Türkiye
- **Dr. Ivica Dodig**, Zagreb University of Applied Sciences (TVZ), Croatia
- **Dr. İsmail Şahin**, Gazi University, Türkiye
- **Dr. Kayode Owa**, Nottingham Trent University, United Kingdom
- **Dr. Kamal Eddine MELKEMI**, University of Batna2, Algeria
- **Dr. Krešimir Rakić**, University of Mostar, Bosnia and Herzegovina
- **Dr. Lidija Tepeš Golubić**, Zagreb University of Applied Sciences (TVZ), Croatia

- **Dr. Lidia Yadira Pérez-Aguilar**, Autonomous University of Sinaloa, Mexico
- **Dr. Mădălin-Dorin Pop** , Politehnica University of Timișoara, Romania
- **Dr. Magdalena Palacz**, Silesian University of Technology, Poland
- **Dr. Mehmet Önder Efe** , Hacettepe University, Türkiye
- **Dr. Mehmet Gök** , İstiklal University, Türkiye
- **Dr. Mehmet Şimşek**, Sinop University, Türkiye
- **Dr. Marko Maričević**, University of Zagreb, Faculty of Graphic Arts, Croatia
- **Dr. M. Kamrul Hasan** , Universiti Kebangsaan Malaysia, Malaysia
- **Dr. M. Ali Akcayol**, Gazi University, Ankara, Türkiye
- **Dr. M. Mutlu Yapıcı** , Ankara University, Türkiye
- **Dr. M. Sabarimalai Manikandan**, Indian Institute of Technology Bhubaneswar, India
- **Dr. M. Shamim Kaiser**, Institute of Information Technology, Bangladesh
- **Dr. M. Mostafizur Rahman**, American International University, Bangladesh
- **Dr. Mufti Mahmud**, King Fahd University of Petroleum and Minerals, Saudi Arabia
- **Dr. M. Arifur Rahman**, Nottingham Trent University, United Kingdom
- **Dr. Murat Aydos** , Hacettepe University, Türkiye
- **Dr. Murat Dörterler** , Gazi University, Türkiye
- **Dr. Necaattin Barışçı** , Gazi University, Ankara, Türkiye
- **Dr. Nursel Yalçın** , Gazi University, Türkiye
- **Dr. Ömer Faruk Bay** , Gazi University, Türkiye
- **Dr. Pedro Machado**, Nottingham Trent University, United Kingdom
- **Dr. Pratik Vyas**, Nottingham Trent University, United Kingdom
- **Dr. Pipit Utami**, Central University of Jharkhand, Indonesia
- **Dr. Rajesh Kaluri** , Vellore Institute of Technology, Vellore, India
- **Dr. Recep Başarıcı** , İstiklal University, Türkiye
- **Dr. Shamim Al Mamun**, Jahangirnagar University, Bangladesh
- **Dr. Suat Özdemir** , Hacettepe University, Türkiye
- **Dr. Sinan Toklu** , Gazi University, Türkiye
- **Dr. Saadin Oyucu** , Gazi University, Türkiye
- **Dr. Stjepan Tvorić**, Zagreb University of Applied Sciences (TVZ), Croatia
- **Dr. Tibor Skala**, University of Zagreb, Faculty of Graphic Arts, Croatia
- **Dr. Thippa Reddy Gadekallu**, Zhongda Group, Jiaxing, China
- **Dr. Yılmaz Vural**, University of California, United States
- **Dr. Yusuf Sönmez** , Gazi University, Ankara, Türkiye
- **Dr. Zafer Ayaz** , Gazi University, Türkiye
- **Dr. Željko Kovačević**, Zagreb University of Applied Sciences (TVZ), Croatia

Secretariat Committee

- **Semiha Güngör , Hacı Bayram Veli University, Ankara, Türkiye**
- **Büşra Duygu Çelik , Gazi University, Ankara, Türkiye**
- **Öznur Şifa Akçam , Karatekin University, Çankırı, Türkiye**

TABLE OF CONTENTS

1. Innovative yet Low-Resource Uses of AI in Teaching: Pedagogical Boundaries and Ethical Considerations for Teachers 1
2. A Methodological Framework for Preparing Future Computer Science Teachers for Sustainable Professional Activity in the Artificial Intelligence Context 10
3. Gender Pay Gaps in Software Engineering: A Literature Review of Attrition, Measurement, and Structural Inequality 21
4. AI-Driven Dynamic Trust Scoring over Self-Sovereign Identity Systems 31
5. Digital twin-based residual analysis for leak detection and localization in high-pressure gas pipelines 40
6. Evaluating Quantum Computing Use Cases in Banking: A Sequential Model-Risk Admissibility Framework 49
7. A New Topological Index-Based Solution Approach for the Traveling Purchaser Problem 59
8. Machine Learning in Agile Project Management: A Bibliometric Analysis 68
9. Real-Time Helmet Detection System with Monitoring and Alert for Restricted Areas 80
10. Efficient Quantum Coherence/Decoherence Emulation Using Parallel-Recursive Computation on FPGAs and Algorithmic Skeletons 90
11. Mining Sequential Rules from Large-Scale Sequence Databases Using an FPTree-Based Method 102
12. Contemplating the Effects of NP-Complete Reductions on Problem Instance Hardness 114
13. Explainable Commit-Level Vulnerability Intelligence in DevSecOps Pipelines: A Systematic Review and Experimental Analysis 131
14. The Illusion of Cultural Competence: Evaluating ChatGPT-Generated Kazakh Proverbs 143
15. A QUBO-Based Reformulation and Quantum Solution Framework for Nonlinear Constrained Optimization Problems 153
16. Long Distance Environmental and Security System 164
17. Comparative Evaluation of Heuristic Search Algorithms for Reward-Constrained Museum Visitor Routing on a Real-World Graph 174
18. Cybersecurity Awareness and Threat Perception Constructs 185
19. Model Predictive Control-Based Trajectory Tracking and Dynamic Obstacle Avoidance for an Autonomous Vehicle in Robot Operating System 2 195
20. From Judgment to Benchmark: An AI-Assisted Wedge Classification Framework for Commercial Loan Spread Governance 204
21. Evolution in Remote Sensing Change Detection: Methods, Challenges, and Next AI Perspectives 220
22. Multi-Objective Hybrid Swarm Optimization for Energy-Delay Trade-off in SDN-enabled MEC 231
23. Enhancing Small Object Detection in Mammography Using a Patch-Based YOLO Framework 242
24. From Regulatory Compliance to Digital Trust: Integrating NIS2 and ISO/IEC 27701 In Transitional Cybersecurity Governance - The Case of Bosnia and Herzegovina 255
25. Reward System For Student Social Activity: Lntu Case Study 269
26. Adaptive Lossless Compression for Event-Based Cameras 275
27. Artificial Intelligence in Online Gambling and Betting Systems: A Knowledge Representation-Based Use Case 284
28. Spatiotemporal Pattern Detection Of Precipitation Using Machine Learning And Remote Sensing Data 293
29. Beyond Aggregate Metrics: Population-Weighted CVaR Auditing for Hidden Performance Failures Along Continuous Attributes 303

30. A Dual-Explainer GRU–TCN for Cyber-Physical Attack Detection in IoT-Based Energy Infrastructure 313
31. Boundary-Contact Modeling of Tumor Growth with Neural Surrogate Acceleration for Embedded Biomedical Systems 322
32. Decision Tree-Based Data Completion in Structured Lexicographic Resources 329
33. A Comparative Analysis of Vision Transformer Models for Multimodal Emotion Recognition 341
34. Intelligent Cyber Threat Detection at Scale: A Comparative Study of Machine Learning and Deep Learning Approaches for Network Intrusion Detection on CICIDS2017 351
35. Hybrid Deep Learning Model and Zonal Clustering for RNA 3D Structure Prediction 362
36. Explainable Multi-Type Loneliness Detection from Reddit Using Classical ML, Neural Networks, and Transformer Models with LIME and SHAP Analysis 372
37. Continuously Adaptive Digital Twins for Sim-to-Real Learning in Agro Food Systems 382
38. Water Quality Monitoring and Pollution Detection Using Edge Internet of Things-Based Hybrid Artificial Intelligence Models: A Systematic Literature Review 395
39. A Practical Evaluation of CNN Architectures for Histopathological Lung Cancer Classification 412
40. Edge-Based Digital Twin for Real-Time Energy Monitoring in Food Manufacturing: A Case Study of a Bakery Enterprise 419
41. Machine Learning Models for Monitoring and Analysis of Mobile Object Movements at a Food Industry Enterprise 425
42. Explainable Mammography Classification via Attention-Guided SE-EfficientNet-B3 and Grad-CAM Diagnostic Interpretation 436
43. Artificial Intelligence in Business: Opportunities and Risks 445
44. An Analysis of the Ministry of Health of the Republic of Türkiye from a Web Accessibility (Barrier-Free Design) Perspective 457
45. Harnessing Data Science and Machine Learning for Financial Fraud Detection Using the Central Bank of Libya Dataset 468
46. Wavelet-Based Machine Learning for Real-Time Burst Detection on Embedded Edge Devices 479
47. Role-Based Phishing to Ransomware Readiness for Clinical Staff 489
48. Explainable Machine Learning for Heart Disease Risk Prediction: Comparative Evaluation of ML Algorithms, Feature Importance Stability, and Clinical Interpretability 500
49. Preliminary Development of an Aircraft Structural Damage Classification System Using Deep Learning 510
50. From Neo4j to Redis: Storing Graph Data and Comparing Graph Algorithm Performance 519
51. Open Cloud Voice Service Architecture 528
52. Evaluating the Effectiveness of the AIM-5 Model for AI Teaching Self-Efficacy and AI Integration Readiness 538
53. Generative AI through the Student Eye: perspectives, attitudes, and usage 548
54. Analysis Of Existing Approaches In The Field Of Cryptographic Protocols In Uavs 559
55. SHRUMAC: An IoT-Smart Hygiene, Refuse Monitoring and Alert Controller System for Real-Time Institutional Campus Sanitation Management 569
56. From Textual Variation to Functional Diversity in Beginner C Programming Tasks Generated by Ollama Cloud-Based Large Language Models 583
57. Impact of AI Coding Agents on Software Engineering with Junior Developers: An Experiment in Situ 597
58. HID Hardening vs. FIDO2: A Security-versus-Security Trade-off 607
59. AI in Decision-Making: The Case of University Metropolitan Tirana 615
60. Emerging Technology Adoption in TVET: A Theoretical and Pedagogical Synthesis 625
61. Randomized Backtracking: Another Unusable Sampling Method for the Traveling Tournament Problem? 634
62. Educational Research in Computer Science: Data Collection, Processing, and Analysis 642
63. Siamese Swin Transformers for Robust Polyp Classification 651

64. Architecture of a Fuzzy Logic Model for Supporting Investigations in Burglary Cases 663
65. Secure Biometric Data Management On A Permissioned Blockchain: A Hyperledger Besu-Based Architecture 673
66. Reinforcement Learning-Based Adaptive Hybrid PSO-GA Framework for Solving Dynamic Optimization Problems 683
67. Assessing the Organizational Adoption of Generative AI: Algorithmic Benchmarking and Empirical Insights into Corporate Transformation 689
68. A Tabletop Exercise Framework for Cross-Border Digital Health Incident Response 707
69. A Multimodal Analysis Approach for Automated Classification of Content Rating Symbols in Video Content 717
70. AI-Supported Emission Factor-Based Approach for Carbon Footprint Analysis and Intersection Prioritization in Sustainable Cities 725
71. Multi-Source Behavior-Based Anomaly Detection for Smart Water Management Networks Using SNMP and Syslog Telemetry 735
72. A Novel PL/SQL-Based Data Transformation and Optimization Framework for Enterprise Data Warehouses 744
73. Multi-Agent Conflict Simulation With World Constraints (MACSWC) 754
74. Trustworthiness Under Compression: Calibration and Explanation Faithfulness of Lightweight IoT Intrusion Detectors 762
75. A Dataset-Based Exploratory Study of Cybersecurity Threat Patterns from 2015 to 2024 771
76. Ability-Based Approaches for Ambient Assisted Living in Smart Homes 780
77. Various Topological Graph Indices In Sierpinski Triangle Networks 791
78. HeritageCare: A Predictive Maintenance And Monitoring System for Heritage Buildings 803
79. AurIA AI for University Administrative Systems 814
80. MuseDSL: A Domain-Specific Language and Federated Framework for Explainable Museum Object Linking 825
81. The Effects of Meta-Heuristic Optimization Algorithms on the Performance of Machine Learning Models for Alzheimer's Diagnosis 838
82. An NLP-Based Review and Taxonomy of Heart Murmur Detection Algorithms (PhysioNet 2022) 848
83. Enabling Clinical-Grade Left Ventricular Hypertrophy Detection in Wearable Devices via Deep Learning 858
84. Enhancing Breast Cancer Screening in Kenya Through Deep Learning-Driven Mammographic Analysis 863
85. Territorial Crime Pattern Classification in Peru Using Unsupervised Learning and K-Medoids, 2015–2024 877
86. Optimized Algorithm towards Addressing the Cold-Starts Issue in the Airline Recommender System 892
87. The Impact of Syntactic Dependency Information on Turkish Coreference Resolution 906
88. A Physics-Informed Hybrid Framework for Predictive Supervision and Multi-Objective Optimization of Ultrafiltration Membrane Fouling in Desalination 916
89. Leakage-Aware and Explanation-Stable XAI for Short-Term Smart Home Appliance Energy Forecasting 925
90. A Work-in-Progress Cross-Case Analysis of Three VR Exposure Prototypes 934
91. Semantic Interoperability of Heterogeneous Research Data: A FAIR-Aligned Ontology-Driven Framework for Interdisciplinary Research 941
92. A Comparative Analysis of Optimal Curtailment Strategies for Distributed Energy Resources 962
93. TRITON: A Modular Transformer for Per-Pixel Marine Pollutant Detection in Sentinel-2 Imagery 975
94. Research Program: Computer-Aided Molecular Target Identification for Tuftsin-Phosphorylcholine in Autoimmune Diseases 989

95. Design of a Compact Asymmetric Biconical Antenna for UAV Applications 998
96. Leveraging AI Agents for Collaborative and Independent Authorship 1008
97. Utilization of Honeypot Systems for Enhancing Cybersecurity in Smart Cities 1019
98. Systematic Analysis of Honeypot Deception Techniques: State-of-the-Art and Empirical Validation 1032
99. Influence of Acquisition Trajectory on Area Target Recognition and Crime Scene Re-Localization Using Consumer LiDAR 1046
100. The Dependency of NIS2 Critical Sectors on Operational Technology: Implications for Cybersecurity Resilience and Critical Infrastructure Protection 1057
101. Learnscrolling: Harnessing Attention Economy Mechanics for Incidental Learning via Synthetic Social Media 1070
102. From NIS to NIS2: Strengthening Cybersecurity for Critical Infrastructure Protection in the European Union 1080
103. Computational Models for Predicting Female Breast Cancer Survival and an Onco-Hospital Feature Engineering Workflow 1093
104. Precise Segmentation of Dental Implants with YOLO-Based Deep Learning Models 1103
105. PhysioReco: An Evidence-Guided Machine Learning System for Personalized Arthritis Exercise Recommendation 1113
106. Blockchain-Based Associate Professor Evaluation System: Transparent Academic Career Management with Ethereum Smart Contracts and IPFS 1131
107. A Region-Ablation Study of MRI Texture Features for Trigeminal Neuralgia Classification 1141
108. From Classical Retrieval to LLM-Native and Multimodal Search: A Synthesis of an Ongoing Convergence 1149
109. Bibliometric Analysis of Artificial Intelligence Assisted Medical Imaging Research: Global Trends and Turkey's Position (2021-2025) 1160
110. aBERT-Based Hybrid Models for Fake News Detection: A Systematic Review from 2021 to 2026 1172
111. Using Long Short-Term Memory (LSTM) Algorithm to Prevent the Foreign Currency Speculation in Libyan Black Markets 1183
112. Towards Multimodal Artificial Intelligence (OMEAI) Framework for Early Detection of Postnatal Depression 1196
113. Development of a Novel Low-Time-Complexity Optimization Technique for Edge-Based Wireless Body Area Networks 1211
114. Comparative Analysis of Evolutionary, Swarm, and Lamarckian Memetic Algorithms for Route Optimization in Industrial Printed Circuit Board (PCB) Drilling Processes 1221
115. Oil Spill Segmentation in SAR Imagery Using Swin Transformer with Compound Loss: A Multi-Sensor Evaluation 1227
116. FedSLM: A Federated Learning Approach Based on Fine-Tuning a Small Language Model for Text Classification 1240
117. Smart Route: A Road-Network-Aware Trip Evaluation and Ranking Microservice for Destination-Bound Ride-Hailing Drivers 1251
118. FSLM-SQL: A Novel Framework Based on Fine-Tuning Small Language Models for Natural Language to SQL 1260
119. Empirical Evaluation and Mathematical Limitations of PDE-Based Smoothing in Keystroke Dynamics Authentication 1271
120. A Seven-Category Error Taxonomy for Implicit Aspect Detection: Systematic Failure Analysis of BERT and GPT-2 in Aspect-Based Sentiment Analysis 1277
121. A Context-Aware Computer Vision-Based Model for ACL Injury Prevention in Female Youth Football: A PRISMA-based Review 1290
122. Synthetic-to-Real Camera Contamination Classification Using Modern Deep Neural Networks 1304

123. Evaluating TOE Determinants of Big Data Analytics Readiness through CRITIC–TOPSIS: Evidence from Albania 1315
124. Traffic Accident Severity Prediction with an Interpretable Crash Severity Risk Score 1325
125. Cloud-CTI-Engine: An Integrated AWS Security Posture and Threat Intelligence Platform 1335
126. Context-Aware Regular Expressions for Sensitive Data Detection 1344
127. Privacy-Preserving Secret Validation: An Empirical Comparison of Probabilistic Filters, k-Anonymity, and Private Set Intersection 1352
128. Evaluating the Impact of Data Augmentation on Cross-Dataset Generalization in Intrusion Detection Systems 1362
129. Selective Data Cleaning with Large Language Models for Improving E-Commerce Product Matching Training Data 1372
130. AI-Powered Smart Sensor for Direct Analysis of Aflatoxins in the Open Air Environment 1382
131. Neuro-Symbolic Correction of Kazakh Word Forms through Morphological Analysis and Selective Abstention 1392
132. Non-intrusive Human Activity Recognition using Imbalanced mm-Wave Doppler Radar Streams and Ensemble of Time-Series Modeling Strategies 1410
133. Full-Frame Sparse Temporal Multitask Learning for Student Affective State Recognition Using DAiSEE 1419
134. Visual Editing and Debugging of Feature Models 1428
135. Issue Analyzer: Similarity-Based Grouping and Team Routing for Mobile Crash Logs 1435
136. Design Science Research for Digital Platforms in Resource-Constrained Environments: The Lumikiza Case 1445
137. Brain-Computer Interface, Brain Science, and Artificial Intelligence 1462
138. Scalability Analysis of CNN-Based sEMG Hand Gesture Recognition Across Increasing Gesture Repertoires 1469
139. Integrating NotebookLM into Flipped Mathematics Instruction: Insights from Pre-Service Teachers through the TPACK Framework 1478
140. SpecGuard: Multi-Layer Quality Assessment of Natural-Language FPGA Requirements 1488
141. Counterfactual Explanations for Gallstone Prediction: A Comparative Evaluation of DiCE and PertCF 1499
142. Classification of Eight Different Retinal Conditions in Retinal OCT Images Using Convolutional Neural Networks 1508
143. AI-assisted Error Analysis to Design a Writing Course Syllabus 1516

CONFERENCE PROGRAM

17 September 2026 08:00 – 09:00 GMT+2	**KEYNOTE SPEECH** **Title:** Impact of Blockchain on Key Enabling Technologies for the Metaverse **Prof. Dr. Thippa Reddy Gadekallu** Professor at Zhejiang A&F University Chief Engineer at Zhongda GroupHaiyan County, Jiaxing City, Zhejiang Province, China Session Chair: Assoc. Prof. Dr. Adem Tekerek

Hall	**FUZULI**
Session	**1**
Topic	**Artificial Intelligence, Machine Learning & Applied AI**
Session Chair	**Assoc. Prof. Dr. Adem Tekerek (Gazi University)**
Date	**17 September 2026**
Time	**09:00 – 14:00 GMT+2**

	Time	#ID	Presentation Title	Authors
1	09:00 – 09:10	#28 Azerbaijan	Innovative yet Low-Resource Uses of AI in Teaching: Pedagogical Boundaries and Ethical Considerations for Teachers	***Mehriban A. Hasanova*** *(Ganja State University)*
2	09:10 - 09:20	#37 Kazakhstan	A methodological framework for preparing future computer science teachers for sustainable professional activity in the artificial intelligence context	***Aizhan Adambekova****, Aigul Aldabergenova, Aiym Yesseikyzy, Ulzhalgas Yesseikyzy, Gulmira Kasteyeva (Zhetysu University)*
3	09:20 – 09:35	#50 México	Machine Learning in Agile Project Management: A Bibliometric Analysis	***Yadira Jazmín Pérez Castillo*** *(Instituto Politécnico Nacional), Sandra Dinora Orantes Jiménez (Instituto Politécnico Nacional)*
4	09:35 – 09:45	#59 Kazakhstan	The Illusion of Cultural Competence: Evaluating ChatGPT-Generated Kazakh Proverbs	***Shynar Auyelbekova*** *(SDU University), Gulbanu Mukhiyayeva*
5	09:45 – 09:50	#69 India	From Judgment to Benchmark: An AI-Assisted Wedge Classification Framework for Commercial Loan Spread Governance	***Anandasubramanian Pranatharthy Codangudi*** *(VELS University)*
6	09:50 – 10:05	#85 North Macedonia	Artificial Intelligence in Online Gambling and Betting Systems: A Knowledge Representation–Based Use Case	***Trajance Angelovski****, Toni Malinovski, Sime Arsenovski, Miodrag Cekikj (University of Skopje)*

7	10:05 – 10:20	#86 México	Spatiotemporal pattern detection of precipitation using machine learning and remote sensing data *Ramón Fernando López Osorio, María Alejandra Quintero Morales, Yedid Guadalupe Zambrano-Medina* ***Lidia Yadira Pérez-Aguilar,** Evangelina Avila-Aceves, Sergio Alberto Monjardin-Armenta (Universidad Autónoma de Sinaloa)*
8	10:20 – 10:30	#90 Georgia	Boundary Contact Modeling of Tumor Growth with Neural Surrogate Acceleration for Embedded Biomedical Systems ***Manana Chumburidze**, Teimuraz Sakhelashvili, Giorgi Chachua, Nona Kukhianidze (Akaki Tsereteli State University)*
9	10:30 – 10:45	#97 Türkiye	A Comparative Analysis of Vision Transformer Models for Multimodal Emotion Recognition ***İlya Kuş**, Cemal Koçak, Ayşe Keleş (Gazi University)*
10	10:45 – 10:55	#102 Türkiye	Deep Learning Model and Zonal Clustering for RNA 3D Structure Prediction ***Mustafa Kemal Binli**, Adem Tekerek, Necaattin Barışçı (Gazi University)*
11	11:30 – 11:40	#104 United Kingdom	Explainable Multi-Type Loneliness Detection from Reddit Using Classical ML, Neural Networks, and Transformer Models with LIME and SHAP Analysis ***Alif Laila**, Arif Ahmed Dar, Hamidreza Khaleghzadeh (University of Portsmouth)*
12	11:40 - 11:55	#123 Azerbaijan, Russia	Artificial Intelligence in Business: Opportunities and Risks Sergey Bogatenkov, Irina Ketova, **Heyran Abbasova**, Nizami Yusubov, Mukhaddin Samadov
13	11:55 – 12:10	#138 Bosnia and Herzegovina	Explainable Machine Learning for Heart Disease Risk Prediction: Comparative Evaluation of ML Algorithms, Feature Importance Stability, and Clinical Interpretability ***Medina Ferhatović**, Belmin Haračić, Narcisa Hadžajlić (University of Zenica)*
14	12:10 – 12:30	#143 Kazakhstan	Evaluating the Effectiveness of the AIM-5 Model for AI Teaching Self-Efficacy and AI Integration Readiness ***Madina Bokan**, Zhomart Zhiyembayev, Mansur Tokanov, Damira Shalkarkyzy (Zhetysu University)*
15	12:30 – 12:45	#144 Kuwait	Generative AI through the Student Eye: perspectives, attitudes, and usage ***Mariam Alshammari**, Khuloud Alkhateeb, Fajer Alshammari, Fatma Alalawi (Gulf University for Science and Technology)*
16	12:45 – 13:00	#151 Albania, USA	AI in Decision-Making: The Case of University Metropolitan Tirana ***Suada Gjimi**, Arben Asllani (University Metropolitan Tirana)*
17	13:00 – 13:15	#162 Israel	Assessing the Organizational Adoption of Generative AI: Algorithmic Benchmarking and Empirical Insights into Corporate Transformation ***Idan Roth** (The Academic College of Tel Aviv-Yaffo)*
18	13:15 – 13:30	#177 México	AurIA: AI for University Administrative Systems **Sergio Yorick Álvarez Montalvo**, Damián Ulises Cedillo Rodríguez, Cindy Nallely Muñiz Pérez (*Universidad Autónoma de Tamaulipas)*
19	13:30 – 13:45	#183 Türkiye	An NLP-Based Review and Taxonomy of Heart Murmur Detection Algorithms (PhysioNet 2022) ***Onuralp Arslan** (Izmir Katip Celebi University), Yalçın İşler (Alanya Alaaddin Keykubat University)*
20	13:45 – 14:00	#185 Kenya	Enhancing Breast Cancer Screening in Kenya Through Deep Learning-Driven Mammographic Analysis *Edna C. Too, Saif Kinyori, David G Mwathi, Julius Gachoki, **Pauline W. Mwaka**, Mary Wanjiku, Lucy Gitonga (Chuka University)*

Hall	**FUZULI**
Session	**2**
Topic	**Artificial Intelligence, Machine Learning & Applied AI**
Session Chair	**Assoc. Prof. Dr. Adem Tekerek (Gazi University)**
Date	**18 September 2026**
Time	**08:30 – 11:00 GMT+2**

		#ID	Presentation Title	Authors
21	08:30 - 8:50	#192 Libya, Nigeria	Optimized Algorithm towards Addressing the Cold-Starts Issue in the Airline Recommender System	*Ayman Mahmud (Aljafara University), Zakaria Suliman Zubi (Sirte University), Asma Alhadi Billayl (Aljafara University),* ***Adud Musa Mabu*** *(Yobe State University)*
22	08:50 - 09:05	#193 Türkiye	The Impact of Syntactic Dependency Information on Turkish Coreference Resolution	***Ebru Çıracı****, Nesrin Aydın Atasoy (Karabük University)*
23	09:05 - 09:20	#205 USA	Leveraging AI Agents for Collaborative and Independent Authorship	*Lamont Grissom (University of Arkansas at Little Rock), Daniel Berleant (University of Arkansas at Little Rock),* ***Venkata Batthula*** *(Southwestern College Winfield), Richard S. Segall (Arkansas State University Jonesboro)*
24	09:20 – 09:35	#214 Nigeria	PhysioReco: An Evidence-Guided Machine Learning System for Personalized Arthritis Exercise Recommendation	*Theresa Omodunbi,* ***Adesola Kareem****, Adekemi Amoo, Temitope Sholanke, Grace Alilu, Adaobi Okonji*
25	09:35 – 09:45	#219 Senegal	From Classical Retrieval to LLM-Native and Multimodal Search: A Synthesis of an Ongoing Convergence	*Fatou Kamara,* ***Mouhamadou Lamine Diakhame*** *(Gaston Berger University)*
26	09:45 - 10:05	#225 Libya	Using Long Short-Term Memory (LSTM) Algorithm to Prevent the Foreign Currency Speculation in Libyan Black Markets	***Zakaria Suliman Zubi*** *(Sirte University), Zakariya A Alsharef (Libyan Academy Misurata), Abdulbsit M Alajnaf (Higher Institute of Science and Technology Misurata)*
27	10:05 – 10:20	#227 United Kingdom	Towards Multimodal Artificial Intelligence (OMEAI) Framework for Early Detection of Postnatal Depression	***Gleslie Sybil Ann A. Maraon****, Xiaohong W. Gao (Middlesex University)*
28	10:20 – 10:35	#235 Vietnam	FedSLM: A Federated Learning Approach Based on Fine-Tuning a Small Language Model for Text Classification	**Nhat-Thien Nguyen**, Quang-Hung Le (*Quy Nhon University*)
29	10:35 – 10:50	#240 Vietnam	FSLM-SQL: A Novel Framework Based on Fine-Tuning Small Language Models for Natural Language to SQL	***Khac-Lap Phan****, Quang-Hung Le (Quy Nhon University)*

Hall	**FUZULI**
Session	**3**
Topic	**Artificial Intelligence, Machine Learning & Applied AI**
Session Chair	**Assoc. Prof. Dr. Diana Bratić (University of Zagreb)**
Date	**18 September 2026**
Time	**11:00 – 14:10 GMT+2**

		#ID	Presentation Title	Authors
30	11:00 – 11:40	#246 Malaysia	A Seven-Category Error Taxonomy for Implicit Aspect Detection: Systematic Failure Analysis of BERT and GPT-2 in Aspect-Based Sentiment Analysis	***Imelda Pangaribuan**, Arifah Che Alhadi, Mohamad Nor Hassan, Masita Jalil (Universiti Malaysia Terengganu)*
31	11:40 – 11:50	#259 Türkiye	Selective Data Cleaning with Large Language Models for Improving E-Commerce Product Matching Training Data	***Oğuz Akif Tüfekcioğlu** (Cimri Inf. Tech. Syst. Inc.), Özgür Aslan (Cimri Inf. Tech. Syst. Inc.), Tuna Çakar (MEF University)*
32	11:50 – 12:05	#261 Kazakhstan	Neuro-Symbolic Correction of Kazakh Word Forms through Morphological Analysis and Selective Abstention	*Laura Baitenova (Turan University), Saule Tussupova (Turan University), Gulnar Mukhamejanova (Narxoz University), Akhmed Baikhojayev (Narxoz University), **Gauhar Munaitbas** (Home Credit Bank JSC), Daryn Nurtaza (Turan University)*
33	12:10 – 12:20	#280 Serbia	Integrating NotebookLM into Flipped Mathematics Instruction: Insights from Pre-Service Teachers through the TPACK Framework	***Aleksandar Milenković**, Nemanja Vučićević, Marina Svičević (University of Kragujevac)*
34	12:20 – 12:35	#41 Türkiye	AI-Driven Dynamic Trust Scoring over Self-Sovereign Identity System	***Deniz Salucu** (TURKCELL), Tunga Sayıcı (TURKCELL)*
35	12:35 - 12:50	#45 India	Evaluating Quantum Computing Use Cases in Banking: A Sequential Model-Risk Admissibility Framework	**Anandasubramanian Pranatharthy Codangudi** (VELS University)
36	12:50 – 13:05	#49 Türkiye	A New Topological Index-Based Solution Approach for the Traveling Purchaser Problem	*Aysun Yurttaş Güneş, **İlker Küçükoglu**, Hacer Özden Ayna, İsmail Naci Cangül (Bursa Uludağ University)*
37	13:05 - 13:20	#54 Venezuela	Efficient Quantum Coherence/Decoherence Emulation Using Parallel-Recursive Computation on FPGAs and Algorithmic Skeletons	***Carlos Alfonso Acosta-León** (Central University of Venezuela)*
38	13:20 - 13:35	#57 Netherlands	Contemplating the Effects of NP-Complete Reductions on Problem Instance Hardness	***Daan van den Berg** (VU University Amsterdam), Thomas Meeus (University of Amsterdam), Joeri Sleegers (Mice & Man Software and A.I. Development), Pieter Adriaans (Institute for Logic, Language, and Computation)*
39	13:35 - 13:50	#60 Türkiye, Kazakhstan	A QUBO-Based Reformulation and Quantum Solution Framework for Nonlinear Constrained Optimization Problems	***Cumali Yaşar** (Çanakkale Onsekiz Mart University), Yerlan Izbassarov (Khalel Dosmukhamedov Atyrau University)*
40	13:50 – 14:10	#148 Germany	Impact of AI Coding Agents on Software Engineering with Junior Developers: An Experiment in Situ	***Sebastian Steger**, Kerstin Fink, Lukas Nock, Sven-Gunnar Klaus (Technische Hochschule Mannheim Mannheim)*

Hall	**GAZALİ**
Session	**1**
Topic	**Cybersecurity, Privacy, Digital Trust & Theoretical Computer Science**
Session Chair	**Prof. Dr. Ömer Faruk Bay (Gazi University)**
Date	**17 September 2026**
Time	**09:00 – 11:00 GMT+2**

	Time	#ID	Presentation Title	Authors
41	09:00 – 09:15	#61 Oman	Long Distance Environmental and Security System	***Mohammad Mohatram**, M. Khalfan Mohammed Al Hudaifi, Muhammad Irfan Memon, Javeed Hussain Shaik (Global College of Engineering and Technology)*
42	09:15 - 09:30	#66 North Macedonia	Comparative Evaluation of Heuristic Search Algorithms for Reward- Constrained Museum Visitor Routing on a Real-World Graph	***Petar Mileski**, Dijana Capeska Bogatinoska (University of Information Science and Technology "St. Paul the Apostle")*
43	09:30 - 09:45	#67 Croatia	Cybersecurity awareness and threat perception constructs	***Katarina Kostelić**, Dario Kukuljan, Mieta Bobanović Dasko (Juraj Dobrila University of Pula)*
44	09:45 - 10:00	#77 Bosnia and Herzegovina	From Regulatory Compliance to Digital Trust: Integrating NIS2 and ISO/IEC 27701 In Transitional Cybersecurity Governance - The Case of Bosnia and Herzegovina	***Edin Alić** (HIFA-OIL d.o.o. Tešanj), Muhamed Ćosić (Centar za održivost i digitalizaciju Centar EkoDigitus), Venan Hadžiselimović (HIFA-OIL d.o.o. Tešanj)*
45	10:00 – 10:10	#87 Georgia	Beyond Aggregate Metrics: Population-Weighted CVaR Auditing for Hidden Performance Failures Along Continuous Attributes	***Irakli Koberidze** (Tbilisi State University), Magda Tsintsadze (Tbilisi State University)*
46	10:10 - 10:15	#89 Türkiye, Ukraine	A Dual-Explainer GRU–TCN for Cyber-Physical Attack Detection in IoT-Based Energy Infrastructure	*Ahmet Nusret Özalp (Kastamonu University), **Viktoriia Hreniukh** (Ukrainian National Forestry University)*
47	10:15 – 10:25	#98 United Kingdom	Intelligent Cyber Threat Detection at Scale: A Comparative Study of Machine Learning and Deep Learning Approaches for Network Intrusion Detection on CICIDS2017	***Md Anas Biswas** (University of Portsmouth), Syed Anisur Rahman (University of Portsmouth), Hamidreza Khaleghzadeh (University of Portsmouth)*
48	10:25 – 10:40	#136 Finland	Role-Based Phishing to Ransomware Readiness for Clinical Staff	*Leon Carpelan, Anderson Siqueira Teixeira, Wimpie Roothe, Robert Simonsuuri, **Jyri Rajamäki** (Laurea University of Applied Sciences)*
49	10:40 – 10:55	#163 Finland	A Tabletop Exercise Framework for Cross-Border Digital Health Incident Response	*Niko Haanpää, Teemu Koski, Tommi Elg, Ville Kivistö, **Jyri Rajamäki** (Laurea University of Applied Sciences)*

Hall	**GAZALİ**
Session	**2**
Topic	**Cybersecurity, Privacy, Digital Trust & Theoretical Computer Science**
Session Chair	**Prof. Dr. Erol Kurt (Gazi University)**
Date	**17 September 2026**
Time	**12:00 – 15:20 GMT+2**

	Time	#ID	Presentation Title	Authors
50	12:00 – 12:15	#141 Hungary, Portugal	From Neo4j to Redis: Storing Graph Data and Comparing Graph Algorithm Performance	***Anikó Vágner*** *(University of Debrecen), Fanni Belics (University of Debrecen), Cristina Maria Costa Rodrigues (Polytechnic Institute of Santarém)*
51	12:15 – 12:30	#145 Azerbaijan	Analysis of Existing Approaches in The Field of Cryptographic Protocols in UAVs	***Ilaha Gahramanova*** *(Azerbaijan Technical University)*
52	12:30 – 12:45	#150 Azerbaijan	HID Hardening vs. FIDO2: A Security-versus-Security Trade-off	***Emin Huseynov*** *(Azerbaijan Technical University)*
53	12:45 – 13:00	#154 Netherlands	Randomized Backtracking: Another Unusable Sampling Method for the Traveling Tournament Problem	*Timothy Böhm (VU University), Daan van den Berg (VU University),* ***Bas Loyen*** *(VU University)*
54	13:00 – 13:15	#209 Bosnia and Herzegovina	The Dependency of NIS2 Critical Sectors on Operational Technology: Implications for Cybersecurity Resilience and Critical Infrastructure Protection	***Anes Mirojević*** *(University of Buckingham), Jasmin Azemović (University of Buckingham)*
55	13:15 – 13:25	#171 United Kingdom	Trustworthiness Under Compression: Calibration and Explanation Faithfulness of Lightweight IoT Intrusion Detectors	*Md Anas Biswas (University of Portsmouth,* ***Alif Laila*** *(University of Portsmouth)*
56	13:25 – 13:40	#172 North Macedonia	A Dataset-Based Exploratory Study of Cybersecurity Threat Patterns from 2015 to 2024	***Hristina Oracheva****, Dijana Capeska Bogatinoska, Daniela Mechkaroska (University of Information Science & Technology St. Paul the Apostle)*
57	13:40 – 14:50	#211 Bosnia and Herzegovina	From NIS to NIS2: Strengthening Cybersecurity for Critical Infrastructure Protection in the European Union	***Anes Mirojević*** *(University of Buckingham), Jasmin Azemović (University of Buckingham)*
58	14:50 – 15:10	#206 Czech Republic	Utilization of Honeypot Systems for Enhancing Cybersecurity in Smart Cities	*Vladimir Sobeslav (University of Hradec Kralove),* ***Daniel Kucera*** *(University of Hradec Kralove), Jan Pulpan (University of Hradec Kralove)*
59	15:10 – 15:20	#207 Czech Republic	Systematic Analysis of Honeypot Deception Techniques: State-of-the-Art and Empirical Validation	*Vladimir Sobeslav (University of Hradec Kralove),* ***Daniel Kucera*** *(University of Hradec Kralove), Jan Pulpan (University of Hradec Kralove)*

Hall	**GAZALİ**
Session	**3**
Topic	**Cybersecurity, Privacy, Digital Trust & Theoretical Computer Science**
Session Chair	**Prof. Dr. Ayhan Erdem (Gazi University)**
Date	**18 September 2026**
Time	**08:30 – 10:30 GMT+2**

	Time	#ID	Presentation Title	Authors
60	08:30 – 08:45	#166 Türkiye	Multi-Source Behavior-Based Anomaly Detection for Smart Water Management Networks Using SNMP and Syslog Telemetry	***Dilara Çetin**, Ayşegül Kara, Deniz Balta, Musa Balta (Sakarya University)*
61	08:45 – 09:00	#175 Türkiye	Various Topological Graph Indices in Sierpinski Triangle Networks	*İpek Akdoğan, Aysun Yurttaş Güneş, Hacer Özden Ayna, Aykut Şen, İlker Küçükoğlu, **İsmail Naci Cangül** (Bursa Uludag University)*
62	09:00 - 09:15	#217 Türkiye	Blockchain-Based Evaluation System: Transparent Academic Career Management with Ethereum Smart Contracts and IPFS	***Kemal Akkanat**, Muhittin Tanoba (Trakya University)*
63	09:15 - 09:30	#245 Türkiye	Empirical Evaluation and Mathematical Limitations of PDE-Based Smoothing in Keystroke Dynamics Authentication	***Levent Yalçın** (Acıbadem Mehmet Ali Aydınlar University), Ramazan Subaşı (Yıldız Teknik University)*
64	09:30 - 09:40	#251 Kosova	Cloud-CTI-Engine: An Integrated AWS Security Posture and Threat Intelligence Platform	***Gerta Hodolli**, Rrezearta Thaqi, Blerim Rexha (University of Prishtina)*
65	09:40 - 09:50	#254 Türkiye	Context-Aware Regular Expressions for Sensitive Data Detection	***Enes Can Güven** (Trendyol Group), Burak Tahtacı (Trendyol Group), Tuna Çakar (MEF University)*
66	09:50 – 10:00	#255 Türkiye	Privacy-Preserving Secret Validation: An Empirical Comparison of Probabilistic Filters, k-Anonymity, and Private Set Intersection	***Burak Tahtacı** (Trendyol Group), Enes Can Güven (Trendyol Group), Tuna Çakar (MEF University)*
67	10:00 - 10:15	#257 Algeria	Evaluating the Impact of Data Augmentation on Cross-Dataset Generalization in Intrusion Detection Systems	***Mounira Zekiouk**, Madjed Bencheikh Lehocine, Ahlam Bouanane (University of Mila)*
68	10:15 – 10:30	#160 Türkiye	Secure Biometric Data Management On A Permissioned Blockchain: A Hyperledger Besu-Based Architecture	***Durmuş Gülbahar**, Ahmet Gürsel, Ali Hakan Işık (Burdur Mehmet Akif Ersoy University)*

Hall	**NICOLA TESLA**
Session	**1**
Topic	**Computer Vision, Data Science, IoT & Edge Computing**
Session Chair	**Assoc. Prof. Dr. Eda Akman Aydın (Gazi University)**
Date	**17 September 2026**
Time	**09:00 – 11:30 GMT+2**

	Time	#ID	Presentation Title	Author
69	09:00 – 09:10	#56 Algeria	Mining Sequential Rules from Large-Scale Sequence Databases Using an FPTree-Based Method	***Imane Seddiki*** *(Mohamed El Bachir El Ibrahimi University), Abdelbasset Barkat (University of M'sila)*
70	09:10 – 09:20	#70 Türkiye	Evolution in Remote Sensing Change Detection: Methods, Challenges, and Next AI Perspectives	***Zeynep Açıkgöz*** *(Düzce University), İbrahim Alper Doğru (Gazi University), Kenan Toklu (Namık Kemal University)*
71	09:20 – 09:30	#76 Kazakhstan	Enhancing Small Object Detection in Mammography Using a Patch-Based YOLO Framework	***Aray Aryn*** *(Kazakh National Research Technical University), Orken Mamyrbayev (Institute of Information and Computing Technologies), Turdybek Kurmetkan (Al-Farabi Kazakh National University)*
72	09:30 - 09:45	#81 Canada	Adaptive Lossless Compression for Event-Based Cameras	*Prottasha D'Cruze,* ***Howard Cheng*** *(University of Lethbridge)*
73	09:45 – 10:00	#91 Georgia	Decision Tree-Based Data Completion in Structured Lexicographic Resources	***Archil Elizbarashvili*** *(Tbilisi State University), Magda Tsintsadze (Tbilisi State University)*
74	10:00 – 10:15	#108 Türkiye	Water Quality Monitoring and Pollution Detection Using Edge-IoT-Based Hybrid Artificial Intelligence Models: A Systematic Literature Review	***Hüseyin Özgür Kazan****, İsmail Atacak, İbrahim Alper Doğru (Gazi University)*
75	10:15 – 10:25	#109 Türkiye	A Practical Evaluation of CNN Architectures for Histopathological	***Nazlı Çıtak*** *(Gazi University), Ömer Faruk Bay (Gazi University)*
76	10:25 – 10:45	#115 Kazakhstan	Edge-Based Digital Twin for Real-Time Energy Monitoring in Food Manufacturing: A Case Study of a Bakery Enterprise	*Bauyrzhan Amirkhanov, Murat Kunelbayev, Miras Tokhtassyn,* ***Alina Raeva****, Gulshat Amirkhanova (Al-Farabi Kazakh National University)*
77	10:45 – 11:00	#116 Kazakhstan	Machine Learning Models for Monitoring and Analysis of Mobile Object Movements at a Food Industry Enterprise	***Bauyrzhan Amirkhanov****, Yenlik Faruzkyzy, Alikhan Amirkhanov, Gulshat Amirkhanova, Dina Baizhanova (Al-Farabi Kazakh National University)*
78	11:00 – 11:10	#121 Türkiye	Explainable Mammography Classification via Attention-Guided SE-EfficientNet-B3 and Grad-CAM Diagnostic Interpretation	***Abdine Ben Ali****, Sinan Toklu (Gazi University)*
79	11:10 – 11:30	#132 Libya	Harnessing Data Science and Machine Learning for Financial Fraud Detection Using the Central Bank of Libya Dataset	***Zakaria Suliman Zubi*** *(Sirte University), Abdulbasit M Alajnaf (Higher Institute of Science and Technology Misurata, Zakariya A Alsharef (Libyan Academy, Misurata)*

Hall	**NICOLA TESLA**
Session	**2**
Topic	**Computer Vision, Data Science, IoT & Edge Computing**
Session Chair	**Prof. Dr. Murat Dörterler (Gazi University)**
Date	**17 September 2026**
Time	**12:00 – 14:30 GMT+2**

	Time	#ID	Presentation Title	Author
80	12:00 – 12:15	#135 Cuba, Spain	Wavelet-Based Machine Learning for Real-Time Burst Detection on Embedded Edge Devices ***Jaime Ernesto Chiang Crúz*** *(Center for Hydraulic Research, University of Havana "José Antonio Echeverría"), Jorge Ramírez-Beltrán Center for Hydraulic Research, University of Havana "José Antonio Echeverría"), Sergio Enrique Rodríguez Pérez Center for Hydraulic Research, University of Havana "José Antonio Echeverría"), Alex Macia-Fiteni (University of Alicante), Iren Lorenzo-Fonseca (University of Alicante)*	
81	12:15 – 12:25	#140 México	Preliminary Development of an Aircraft Structural Damage Classification System Using Deep Learning ***Reynaldo Ángel Serrano Cruz****, Gloria Lilia Osorio Gordillo, Rodolfo Amalia Vargas Méndez (Centro Nacional de Investigación y Desarrollo Tecnológico (CENIDET))*	
82	12:25 – 12:35	#146 Nigeria	SHRUMAC: An IoT-Smart Hygiene, Refuse Monitoring and Alert Controller System for Real-Time Institutional Campus Sanitation Management ***Shobowale, Rukayat Temitope*** *(Federal University Otuoke), Maclean, Friday Maclean (Federal University Otuoke)*	
83	12:35 – 12:50	#156 Türkiye	Siamese Swin Transformers for Robust Polyp Classification ***Mesut Şeker*** *(Dicle University)*	
84	12:50 – 13:05	#164 Türkiye	A Multimodal Analysis Approach for Automated Classification of Content Rating Symbols in Video Content ***Barış Şenel****, Murat Dörterler, Adem Tekerek (Gazi University)*	
85	13:05 - 13:20	#174 Sweden	Ability-Based Approaches for Ambient Assisted Living in Smart Homes ***Marijana Teljega*** *(Kristianstad University), Daniel Einarson (Kristianstad University)*	
86	13:20 – 13:30	#176 Malaysia	HeritageCare: A Predictive Maintenance and Monitoring System for Heritage Buildings ***Chan Rou Mei*** *(TAR UMT), Cho Sook Fong (TAR UMT), Loke Sue Voon (TAR UMT)*	
87	13:30 – 13:45	#184 Türkiye	Enabling Clinical-Grade Left Ventricular Hypertrophy Detection in Wearable Devices via Deep Learning ***Arda Sarpay*** *(Izmir Katip Celebi University), Yalçın İşler (Alanya Alaaddin Keykubat University)*	
88	13:45 - 13:55	#186 Peru	Territorial Crime Pattern Classification in Peru Using Unsupervised Learning and K-Medoids, 2015–2024 ***Renzo Alberto Taco Coayla****, Martha Judith Paredes Vignola, Enrique Félix Lanchipa Valencia, Elard Ricardo Rodríguez Marca, Hugo Martín Alcántara Martínez, Josué Abraham Emanuel Chambilla Zúñiga* *(Universidad Privada de Tacna, Tacna, Perú)*	
89	13:55 - 14:10	#194 Morocco	A Physics-Informed Hybrid Framework for Predictive Supervision and Multi-Objective Optimization of Ultrafiltration Membrane Fouling in Desalination ***Zineb Idabella*** *(Cadi Ayyad University), Laila Amir (Cadi Ayyad University)*	

90	14:10 – 14:25	#195 New Zealand	Leakage-Aware and Explanation-Stable XAI for Short-Term Smart Home Appliance Energy Forecasting ***Ahmad Wedyan*** *(Manukau Institute of Technology), David McCurdy (Manukau Institute of Technology)*
91	14:25 – 14:40	#249 Albania	Evaluating TOE Determinants of Big Data Analytics Readiness through CRITIC–TOPSIS: Evidence from Albania ***Megi Marku*** *(Agricultural University of Tirana)*

Hall	**NICOLA TESLA**
Session	**3**
Topic	**Computer Vision, Data Science, IoT & Edge Computing**
Session Chair	**Assoc. Prof. Dr. Saadin OYUCU (Gazi University)**
Date	**18 September 2026**
Time	**08:30 – 12:30 GMT+2**

	Time	#ID	Presentation Title	Authors
92	08:30 - 08:50	#198 Uganda	Semantic Interoperability of Heterogeneous Research Data: A FAIR-Aligned Ontology-Driven Framework for Interdisciplinary Research	***Kevin Aber*** *(Gulu University), Geoffrey Olok Tabo (Gulu University), Benedict Oyo (Gulu University), Lone Dirckinck Holmfeld (Aalborg University), Christine Kalumera Akello (Gulu University), Daniel Ogenrwot (Gulu University)*
93	08:50 – 09:05	#202 Mexico	TRITON: A Modular Transformer for Per-Pixel Marine Pollutant Detection in Sentinel-2 Imagery	*José Luis de León Carmona (Center for Research in Mathematics (CIMAT),* ***Rogelio Hasimoto-Beltrán*** *(Center for Research in Mathematics (CIMAT))*
94	09:05 – 09:20	#212 Brazil, Portugal	Computational Models for Predicting Female Breast Cancer Survival and an Onco-Hospital Feature Engineering Workflow	***Daniela Schimitz de Carvalho*** *(University of Porto), Maximiliano Ribeiro Guerra (Federal University of Juiz de Fora), Marco Paulo Lages Parente (University of Porto), Priscila Vanessa Zabala Capriles Goliatt (Federal University of Juiz de Fora)*
95	09:20 – 09:35	#213 Türkiye	Precise Segmentation of Dental Implants with YOLO-Based Deep Learning Models	*Hüseyin POLAT (Gazi University), Emin UYSAL (Pi Health Technologies),* ***Hakan ÜNAL*** *(Gazi University), Elif Meltem ASLAN (University of Health Sciences)*
96	09:35 - 09:50	#218 Türkiye	A Region-Ablation Study of MRI Texture Features for Trigeminal Neuralgia Classification	***Önder Polat*** *(Gaziantep Islam Science and Technology University), Zeynep Ziroğlu (Ankara Training and Research Hospital), Habip Eser Akkaya (Ankara Training and Research Hospital), Hafize Nalan Güneş (Ankara Training and Research Hospital)*
97	09:50 – 10:05	#220 Türkiye	Bibliometric Analysis of Artificial Intelligence-Assisted Medical Imaging Research: Global Trends and Turkey's Position (2021-2025)	***Kemal Akkanat*** *(Trakya University), Muhittin Tanoba (Trakya University)*
98	10:30 – 10:45	#229 SriLanka, Malaysia	Development of a Novel Low-Time-Complexity Optimization Technique for Edge-Based Wireless Body Area Networks	***Sachinthani Alahakoon*** *(Gampaha Wickramarachchi University and Indigenous Medicine), Mustafa Muwafak Alobaedy (City University)*
99	10:45 -11:00	#234 Mexico	Oil Spill Segmentation in SAR Imagery Using Swin Transformer with Compound Loss: A Multi-Sensor Evaluation	*Jose Daniel Foronda Ortiz (Center for Research in Mathematics),* ***Rogelio Hasimoto Beltrán*** *(Center for Research in Mathematics)*
100	11:00 – 11:10	#248 Hungary	Synthetic-to-Real Camera Contamination Classification Using Modern Deep Neural Networks	***János Hollósi*** *(Széchenyi István University)*
101	11:10 – 11:25	#250 Türkiye	Traffic Accident Severity Prediction with an Interpretable Crash Severity Risk Score	***Sevcel Gözde BILGIN*** *(Gazi University), Cemal KOCAK (Gazi University)*

102	11:25 – 11:35	#260 Uganda	AI-Powered Smart Sensor for Direct Analysis of Aflatoxins in the Open Air Environment ***Fred Paul Mark Jjunju*** *(Universal Technology and Management University), Denis Bbosa (Mbarara University of Science and Technology)*
103	11:35 – 11:45	#262 United Kingdom	Non-intrusive Human Activity Recognition using Imbalanced mm-Wave Doppler Radar Streams and Ensemble of Time-Series Modeling Strategies ***Khadija Adam Nasir*** *(Swansea University), Sara Sharifzadeh (Swansea University), Alaa Humaidan (Swansea University), Jeny Roy (Swansea University)*
104	11:45 -11:55	#263 Türkiye	Full-Frame Sparse Temporal Multitask Learning for Student Affective State Recognition Using DAiSEE ***İbrahim Dolaş*** *(Gazi University), Hüseyin Polat (Gazi University)*
105	11:55 – 12:10	#247 South Africa	A Context-Aware Computer Vision-Based Model for ACL Injury Prevention in Female Youth Football: A PRISMA-based Review ***Zodzwainashe Kudyachete*** *(Nelson Mandela University), Chinonye Leuna Obioha (Nelson Mandela University), Darelle Van Greunen (Nelson Mandela University)*

Hall	**DA VINCI**
Session	**1**
Topic	**Software Engineering, HCI, Robotics & Applied Computing**
Session Chair	**Assoc. Prof. Dr. Sinan Toklu (Gazi University)**
Date	**17 September 2026**
Time	**09:00 – 11:00 GMT+2**

	Time	#ID	Presentation Title	Author
106	09:00 – 09:15	#38 Croatia	Gender Pay Gaps in Software Engineering: A Literature Review of Attrition, Measurement, and Structural Inequality ***Marija Macek*** *(University of Zagreb)*	
107	09:15 – 09:30	#42 Azerbaijan	Digital twin-based residual analysis for leak detection and localization in high-pressure gas pipelines ***Murad Sharifov*** *(Baku Higher Oil School), Naila Allahverdiyeva (Baku Higher Oil School)*	
108	09:30 – 09:45	#51 Oman	Real-Time Helmet Detection System with Monitoring and Alert for Restricted Areas ***Mohammad Mohatram****, Asma Abdallah Al Reesi, Javeed Hussain Shaik, Muhammad Irfan Memon (Global College of Engineering and Technology)*	
109	09:45 – 09:50	#58 Sri Lanka	Explainable Commit-Level Vulnerability Intelligence in DevSecOps Pipelines: A Systematic Review and Experimental Analysis ***Dasun Sandeepa Wilathgamuwa*** *(University of Sri Jayawardanapura), Malshani Heetiarachchi (University of Moratuwa)*	
110	09:50 – 10:00	#68 Türkiye	MPC-Based Trajectory Tracking and Dynamic Obstacle Avoidance for an Autonomous Vehicle in ROS2 ***Ibrahim Toy*** *(MPG Inc.), Akif Durdu (Konya Technical University)*	
111	10:00: 10:15	#73 Algeria	Multi-Objective Hybrid Swarm Optimization for Energy-Delay Trade-off in SDN-enabled MEC ***Cherhabil Fatima Z.*** *(Mustafa Benboulaid University (Batna2)), Bendib Sonia-Sabrina (Mustafa Benboulaid University (Batna2)), Sedrati Maamar (Mustafa Benboulaid University (Batna2))*	
112	10:15 - 10:30	#80 Ukraine	Reward System for Student Social Activity: Lntu Case Study ***Iurii Lukianchuk****, Lev Boyko, Yurii Tulashvili, Olga Nedilko (Lutsk National Technical University)*	
113	10:30 - 10:40	#107 Greece	Continuously Adaptive Digital Twins for Sim-to-Real Learning in Agro-Food Systems ***Georgios Protogeros****, Aikaterini Protogerou, Manos Roumeliotis (University of Macedonia)*	
114	10:40 - 10:50	#126 Türkiye	An Analysis of the Ministry of Health of the Republic of Türkiye from a Web Accessibility (Barrier-Free Design) Perspective ***Halime Suvay EKER*** *(İstanbul Gedik University)*	
115	10:50 – 11:00	#142 Spain, Cuba	Open cloud voice service architecture ***Alex Macia Fiteni*** *(University of Alicante), Jaime E. Chiang Cruz (Technological University of La Habana "José Antonio Echeverría"), Iren Lorenzo Fonseca (University of Alicante), Francisco Maciá Pérez (University of Alicante)*	
116	11:00 – 11:10	#147 Slovakia	From Textual Variation to Functional Diversity in Beginner C Programming Tasks Generated by Ollama Cloud-Based Large Language Models *Ladislav Végh (J. Selye University), Ondrej Takáč (J. Selye University),* ***Dávid Demeter*** *(J. Selye University),* *Krisztina Czakóová (J. Selye University)*	
117	11:10 – 11:20	#153 Zambia	Understanding Emerging Technology Adoption in Technical and Vocational Education and Training through Theoretical and Pedagogical Perspectives ***Twaambo Chiinza*** *(Technical and Vocational Teachers' College), Alice P. Shemi (Copperbelt University)*	
118	11:20 – 11:40	#155 Hungary	Educational Research in Computer Science: Data Collection, Processing, and Analysis ***Carolin Hannusch*** *(University of Debrecen), Mária Csernoch (University of Debrecen)*	

Hall	**DA VINCI**
Session	**2**
Topic	**Software Engineering, HCI, Robotics & Applied Computing**
Session Chair	**Assist. Prof. Dr. Halime Suvay EKER (İstanbul Gedik University)**
Date	**17 September 2026**
Time	**12:00 – 14:20 GMT+2**

	Time	#ID	Presentation Title	Author
119	12:00 - 12:10	#157 Bulgaria	Architecture of a Fuzzy Logic Model for Supporting Investigations in Burglary Cases ***Radmila Radostinova*** *Roydeva (Burgas Free University), Penka Georgieva (Burgas Free University)*	
120	12:10 – 12:25	#161 Uzbekistan	Reinforcement Learning-Based Adaptive Hybrid PSO-GA Framework for Solving Dynamic Optimization Problems ***Mageshkumar Chinnasamy*** *(Webster University), Nitin S. Goje (Webster University)*

Abstract
Generative artificial intelligence is increasingly entering educational practice. Yet, many current discussions still assume access to advanced infrastructure, paid platforms, and institutional support that teachers in low-resource settings often lack. This paper addresses that gap by proposing a conceptual and scenario-based framework for low-threshold AI use grounded in three criteria: feasibility in constrained contexts, preservation of teacher agency, and ethical low-risk application. Three scenarios are considered: AI-supported lesson planning, reflective practice, and task differentiation. Across them, AI is framed not as an instructional authority but as a bounded support tool for drafting, questioning, and structuring under teacher control. The paper argues that low-resource use of AI can provide a realistic, responsible, and professionally disciplined pathway for integrating generative AI into everyday teaching.

Keywords: artificial intelligence in education; low-resource teaching contexts; teacher-centered innovation; pedagogical boundaries; ethical use of AI; teaching practice

I. INTRODUCTION

Artificial intelligence (AI) has become an increasingly visible part of educational discourse, with growing expectations regarding its capacity to support teaching, personalize learning, and improve instructional decision-making [1], [2]. More recently, generative AI has intensified these discussions by expanding access to text-based support tools while also raising new concerns related to governance, implementation, and educational responsibility [3], [4]. Yet much of the current literature and many implementation models still assume access to robust digital infrastructure, subscription-based platforms, and sustained institutional support.

These assumptions reduce the relevance of many AI-in-education models for teachers working in low-resource contexts shaped by limited technology, restricted budgets, heavy workloads, and insufficient professional development. In such settings, the key issue is not whether AI can be used, but how it can be used meaningfully without undermining teacher judgment or increasing ethical risk. This paper, therefore, proposes a practice-oriented framework for the use of low-resource AI in teaching, focusing on feasible applications that remain pedagogically bounded and ethically responsible.

II. CONCEPTUAL AND DESIGN APPROACH

This study adopts a conceptual and scenario-based design approach. It is not presented as an empirical intervention, but as a practice-oriented framework for identifying realistic uses of generative AI in low-resource teaching contexts. The proposed scenarios were selected based on three criteria: feasibility in constrained settings, preservation of teacher agency, and ethical, low-risk use.

First, each scenario had to be implementable with freely available or open-access text-based AI tools, without requiring specialized software, advanced technical expertise, or data-intensive infrastructure [4]. Second, AI had to function only as a support tool for drafting, structuring, or reflection rather than as an instructional authority. Third, each scenario had to avoid using identifiable student data, automated profiling, and the delegation of assessment or instructional judgment to AI systems [3], [5]. Based on these criteria, three scenarios were selected because they correspond to recurring dimensions of everyday teaching practice: lesson planning, reflective professional thinking, and task differentiation for inclusive instruction.

III. INNOVATIVE LOW-RESOURCE USES OF AI IN TEACHING PRACTICE

Building on the conceptual and design-oriented framework outlined above, this section presents three worked scenarios that show how low-resource AI use can support everyday teaching practice while remaining pedagogically bounded and ethically responsible. Freely available, open-access generative AI tools offer opportunities for incremental innovation that can be integrated into existing teaching routines without requiring specialized infrastructure or extensive technical training [6].

1. AI-Supported Simplification of Lesson Planning

Lesson planning is a cognitively demanding and time-intensive component of teaching, particularly in low-resource contexts where teachers often work under conditions of high curricular pressure, limited preparation time, and restricted access to ready-made instructional materials. In such settings, the value of generative AI does not lie in replacing the pedagogical work of planning, but in supporting the early structuring of instruction through low-threshold, text-based assistance. Used appropriately, open-access AI tools can help teachers generate preliminary lesson outlines, propose sequences of classroom activities, and draft formative assessment prompts that can later be reviewed and refined through professional judgment.

The pedagogical significance of this support is especially apparent in subjects that require teachers to balance conceptual explanation, procedural modeling, classroom interaction, and differentiated learner engagement within a limited lesson period. One illustrative example is a Grade 8 Informatics lesson on algorithmic thinking and flowchart design. This topic requires more than the transmission of factual knowledge: it involves conceptual clarity, the sequencing of examples, opportunities for guided practice, and the translation of abstract ideas into manageable student activity. For a teacher working in a low-resource school environment, preparing such a lesson from scratch may require substantial time and cognitive effort, particularly when materials must be adapted without relying on specialized software or digital infrastructure.

In this scenario, a teacher may use a freely accessible generative AI tool to create an initial lesson structure by entering a prompt such as: “Create a 40-minute Grade 8 Informatics lesson outline on algorithmic thinking and flowchart design. Include a short warm-up based on everyday problem-solving, a teacher-guided explanation, one paired classroom task, and a brief formative assessment. The lesson should rely only on ordinary classroom resources and should support mixed-ability learners.” In response, the AI might generate a draft sequence that begins with an introductory discussion on everyday step-by-step processes, followed by an explanation of algorithms, sequence, and decision points, then a paired activity in which students convert a familiar everyday task into a simple flowchart, and finally a short exit task requiring students to identify errors in a partially completed flowchart.

At this stage, however, the generated output remains only a provisional scaffold. The pedagogical quality of the lesson still depends on the teacher’s interpretation and adaptation of that draft. The teacher may decide to simplify the terminology used during the explanation phase, replace generic examples with culturally or contextually familiar ones, adjust timing to the class's actual pace, and introduce additional scaffolding for students with limited prior exposure to symbolic representations. Similarly, for stronger learners, the teacher

may extend the paired activity by asking them to compare two possible flowchart structures for the same task and justify which one is clearer or more efficient. In this way, AI reduces the burden of initial lesson structuring without displacing the teacher's role as the designer of learning.

From a pedagogical standpoint, the contribution of AI in this context is therefore not automation, but assisted preparation. It can help teachers move more efficiently from instructional intention to a usable draft structure, especially where time, materials, and collegial support are limited. Yet the pedagogical boundary remains explicit: AI may support the drafting of a lesson outline, but it does not determine learning objectives, interpret learner misconceptions, select the final level of task difficulty, or make assessment decisions. Those responsibilities remain fully with the teacher. In low-resource contexts, this bounded use of AI is particularly valuable because it offers practical support while preserving contextual judgment, professional autonomy, and accountability for student learning

2. AI-Supported Reflective Teaching Practices

Reflective practice is widely recognized as a central dimension of effective teaching and professional growth. However, in low-resource educational contexts, sustained reflection is often constrained by heavy workloads, limited access to mentoring, and the absence of structured professional dialogue. Under such conditions, teachers may have valuable classroom insights but insufficient time or support to analyze them systematically. Generative AI can offer modest but meaningful assistance in this area by helping teachers structure reflective inquiry without displacing professional judgment.

The pedagogical value of such use lies in supporting reflection as a disciplined process rather than as an occasional impressionistic activity. In this scenario, AI is not used to evaluate teaching quality, assign performance judgments, or prescribe "correct" instructional decisions. Instead, it is used to expand the teacher's reflective field by generating questions, alternative interpretations, or lines of inquiry based on the teacher's own post-lesson observations. This bounded role is particularly suitable for low-resource settings because it requires only a short written input from the teacher and does not depend on classroom recordings, platform analytics, or student-level data.

This scenario may be illustrated by continuing the Grade 8 Informatics lesson on algorithmic thinking and flowchart design described in the previous section. After the lesson, the teacher writes a short reflective note such as the following: "Students were highly engaged during the opening discussion on everyday step-by-step processes, and most pairs were able to start the flowchart task. However, several students confused sequence and decision symbols, and the explanation stage took longer than expected. The final exit task showed that some students could identify flowchart errors, but others still seemed uncertain about when a decision point is needed." The teacher may then enter a prompt such as: "Based on this post-lesson note, generate five reflective questions to help a teacher analyze what worked well, what students found difficult, and what could be adjusted in the next lesson. Do not evaluate the teacher. Focus only on reflective inquiry."

In response, the AI might generate questions such as: Which part of the opening discussion appeared to make the concept of algorithm most accessible to students? At what point did confusion between sequence and decision symbols become most visible? How might the explanation stage be shortened while preserving conceptual clarity? What additional example or representation could help students distinguish between linear steps and decision points? How might the next lesson begin in a way that revisits uncertainty without discouraging learners who struggled? These outputs do not replace reflection; rather, they help the teacher move from a general impression of the lesson to a more structured pedagogical analysis.

The teacher remains fully responsible for interpreting these questions and deciding which insights are educationally meaningful. The AI does not know the classroom atmosphere, the prior attainment of particular learners, or the contextual reasons why some activities succeeded while others did not. Its contribution is

limited to supporting professional noticing and reflective questioning. In this sense, AI functions as a cognitive mirror rather than an evaluator: it reflects possible angles of analysis, but it does not determine conclusions. This distinction is essential. Reflection remains grounded in teacher-authored observations, contextual understanding, and professional values.

The ethical boundary in this scenario is equally important. No identifiable student data are entered into the system, and no student is individually described, classified, or profiled. The teacher's note remains focused on patterns of engagement, misunderstanding, pacing, and instructional flow rather than on personal learner records. Such use aligns with the principle of data minimization and reduces the risk of inappropriate disclosure. In low-resource contexts, where formal policy guidance may be limited, this low-input, low-risk form of reflective support is a realistic and responsible way to engage with AI.

From a pedagogical perspective, the contribution of AI here lies in strengthening reflective capacity under constrained conditions. Rather than offering automated advice, it helps teachers organize reflection in ways that may support more intentional follow-up planning, clearer recognition of learners' difficulties, and stronger continuity between lessons. The pedagogical boundary, however, remains explicit: AI may prompt reflective analysis, but it does not interpret teaching quality, determine pedagogical priorities, or replace the teacher's professional reasoning.

3. AI-Supported Task Differentiation for Inclusive Teaching

Task differentiation is an important but demanding aspect of inclusive teaching, particularly in classrooms where students vary in prior knowledge, pace of learning, language confidence, and readiness for abstraction. In low-resource settings, teachers are often expected to respond to this diversity without access to specialized support materials, adaptive software, or substantial preparation time. Under such conditions, generative AI can assist by producing alternative versions of the same task at different levels of complexity while preserving a common learning objective.

This form of support is especially relevant in subjects such as Informatics, where conceptual understanding and procedural reasoning may develop unevenly across learners. Continuing the Grade 8 lesson on algorithmic thinking and flowchart design, a teacher may wish to prepare differentiated follow-up tasks after noticing that some students are still uncertain about basic symbol use. In contrast, others are ready to analyze more complex structures. Rather than designing each variation from the beginning, the teacher may use a prompt such as: "Create three versions of a classroom task on flowchart design for Grade 8 students: one simplified version for learners who need more structure, one standard version, and one extension task for learners ready for deeper reasoning. All three tasks should address the same learning objective: understanding sequence and decision points in a simple algorithm. Do not require computers or specialized software."

In response, the AI might generate a simplified task in which students complete a partially structured flowchart using a limited set of symbols and labelled prompts; a standard task in which students design a full flowchart for an everyday process such as borrowing a library book or preparing for school; and an extension task in which students compare two different flowchart solutions for the same problem and explain which one is logically clearer or more efficient. These task variations share a common conceptual focus but differ in the degree of independence, abstraction, and explanation required.

The instructional value of this support lies in accelerating the production of parallel learning tasks without fragmenting the lesson into unrelated activities. The teacher can review the generated options, adjust wording, simplify or enrich the demands of each version, and ensure that the final tasks remain aligned with the curriculum and appropriate for the actual classroom context. This is particularly useful in constrained environments, where differentiation is often recognized as pedagogically necessary but is difficult to implement consistently due to time pressure.

At the same time, the educational boundary in this scenario is specific and important: AI may assist in generating alternative task formats, but it does not decide which learner receives which task, nor does it infer ability profiles from student data. Decisions about grouping, task allocation, pacing, and support remain matters of teacher judgment. This distinction helps preserve inclusive practice as a pedagogical process rather than allowing it to drift into automated categorization. In this respect, low-resource use of AI is most defensible when it supports preparation for differentiated teaching without automating decisions about learners.

Table 1. Mapping low-resource AI use scenarios to pedagogical boundaries and ethical safeguards

Scenario	Primary teaching needs	Example AI support	Pedagogical boundary	Ethical safeguard
AI-supported lesson planning	Reducing the time and cognitive load involved in structuring lessons under constrained conditions	Drafting a preliminary lesson outline, suggesting a sequence of activities, and proposing brief formative assessment prompts	AI supports initial structuring only; final decisions on objectives, sequencing, explanation, and assessment remain with the teacher.	No identifiable student data are required; AI-generated plans are treated as provisional drafts subject to teacher review and contextual adaptation.
AI-supported reflective practice	Supporting structured post-lesson reflection where time, mentoring, or professional dialogue may be limited	Generating reflective questions or alternative angles of analysis from teacher-authored post-lesson notes	AI does not evaluate teaching quality or prescribe pedagogical judgments; reflection remains grounded in the teacher's own interpretation.	Reflection is based on non-identifiable classroom observations; no personal learner data, profiling, or individual records are entered.
AI-supported task differentiation	Preparing parallel versions of learning tasks to support inclusive teaching across varied learner readiness levels	Producing simplified, standard, and extension versions of tasks aligned with the same learning objective	AI may suggest differentiated task formats, but task allocation, grouping, and instructional adjustment remain teacher decisions.	No automated grouping or learner profiling is used; differentiation remains a pedagogical strategy rather than a technical classification process.

As Table 1 indicates, the educational value of low-resource AI use lies not in autonomous instructional decision-making, but in bounded forms of support that remain pedagogically guided and ethically constrained.

IV. PEDAGOGICAL BOUNDARIES OF AI USE IN TEACHING

The educational value of low-resource AI use depends not on the expansion of automation, but on the clarity of its pedagogical limits. In the scenarios outlined above, AI contributes most meaningfully when it supports preparatory and reflective aspects of teaching without assuming instructional authority. For this reason, responsible AI use in teaching requires a bounded framework in which pedagogical purpose remains primary and professional judgment remains non-transferable.

The first boundary concerns the location of instructional authority. AI may assist with drafting lesson structures, generating reflective prompts, or proposing differentiated task formats. Still, it does not determine learning objectives, interpret classroom realities, or decide how instruction should be adapted for particular learners. These functions depend on contextual judgment, curricular awareness, and knowledge of students that remain irreducibly human and professionally situated. AI output is therefore pedagogically useful only when treated as provisional material for teacher review rather than as guidance to be implemented uncritically.

A second boundary concerns evaluative responsibility. Even where AI can help organize ideas, suggest feedback language, or surface possible misconceptions, it must not displace the teacher's role in assessment, interpretation, and follow-up decision-making. Educational judgment is not merely a technical act of classification; it is a relational and normative process tied to fairness, context, and professional accountability. In this respect, bounded use of AI protects not only instructional quality but also the integrity of assessment, a core pedagogical responsibility.

A third boundary concerns the relationship between efficiency and educational purpose. In low-resource settings, the appeal of AI often lies in its capacity to save time or reduce workload. While such efficiency may be valuable, it is not in itself a sufficient pedagogical justification. AI use becomes educationally defensible only when it strengthens instructional coherence, supports inclusion, deepens teacher reflection, or otherwise contributes to meaningful learning processes. The criterion is therefore not whether AI can do something quickly, but whether its use serves a recognizable educational purpose under teacher direction.

Taken together, these boundaries position AI not as a teaching agent, but as a constrained pedagogical support tool. Such a position is especially important in low-resource contexts, where the absence of extensive infrastructure or institutional regulation can increase the temptation to use AI pragmatically without sufficient educational scrutiny. Clear pedagogical limits help ensure that innovation remains teacher-centered, context-sensitive, and aligned with the core purposes of teaching. This bounded approach also provides the necessary foundation for the ethical considerations discussed in the following section.

V. ETHICAL CONSIDERATIONS IN LOW-RESOURCE AI USE

Ethical questions surrounding artificial intelligence in education become particularly significant in low-resource contexts, where institutional guidance, technical safeguards, and digital literacy may be uneven or underdeveloped. Under such conditions, responsible AI use cannot rely solely on formal regulation or platform design; it must also be sustained through clear professional norms. For this reason, ethical considerations are not secondary to pedagogical concerns but are an essential condition for the adoption of low-resource AI in teaching [3], [5].

A first ethical priority is data minimization. Many AI systems operate through large-scale data processing, which raises concerns about what information is entered, how it may be stored, and whether it could later be reused in ways that are not fully visible to teachers. In low-resource classroom practice, the most defensible approach is therefore to avoid entering identifiable student information altogether. The scenarios proposed in this paper are intentionally designed around teacher-authored notes, generic lesson content, and non-identifiable task materials rather than individual learner records. This reduces privacy risk while keeping AI use compatible with ordinary classroom realities [3].

A second ethical consideration is transparency of use. When AI contributes to lesson preparation, reflective questioning, or task design, that support should not be concealed behind an appearance of purely teacher-generated authority. Transparency matters not because every technical detail must be disclosed, but because teachers and institutions should maintain clarity about the role AI has played in shaping instructional materials. In low-resource settings, where misconceptions about AI may be widespread, such openness helps preserve trust. It prevents the mistaken assumption that AI-generated outputs are inherently objective, authoritative, or pedagogically neutral [3], [5].

A third issue concerns the avoidance of learner profiling and automated categorization. This is especially important in contexts where educational disadvantage may already be shaped by language background, unequal access to resources, or variable prior preparation. If AI is used to classify students too quickly into ability-based categories, it risks reinforcing existing inequities under the appearance of technical efficiency. For this reason, AI may support differentiated task design, but the interpretation of learner needs and the allocation of tasks must remain pedagogical decisions rather than algorithmic ones. Ethical low-resource AI use therefore resists the drift from instructional support toward hidden classification [5].

A fourth ethical concern is the preservation of clear responsibility. Even where AI contributes to drafting, structuring, or idea generation, responsibility for instructional choices and their consequences remains human and professional. In low-resource environments, where policy frameworks may lag behind practice, this clarity is particularly important. Ethical use of AI requires that teachers remain able to explain, justify, and, if necessary, revise the educational decisions associated with AI-supported materials. The ethical issue here is not only who uses AI, but who remains answerable for its pedagogical consequences [3].

Taken together, these considerations suggest that the ethical legitimacy of low-resource AI use lies less in the technology's sophistication than in the discipline of its application. Simplicity, restraint, and contextual awareness are not signs of limited innovation; they are conditions for responsible adoption. In this sense, ethical low-resource AI use is best understood as a cautious professional practice that enables teachers to benefit from generative tools without normalizing opacity, overreach, or new forms of inequity.

VI. IMPLICATIONS FOR TEACHING PRACTICE

The analysis developed in this paper has implications not only for individual classroom practice but also for teacher learning and institutional support in low-resource educational settings. Its central practical implication is that meaningful AI integration does not require comprehensive technological transformation. Instead, it can begin through bounded, low-threshold uses that address familiar teaching tasks while remaining compatible with existing classroom realities.

For teachers, this means that AI adoption may be approached as a form of disciplined pedagogical support rather than as a demand for technical specialization. Low-resource uses such as lesson structuring, reflective prompting, and task variation offer manageable entry points because they do not depend on advanced infrastructure, large datasets, or formal automation. Their practical value lies in helping teachers work more efficiently in areas where preparation time, material support, or collegial collaboration may be limited.

For teacher education and professional development, the findings suggest that AI-related preparation should focus less on mastery of specific platforms and more on cultivating transferable judgment. Pre-service and in-service programs can use low-resource scenarios to help teachers examine when AI support is educationally useful, where its limits should be drawn, and how ethical considerations shape classroom decision-making. In this sense, AI competence in teaching should be understood not primarily as technical fluency, but as the ability to use generative tools selectively, critically, and contextually [7].

At the institutional level, the paper points toward the need for flexible guidance rather than uniform mandates. Schools and teacher education providers should recognize that educational contexts differ significantly in infrastructure, policy readiness, and staff confidence. In settings where formal AI frameworks are still emerging, a minimal responsible-use protocol may be more realistic and more useful than ambitious implementation models [8], [9]. Such a protocol may include avoiding the use of identifiable student data, requiring teacher review of all AI-supported materials, maintaining transparency in use, and prohibiting automated learner classification or assessment decisions.

Taken together, these implications suggest that sustainable AI integration in education is more likely to develop through professionally governed, context-sensitive practices than through top-down technological expectation. In low-resource settings, especially, the most durable forms of innovation may be those that remain modest in technical demands but clear in pedagogical purpose [9].

VII. CONCLUSION

This paper has argued that generative AI can have educational value in low-resource contexts when its use is framed not by technological ambition, but by pedagogical discipline. Rather than treating limited infrastructure, time, or institutional support as conditions that exclude meaningful innovation, the study has shown that such contexts may instead call for more selective, bounded, and teacher-centered forms of AI adoption.

By organizing the discussion around lesson planning, reflective practice, and task differentiation, the paper has identified three areas in which low-threshold AI use can support everyday teaching without displacing professional judgment. Its central contribution lies in showing that the question is not simply whether AI is available, but under what pedagogical and ethical conditions its use becomes educationally defensible.

The framework proposed here, therefore, shifts attention away from high-resource models of AI integration and toward a more realistic account of responsible classroom use. In this account, accessibility, contextual adaptation, and professional restraint are not signs of reduced innovation; they are part of what makes the use of AI sustainable and educationally credible. This perspective may be especially relevant for systems in which teachers are expected to engage with AI before comprehensive policy, infrastructure, or technical support is in place [3], [4]. As generative AI continues to develop, its educational significance will depend less on its novelty than on the quality of the professional boundaries within which it is used.

This paper is intentionally conceptual and scenario-based and therefore does not claim empirical validation of the proposed framework. Its purpose is to clarify how low-resource uses of generative AI may be structured in pedagogically bounded and ethically responsible ways, rather than to test their effectiveness through classroom intervention. The three scenarios presented here are intended as illustrative models of practice, designed to support discussion, adaptation, and future application. Further research is needed to examine these uses empirically across subjects and school settings, particularly regarding teacher uptake, contextual adaptation, perceived usefulness, and the institutional conditions required for sustainable and responsible implementation.

Abstract
The integration of artificial intelligence in education demands new approaches to computer science teacher preparation that go beyond technical training. This paper presents a three-component model treating technical, ethical, and social competencies as coequal, interdependent pillars within a structural-functional framework. Its distinguishing feature—compared to existing frameworks such as DigCompEdu, TPACK, and AI4K12, which treat ethics as a sub-competency or supplementary module—is the cross-cutting integration matrix (3×4), which operationalizes all three dimensions simultaneously across every component of professional readiness. The model is grounded in SDG 4 and informed by a survey of 899 CS teachers across five regions of Kazakhstan ($\alpha = 0.93–0.97$), revealing critical gaps in AI competency ($M = 3.48$). Six pedagogical conditions for implementation and practical implications for curriculum developers are discussed.

Keywords: artificial intelligence, AI ethics, computer science teacher preparation, SDG 4, three-component model, DigCompEdu, structural-functional approach.

I. INTRODUCTION

Artificial intelligence has moved far beyond the boundaries of computer science and is now shaping economies, healthcare systems, public administration, and – most importantly – education. By 2025, AI tools had reached massive scale: ChatGPT surpassed 700 million weekly active users, fundamentally transforming learning, teaching, and the way educational institutions function [1]. Against this backdrop, the global sustainable development agenda takes on new meaning: the UN Sustainable Development Goals adopted in 2015, and SDG 4 in particular – ensuring quality, inclusive, and equitable education for all [2] – now face a fundamentally new challenge. These two forces – AI and sustainable development – converge on one of the most pressing questions of our time: how to prepare teachers who can convey not only technical knowledge but also ethical responsibility and the social dimension of technology. Existing models of computer science teacher preparation primarily focus

on technical and methodological training. An analysis of international frameworks shows that the ethical dimension appears only as a sub-competency (DigCompEdu) or is absent as a central focus altogether (TPACK), and the social dimension is only partially addressed [3], [4]. UNESCO explicitly calls for integrating AI ethics into teacher education [2], and the OECD has documented a critical gap between teachers' technical skills and their readiness to analyze technological systems [5]. This gap is particularly relevant in the context of Kazakhstan's national policy, which has committed to digitalization and the development of AI literacy. Kazakhstan's Education Development Concept for 2023–2029 provides for updating computer science content, introducing AI elements into curricula, and training a new generation of teachers [6]. However, structural mechanisms to integrate ethical and social competencies into this preparation remain underdeveloped. This paper presents an AI-integrated three-component model for computer science teacher preparation, grounded at the intersection of international competency frameworks (DigCompEdu, TPACK, AI4K12), the Sustainable Development Goal (SDG) 4, the national context of Kazakhstan, and empirical data from a large-scale teacher survey. The scientific novelty lies in three contributions absent from prior work: (1) elevating ethical and social competencies to structural, non-optional elements of every training component rather than separate electives; (2) operationalising this integration through a cross-cutting matrix (3×4) that functions as both a curriculum design tool and an audit instrument; and (3) contextualising global frameworks (DigCompEdu, TPACK, AI4K12) within a post-Soviet pedagogical tradition, thereby creating a model directly applicable to Kazakhstan and similar national contexts.

II. THEORETICAL BACKGROUND

1. International Competency Frameworks

The DigCompEdu framework [4] defines seven areas of digital competence for educators and six proficiency levels (A1–C2), emphasizing the need for critical reflection on technology. Area 6, "Empowering Learners' Digital Competence," includes elements of digital citizenship, but the ethical dimension of AI – bias analysis, algorithm auditing, and data protection is not identified as a standalone competency. The TPACK model [3] holds that effective technology integration requires the simultaneous operation of technological (TK), pedagogical (PK), and content (CK) knowledge at their intersections: a computer science teacher must not only understand how AI works but also know how to teach it. Yet neither TK nor TPK contains an explicit ethical or social component.

The AI4K12 framework [7] identifies five big ideas in AI for K-12 education (perception, representation, learning, interaction, and societal impact), with the fifth idea directly addressing social consequences. The UNESCO Recommendation on the Ethics of Artificial Intelligence [8] articulates principles of fairness, transparency, and accountability. However, none of these frameworks offers a pedagogical architecture that structurally integrates the ethical and social dimensions into all components of teacher preparation.

2. The Structural-Functional Approach: Rationale for Selection

Educational theory offers several frameworks that describe the cyclical nature of professional development. Kolb's experiential learning cycle [9] models learning through experience as a four-phase sequence (concrete experience → reflective observation → abstract conceptualization → active experimentation) but does not differentiate types of professional readiness. Schön's reflective practice [10] emphasizes the role of "reflection-in-action" but focuses on a single component. Shulman's pedagogical content knowledge (PCK) [11], which became the foundation of TPACK, describes the intersection of subject-matter and pedagogical knowledge but does not include a motivational component.

Three advantages justify the choice of the structural-functional approach. First, structural completeness: the approach explicitly identifies four qualitatively distinct components of readiness – motivational, cognitive, activity-based, and reflective. This creates an architecture that embeds three-component integration across all components simultaneously. Second, a built-in motivational component: professional identity is treated as a foundational element, and developing a conscious attitude toward the ethical and social dimensions of AI is a necessary precondition for lasting competence [12]. Third, contextual compatibility: the approach has a strong tradition in pedagogical scholarship in Kazakhstan and the post-Soviet region, ensuring the model is practically applicable within the national context. The structural-functional approach was thus chosen not as an alternative to Western models but as the most appropriate architectural foundation, synthesizing insights from different pedagogical traditions. Kolb's cycle informs the activity-based and reflective components; Shulman's PCK resonates with the cognitive. The proposed framework provides a structure for simultaneously developing all four components of readiness across all three dimensions.

III. EMPIRICAL PROBLEM STATEMENT

To assess the scope of the problem in the national context, a survey of 899 computer science teachers from five regions of Kazakhstan was conducted in July–August 2025. A mixed methodology was used: a quantitative component (Likert scale, 1–5) supplemented by open-ended questions. The sample was purposive, ensuring representativeness by school type (urban/rural), teaching experience, and qualification category. Instrument reliability: Cronbach's $\alpha = 0.93–0.97$ across scales. Results are presented in Table 1.

Table 1. Assessment Results for Computer Science Teacher Competencies

Competency Area	M	SD	Level
Office Applications	4.26	0.94	High
Cloud Services	4.02	0.93	High
Cybersecurity	3.73	0.95	Moderate
Algorithmic Thinking	3.63	0.84	Moderate
Artificial Intelligence	3.48	0.91	Below average

The results reveal a consistent pattern: teachers are confident with familiar tools (office applications: $M = 4.26$; cloud services: $M = 4.02$) but lag significantly in areas that define new directions in computer science — artificial intelligence ($M = 3.48$), algorithmic thinking ($M = 3.63$), and cybersecurity ($M = 3.73$). The spread of SD values indicates considerable variability in preparation: some teachers have already adopted new technologies, while a large share remains at a basic level. A regional analysis found statistically significant differences between urban and rural schools: urban teachers scored higher on AI competencies ($M = 3.72$ vs $M = 3.21$, $p < 0.01$, $\eta^2 = 0.013$), confirming that the gap is real. However, its modest effect size suggests it cannot be resolved by targeting individual teachers alone — structural support in preparation programs is required. A parallel deficit appears in methodological competencies ($\alpha = 0.97$; composite $M = 3.77$): while teachers rated online platform use highly ($M = 3.89$), AI use in teaching scored only $M = 3.66$ and project-based learning $M = 3.47$ — confirming that the gap is not merely technical but extends to the pedagogical application of new technologies. Teachers know the tools; they lack a framework for integrating them meaningfully into instruction. This is precisely the gap the proposed model is designed to address. Open-ended responses corroborated the quantitative findings: 68% of respondents noted a lack of specialized professional development courses on AI, and 43% reported a shortage of teaching materials in Kazakh and Russian.

It is important to note that these data represent the lower bound of the problem. The survey measured technical and methodological competencies but did not include questions about ethical competency (the ability to analyze algorithmic bias and conduct ethical audits of AI systems) or social competency (awareness of digital inequality and assessment of the social consequences of technology). If technical competency — the most measurable and traditionally cultivated dimension — already shows gaps, the ethical and social dimensions, which are not systematically developed in current training programs, are likely at an even lower level. International evidence supports this conclusion: UNESCO [2] and the OECD [5] document the systematic absence of ethical competencies in computer science teacher preparation programs; Nabi et al. [13] note that issues of algorithmic bias, ethics, and data privacy remain underrepresented in such programs.

Moreover, the technical deficit cannot be addressed in isolation. A teacher who masters the inner workings of a neural network but does not understand why it can discriminate is not ready to teach AI in school. Technical knowledge without an ethical context is incomplete knowledge. This defines the structural priorities of the proposed model: not simply strengthening technical training, but simultaneously developing technical, ethical, and social competencies as interdependent dimensions.

IV. THE THREE-COMPONENT INTEGRATION MODEL

The model operates on two levels. The first is the structural-functional framework, which describes the overall architecture of preparation through four cyclically linked components. The second – and this is where the main scientific contribution lies – is the three-component integration of technical, ethical, and social competencies, which constitutes the model's innovative core.

1. The Structural-Functional Framework

Table 2. Structural-Functional Components of the Model

Component	Function	Key Mechanisms
Motivational	Builds professional identity	Career guidance, mentoring, success experiences, and role models
Cognitive	Develops integrated knowledge	Three-component integration; AI literacy; pedagogical competence
Activity-based	Applies knowledge in practice	Project-based learning, teaching practice, hackathons, service-learning
Reflective	Consolidates through metacognition	Reflective journals, peer-feedback, video reflection, mentoring cycles

The four components operate cyclically: motivational readiness creates conditions for learning; cognitive development provides a foundation of integrated knowledge; activity-based learning deepens knowledge through practice; and reflection transforms experience into lasting competence and generates new motivational impulses. The cycles are not strictly sequential – all four components are active at every stage of the preparation program, but with varying intensity.

The motivational component plays a particularly important role in the context of three-component integration. Technical motivation is built through career orientation in the AI industry and the experience of successfully creating working systems. However, ethical and social motivation require different mechanisms: mentoring by practitioners who have faced real ethical dilemmas; analysis of cases in which technologies amplified inequality;

and developing awareness of the computer science teacher's social mission as a guide to responsible technology. Without a motivational foundation, students treat the ethical and social components as a formality rather than as an integral part of the profession.

2. Three-Component Integration

The model's innovative core treats three competencies as equally important, interdependent dimensions. Technical competency includes programming and algorithmic thinking, AI system architecture (machine learning, neural networks, generative AI), cybersecurity, and Green IT — awareness of the environmental impact of digital technologies, energy-efficient software design, and responsible resource consumption. Green IT is deliberately placed within the technical dimension rather than the ethical one because its content is primarily about engineering choices (algorithm efficiency, server energy consumption, hardware lifecycle management) rather than value judgments. A future teacher who can compare the carbon footprint of two equivalent algorithms is better equipped to address SDG 13 (Climate Action) in a classroom context, reinforcing the model's grounding in the sustainability agenda.

Ethical competency is defined as an individual teacher's capacity to evaluate the moral dimensions of a specific technological artifact or pedagogical decision: it covers algorithmic bias analysis (bias audit), the principles of transparency, explainability, and accountability articulated in the UNESCO Recommendation [8], personal data protection and privacy, and digital citizenship. Social competency, by contrast, operates at the level of structural and societal consequences: it encompasses awareness of digital inequality at both the global and national levels (e.g., the documented gap between urban and rural schools in Kazakhstan), analysis of AI's impact on the labor market, service-learning as a method for integrating social design into the curriculum, and Social Impact Assessment of technological decisions. The key distinction is analytical: ethical competency asks, "Is this particular system fair and responsible?"; social competency asks, "What broader inequalities does this technology reinforce or alleviate?" Both are necessary because a teacher can uphold data-privacy principles while remaining unaware that the same tool widens the digital divide.

These three dimensions are inseparable. Technical competency without an ethical foundation produces specialists who can build powerful but potentially dangerous systems – a neural network trained on biased data will reproduce discrimination regardless of its technical quality. Ethical thinking without technical literacy produces critics who cannot engage with the systems they evaluate – it is impossible to analyze algorithmic bias without understanding how the algorithm works. Social awareness without the other two produces activists disconnected from the mechanisms of change.

Three-component integration directly addresses SDG 4. The ethical component ensures the fairness of educational technologies through systematic bias analysis and the protection of student data. The social component ensures inclusivity by raising awareness of and taking action on digital inequality. The technical component ensures quality education through sound technology management. The overall architecture of the model is presented in Figure 1.

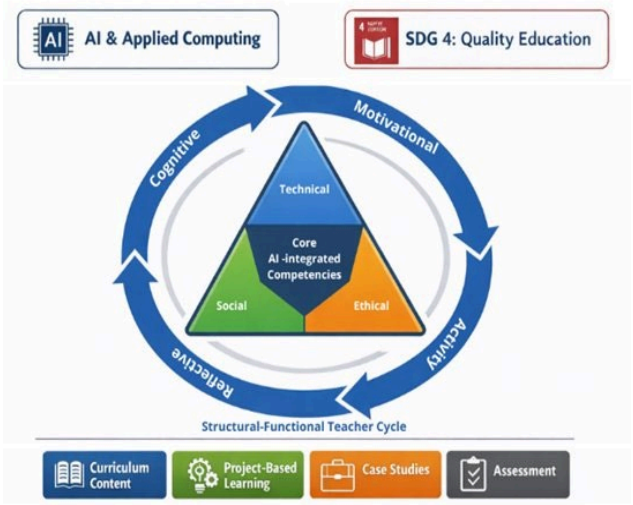

Figure 1. AI-integrated three-component model for computer science teacher preparation

3. Integration Levels and Implementation Examples

Integration is implemented at four levels. At the curriculum level, modules on AI ethics and social implications are embedded directly into technical courses rather than offered as separate electives.

At the case-study level, complex real-world scenarios are examined from all three perspectives. For example, the case "Using spreadsheets and databases in an informatics lesson" requires students to conduct a technical analysis — examining how data structures are organized and how sorting, filtering, and information retrieval are implemented; an ethical audit — ensuring responsible handling of student data without violating privacy or misinterpreting results; and a social evaluation — assessing whether the task creates additional barriers for students with different levels of digital competence and how it can be adapted for inclusive learning. At the same time, the discussion may incorporate elements of modern AI systems that operate on data, thereby expanding the context without going beyond the official curriculum.

Another example is the case "Using Python programming in student projects (e.g., developing a 2D game or a simple application)". Students analyze the technical aspects of development — program structure, algorithms, and interaction logic; ethical considerations — including acceptable content of digital products, responsibility for created materials, and issues of academic integrity when using pre-existing code; and social implications — such as differences in learning pace, access to devices, and availability of support outside school. Additionally, the impact of modern AI tools (e.g., code generators) on the learning process is examined, particularly how their use may either support or undermine students' independence.

Table 3. Sample Learning Objectives by Topic — "Methods of Teaching Computer Science" Course

Course Topic	Technical Objective	Ethical Objective	Social Objective
Designing a lesson on algorithms and data sorting	The student develops a lesson plan with clearly defined learning outcomes,	The student incorporates a case discussion into the lesson plan: what ethical	The student provides two differentiated versions of the lesson task — one for a

Course Topic	Technical Objective	Ethical Objective	Social Objective
	a step-by-step task structure, and assessment criteria aligned with the school curriculum.	risks arise when a sorting algorithm is applied to personal data (e.g., student records), and how should a teacher address this with pupils.	well-equipped urban school and one for a rural school with limited access to devices — and justifies the adaptations.
Designing a lesson on programming in Python	The student produces a full technological map of the lesson, including learning objectives, instructional methods, time allocation, and sample code tasks at three difficulty levels.	The student designs a classroom discussion protocol on academic integrity when pupils use AI code generators, specifying discussion questions and teacher response strategies.	The student analyses how unequal home internet access affects pupils' ability to complete programming homework and proposes at least one compensatory measure within the lesson design.

Table 3 illustrates how the three-component integration operates in a university methods course. Each objective describes what the student-teacher learns to design, analyze, and justify.

At the assessment level, evaluation criteria explicitly capture competencies across all three dimensions, making integration visible and accountable: the final project is assessed not only in terms of the technical quality of the developed instructional materials, but also in terms of the depth of ethical analysis of pedagogical decisions and the validity of the social evaluation of their impact on a specific group of learners.

4. The Cross-Cutting Integration Matrix

The key instrument of the model is the cross-cutting integration matrix (3×4), which shows how each of the three competency dimensions manifests across the four structural components of readiness (Table 4).

Table 4. Cross-Cutting Integration Matrix (3×4)

Dimension	Motivational	Cognitive	Activity-based	Reflective
Technical	Career orientation in AI	AI architecture, programming, cybersecurity	AI project development, hackathons	Technical analysis of decisions
Ethical	Professional responsibility of the teacher	AI ethics, bias analysis, data protection	Ethical audit of projects	Reflection on ethical dilemmas
Social	Awareness of social mission	AI and society, digital inequality	Service-learning, social design	Social impact analysis

The matrix illustrates the principle of structural simultaneity: no technical action is taken without ethical reflection and social evaluation. Each cell represents a specific educational objective that can be operationalized in a curriculum. For example, the cell "Ethical × Activity-based" is set to require a mandatory ethical audit for every student AI project, using a structured checklist. This distinguishes the model from frameworks that treat ethics as an add-on rather than a foundational element.

To make the matrix actionable for curriculum developers, a sample assessment rubric for a capstone AI lesson-design project assigns equal weight to each dimension: (a) Technical — correct AI tool selection, algorithmic soundness, cybersecurity safeguards in place (33%); (b) Ethical — bias audit completed with reference to UNESCO ICT-CFT principles, data-privacy protections explicitly documented (33%); (c) Social — explicit adaptation for rural or low-resource learners, inclusivity analysis provided (33%). The equal weighting is itself a pedagogical statement: it prevents the technical dimension from crowding out the other two, a documented risk when rubric design is not aligned with the integration model [12].

5. Pedagogical Conditions for Implementation

A review of the literature and the barriers identified in the empirical study led to the identification of six pedagogical conditions necessary for successful implementation of the model:

1. Integration of AI ethics into all computer science modules – not as a separate course but as a thread running through every discipline [2], [8]. In practice, this means a machine learning lab assignment should include a task on analyzing bias in the training dataset.

2. Availability of AI simulation tools and a case study library for modeling ethical dilemmas in a safe environment.

3. Interdisciplinary collaboration between departments of computer science and the humanities (philosophy, sociology), ensuring expertise in ethics and social theory.

4. Ongoing professional development for university faculty in AI ethics – a teacher who has no personal experience with ethical analysis of technology cannot develop that competency in students.

5. An institutional culture that values ethical reflection on a par with technical achievement – without this, students will treat the ethical component as a formality with no bearing on academic success.

6. Alignment of assessment criteria with all three competency dimensions: if 90% of the marks in a capstone project rubric go to technical execution and only 10% to ethical analysis, the integration model remains declarative.

Without all of these conditions being met simultaneously, a model that integrates ethical and social dimensions in theory may, in practice, default to a primarily technical program.

V. DISCUSSION

The proposed model makes three contributions to the existing literature. First, it elevates the ethical and social dimensions from supplementary modules to structural elements integrated into all components of readiness. This is a key distinction from approaches in which “AI ethics” is offered as a separate elective course, isolated from technical training. Research on computer science teacher preparation shows that lasting professional competencies develop when key content elements are embedded in disciplinary and pedagogical training rather than studied outside that context [12]. Analogous to the integration of computational thinking into teacher preparation programs, the ethical and social dimensions of AI should be embedded directly into the structure of technical disciplines, ensuring their organic integration into future teachers’ professional identity.

Second, the 3×4 matrix offers a concrete curriculum design tool. Unlike general declarations about the need for ethical education, the matrix shows exactly where each dimension appears at each stage of preparation. This shifts the discussion from declarations to design: a curriculum developer can use the matrix as a checklist to verify that each cell contains specific educational content.

Third, the model was developed at the intersection of international frameworks and Kazakhstan's national context, demonstrating how global principles can be adapted to regional conditions. The structural-functional approach, with its strong tradition in post-Soviet pedagogy, serves as a "translator" between international competency frameworks and local teacher preparation practice.

For Kazakhstan, the model is particularly relevant in light of the implementation of the Education Development Concept for 2023–2029 [6], which provides for updating computer science content and introducing AI elements. The current Concept emphasizes the technical aspects of digitalization. Still, the proposed model demonstrates that sustainable digital transformation of education is impossible without the parallel development of teachers' ethical and social competencies. The 3×4 matrix can serve as an audit tool for existing computer science teacher preparation programs at Kazakhstani universities, identifying "empty cells" – areas where the ethical or social dimension is absent.

The model complements rather than replaces existing frameworks. TPACK remains relevant for describing the intersection of knowledge types; DigCompEdu for assessing levels of digital competence; AI4K12 for content-level guidance. The proposed model adds an architectural foundation that ensures the structural integration of ethical and social dimensions across all components of professional readiness, functioning as a "meta-framework."

The study has several limitations. First, the model at this stage is a theoretical construct informed by empirical data but not yet experimentally validated. The empirical survey established the problem's relevance, not the model's validity. Second, reliance on self-reported data may overestimate actual competency levels: teachers tend to rate their own skills higher than objective tests would show. Third, the purposive sample, limited to five regions of Kazakhstan, does not allow generalization to the entire national education system. Fourth, as noted above, the survey instrument did not directly measure ethical and social competencies, a deliberate methodological limitation rather than an oversight.

At the same time, the very absence of validated instruments to measure the ethical and social competence of computer science teachers underscores the innovative nature of the proposed model and points the way for future work. How might ethical and social competencies be measured in practice? Existing psychometric approaches offer a useful starting point. Ethical competency can be assessed using scenario-based instruments, in which respondents analyze a vignette describing a biased recommendation algorithm or a data privacy breach. They are scored on the accuracy of their bias identification, the quality of their remediation proposal, and their reference to relevant principles. Such instruments echo established approaches in medical ethics education (Objective Structured Clinical Examination) and can be adapted to teacher preparation contexts. Social competency, operating at a structural level, is better captured through portfolio and performance assessments: for example, a Social Impact Assessment rubric applied to a student-designed lesson plan, or a structured reflection on how a specific tool might differentially affect urban and rural learners. Pre/post quasi-experimental designs using these instruments, combined with a Sustainable Digital Competency diagnostic instrument currently under development by the authors, constitute the measurement plan for the forthcoming pilot study. Directions for future work include: piloting the model at one or more Kazakhstani universities using a quasi-

experimental design; validating the scenario-based and portfolio instruments across institutional contexts; and conducting a comparative study with similar programs in Central Asian and post-Soviet countries.

VI. CONCLUSION

This paper has presented an AI-integrated three-component model for computer science teacher preparation, grounded at the intersection of international frameworks, sustainable development policy, and empirical data from a survey of 899 teachers across five regions of Kazakhstan. The model demonstrates that effective preparation of computer science educators in the age of AI cannot be limited to a purely technical focus. Technical, ethical, and social competencies must be developed simultaneously as interdependent dimensions of a unified professional system. The principle of structural simultaneity, embodied in the 3×4 matrix, ensures that all three dimensions are present at every stage of preparation.

The practical implications of the model include: (a) for curriculum developers – the 3×4 matrix as a tool for auditing and designing study plans; (b) for university administrators – a rationale for the necessity of interdisciplinary collaboration and institutional support; (c) for education policymakers – an argument for including ethical and social competencies in computer science teacher preparation standards.

The model can serve as a reference framework for education policy developers in Kazakhstan and in regions with similar conditions of digital transformation in education. Future work includes: experimental piloting of the model at a university; development of validated assessment instruments for all three dimensions, aligned with indicators of the DigCompEdu progression; and a longitudinal study of the effects of model implementation on teacher professional development and student learning outcomes.

Abstract
The gender pay gap in software engineering is often discussed as a labor-market outcome. Yet, existing estimates are shaped by how gendered participation in the profession is defined and measured. This paper presents a literature review of empirical studies published between 2016 and 2026 on gender pay gaps in software engineering and closely related IT roles. Following PRISMA 2020 guidelines, 28 studies were selected from Scopus, Web of Science, and IEEE Xplore and analyzed across three dimensions: factors affecting women's retention in or exit from software engineering; reported causes and characteristics of pay disparities; and methods used to estimate these gaps. The review shows that conventional human capital variables do not fully account for the observed disparities, and that organizational and sociotechnical factors influence both wage outcomes and women's retention in the profession. Recurrent threats to validity include broad role definitions, mixed employment contexts, and limited treatment of sample selection and survival bias. By integrating evidence on pay, retention, and attrition, the paper reframes the estimation of the gender pay gap in software engineering as a sociotechnical and methodological problem.

Keywords: gender pay gap; software engineering; attrition; literature review

I. INTRODUCTION

Despite decades of progress and formal commitments to equality in the technology sector, software engineering continues to show persistent gender inequalities, especially in the form of a gender pay gap and low retention of women in the profession. These patterns carry social and economic consequences for individuals, organizations, and the wider software ecosystem. Empirical studies show that conventional human-capital variables, such as education and experience in the human-capital theory sense [1], do not fully explain pay disparities in software engineering [2], [3]. Instead, wage outcomes are also shaped by organizational and sociological mechanisms, including biased performance evaluations, limited career progression, gendered labor market segmentation, unequal care burdens, and sociotechnical exclusion [4], [5]. This broader perspective matters because software engineering is embedded in institutional and economic arrangements that shape access, progression, and exit. A central challenge is that most pay-gap studies rely on samples of those currently employed in the sector. When workforce participation is non-random, estimates may be distorted by sample selection and survival effects, potentially leading to underestimation of inequality [6], [7]. Research on attrition and return pathways in technology work supports this concern and shows that retention is substantively as well as statistically important [8]. Software engineering also deserves separate attention from broader ICT categories because its work organization, including project-based deadlines, continuous upskilling, and promotion systems tied to visibility and access to high-value projects, may affect women disproportionately [2], [4]. Evidence from broader ICT and labor-market research further suggests that these processes do not operate uniformly across all technology occupations [9], [10]. In addition, software engineering combines technical prestige with organizational informality. While meritocratic ideals may reduce

inequality in principle, informal evaluation and culturally coded notions of who "fits" the field can reproduce disadvantage [11], [12]. Findings on glass-ceiling dynamics and organization-specific inequalities likewise indicate that pay gaps should be interpreted within wider institutional structures rather than as isolated salary outcomes [13], [14]. From this perspective, ignoring attrition may make inequality less visible [10], [15], while research on comeback pathways and gendered career trajectories reinforces the same interpretation [8], [16].

Accordingly, this paper synthesizes contemporary research (2016–2026) on the gender pay gap in software engineering, with particular attention to how gendered participation, retention, and exits shape the production and interpretation of pay-gap evidence. Using the PRISMA 2020 protocol, the review integrates findings from 28 studies to answer three research questions: (RQ1) which factors influence women's retention or exit from software engineering, (RQ2) what are the reported causes and characteristics of the pay gap, and (RQ3) which methods are used to estimate it. By linking retention evidence with pay-gap estimation practices, the review highlights where current approaches may mismeasure inequality and outlines implications for both empirical software engineering and gender-and-technology research. It argues that the visible population of senior women in software engineering may be selective rather than representative, meaning that apparent improvements in outcomes may partly reflect cumulative filtering of the labor force rather than reduced inequality [8], [16]. The review contributes by offering a structured synthesis of recent evidence, integrating pay-gap and attrition research, and showing that methodological design choices shape the empirical visibility of inequality, particularly when studies define samples through current sector participation [17], [7]. In this paper, "gender pay gap" refers to differences in earnings between women and men, both unadjusted and adjusted for productivity-related factors; "sample selection bias" refers to bias arising when inclusion depends on participation in the sector; and "survival bias" refers to conclusions based only on those who remain in the profession. This interpretation is consistent with labor-market research on computer-science workers [2], methodological work on pay-gap decomposition [7], and the original logic of sample-selection correction models [6].

II. METHODS

This review followed PRISMA 2020 recommendations to structure identification, screening, eligibility assessment, and synthesis. The aim was to make the review process transparent and reproducible while retaining enough flexibility to interpret heterogeneous evidence on pay, attrition, and labor-market participation in software engineering. The paper asks three research questions: **RQ1)** Which factors influence women's retention in, or exit from, software engineering? RQ2) What are the reported causes and characteristics of the gender pay gap in software engineering? **RQ3)** Which empirical and analytical methods are used to estimate the gender pay gap in software engineering?

Searches were performed in Scopus, Web of Science (WoS), and IEEE Xplore databases. The search strategy combined software engineering role terms, gender terms, and pay/retention terms. Filters were applied to include studies published between 2016 and 2026, written in English, and published as journal articles or conference papers. Studies from unrelated domains and studies focusing on students or school populations were excluded to maintain a labor-market focus. [17]. For this review, the inclusion of retention, turnover, and labor-force participation terms is especially important because the review addresses gendered participation in technology work, not only wage estimation formulas. Inclusion criteria covered empirical studies addressing pay, wages, earnings, retention, turnover, or career progression in software engineering or closely related IT roles; studies reporting gender-disaggregated outcomes or gender pay gap estimates; and peer-reviewed journal or conference publications (2016-2026, English). Exclusion criteria covered student-only samples, unrelated disciplines, duplicates, and records with incomplete metadata that prevented reliable assessment.

Where studies combined software engineering with broad ICT categories, this was retained but explicitly coded as a source of interpretive heterogeneity in the synthesis.

Search results were de-duplicated and screened in two stages: (1) title/abstract screening, followed by (2) full-text eligibility assessment. In total, 711 records were initially identified (Scopus: 514; WoS: 186; IEEE Xplore: 11). After screening and eligibility checks, 28 studies were included in the final synthesis. Both authors participated in study selection and appraisal. Rather than calculating a formal inter-rater agreement coefficient, we used a qualitative consistency check on a shared subset of records and resolved uncertainties through discussion. This procedure strengthened interpretive consistency, although the absence of a reported agreement statistic remains a limitation. The study selection process is summarized in Figure 1.

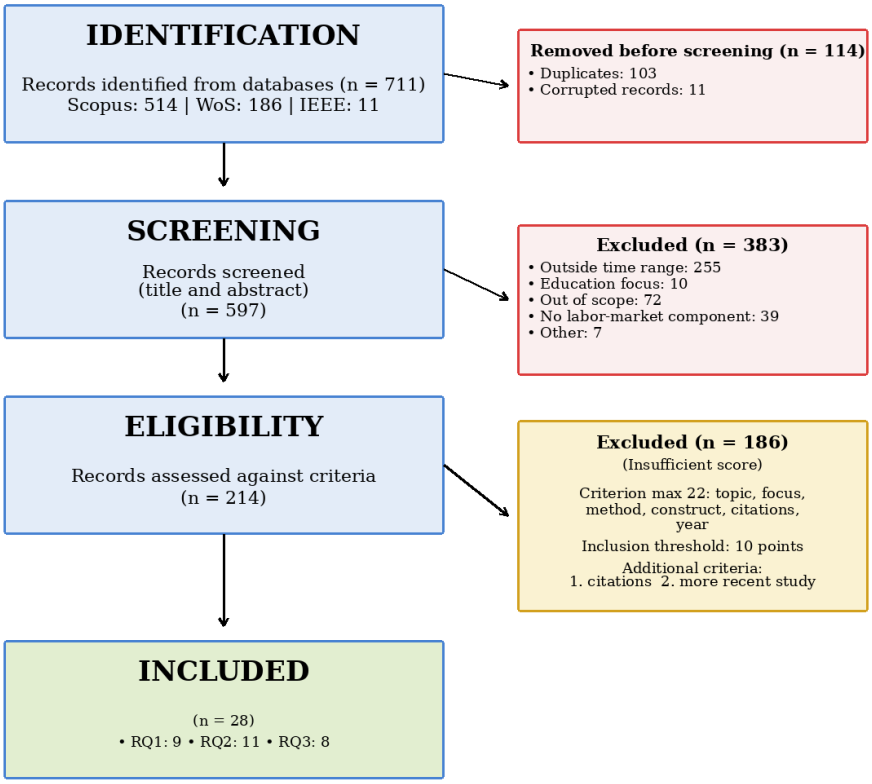

Figure 1. PRISMA 2020 literature selection flow diagram (Source: author's own elaboration)

To support the interpretation of heterogeneous evidence, a structured quality appraisal was performed at the study level. Given the diversity of study designs, the appraisal focused on role-scope definition (software engineering vs. broad IT), transparency of data and sample construction, control of key confounders, transparency of estimation methods, and discussion of attrition or non-participation. These criteria were selected because methodological work on wage gaps and studies of attrition in technology work both show that weak reporting can obscure how inequality is produced and observed [7], [6]. In this review, the appraisal also serves to identify how mechanisms of inequality are rendered visible or obscured by methodological choices. An evidence-weighting scheme (maximum 22 points) was retained as a secondary prioritization indicator (topic relevance, focus, method strength, theoretical construct, citations, and recency), while the quality appraisal functions as the primary basis for methodological interpretation.

For each included study, the review extracted country/region, population definition (SE vs. IT), employment context (corporate vs. freelance/self-employment where applicable), dataset type, sample size, outcome measure (pay/wage/earnings), estimation method (for example, OLS, Blinder-Oaxaca decomposition, quantile regression), controlled covariates, and key findings. Synthesis was narrative and thematic due to heterogeneity in populations, operationalizations, and methods, which precluded a meaningful quantitative meta-analysis. Themes were synthesized not only by method and outcome but also by the institutional and sociotechnical mechanisms that shape gendered participation and inequality. The review strategy was designed to balance software-engineering specificity with sufficient breadth to capture relevant adjacent IT roles discussed in the pay-gap literature. This choice reflects that many empirical studies do not clearly distinguish software engineers from software developers, ICT professionals, or broader technology workers. Rather than excluding such studies entirely, the review coded this domain ambiguity as an analytical issue in its own right [18], [9]. Broader comparative evidence on ICT work further shows why this distinction matters for interpretation [3]. A quantitative meta-analysis was not undertaken for both substantive and methodological reasons. The included studies differ substantially in the populations they examine, the operationalization of wages or earnings, the units of analysis, and the statistical models used to estimate gender differences. Some analyze corporate wage structures, others platform or freelance work, and others broader ICT labor markets, with only partial relevance to software engineering. Under such conditions, combining estimates into a single pooled effect would risk creating a misleading impression of comparability. Following PRISMA 2020 principles, the review instead emphasizes transparent documentation of selection and a narrative synthesis that foregrounds heterogeneity, methodological assumptions, and threats to validity [17]. The quality appraisal was also intended to go beyond a simple ranking exercise. In literature on gendered work, weak role definitions and poor reporting of sample construction can themselves be analytically significant because they shape which inequalities become visible in the evidence. Studies that do not separate freelancers from salaried employees, or that pool software engineers with broad ICT categories, may understate the organizational sources of inequality found in more role-specific analyses [19], [20]. The absence of discussion of attrition or non-participation adds a further interpretive limitation [7].

For language improvement, sentence-level restructuring, and grammatical checking, the author used ChatGPT (GPT-5.2 Thinking, OpenAI). The tool was used only to support wording, language refinement, and editorial consistency of author-written text. All substantive arguments, literature searching, study selection, appraisal, synthesis, interpretation, and final verification of the manuscript were performed and validated by the authors, in line with the publisher's AI policy [21].

III. RESULTS

A total of 711 records were identified across Scopus, Web of Science, and IEEE Xplore. After deduplication, screening, eligibility assessment, and evidence weighting, 28 studies were included in the final synthesis. The reviewed studies span multiple geographical contexts and combine journal articles and conference papers, with substantial variation in populations, data sources, and analytical methods. Cross-national evidence from Canada and Central Europe illustrates this heterogeneity [22], [18]. Additional studies from the Czech ICT context and broader IT settings point to similar variation in wage patterns and labor-market composition [23], [24]. Broader comparative work in IT also supports this reading [3]. This variation is analytically important because it reflects different labor regimes, occupational classifications, and institutional settings rather than only technical differences in datasets.

1. RQ1: Factors influencing women's retention in, or exit from, software engineering

The reviewed studies indicate that a non-linear interaction between structural constraints and organizational climate shapes women's retention in software engineering. Across contexts, retention is associated less with

pay levels alone and more with workplace inclusiveness, managerial support, promotion processes, and compatibility between job demands and family responsibilities [15], [10]. Several studies also highlight the protective role of role models and inclusive culture in reducing isolation and supporting persistence in the profession [12], [11]. These findings suggest that attrition is not random and should be understood as both a methodological concern and a gendered exclusion process within technology work. If women are more likely to exit due to adverse organizational or structural conditions, then the subgroup of women observed in wage datasets is positively selected [10], [15]. Return-to-work research in IT points to similar cumulative effects over time [8]. Across the reviewed studies, retention emerges as a cumulative process rather than a one-time decision. Women do not simply respond to one factor such as salary; rather, they navigate a layered environment in which work intensity, family demands, managerial support, promotion transparency, and role models jointly shape whether remaining in the field is perceived as sustainable [15], [8]. Evidence from firm-level studies further supports the importance of inclusive organizational cultures [12].

2. RQ2: Causes and characteristics of the gender pay gap in software engineering

The synthesis confirms that the gender pay gap is reported across multiple national and organizational contexts, although its magnitude and mechanisms vary. In many studies, a gap persists after controlling for conventional human capital variables, suggesting that differences in education and experience are insufficient to explain the observed disparities [22], [18]. The reviewed evidence instead points to structural mechanisms such as biased performance evaluation, glass-ceiling effects, and differential career progression [13], [5]. From a gender and technology perspective, these mechanisms should be read as part of broader gendered divisions of labor and organizational power. Professional norms and evaluation systems matter for advancement [13], [5], and they also interact with care-related constraints and occupational sorting in technology work [4], [2]. The results also show that the nature of the gap depends on employment context and job classification. Studies focusing on freelancing or platform-based work often report dynamics that differ from those observed in corporate settings [20], [19]. In organizations, compensation structures may also include opaque bonuses, promotion-related rewards, and evaluation-driven pay growth [25]. Wage gaps are also not static across contexts or career stages. In some national settings, gaps appear early among recent graduates or early-career professionals [22], [26]. In others, inequality becomes more pronounced through promotion systems, accumulation of seniority, or unequal access to high-reward roles [23], [27]. A further distinction concerns employment form. Studies focused on freelancing or firm ownership often find different gendered pay dynamics than studies of salaried corporate employment [20], [19]. These contrasts are analytically useful because they reveal which dimensions of inequality are specific to corporate hierarchies and which travel across labor-market arrangements [4].

3. RQ3: Methods used to estimate the gender pay gap

The dominant methodological approaches in the reviewed literature are regression-based models and decomposition techniques, especially the Blinder-Oaxaca decomposition. More recent studies extend this baseline through quantile regression, machine-learning-based prediction, and digitally oriented analyses of labor-market change [28], [27]. These methods improve descriptive granularity and may better capture heterogeneity across the wage distribution [29], [30]. Related work on digitalization and wage inequality also broadens the methodological context in which gendered pay outcomes are interpreted [31]. However, despite increasing methodological sophistication, explicit correction for sample selection remains rare in studies focused on software engineering and closely related IT roles. In practice, most models estimate pay gaps conditional on current participation in the sector, while treating labor-force presence as exogenous. This assumption is difficult to justify in a domain characterized by gender-differentiated retention and career interruptions [6], [7]. Attrition research in IT points to the same problem from a different angle [8]. From a gender and technology perspective, this methodological omission matters because it can depoliticize structural

attrition by treating exclusion from the field as analytically irrelevant to interpreting the pay gap. Methodologically, the literature demonstrates both progress and a persistent blind spot. On the one hand, the shift from simple mean comparisons to decomposition methods, quantile regression, and machine-learning approaches has improved the ability to distinguish between explained and unexplained components of wage disparities [28], [29]. On the other hand, many of these advances still operate on samples defined by current participation and therefore inherit the same underlying selection problem [30], [25]. This is where the absence of selection correction becomes especially consequential. Heckman's [6] formulation makes clear that when participation in the observed sample is non-random, estimated outcome equations may be systematically biased. Yet in the reviewed software-engineering and adjacent IT literature, the problem is more often acknowledged indirectly through concepts such as the leaky pipeline or career breaks than modeled directly in pay-gap estimation [8], [7].

4. Cross-study synthesis: recurrent threats to validity

Across RQ1-RQ3, five recurrent threats to validity emerge: (1) population-definition heterogeneity (software engineering vs. broad IT/ICT categories), (2) mixing of employment contexts (corporate employment vs. freelancing/self-employment), (3) incomplete treatment of compensation components, (4) limited modeling of attrition and non-participation, and (5) weak comparability of methods and covariate sets across studies. These issues recur across EU labor-market studies and work on platform or freelance arrangements [9], [20]. They also connect directly to methodological debates about correcting for composition and selection effects [19], [7]. These threats do not invalidate the literature; rather, they delimit what can be concluded and show how empirical visibility of inequality depends on methodological design choices.

IV. DISCUSSION

Table 1 synthesizes evidence across RQ1-RQ3 and makes explicit the methodological gap linking attrition, pay-gap estimation, and sample-selection/survival bias. The central contribution of this review is the identification of a methodological gap at the intersection of two research streams that are often studied separately: (1) women's retention and attrition in software engineering and (2) gender pay gap estimation. The former literature documents mechanisms that systematically affect who remains in the profession [15], [10], while the latter typically estimates pay differences among those currently employed [2], [27]. When these strands are not integrated, pay-gap estimates can be interpreted as if they were based on random samples of the original workforce. From a gender and technology perspective, this integration also reveals a sociotechnical inequality mechanism: institutions and work arrangements shape exits, and those exits, in turn, shape what later appears as evidence of equality.

Table 1. Research gap matrix linking findings from RQ1, RQ2, and RQ3 (Source: authors' own elaboration)

Factors influencing women's retention and exit in SE (RQ1)	**Causes of the gender pay gap (RQ2)**	**Applied methods (RQ3)**	**Identified research gap**
Organizational climate and support [15], [12]	Bias in performance evaluation [5]	Standard OLS regression [28], [32]	Sample selection bias OLS models estimated on a selected sample underestimate the true gap because they ignore women who left SE.

Psychological pressure [10], [11] Transparency [25]		Machine learning [31]	Lack of exclusion variables in models Psychological factors and transparency are rarely used as corrective factors in wage equations.
Family status [2], [4]	Glass ceiling [13], [33], [14]	Quantile regression [29], [30]	Survival bias Decomposition methods explain the gap only for the "survivors" in software engineering. The economic loss caused by exits from the sample is not estimated.
Career interruption [8]	Work arrangement [20], [19]	Comparative analysis of secondary data [9]	Ignoring the inactive population Standard wage analyses do not capture women temporarily outside the labor market.
Perception of the gender gap [9]	Global presence [3], [22], [18], [23], [24]	Blinder-Oaxaca [27] Resume/CV analysis [16]	Lack of correction Although theoretically recognized, a sample-selection correction method is not applied specifically to the software engineering domain.

The findings support stronger connections between empirical software engineering and gendered labor-process analysis. Future studies should report population scope with greater precision, distinguish software engineering roles from broader IT categories where possible, and explicitly discuss the implications of attrition and labor-force non-participation [9], [11]. The review also shows why structural barriers and wage dynamics should be interpreted together rather than separately [27]. The review also cautions against interpreting small observed pay gaps as evidence of equity when high differential attrition may already have reshaped the workforce and hidden cumulative disadvantage [10], [15]. Return pathways and re-entry studies suggest that this cumulative disadvantage is not always visible in cross-sectional pay estimates [8]. This review does not empirically test selection-correction models; however, it shows why such approaches are methodologically relevant for software engineering pay-gap estimation. In particular, the literature supports the need for future studies that jointly model workforce participation and wage outcomes, or otherwise assess the sensitivity of conclusions to plausible selection mechanisms [6], [7]. For gender and technology scholarship, this also implies a need for designs that better capture career interruptions, care-related constraints, and transitions between formal employment, freelance work, and non-participation [4], [2]. Comparative work on platform and self-employment settings suggests that these transitions may change how inequality is expressed rather than eliminate it [20], [19]. The review further highlights the value of richer longitudinal data and clearer reporting of role classifications, compensation structures, and career interruptions [27], [30]. It also supports closer attention to self-perception and invisible barriers in technology careers [16].

This review is limited by database coverage, publication-language restrictions, heterogeneity of included studies, and the absence of a quantitative meta-analysis. The synthesis also depends on the reporting quality of primary studies, which varies substantially across contexts and methods. In addition, because many studies conflate software engineering with broader ICT categories, some conclusions should be read as SE-centered rather than SE-exclusive. This is one of the central trade-offs of the review design: retaining broader ICT evidence improves coverage, but it also reduces precision when findings are interpreted as describing software engineering alone. The uneven maturity of the underlying literature also constrains the review's interpretation. Some studies use advanced quantitative methods but broad occupational categories, while others are more contextually specific but less directly comparable in statistical terms. In addition, the review necessarily relies

on what published studies report about their samples, variables, and model decisions; when attrition, bonus structures, or internal promotion criteria are not well described, this limits the precision with which one can assess the likely direction and magnitude of bias. These limitations do not undermine the value of the review, but they reinforce its central claim that stronger inference requires stronger reporting and more explicit treatment of participation dynamics. A further limitation is procedural. Both authors participated in study selection and appraisal, and uncertainties were resolved through qualitative discussion of a shared subset of records. However, the review did not calculate a formal inter-rater agreement statistic such as Cohen's kappa. This means that consistency was strengthened through collaborative judgment rather than quantified agreement, and the results should be read with that limitation in mind.

IV. CONCLUSION

This literature review shows that both wage-setting mechanisms and gendered retention and attrition shape the estimation of the gender pay gap in software engineering. By synthesizing evidence on pay disparities, exits from the profession, and analytical methods, the paper demonstrates that methodological choices can obscure or reveal inequality. Its main contribution is to show that pay-gap measurement, labor-force participation, and sociotechnical exclusion are analytically inseparable. The findings suggest that the issue is not only whether women are paid less than men, but also how software engineering is constituted as an observable labor market. Recent evidence from the broader IT sector also suggests that the interaction between experience and education may shape observed patterns in the gender pay gap [34].

Abstract
Digital identity systems are under increasing pressure from sophisticated fraud mechanisms and rapidly evolving user behavior, exposing the limitations of traditional static verification models and centralized architectures. Although Self-Sovereign Identity (SSI) introduces a paradigm shift by enabling decentralized identity ownership through decentralized identifiers (DIDs) and verifiable credentials (VCs), it primarily addresses identity authenticity and lacks mechanisms for continuous trust evaluation. This limitation creates a critical gap in modern digital ecosystems, where verified identities can still exhibit risky or anomalous behavior. This paper proposes a novel AI-driven trust framework that augments SSI with dynamic trust scoring, transforming trust from a static verification outcome into a continuously adaptive metric. The proposed architecture integrates cryptographic identity validation with real-time behavioral analytics, incorporating identity confidence, behavioral consistency, transaction risk, and contextual signals into a unified and time-dependent trust function. Privacy is preserved through Zero-Knowledge Proof (ZKP) mechanisms, enabling secure, selective disclosure of identity attributes without exposing sensitive data. At the same time, blockchain technology ensures transparency and auditability via an immutable record of trust-related decisions. To achieve scalability and real-time responsiveness, the framework adopts an event-driven architecture supported by distributed and federated learning techniques, allowing trust models to evolve without compromising data sovereignty. The main contributions of this work are a formal, time-dependent, and multi-dimensional trust-scoring function that augments SSI; a privacy-preserving reference architecture that unifies event-driven analytics, federated learning, and blockchain-based auditability; and an evaluation methodology that defines the accuracy, latency, privacy, and scalability metrics against which the framework should be validated. By bridging the gap between identity verification and behavioral trust assessment, the proposed model introduces a generalized, interoperable, and privacy-preserving trust paradigm applicable to finance, healthcare, IoT, and digital governance, representing a significant step toward next-generation digital identity systems that are adaptive, context-aware, and inherently trustworthy.

Keywords: Self-Sovereign Identity (SSI), Decentralized Identifiers (DID), Verifiable Credentials (VC), Artificial Intelligence, Trust Scoring, Zero-Knowledge Proof (ZKP), Blockchain, Behavioral Analysis, Digital Identity, Privacy-Preserving Systems, Federated Learning

I. INTRODUCTION

The rapid digitalization of services in finance, healthcare, telecommunications, and public governance has significantly increased the importance of secure and reliable identity management systems. Digital identity is no longer merely an authentication mechanism; it has become a foundational layer enabling trust, access control, and secure interactions in distributed environments. However, traditional identity systems, which are predominantly built on centralized architectures and static authentication models, are increasingly inadequate to

address the complexity of modern digital ecosystems. These systems operate under the implicit assumption that once a user's identity is verified, trust can be continuously granted without reassessment. This assumption fails to account for the dynamic and evolving nature of user behavior, as well as the growing sophistication of fraud, account takeovers, and insider threats [1].

Self-Sovereign Identity (SSI) has emerged as a transformative approach that shifts identity ownership from centralized authorities to individuals. By leveraging decentralized identifiers (DIDs) and verifiable credentials (VCs), SSI enables users to control, manage, and selectively share their identity attributes without relying on intermediaries. This decentralized model enhances privacy, reduces dependency on centralized data stores, and minimizes the risk of large-scale data breaches. Furthermore, cryptographic primitives such as Zero-Knowledge Proofs (ZKPs) enable users to prove specific claims about their identity without disclosing the underlying data, aligning with modern data protection regulations such as GDPR [2] and reinforcing the principle of data minimization [3]. Despite these advantages, SSI systems are inherently limited in their ability to assess trust dynamically. They provide strong guarantees about identity authenticity, but do not evaluate behavioral trustworthiness over time. In real-world scenarios, a verified identity does not imply benign behavior; legitimate users can still engage in anomalous or malicious activities due to compromised accounts, insider threats, or evolving behavioral patterns. This limitation highlights a fundamental gap between identity verification and trust assessment. Artificial Intelligence (AI) offers powerful capabilities to bridge this gap by enabling real-time behavioral analysis, anomaly detection, and risk assessment. Machine-learning models can continuously learn from user interactions and identify deviations from expected behavior patterns. However, existing AI-driven trust systems are typically centralized, opaque, and difficult to audit, raising concerns about the transparency, fairness, and trustworthiness of the decision-making process [4]. To address these challenges, this paper proposes a unified framework that integrates Self-Sovereign Identity with AI-driven dynamic trust scoring and is supported by blockchain-based auditability. By redefining trust as a continuously evolving metric shaped by behavioral and contextual factors, the proposed architecture enables adaptive, privacy-preserving, and verifiable trust evaluation, introducing a new paradigm for digital identity systems in which trust is continuously assessed rather than statically assumed. The principal contributions of this paper are fourfold. First, we formalize trust as a time-dependent, multi-dimensional scoring function that augments SSI without weakening its privacy guarantees. Second, we propose a privacy-preserving reference architecture that unifies event-driven behavioral analytics, hybrid AI models, federated learning, and blockchain-based auditability within a single trust layer. Third, we describe a trust-portability mechanism that allows verifiable trust attributes to be reused across domains through Zero-Knowledge Proofs. Fourth, we define an evaluation methodology that specifies the accuracy, latency, privacy preservation, and scalability metrics by which such a framework should be validated, as well as its qualitative advantages over static and centralized alternatives.

II. METHODOLOGY AND TECHNICAL FRAMEWORK

1. Self-Sovereign Identity Foundations

Self-Sovereign Identity (SSI) represents a fundamental paradigm shift in digital identity management by redefining how identity is established, controlled, and verified in distributed environments. Unlike traditional identity systems that depend on centralized authorities for credential issuance, storage, and validation, SSI introduces a decentralized architecture in which individuals retain full ownership and control over their identity data. This transformation is enabled through the integration of decentralized identifiers (DIDs), verifiable credentials (VCs), and cryptographic verification mechanisms, effectively eliminating the need for trusted intermediaries and significantly reducing vulnerabilities associated with centralized data repositories, such as large-scale data breaches and single points of failure [1], [3]. Within this architecture, decentralized identifiers

function as globally unique, persistent, and cryptographically verifiable identity references. Each DID is associated with a DID Document that contains essential cryptographic materials, including public keys and service endpoints, enabling secure authentication without reliance on centralized identity providers. These DID Documents are typically anchored on distributed ledger technologies, allowing independent resolution and verification by relying parties in a trustless manner. Complementing this structure, verifiable credentials provide a standardized and interoperable framework for expressing identity attributes; they are issued by trusted entities, stored in user-controlled digital wallets, and can be presented without requiring real-time communication with the issuer, thereby ensuring both scalability and privacy preservation across heterogeneous systems [4].

A defining characteristic of SSI systems is their support for selective disclosure and Zero-Knowledge Proof (ZKP) mechanisms, which significantly enhance privacy and data minimization. Using ZKP protocols, users can prove the validity of specific claims without revealing sensitive information [5]. For example, instead of sharing a full identity record or disclosing personally identifiable attributes such as date of birth or income, users can cryptographically demonstrate compliance with a predefined condition, such as being over a legal age threshold. This capability aligns with modern regulatory requirements, including GDPR, and minimizes unnecessary exposure of personal data [2]. However, despite these strong guarantees of identity, authenticity, and privacy, SSI systems inherently lack mechanisms for dynamically evaluating trust. They effectively answer the question of identity, that is, who the user is, but do not address behavioral trustworthiness, that is, whether the user can be trusted at a given time. This limitation becomes increasingly critical in modern digital ecosystems characterized by identity theft, account compromise, insider threats, and behavioral fraud.

2. Dynamic Trust-Scoring Model

To address this gap, the proposed framework introduces an AI-driven trust-scoring layer that operates alongside SSI, transforming trust from a static attribute into a continuously evolving metric influenced by behavioral, transactional, and contextual factors. Trust is modeled as a time-dependent, multidimensional function that incorporates identity confidence, behavioral consistency, transaction risk, and contextual signals. Identity confidence reflects the strength and reliability of the underlying credentials, including the issuer's reputation, the credential's freshness, and the precision of biometric verification [6]. Behavioral consistency evaluates the alignment between current and historical user activity patterns, enabling the detection of anomalies indicative of fraudulent behavior. Transaction risk assesses the inherent sensitivity and potential impact of user actions, while contextual signals capture environmental factors such as device characteristics, geolocation, network conditions, and temporal patterns.

Formally, let the composite trust score of a user u at time t be defined over the set of trust dimensions D = {IC, BC, TR, CS, XD}, corresponding to identity confidence, behavioral consistency, transaction risk, contextual signals, and cross-domain trust, respectively. Each dimension is mapped to a normalized score φi(u,t) ∈ [0,1], and the composite trust score is expressed as:

$$T(u,t) = \Sigma_i \, w_i(c) \cdot \varphi_i(u,t) \,, \qquad \Sigma_i \, w_i(c) = 1 \qquad (1)$$

where wi(c) are context-dependent weights that sum to one and c denotes the interaction context. For the transaction-risk dimension, φTR is defined as one minus the normalized risk, so that higher values consistently denote greater trustworthiness. Because trust must reflect recent behavior more strongly than distant history, the behavioral-consistency dimension aggregates the per-event consistency of the user’s event history using an exponential time-decay weight:

$$\varphi_{BC}(u,t) = (\Sigma_k \alpha_k c(e_k)) / (\Sigma_k \alpha_k) , \quad \alpha_k = exp(-\lambda (t - t_k)) \qquad (2)$$

where tk is the timestamp of event ek, c(ek) is its instantaneous consistency, and $\lambda \geq 0$ controls the decay rate. The composite score is continuously updated as new events arrive, enabling real-time and adaptive decision-making. A policy engine compares T(u,t) against context-specific thresholds: when T(u,t) falls below a threshold τ, the system triggers additional safeguards such as step-up authentication or Zero-Knowledge-based re-validation, whereas high scores permit low-friction access. For example, a user who consistently accesses a system from a specific location and device may suddenly initiate access from an unfamiliar environment. However, the identity remains valid under SSI, the behavioral deviation lowers φBC and hence T(u,t), triggering re-validation. This represents a significant departure from binary authentication models, introducing a continuous trust-assessment paradigm in which every interaction contributes to an evolving assessment of user reliability. Table 1 summarizes the trust dimensions and their mapping to data sources and AI techniques.

Table 1. Trust-Scoring Dimensions and Technical Mapping

Dimension	Description	Data Source	AI Technique
Identity Confidence	Credential strength, issuer trust, and biometric validation	VC, DID, KYC systems	Rule-based + classification
Behavioral Consistency	Alignment with historical user behavior	User activity logs	LSTM, anomaly detection
Transaction Risk	Risk level of specific actions	Transaction systems	Supervised ML
Contextual Signals	Device, location, time, network patterns	Device telemetry, metadata	Feature engineering + ML
Cross-domain Trust	Trust portability across systems	External trust oracles	Graph-based learning

3. System Architecture

From a system architecture perspective, implementing this model requires a scalable, low-latency, and event-driven infrastructure capable of processing large volumes of streaming data. Figure 1 summarizes the proposed architecture and the flow of information among its components.

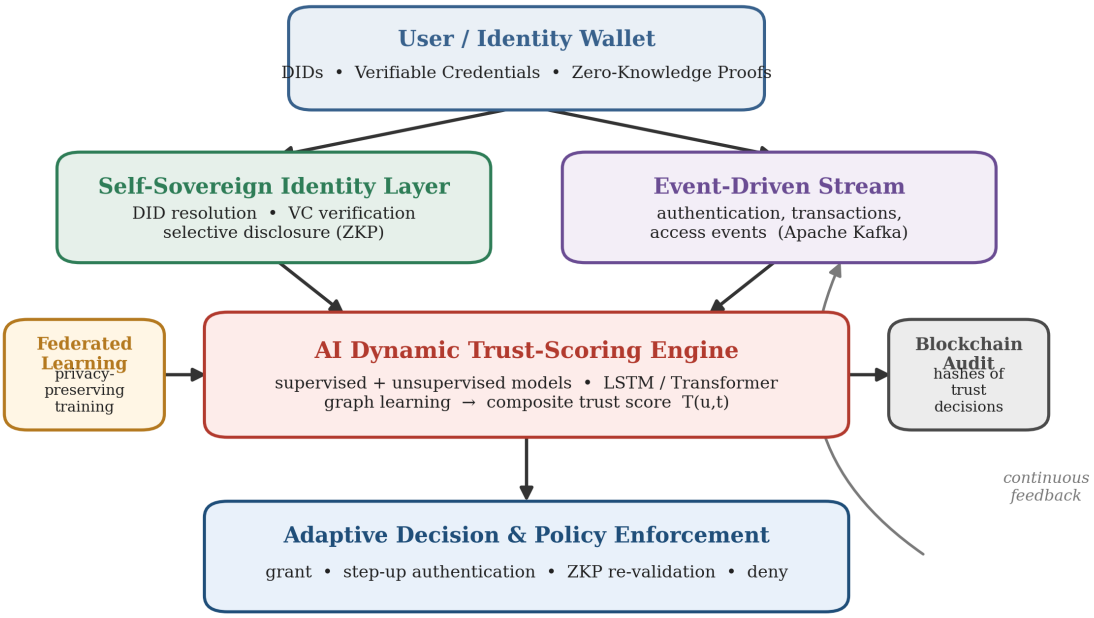

Figure 1. Reference architecture of the proposed AI-driven dynamic trust-scoring framework over Self-Sovereign Identity. *(system architecture)*

Each user interaction, such as an authentication attempt, a financial transaction, or a data access request, is treated as a discrete event and processed in real time by the trust evaluation engine. Events are ingested into a stream-processing pipeline, where machine-learning models analyze patterns, detect anomalies, and update trust scores with minimal latency. Technologies such as Apache Kafka and real-time processing frameworks enable efficient handling of high-throughput data streams, ensuring that trust assessments are performed without introducing system bottlenecks.

4. AI Modeling Layer

The AI layer in this architecture employs a hybrid approach that combines supervised and unsupervised learning techniques. Supervised models are trained on labeled datasets to identify known fraud patterns. In contrast, unsupervised models, such as anomaly-detection algorithms, can identify previously unseen threats by learning baseline behavioral patterns. In addition, sequence-based models such as Long Short-Term Memory (LSTM) networks [7] or Transformer architectures [8] can be employed to capture temporal dependencies in user behavior. Graph-based learning approaches further enhance the system by identifying complex relationships among entities, such as coordinated fraud networks or shared device usage patterns [9].

5. Privacy Preservation and Federated Learning

To address privacy concerns associated with centralized data processing, the proposed architecture incorporates federated learning, allowing machine-learning models to be trained across distributed data sources without transferring raw data to a central server [10]. This approach ensures data sovereignty and compliance with privacy regulations while maintaining model performance. Additional privacy-preserving techniques, such as

differential privacy [11] and secure multi-party computation, can further enhance the confidentiality of user data during model training and inference [12].

6. Blockchain-Based Auditability

Blockchain technology serves as a complementary component by providing an immutable and verifiable audit layer. Instead of storing sensitive identity or behavioral data on-chain, the system records cryptographic hashes of trust-related decisions, enabling independent verification without exposing the underlying information [13]. This design addresses the transparency limitations of AI-driven systems by providing a tamper-resistant record of decision-making processes, thereby increasing trust in both user interactions and system operations.

7. Trust Portability and Cross-Domain Interoperability

An additional dimension that extends the proposed framework beyond isolated identity and trust systems is the concept of trust portability and cross-domain interoperability, which fundamentally redefines how trust can be established, transferred, and reused across different platforms and organizational boundaries. In traditional architectures, trust is inherently siloed within individual systems, meaning that a user's reliability, reputation, or risk profile must be independently reassessed in each new environment. This leads to redundant onboarding processes, repeated verification steps, and significant inefficiencies in user experience. By leveraging the principles of Self-Sovereign Identity, trust can be partially decoupled from platform-specific contexts and instead associated with user-controlled credentials, enabling a more fluid and reusable trust layer [3].

Within this paradigm, trust is no longer confined to a single system but becomes a transferable attribute that can accompany the user across different domains. AI-generated trust scores or derived trust attributes can be embedded in verifiable credentials or dynamically generated through interoperable trust frameworks. For example, a user who has demonstrated consistent, low-risk behavior in a financial application may carry a cryptographically verifiable behavioral trust proof when interacting with a new service provider. Importantly, this proof does not expose raw behavioral or transactional data; instead, it relies on privacy-preserving constructs such as Zero-Knowledge Proofs or selective disclosure mechanisms to demonstrate that certain trust thresholds have been met [5].

This concept becomes particularly powerful in multi-domain ecosystems. Consider a scenario in which a user participates in a decentralized finance platform, a digital healthcare system, and an e-government service. Each of these systems may generate trust-related signals based on domain-specific interactions. Through an interoperable SSI framework, these signals can be abstracted into standardized trust indicators that can be reused across domains. For example, a high trust score in a financial system, reflecting consistent transaction behavior and low fraud risk, could contribute positively to access decisions in a separate system, such as granting expedited onboarding in a digital service platform. This reduces friction while maintaining a strong security posture. Similar cross-domain trust-propagation concepts have been explored in decentralized reputation systems and digital-trust frameworks [14], [15].

From a technical perspective, enabling trust portability requires defining standardized trust schemas and interoperable credential formats. Trust-related attributes must be encoded in a way that preserves semantic meaning across systems while remaining flexible enough to accommodate domain-specific variations. This introduces the need for trust-normalization mechanisms, in which scores generated in different environments are calibrated to a common scale or interpreted through context-aware weighting models. Without such

normalization, a trust score derived in one domain may be misinterpreted in another, leading to inaccurate or unfair decisions [14].

The role of decentralized reputation oracles further enhances this architecture by enabling the aggregation of trust signals from multiple independent sources. These oracles can act as intermediaries that collect anonymized behavioral indicators, compute aggregated trust metrics, and provide verifiable outputs to requesting systems. By operating in a decentralized manner, these oracles reduce reliance on single entities and mitigate the risk of manipulation or bias, while cryptographic guarantees preserve the integrity of aggregated trust data [13].

However, cross-domain trust sharing also presents several challenges. One primary concern is the risk of trust inflation or manipulation, in which users may attempt to artificially boost their trust scores in one domain to gain an advantage in another. To mitigate this, trust models must incorporate mechanisms for decay, contextual weighting, and anomaly detection. Additionally, the heterogeneity of trust requirements across domains necessitates adaptive scoring strategies that account for domain-specific risk profiles [15]. Privacy considerations are equally critical: techniques such as differential privacy, secure multi-party computation, and Zero-Knowledge Proofs can be employed to ensure that trust signals are shared without exposing underlying sensitive data [11], and user consent and control must remain central, allowing individuals to decide when and how their trust attributes are utilized across systems.

III. RESULTS AND DISCUSSION

The framework presented in this paper is architectural and conceptual; a full empirical evaluation on production-scale data is left for future work. Nevertheless, to make the proposal verifiable and comparable, this section defines the evaluation methodology, the metrics of interest, and the expected qualitative behavior of the system relative to existing approaches.

We envisage a prototype in which behavioral events are streamed via Apache Kafka, trust scores are computed by the hybrid AI models described in Section II, model updates are coordinated via federated learning across simulated organizational nodes, and decision hashes are anchored in a permissioned ledger such as Hyperledger Fabric. The framework should be evaluated along four dimensions. (i) *Detection quality* measures how accurately the trust score separates benign from malicious behavior, reported through precision, recall, F1-score, and the area under the ROC curve (AUC) on labeled fraud datasets and injected-anomaly scenarios. (ii) *Decision latency* measures the end-to-end time from event ingestion to trust-score update and policy decision, which must remain within interactive bounds, with a sub-second-per-event target, to support real-time authentication. (iii) *Privacy preservation* is assessed by verifying that raw behavioral data never leaves its origin node under federated training and by quantifying the utility–privacy trade-off introduced by differential-privacy noise. (iv) *Scalability* measures sustained event throughput and score-update latency as the number of users, events per second, and federated nodes increases.

Qualitatively, the proposed framework differs from prevailing approaches in three respects. Compared with static SSI verification, it adds a continuous, behavior-aware trust assessment, so that a valid credential no longer implies indefinite trust. Compared with centralized AI-based fraud-detection systems, it preserves data sovereignty through federated learning. It provides tamper-evident accountability through blockchain-anchored decision hashes, mitigating the opacity and single point of failure concerns of centralized models. Compared with decentralized reputation systems that expose reputation values directly, it discloses only Zero-Knowledge attestations that a trust threshold has been met, thereby preserving privacy during cross-domain reuse.

This analysis also surfaces the principal trade-offs. Federated learning and differential privacy improve privacy at some cost to model convergence speed and accuracy; blockchain anchoring adds auditability at the cost of additional write latency, which the design mitigates by recording only compact hashes rather than raw data; and cross-domain trust reuse improves user experience but requires trust-normalization and anti-inflation safeguards to remain sound. Establishing the quantitative operating points of these trade-offs, on representative datasets and workloads, together with an analysis of AI bias, explainability, and regulatory compliance, is the central objective of the planned experimental study.

IV. CONCLUSION

This study proposes a novel framework that integrates Self-Sovereign Identity (SSI) with AI-driven dynamic trust scoring to address the limitations of static and centralized identity systems. By distinguishing identity authenticity from behavioral trustworthiness, the model introduces a continuous trust-evaluation mechanism that adapts to real-time user behavior and contextual signals, formalized as a time-dependent, multi-dimensional trust function. The incorporation of Zero-Knowledge Proofs ensures strong privacy guarantees, while blockchain provides a transparent and verifiable audit layer, enabling accountability without exposing sensitive data. Together, these components establish a decentralized, privacy-preserving, and adaptive trust architecture suitable for modern digital ecosystems.

The proposed approach demonstrates that trust should be treated not as a fixed attribute but as a dynamic metric that evolves. While the framework offers significant advantages in security, flexibility, and interoperability across domains such as finance, healthcare, and IoT, challenges related to AI bias, explainability, and regulatory compliance remain. Guided by the evaluation methodology defined in Section III, future research will focus on prototype implementation and quantitative validation, improving model transparency, optimizing scalability, and developing interoperable trust standards. Overall, this work highlights a fundamental shift toward intelligent, context-aware trust models as a cornerstone of next-generation digital identity systems.

Abstract
This work proposes developing a physics-based digital twin (DT) system for detecting and locating leaks in high-pressure gas transmission pipelines. The DT is based on the quasi-steady Weymouth flow equation and discretized across N = 20 spatial segments. First-order dynamics are introduced using time constants derived from the acoustic wave speed, thereby capturing dynamic behavior. Two complementary techniques for leak detection are used and compared: dual-channel fixed-threshold testing at the 3σ level and dual-channel cumulative sum (CUSUM) testing. To localize leaks, a normalized least-squares error surface is evaluated across all candidate pipeline segments, with sub-segment resolution obtained using parabolic interpolation. A 60-seed Monte Carlo simulation is performed on a 40 km pipeline with a nominal leak size of 8%. The CUSUM detector achieves an average detection delay of 50 s, compared with 80 s for the 3σ detector. The 3σ detector exhibits no false alarms, whereas the CUSUM detector has a false alarm rate of 3.3%. The average localization error is 1.77 km, corresponding to a single 2 km pipeline segment. Additional evaluation under a benchmark scenario consistent with the literature demonstrates that the proposed method produces realistic detection behavior across diverse pipeline conditions. This study provides a computationally efficient, interpretable, and low-cost solution for simultaneous leak detection and localization that requires only standard inlet and outlet pressure measurements.

Keywords: SCADA, Digital Twin, CUSUM, gas pipeline monitoring, leak detection, Weymouth equation, residual-based fault detection

I. INTRODUCTION

The safety and reliability of natural gas transmission lines are of utmost importance for ensuring energy security in both developed and developing countries today. The absence of gas leak detection systems can lead to direct economic losses from product loss, environmental damage from methane emissions, and the risk of catastrophic accidents from ignited gas. Multiple regulatory frameworks govern the operational requirements for leak detection systems, including the ENTSOG standards in Europe and the PHMSA integrity management program in the United States. Consequently, operators are required to have leak detection systems capable of determining the existence and location of any leak by comparing the amount of gas lost against “threshold” levels established by regulatory bodies. Recent digital twin approaches have demonstrated detection accuracy exceeding 90% for leak rates as low as 1–3%, yet these methods lack localization capability, which the present work addresses [1]. Conventional supervisory control and data acquisition (SCADA) systems generally use pressure monitoring heuristics that are inherently reactive: an alarm is triggered when a transient pressure event propagates through the pipeline to an instrumented node, causing the node to exceed a predefined threshold. A comprehensive review of leak detection methods based on digital twin (DT) confirms that current models primarily focus on detection rather than on identifying leak size or location [2]. These systems can have high

false-alarm rates and limited sensitivity to very small leaks (e.g., less than 1%- 2% of the nominal throughput). They cannot provide information on the spatial location of the fault unless the system is instrumented with densely spaced sensors. Transient model-based methodologies (hydraulic simulators that run in real time alongside the physical pipeline) do not share the same shortcomings as traditional SCADA systems. However, the principal challenge with transient model-based methodologies is ensuring that the hydraulic simulator accurately models the physical pipeline's behavior, so that model-reality residuals remain statistically stationary under fault-free conditions. The contributions of this work consist of three primary dimensions. First, we present our work, which offers a digital twin built from the quasi-steady Weymouth equation using physics-based first-order dynamics. This model was also verified against a noisy simulation of an actual system. Next, the second contribution to the literature includes the two separate detection methods used for event detection within the pipeline. These have been compared using a Monte Carlo simulation to determine the distribution of detection delay. Lastly, the third contribution evaluates a least-squares localization algorithm that uses parabolic interpolation across sub-segments. Collectively, these contributions provide pipeline operators with an interpretable, computationally efficient, and infrastructure-compatible framework for managing both detection and localization under realistic operating conditions.

II. BACKGROUND AND RELATED WORK

There is extensive information available on model-based detection of pipeline leaks. Begovich et al. illustrated that pressure-flow residuals from a steady-state hydraulic balance can be used to detect leaks in water systems. However, they lack temporal sensitivity to transients [3]. Ostapkowicz used cumulative sum tests to detect flow-imbalance signals in pipe systems, resulting in several-minute detection delays for liquid pipelines; however, no method for localizing leaks was proposed [4]. Liang et al. proposed a data-driven DT method using an autoencoder-CNN architecture trained on normal operating data from a real gas pipeline, achieving 97% accuracy but providing no leak localization [5]. Unlike data-driven approaches, the present work derives all model parameters from first principles, eliminating the need for historical leak samples. The current study addresses a very specific need by providing a physics-based detection method that is computationally feasible for real-time applications and provides both detection and localization using a unified, interpretable set of methodologies. In model-based systems, leak location is often treated as an inverse problem. Given a library of fault signatures, one for each possible proximity to the fault, the objective is to find the fault signature that best explains the observed residuals. In pipeline systems, each possible segment produces a unique pressure-flow profile at each observable node, allowing calculation of the least-squares error between the measured pressure-flow profile and each potential profile, thereby creating an error surface with a well-defined minimum. This defined minimum error value will correspond directly with the location of the leak [6]. Table I summarizes the key characteristics of representative prior works, along with the results of the present study.

Table 1. Comparison of Leak Detection Methods

Study	Method	Localization	Validation	Key Findings	Main Limitation
Al-Ammari et al. [2]	Hybrid DT + residual analysis	Yes	Real-field + experimental	100% detection, ARE < 3.21%	Mainly steady-state evaluation
Liang et al. [5]	AE-CNN digital twin	No	Real pipeline	R^2 = 0.9915, low FAR	No localization

Study	Method	Localization	Validation	Key Findings	Main Limitation
Liang et al. [7]	CNN-BiLSTM-AM residual model	No	Two real pipelines	Small-leak F2 = 88.04%	High computational complexity
Ebrahimi et al. [8]	Deep-learning DT framework	Yes	Simulation	>98% localization accuracy	Requires large simulated datasets; limited interpretability
This study	Physics-based DT + CUSUM	Yes	Simulation + Benchmark validation	50s average delay; ≈1 segment localization error	Experimental validation needed

III. MATHEMATICAL MODELLING

1. Quasi-Steady Weymouth Equation

Physics-based models remain foundational to pipeline integrity management, as data-driven approaches depend on sufficient historical anomaly data, which is rarely available in field operations [9]. Consider a pipeline of length L = 40 km and inner diameter D = 0.6 m, discretized into N = 20 equal segments of length $\Delta x = L/N = 2$ km. The Weymouth pressure-drop relation describes each segment:

$$p^2_{i+1} = p^2_i - K_{seg} \cdot q^2_i, \quad i = 0, 1, \ldots, N-1, \tag{1}$$

where p_i is the absolute pressure at node i, q_i is the local mass flow rate, and K_{seg} is the per-segment hydraulic resistance coefficient, which is defined as:

$$K_{seg} = f_D \cdot \Delta x \cdot Z \cdot R_g \cdot T_g / (D \cdot A^2), \tag{2}$$

with Darcy friction factor $f_D = 4 \times 0.0045$ (smooth-pipe approximation), compressibility factor Z = 0.90, specific gas constant $R_g = 518.3$ J/(kg·K), temperature $T_g = 293.15$ K, and cross-sectional area A. The pipeline is driven by a time-varying inlet pressure $p_{in}(t)$ and delivers flow to an atmospheric-referenced outlet. Nominal operating conditions correspond to an inlet pressure of 50 bar and a baseline mass flow of approximately 103 kg/s.

Because the Weymouth equation is algebraic, it yields quasi-steady-state (QSS) values $p_{qss}(t)$ and $q_{qss}(t)$ instantaneously for any given boundary conditions. Physical pipeline dynamics dominated by acoustic wave propagation are captured by first-order filters applied to both pressure and flow:

$$dp/dt = (p_{qss} - p) / \tau_p \tag{3}$$

$$dq/dt = (q_{qss} - q) / \tau_q \tag{4}$$

Critically, the time constants are not treated as free calibration parameters but are derived from the acoustic wave speed in the gas. For isothermal compressible flow, $c_s \approx 348$ m/s, giving:

$$\tau_p = L / c_s \approx 115\ s \tag{5}$$

$$\tau_q = \Delta x / c_s \approx 5.7\ s, \tag{6}$$

τ_p is the whole-pipeline wave travel time, and τ_q is the single-segment response time. This physics-based parameterization eliminates a degree of freedom that is problematic to identify from operational data alone and ensures that the dynamic model remains valid without re-tuning.

2. Leak Model

A leak at segment i_{leak} is represented as a point mass extraction: the downstream flow becomes

$$q_d = q_u - m_{leak}, \tag{7}$$

where q_u is the upstream mass flow, q_d is the downstream mass flow, and m_{leak} is the leaked mass flow rate [3]. In the main validation scenario, mleak = $0.08 \times q_b \approx 8.2$ kg/s (8% of baseline), placed at segment 12 (x = 24 km from inlet) and activated at $t_f = 1200$ s (20 min). The real system (RS) receives additive white Gaussian noise on both pressure and flow sensors with standard deviations $\sigma_p = 0.004 \times p_0$ and $\sigma_q = 0.004 \times q_b$.

IV. DIGITAL TWIN AND DETECTION FRAMEWORK

1. Parallel Twin Architecture

Two identical Weymouth models run in parallel at each sample instant, with the sampling period of $\Delta t = 2$ s. The measured inlet boundary conditions drive the digital twin (DT), but the DT receives no information about the leak. The real system (RS) comprises the same physical pipeline model, augmented by the active leak and measurement noise. The DT outputs the predicted pressure $\hat{p}(t)$ and mass flow $\hat{q}(t)$; the RS outputs the measured pressure pm(t) and mass flow $q_m(t)$. Residuals are formed at the pipeline outlet as follows [2]:

$$r_p(t) = p_m(t) - \hat{p}(t) \tag{8}$$

$$r_q(t) = q_m(t) - \hat{q}(t) \tag{9}$$

Under fault-free conditions, both residuals are zero-mean with standard deviations equal to the sensor noise levels. A leak shifts r_p negative (lower measured pressure than predicted) and r_q negative (lower measured flow than predicted) simultaneously, enabling a dual-channel detection strategy that is inherently more robust to single-channel noise exceedances than univariate tests.

2. Dual-channel 3σ Detection

The fixed-threshold detector compares both normalized residuals simultaneously against the 3σ level. A fault flag $F_{3\sigma}$ is asserted if and only if both conditions hold over at least two consecutive samples [10]:

$$|r_{p(t)}| > \varepsilon_p \ \ AND \ \ |r_{q(t)}| > \varepsilon_q \tag{10}$$

where thresholds are defined as:

$$\varepsilon_p = 3\sigma_p, \quad \varepsilon_q = 3\sigma_q \tag{11}$$

The dual-channel AND logic reduces the probability of a false alarm by squaring the single-channel false alarm probability:

$$P_{FA,dual} \approx P^2_{FA,single} \approx 9 \times 10^{-5} \tag{12}$$

This approximation assumes independence between channels and therefore represents a lower-bound estimate.

3. Leak Localization and Magnitude Estimation

Following detection, the localization is formulated as a model-based inverse problem. The digital twin is re-simulated for each candidate segment $i \in \{0, 1, \ldots, N-1\}$, with a hypothetical leak of estimated magnitude $\hat{m}_{leak} = \hat{q} - q_m$. This yields candidate predictions $p_{model}(t; i)$ and $q_{model}(t; i)$. The least-squares error at time t is defined as the sum over a sliding window W of normalized squared residuals (30 samples):

$$e(i) = \sum_{t \in W} \left[\frac{\left(p_m(t) - p_{\text{model}}(t,i)\right)^2}{\sigma_p^2} + \frac{\left(q_m(t) - q_{\text{model}}(t,i)\right)^2}{\sigma_q^2} \right] \quad \square\square\square\square$$

The normalized least-squares cost function (Eq. 13) is adapted from Al-Khomairi's inverse problem formulation and extended here to include dual-channel (pressure and flow) residuals [6]. The coarse segment estimate is obtained by minimizing the error surface:

$$i_{est} = arg\ min_i\ e(i) \tag{14}$$

$$x_{est} = (i_{est} + 0.5) \cdot \Delta x \tag{15}$$

Once the fault flag is asserted, the leak magnitude is estimated from the flow residual:

$$\hat{m}_{leak}(t) = \hat{q}(t) - q_m(t) \tag{16}$$

This estimate quantifies the missing mass flow between the predicted and measured signals. Additionally, this approach is consistent with the mass-conservation approach in [4]. Under quasi-steady conditions, it provides information on the accuracy of the approximation of the true leak rate. To reduce noise and improve stability, the estimate is smoothed with a short moving-average window.

V. EXPERIMENTAL RESULTS

1. Main Scenario

Figure 1 demonstrates the system response for an 8% leak at 24 km. Before the leak, the digital twin and the measured signals matched quite closely. Following the leak, however, both pressure and flow clearly diverged, resulting in negative residuals. About detection of the leak via the dual-threshold method, there is an elapsed time of approximately 80 seconds before a leak is detected. However, when using the cumulative sum (CUSUM) method, the elapsed time to detect the leak is reduced to 50 seconds. Thus, indicating that the leak is detected at a faster rate with CUSUM than with the dual-threshold approach.

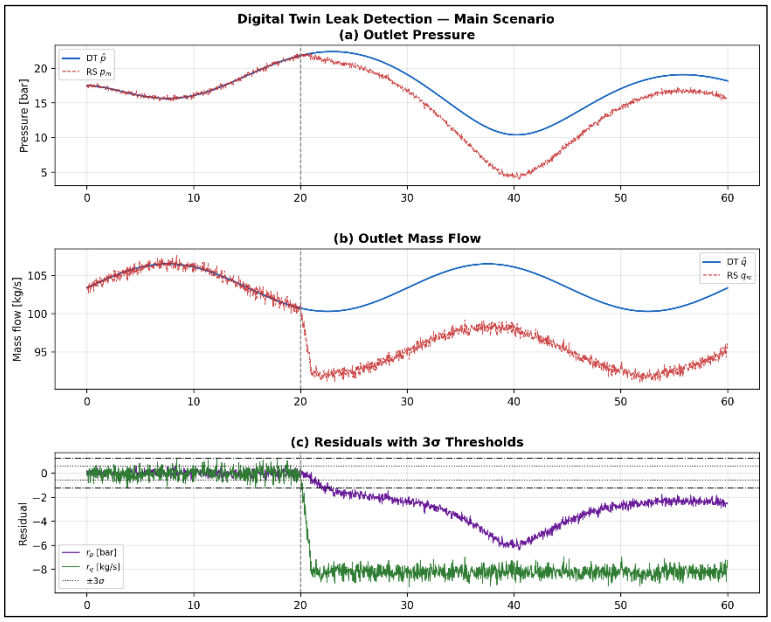

Figure 1. Main scenario. (a) Outlet pressure: DT prediction vs. noisy real-system measurement. (b) Outlet mass flow. (c) Dual-channel residuals with ±3σ thresholds

2. Monte Carlo Analysis

The accuracy of all detection and localization methods was assessed across 60 noise realizations to characterize the statistical distributions of relevant performance metrics. The average detection delay using the threshold-based method is 80 seconds, while the average detection delay using CUSUM is 50 seconds and exhibits statistically lower variability.

Figure 2(b) shows the distribution of the localization error obtained using the least-squares residual surface with sub-segment interpolation. In terms of leak localization accuracy, the localization error is predominantly within a single pipeline segment, centered at 1.77 km with a 95% confidence interval of [1.27, 2.16] km, thereby supporting consistent, accurate detection and localization regardless of noise.

Figure 2(c) summarizes the mean detection delays and associated 95% confidence intervals for both detection strategies. Overall, the Monte Carlo analysis indicates that the proposed digital twin framework delivers stable, statistically consistent leak detection and localization performance under measurement uncertainty.

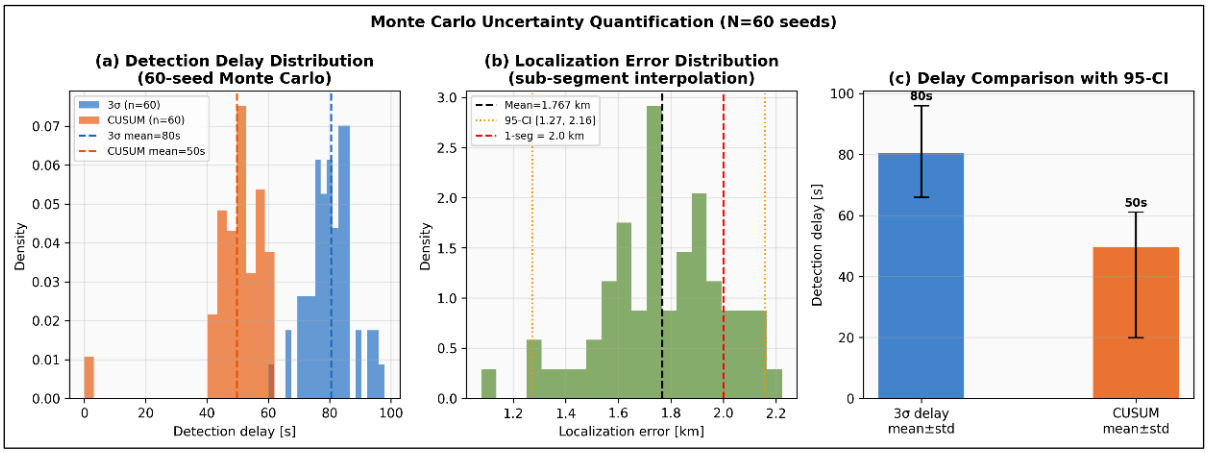

Figure 2. Monte Carlo uncertainty quantification. (a) Detection delay distributions for 3σ (mean 80 s) and CUSUM (mean 50 s). (b) Localization error distribution: mean 1.77 km, 95-CI [1.27, 2.16] km. (c) Delay comparison with ±1σ error bars.

3. Localization: LS Error Surface and Temporal Convergence

The localization algorithm converges to the correct region after the transient phase. While instantaneous estimates may fluctuate due to noise, temporal filtering stabilizes the result within 1 km of the true location. Figure 3 presents localization performance for the primary scenario examined. The LS reference error surface e(i) after t = 30 min is shown in panel (a). The location of the global minimum was segment 10; using parabolic interpolation gives an approximate new location estimate of 20.42 km. Given that the actual leak is located at segment 12 (x=24 km), with the addition of a median filter over the entire period after event onset, the final estimate is 23.258 km, corresponding to a localization error of 0.742 km. Figure 3(b) illustrates the time-series evolution of both unfiltered and filtered location estimates (represented by the orange and red colored dots).

To analyze generalization, the proposed method was qualitatively evaluated against published benchmark behavior, as per [4]. During this test, a 3% leak over 57 km was detected associated with this pipeline configuration. Under these circumstances, the CUSUM detected the leak in 134 seconds, which falls within the 3 to 8 minutes range reported by CERA [4]. On the contrary, the fixed 3σ threshold method took much longer, at 1736 seconds, to detect the leak, which reflects the low sensitivity of this method to leaks of that magnitude. Although the benchmark pipeline uses liquid flow, the acoustic-delay and flow-imbalance principles underlying the CUSUM detector are analogous, and the comparison is therefore indicative rather than directly equivalent. These results are consistent with existing literature indicating that cumulative detection methods are superior to fixed-threshold detection methods for detecting small-amplitude faults. Thus, it has been confirmed that the proposed framework yields realistic and comparable leak detection across various pipeline regimes.

VI. DISCUSSIONS

All components of the proposed framework are derived from physical pipeline principles, providing transparency and interpretability for safety-critical applications. The CUSUM detector has reduced the detection delay from 80 seconds to 50 seconds, thereby demonstrating its utility for small leak detection. The accuracy of localization stays within the bounds of one segment (±2 kilometers) using only traditional inlet and outlet measurements, therefore making this technique practical to use with existing infrastructure. The performance of the localization is sensitive to model calibration; for example, a ±10% error in the friction coefficient would degrade accuracy, indicating the need for periodic calibration.

Several limitations of the present study warrant acknowledgment. The current work uses a simplified isothermal model, relies on simulated data, and assumes a single leak. The present framework assumes a single active leak. Numerical studies indicate that when two simultaneous leaks occur, the smaller leak becomes undetectable if its size is below 25% of the larger leak, a limitation that future extensions of this work should address [11]. Real-world variability, including changes in gas composition, was not included in the analysis. Additionally, the framework was validated exclusively on simulated data, which represents a significant limitation relative to field deployment. The CUSUM detector's performance is sensitive to the choice of drift parameter k and control limit h, which were empirically tuned for the simulated scenario; an automated tuning procedure would be required across different pipeline configurations. Furthermore, the localization accuracy reported here assumes a single active leak; the framework does not extend to multiple simultaneous leaks, a scenario that warrants future investigation. Future work will include parameter estimation, validation against actual data, and extension to multi-leak detection scenarios.

VII. CONCLUSION

A physics-based digital twin framework has been developed and validated for detecting and locating leaks in gas pipelines. This approach utilizes both residual analysis and two detection strategies, threshold and CUSUM, providing reliable detection with 50 to 80-second delays and relatively low false-alarm rates. Leak localization is performed using a least-squares scanning method, yielding an average error of 1.77 km along a 40 km

pipeline. The results indicate that the method works reliably under normal operating conditions; however, it is sensitive to model mismatch, underscoring the importance of regular calibration of the entire system.

In summary, the framework's overall results indicate that a physics-based approach to leak detection and localization offers a computationally efficient solution that does not require machine learning to produce accurate, interpretable results.

ACKNOWLEDGEMENT

Special thanks to Associate Professor Dr. Naila Allahverdiyeva for supervision and guidance throughout this research.

Evaluating Quantum Computing Use Cases in Banking: A Sequential Model-Risk Admissibility Framework

Anandasubramanian Pranatharthy Codangudi
PhD Candidate, Department of Economics
VELS University
Chennai, India
anandcp@mac.com

Abstract
Quantum and hybrid methods are increasingly proposed for banking workloads, but theoretical speedups and favorable benchmarks do not establish that a regulated bank should pilot a given use case. What a bank needs is narrower: whether a specific candidate has enough surviving evidence to justify the next, more expensive stage of evaluation. This paper contributes a quantum-specific pre-pilot falsification framework built on four evidence objects: mechanism and advantage-source fit, classical benchmark sufficiency, encoding and end-to-end cost survivability, and governance admissibility. The gates are applied in a dependency-informed default sequence, distinguishing satisfied conditions, unresolved conditions, affirmative failures, and deployment-specific questions that cannot yet be assessed. Applied illustratively to the reviewed corpus, quantum amplitude estimation for pricing and risk is deferred; quantum optimization is deferred pending comparison against strong classical solvers; quantum machine learning that depends on quantum random access memory is rejected where dequantization applies; and near-term quantum machine learning is deferred. These are classifications based on the evidence reviewed, not on measured performance. The framework demonstrates no quantum advantage, has not received regulatory approval, and has not been empirically validated.

Keywords: quantum computing in finance, model risk management, classical benchmarking, pre-pilot screening, banking governance

I. INTRODUCTION

Banks use computationally intensive models for pricing, exposure assessment, risk management, optimization, and financial crime screening. Quantum and hybrid methods have been proposed for several of these workloads, but theoretical promise alone does not justify a bank pilot. Three claims must be separated. An algorithm may have an asymptotic advantage under stated assumptions; that advantage may or may not survive data preparation, encoding, execution, and a strong classical comparator; and an end-to-end advantage may still fail deployment requirements for validation, monitoring, controls, and reversibility. A bank, therefore, needs to know whether a specified candidate deserves the next unit of evaluation effort. The required evidence already exists in separate literatures: quantum mechanisms and resource estimates, classical benchmarking, encoding costs, model-risk governance, and staged investment under uncertainty. The gap is their integration into a pre-pilot decision protocol for regulated banking. This paper asks what evidence a quantum or hybrid banking use case must survive before further evaluation resources are committed. The proposed protocol uses four evidence objects: G1, mechanism and advantage-source fit; G2, strong classical benchmark sufficiency; G3, encoding and end-to-end cost survivability; and G4, governance admissibility. The default order is dependency-informed, not proven optimal. PASS permits normal advancement; CONDITIONAL permits diagnostic examination of later gates but remains binding; FAIL stops normal progression. Decisions are PROCEED, DEFER, REJECT, or REFRAME. The paper introduces no quantum algorithm or regulatory rule, proves no quantum advantage, and does not empirically validate the framework. SR 26-2 [1] and PRA SS1/23 [2] are governance reference points applied

within their stated scope and by analogy where appropriate. Sections II-III establish prior art and method, Section IV applies the framework, and Sections V-VII discuss implications, limitations, and conclusion.

II. RELATED WORK AND CONTRIBUTION GAP

1. Sequential Evaluation as Prior Art

Stage-Gate uses staged Go/Kill decisions [3]; real-options theory explains contingent commitment under uncertainty [4]; sequential experimentation values further information against acquisition cost [5]; and test-ordering theory shows that cost, rejection probability, and precedence can affect expected resource use [6]. These are prior art, not contributions of this paper. What they do not provide is quantum-banking test content: the correct classical comparator, whether data preparation destroys a speedup, or which governance requirements apply to a proposed banking model.

2. Pricing and Risk: Mechanism, Comparator, and Encoding

For pricing and risk, quantum amplitude estimation (QAE) offers $O(1/\varepsilon)$ expected-value query scaling, compared to $O(1/\varepsilon^2)$ for standard Monte Carlo under stated preparation assumptions [7], with applications to value-at-risk (VaR) and conditional value-at-risk (CVaR) [8]. For admissibility, however, the relevant comparison is stronger: quantum-accelerated multilevel Monte Carlo (MLMC) provides one such benchmark setting [9]. Resource estimates remain large: a representative derivative-pricing case requires about 8,000 logical qubits and T-depth 5.4×10^7 [10], reduced to about 4,700 qubits in a quantum-signal-processing formulation [11]. More importantly, Grover-Rudolph state preparation can eliminate QAE speedup for the distribution class studied [12], while mitigation is distribution-specific [13]. Thus, the query advantage does not establish an end-to-end advantage. Within this structured corpus, no peer-reviewed paper establishes that real bank pricing or risk distributions preserve the required state-preparation advantage end-to-end or convert resource estimates into bank-operational stop rules.

3. Optimization and Quantum Machine Learning

For optimization, comparator strength is binding. Quantum approximate optimization algorithm (QAOA) portfolio performance is sensitive to formulation, depth, and hardware [14]; quantum interior-point methods remain impractical at near-term scales [15]; and classical simulated annealing has outperformed quantum annealing in a studied multi-objective portfolio setting [16]. Hybrid annealing and constrained-QAOA studies provide evidence of implementation but do not establish an advantage over a modern mixed-integer programming (MIP) solver or an equally strong problem-specific baseline [17], [18]. For quantum machine learning (QML), input access and baseline choice are central. Quantum random access memory (QRAM)-dependent speedup claims carry strong practical assumptions [19], and dequantization shows that, for some such claims, equivalent classical data access removes the purported quantum advantage [20]. Classical data-rich models can also be competitive [21]; on finance data, preprocessing can drive apparent QML advantage [22], while quantum deep hedging at 16 qubits achieved comparable rather than superior accuracy [23]. No peer-reviewed paper identified in this corpus establishes a quantum advantage in optimization or QML over strong classical baselines on operationally realistic banking problems.

4. Hardware, Governance, and Evidence Boundaries

Hardware assumptions are dated inputs: noisy intermediate-scale quantum (NISQ) limitations and barren plateaus constrain variational methods [24], [25], while advances in fault tolerance can materially revise resource budgets [26].

SR 26-2, which superseded SR 11-7 and SR 21-8 in April 2026, supplies the current U.S. interagency model-risk framework within its stated scope [1], [27]; PRA SS1/23 supplies the UK reference point [2]. Neither creates quantum-specific validation rules. They are used here as governance principles, not as evidence of regulatory approval. The review is structured, not systematic: the corpus was assembled for framework construction, was current to May 2026, and used no preregistered search or independent second coding. Absence claims, therefore, mean only that no paper was identified in this corpus.

5. Surviving Contribution

The contribution is not staged screening, real options, sequential testing, mechanism analysis, benchmarking, resource estimation, or model-risk validation. It is their domain-specific integration into necessary-condition tests for a specified quantum banking candidate: mechanism source, strong classical comparator, end-to-end cost, and governance admissibility. The G1-G4 order is a dependency-informed default, not a proven cost-minimizing sequence. Test-ordering theory permits different orders when costs, rejection probabilities, and precedence differ [6]. This paper estimates none of those parameters; a cheap, decisive constraint may therefore be examined earlier.

III. METHODOLOGY: PRE-PILOT ADMISSIBILITY FRAMEWORK

1. Assessment Object and Sequence

The framework assesses a specified candidate, not a technology family. A candidate fixes seven elements: banking workload; claimed quantum mechanism and advantage source; data/input model; hardware assumption; classical comparator; operational time budget; and deployment boundary. A material change creates a new candidate. Thus, "QAE accelerates derivative pricing" is not assessable until the calculation, input/access model, hardware, comparator, accuracy/time requirement, and deployment boundary are specified. The default sequence is G1 - G2 - G3 - G4. PASS permits normal advancement. CONDITIONAL permits later diagnostic assessment but remains binding and blocks PROCEED. FAIL stops normal progression; later assessable gates are NOT REACHED. A cheap, decisive constraint may be examined earlier.

2. Four Evidence Gates

G1 - Mechanism and advantage-source fit. The candidate must identify the quantum mechanism, computational structure, hardware/input assumptions, and claimed source of advantage. FAIL requires no identifiable mechanism, a merely quantum label, or applicable evidence that the claimed advantage arises from asymmetric input access rather than the quantum mechanism. If the mechanism is genuine but a classical method matches it, the issue belongs to G2. G2 - Strong classical benchmark sufficiency. The claimed benefit must outperform a credible contemporary comparator for the same task, with matched data access, accuracy, number of instances, and operational constraints. Examples include MLMC with variance reduction for the QAE formulation [9], adjoint algorithmic differentiation (AAD) for suitable sensitivities [28], modern MIP- and problem-specific

solvers for optimization, and tuned classical classifiers. Missing decisive comparison is CONDITIONAL; matched evidence showing no benefit is FAIL.

G3 - Encoding and end-to-end cost survivability. The advantage must survive material preparation, loading, oracle/payoff construction, constraint encoding, connectivity, repeated execution, and, where applicable, measurement costs. Herbert shows why: state preparation can remove QAE speedup for the studied method and distribution class [12]. Unquantified material cost is CONDITIONAL; evidence that it negates the advantage is FAIL.

G4 - Governance admissibility separates class-level requirements from deployment evidence.

G4a asks whether applicable controls or structural constraints can be identified from supervisory/model-risk principles [1], [2]. It does not confer approval and may be examined early when a decisive constraint is known.

G4b asks whether a specific institution and implementation can provide required validation, monitoring, lineage, integration, fallback, third-party, and jurisdictional controls. Without an institutional deployment, it is NOT ASSESSABLE AT CLASS LEVEL, a scope designation rather than an adverse status.

Table 1. Operational Coding Rules

Gate	Test	Minimum evidence	Stop condition
G1 — Mechanism and advantage source	Is the claimed advantage attributable to a specified quantum mechanism under the stated input model?	Named mechanism; computational structure; hardware and input assumptions; claimed source of advantage	No identifiable mechanism; quantum label only; applicable evidence shows the claimed advantage comes from asymmetric input access rather than the quantum mechanism
G2 — Classical benchmark	Does the claimed benefit survive an appropriately strong classical comparator under matched conditions?	Credible contemporary comparator; matched data access, accuracy, instance, and operational constraint	**CONDITIONAL** if decisive matched comparison is missing; **FAIL** if matched evidence shows the claimed benefit does not survive
G3 — End-to-end cost	Does the claimed advantage survive the relevant computational pipeline?	Material preparation, loading, encoding, execution, and measurement costs were quantified where applicable	**CONDITIONAL** if a necessary material cost remains unquantified; **FAIL** if evidence shows the cost negates the claimed advantage

Gate	Test	Minimum evidence	Stop condition
G4a — Class governance	Can applicable controls or structural constraints be identified?	Relevant supervisory or model-risk principles and use-case characteristics	**CONDITIONAL** if material requirements remain unresolved; **FAIL** only where an identified structural constraint prevents the specified formulation
G4b — Deployment governance	Can the institution and implementation satisfy applicable requirements?	Deployment-specific validation, monitoring, lineage, integration, fallback, third-party, and jurisdictional evidence	**FAIL** only where required controls are demonstrably absent or inadequate; otherwise, outside scope when no deployment is specified

[a] Source: Author framework; gate criteria draw on [1], [2], [9], [12], and [28].

3. Coding and Decision Rules

Each assessable gate receives PASS, CONDITIONAL, FAIL, or NOT REACHED. PASS satisfies the necessary condition; CONDITIONAL marks unresolved evidence or assumptions; FAIL requires affirmative evidence that the condition does not hold; NOT REACHED follows an earlier FAIL. Missing evidence is therefore not converted into failure. Gate findings yield PROCEED, DEFER, REJECT, or REFRAME. PROCEED permits the next bounded step with no unresolved necessary condition; DEFER leaves a potentially satisfiable condition unresolved; REJECT records affirmative failure for the assessed formulation; REFRAME changes a material candidate element and therefore creates a new candidate.

4. Scope and Boundaries

The framework is an expert-review pre-pilot screen, not production validation, regulatory approval, procurement scoring, automated compliance, or a proven cost-minimizing algorithm. Whether it improves decisions, reduces evaluation expenditure, or yields reproducible classifications remains an empirical question.

IV. ILLUSTRATIVE APPLICATION

This section applies Section II evidence using Section III rules. Classifications are the author's analytical judgments of specified formulations, not measured performance, regulatory determinations, or empirical validation.

1. Quantum Amplitude Estimation for Pricing and Risk

For QAE pricing/risk, G1 is PASS because QAE has an identifiable mechanism and theoretical query-complexity advantage under stated assumptions [7], [8]. G2 is CONDITIONAL because the reviewed evidence does not establish a matched bank-operational comparison against the stronger MLMC setting [9]. G3 is CONDITIONAL because state preparation can eliminate the speedup under certain conditions [12], and mitigation is distribution-specific [13]; the corpus does not specify which condition characterizes the bank

workload. G4a is CONDITIONAL, and G4b is NOT ASSESSABLE AT CLASS LEVEL—decision: DEFER pending matched benchmarking and end-to-end encoding evidence.

2. Quantum Optimization

For portfolio optimization, G1 is CONDITIONAL because the broad formulation does not fix a single advantage source sufficiently for PASS [14]. G2 is CONDITIONAL: adverse classical comparisons exist [16], but no decisive matched comparison against an appropriate modern MIP or equivalent strong solver is established for the specified operational constraints. G3 and G4a are CONDITIONAL; G4b is NOT ASSESSABLE AT CLASS LEVEL. Decision: DEFER pending mechanism specification, strong benchmarking, and implementation-cost evidence.

3. Quantum Machine Learning

For the QRAM-dependent QML formulation to which the reviewed dequantization result applies, G1 is FAIL: comparable classical input access removes the claimed specifically quantum source of advantage [20]. This is not a claim against QML generally. G2-G4a are NOT REACHED; G4b is outside class-level scope. Decision: REJECT the formulation; a materially different input model or advantage source would be a new, reframed candidate. For broader near-term QML, G1 and G2 are CONDITIONAL. Classical models can be competitive [21], preprocessing can drive apparent advantage [22], and small quantum implementations can be comparable rather than superior [23]. Still, these findings do not affirmatively defeat every matched banking formulation. G3 and G4a are CONDITIONAL; G4b is NOT ASSESSABLE AT CLASS LEVEL. Decision: DEFER pending a specified mechanism, matched baseline, and end-to-end evidence.

4. Cross-Case Result

Across cases, the framework distinguishes affirmative failure, unresolved necessary evidence, and evidence outside the current unit of analysis. Only the first two affect the current decision; G4b non-assessability carries no adverse inference. Table 2 records the first failed or unresolved condition and the evidence required next; this is a framework implication, not evidence that the framework improves decisions.

Table 2. Illustrative Pre-Pilot Classifications

Use case	G1	G2	G3	G4a	G4b*	Decision	First binding issue
QAE pricing/risk	PASS	CONDITIONAL	CONDITIONAL	CONDITIONAL	Not assessable	DEFER	Strong matched comparator
Quantum optimization	CONDITIONAL	CONDITIONAL	CONDITIONAL	CONDITIONAL	Not assessable	DEFER	Mechanism-to-benefit specification
QRAM-dependent QML†	FAIL	NOT REACHED	NOT REACHED	NOT REACHED	Not assessable	REJECT / REFRAME	Advantage-source assumption
Near-term QML	CONDITIONAL	CONDITIONAL	CONDITIONAL	CONDITIONAL	Not assessable	DEFER	Mechanism and strong baseline

[b.] Source: Author classifications based on the evidence reviewed in Section II and cited in Section IV.

V. DISCUSSION

1. The Decision Object Is Evidence Survival, Not Algorithmic Advantage

Algorithmic, end-to-end, and bank-deployable advantage are different claims. Evidence does not automatically transfer between them. QAE illustrates the distinction: its mechanism survives G1 while the strong comparison and state-preparation questions remain unresolved. Optimization and near-term QML are deferred for incomplete comparative or implementation evidence; only the specified QRAM-dependent QML formulation has an affirmative G1 failure. The framework, therefore, separates FAIL, CONDITIONAL, and deployment-level non-assessability. A single readiness score can collapse these different evidentiary states and obscure what must be tested next.

2. Sequential Falsification and the Limits of the Ordering Claim

Sequential assessment does not prove that earlier gates are always cheaper. Its narrower rule is that unresolved or failed necessary conditions should not be treated as satisfied. A proof of concept cannot establish comparative advantage without a matched baseline, and circuit performance cannot establish end-to-end advantage when the material-loading cost remains unresolved. Stage-Gate, real options, sequential experimentation, and test-ordering already provide the general logic [3-6]. This paper contributes to the quantum-banking content of the tests, not new decision theory. G1-G4 is only a dependency-informed default; a formal ordering model could rationally reorder gates for particular candidates.

3. Governance Is a Distinct Evidence Object, Not a Final Veto

G4 is not a final bureaucratic veto. G4a identifies class-level controls or structural constraints and may be relevant at intake; G4b concerns institution-specific validation, monitoring, lineage, integration, fallback, and third-party controls that published literature cannot establish. The sequence is analytical, not an organizational workflow.

4. Practical Implication

Operationally, the framework first forces a candidate to specify its seven elements, then asks which necessary condition has failed, remains unresolved, or lies outside the current scope. That answer determines the next evidentiary task. This is a framework implication, not evidence that the protocol improves decisions or reduces cost.

VI. LIMITATIONS AND RESEARCH AGENDA

The framework has four principal limitations. First, the review is structured rather than systematic, was current to May 2026, and used no preregistered search or independent second coding; absence claims apply only to this corpus. The same corpus constructs and illustrates the framework, so Section IV is not an independent validation.

Second, classifications are single-author judgments. No inter-rater study establishes reproducibility, especially for candidate definition, comparator strength, material end-to-end costs, or the boundary between unresolved evidence and affirmative failure. Third, the default ordering is not optimized: test costs, rejection probabilities, information value, and precedence could justify a different sequence [5], [6]. Fourth, G4b cannot be established without a specific institutional implementation, and changes to hardware, algorithms, classical baselines, or deployment assumptions may require reassessment. Validation should therefore proceed in four directions: independent reviewers coding identical evidence packets; retrospective application to documented quantum-finance pilots without using eventual outcomes during initial coding; prospective comparison with existing bank evaluation processes; and a formal value-of-information/test-ordering model. Relevant outcomes include agreement, evidence requested, decision reversals, evaluation effort, and decision time. These are proposed tests, not demonstrated benefits. They may validate, modify, reorder, or reject parts of the present protocol.

VII. CONCLUSION

Quantum banking candidates should not be advanced based on theoretical speedups or favorable benchmarks alone. A specified formulation must establish a defensible source of quantum advantage, withstand an appropriate strong classical comparator, preserve that benefit through material end-to-end costs, and identify the governance requirements relevant to deployment. The paper contributes a quantum-specific pre-pilot falsification protocol integrating those evidence objects as necessary-condition tests. The illustrative cases distinguish affirmative failure from unresolved evidence and deployment-level non-assessability: QAE, optimization, and near-term QML are deferred in the reviewed formulations, while the narrowly specified QRAM-dependent QML formulation is rejected where the applicable dequantization result undermines its claimed source of advantage. The classifications are analytical, the gate order has not been proven optimal, and the framework has not been empirically validated. Its bounded claim is therefore simple: a plausible quantum mechanism is a reason to investigate, not a reason to pilot; escalation requires the specified banking use case to survive the relevant evidence tests.

Abstract
In this study, we propose a graph-theory-based solution approach to one of the well-known routing problems, the traveling purchaser problem (TPP), using topological graph indices. The main aim is to measure the relationship between suppliers and products in TPP by calculating new topological indices to be developed here based on graph-theoretical methods. These novel topological indices, called the affordability index and the closeness index, generate efficient routes and purchasing plans for purchasing different types of products from suppliers located in different locations. The solutions obtained using topological graph indices are compared with those obtained without graph theory in the literature, and the advantages of this graph-theoretic approach over existing methods are revealed through these benchmarks.

Keywords: traveling purchaser problem, topological indices, affordability index, closeness index

I. INTRODUCTION

In this study, the traveling purchaser problem (TPP), which is a variation of the traveling salesperson problem (TSP) frequently studied in the literature, is considered. One of the most important sub-branches of graph theory in the last century is the study of topological graph indices. In this field, a daily event can be modeled with a suitable graph, and this model can be studied either manually or using computer programming languages, with mathematical arguments and tools. A graph consists of vertices and edges. In real-life problems, we can model people, institutions, streets, intersections, metro or bus stops, companies, cities, countries, cells, neurons, factories, landmasses, etc., with vertices, and the relationships between them with edges. For example, we can draw lines between two people who know each other and determine the popularity of individuals in a group or network by looking at these lines. When we model these kinds of relationships with graphs, we transform our everyday problems into mathematical problems that we can solve using mathematical methods. Using matrices, determinants, vectors, numbers, polynomials, functions, etc., corresponding to these graphs, we first determine some numbers for the graphs. Then, by interpreting them, we can access valuable information that would normally require a lot of money, human resources, time, and effort to obtain in an everyday problem. There are several tools and methods to study a graph mathematically. Graph parameters and graph matrices are two of them. Nevertheless, a more frequent and popular way to study graphs is through various topological graph indices defined in recent years. The first examples are Wiener [1] and Gutman and Trinajstic [2]. Nowadays,

there are over 4,000 such indices defined for various purposes, most of which are mathematical or chemical. These indices, which are nothing more than mathematical formulas, can be used to classify graphs, derive their properties, make approximations, or comment on their corresponding applications [3-5]. Studying the effects of adding or removing vertices and edges on various graph properties yields valuable insights. For example, when calculating the effect of removing a vertex or edge, repeatedly applying this operation yields smaller graphs, usually with pre-existing properties. By working backward, the properties of the large graph under investigation can be obtained by applying the formula we derived from the properties of the small graph obtained at the end. This method was used to calculate the effects of adding and removing edges on Zagreb indices in [6]. A topological graph index is a formula that is generally defined by means of vertex degrees, distances, or other graph parameters, and often contains simple mathematical expressions. To apply this formula, a data set from the graph is needed. This data set is nothing more than a numerical table that can be given depending on the graph's vertex partition, edge partition, distance partition, or another graph parameter. TPP is known to be NP-hard in terms of solution difficulty because it encompasses decisions related to the traveling salesperson problem, facility location selection, and cluster covering problems [7]. Therefore, many solution approaches have been developed in the literature for solving TPP. These solution approaches are divided into two groups: exact solution methods that guarantee an optimal result and heuristic methods that aim to find a near-optimal result. Among the methods that give exact solutions, branch-and-bound, branch-and-cut, and branch-and-price algorithms are frequently used [8]. In addition to these approaches, dynamic programming was used by [9], and constraint programming by [10]. These methods, which guarantee optimal results, have been considered solution methods for many TPP variants. On the other hand, many heuristic methods have been developed to solve TPP and produce optimal or near-optimal solutions with shorter processing times. In this study, a heuristic approach based on graph theory is developed to solve the TPP. It aims to measure the relationship between suppliers and products in TPP using new topological index calculations to be developed based on Graph theory. The heuristic approach is used for supplier selection in TPP, and supplier routes are generated based on the index values. The solutions obtained using the topological graph index or indices are compared with those obtained without graph theory in the literature, and the advantages of this graph-theoretic approach over existing methods are revealed. The ability to model with graphs has broadened their application areas.

II. PROBLEM DEFINITION AND MODEL FORMULATION

The TPP is a well-known extension of the TSP, in which a purchaser satisfies the demand for a set of products from a set of markets. At each market, several products are available at a given price and capacity. To satisfy the demand for products, the purchaser starts their tour, visits several markets, and returns to the depot. Unlike the TSP, the purchaser does not have to visit all markets if they can satisfy the demand for the products from a subset of the markets. Additionally, the purchaser can meet the demand for a product across multiple markets, since the number of available products is limited in each market. Within the restrictions above, the purchaser aims to minimize total procurement and transportation costs. In this context, the model formulation of the TPP is as follows.

Assumptions

- The tour of the purchaser starts and ends at the depot node.
- The purchaser visits several markets to satisfy the demand for several products, where each market can be visited once at most.
- The available quantity of a product at a market can be zero or less than the product demand due to the capacity restriction of the market.

Parameters

K Set of products
M Set of markets
M_k Set of markets in which the product k is available ($M_k \subseteq M$), $k \in K$
$\{0\}$ Depot node
V Set of markets and depot node ($M \cup \{0\}$)
d_k Demand amount of product k, $k \in K$
q_{ik} Available amount of product k at market i, $k \in K$, $i \in M_k$
p_{ik} Price of product k at market i, $k \in K$, $i \in M_k$
c_{ij} Traveling cost from node i to node j, $i, j \in V$
γ Large number

Decision variables

x_{ij} Binary variable and equals 1 if the purchaser travels from node i to node j, otherwise 0; $i, j \in V$, $i \neq j$
Yy_i Binary variable and equals 1 if mthe purchaser, otherise 0 visit market i.therise 0; $i \in M$
z_{ik} Amount of product k purchased from market i; $k \in K$, $i \in M_k$
u_i Integer variable used in the MTZ sub-tour elimination; $i \in$ V

Model

$$Min \sum_{i \in V} \sum_{j \in V} c_{ij} x_{ij} + \sum_{k \in K} \sum_{i \in M_k} p_{ik} z_{ik} \quad (1)$$

s.t.

$$\sum_{i \in M_k} z_{ik} = d_k \qquad k \in K \quad (2)$$

$$z_{ik} \leq q_{ik} y_i \qquad k \in K, \qquad i \in M_k \quad (3)$$

$$\sum_{\substack{j \in V \\ i \neq j}} x_{ij} = y_i \qquad i \in M \quad (4)$$

$$\sum_{\substack{i \in V \\ i \neq j}} x_{ij} = y_j \qquad j \in M \quad (5)$$

$$\sum_{i \in M} x_{i0} = 1 \quad (6)$$

$$\sum_{i \in M} x_{0i} = 1 \quad (7)$$

$$u_j - u_i \geq 1 - \gamma(1 - x_{ij}) \qquad i \in M, \qquad j \in V, \qquad i \neq j \quad (8)$$

$$x_{ij} \in \{0,1\} \qquad i, j \in V, \qquad i \neq j \quad (9)$$

$$y_i \in \{0,1\} \qquad i \in M \quad (10)$$

$$z_{ik} \geq 0 \qquad k \in K, \qquad i \in M_k \quad (11)$$

$$u_i \geq 0 \qquad i \in V \tag{12}$$

Equation (1) describes the model's objective function, which aims to minimize the purchaser's total procurement and transportation costs. Constraints (2) ensure that the demand of each product type must be satisfied. Constraints (3) provide that the quantity of a product purchased from a market cannot exceed the quantity of that product available in the market. These constraints also ensure that if a product is purchased from a market, that supermarket must be within the purchaser's route. Constraints (4) and (5) guarantee that a market can be visited once by the purchaser if a procurement is made at the corresponding market. Constraints (6) and (7) assure that the tour of the purchaser starts and ends at the depot node. Constraints (8) define the MTZ sub-tour elimination constraints. Finally, constraints (9)-(12) identify the model's decision variables.

III. METHODOLOGY

The proposed graph indices-based solution approach consists of two stages. In the first stage of the approach, the subset of the markets to be visited in the solution is formed by using two new topological indices. Following the first stage, the purchaser's route is determined across the selected markets. In this stage, the simulated annealing (SA) algorithm, one of the effective metaheuristic algorithms for routing problems, is employed. The following subsections provide details of the proposed solution approach.

1. Market Selection

In TPP, the purchaser can satisfy product demand through a subset of markets. In this context, the selection of markets to be visited by the purchaser is a critical decision layer for the problem, as it directly affects procurement and transportation costs. To make an efficient selection, two different topological indices are introduced to identify the offer-cost-based and transportation-cost-based relations between the markets. The indices are called the affordability index and the closeness index, respectively. The affordability index measures how affordable a market is relative to other markets in the problem. To calculate a market's affordability index, the prices of products available in that market are compared with those in other markets. For each product k at a market i, first the competitor market (i) cis found, where the competitor market is the market that sells the corresponding product at the lowest price i. c, k son alt simge, this means that market i. is selling product k at a better price, and this provides a benefit to market i. proportional to the number of products available in the market. Conversely if $p_{ik} > p_{i^c k}$, there is another market that sells it at a better price than market i. In this context, the affordability index of a market is determined by using Equation (13).

$$Aff_i = \sum_{k \in K} \begin{cases} (p_{i^c k} - p_{ik}) \times min\{q_{ik}, d_k\}, & if \quad p_{ik} < p_{i^c k} \\ (p_{i^c k} - p_{ik}) \times min\{q_{i^c k}, d_k\}, & if \quad p_{ik} > p_{i^c k} \end{cases} \quad i \in M \tag{13}$$

As the second topological index for the TPP, the closeness index measures the average distance of a market from a given number of other markets. For a market, i, the closeness index is determined by using the following equation,

$$Clos_i = \sum_{j \in M^c} c_{ij} \qquad i \in M \tag{14}$$

where M^c is the subset of M and consists of the markets closest to the market i..he size of the M^c is set to $\sqrt{|M|}$.

Once the markets are evaluated using an index, they are ranked according to the index value, which is denoted by büyük ha M üssü büyük hrf R. The markets re ranked in descending order f Aff_i and ascendig order of $Clos_i$. Following the ranking procedure, the market selection is made by including the markets from M^R into the solution until all product demand is satisfied. The set of selected markets is described as M^*.

2. Route Planning

Once the market selection is completed in the first stage, the TPP becomes the TSP, as procurement decisions have been eliminated. To determine an effective route plan for the purchaser, the SA is used to find the optimal order of visits to the selected markets. In the proposed SA, the initial solution is constructed using the nearest-neighborhood search algorithm, one of the best-known and most effective route-construction heuristics. After the initial solution is generated, the SA iteratively searches the solution space by using local search procedures. In each iteration of the SA, a new solution ($\boldsymbol{X'}$) is generated from the current solution ($\boldsymbol{X}$). In the proposed SA, the order of the selected markets is changed by using four different moves: exchanging a pair of markets (see in Figure 1a), moving a market to a forward position (see Figure1b), moving a market to a backward position (see in Figure 1c), and reversing a sub-path in the route (see Figure 1d). In each iteration, one of the local search procedures is randomly selected to apply to the current solution. $\boldsymbol{X'}$ is accepted according to the SA solution acceptance criterion where $\boldsymbol{X} = \boldsymbol{X'}$ if $f(\boldsymbol{X'}) < f(\boldsymbol{X})$ or $e^{-\Delta/T} \geq rnd$. Here, Δ is the total cost difference between the new solution and the existing solution ($\Delta = f(\boldsymbol{X'}) - f(\boldsymbol{X})$), T is the temperature, and rnd is the standard uniform distributed random number.

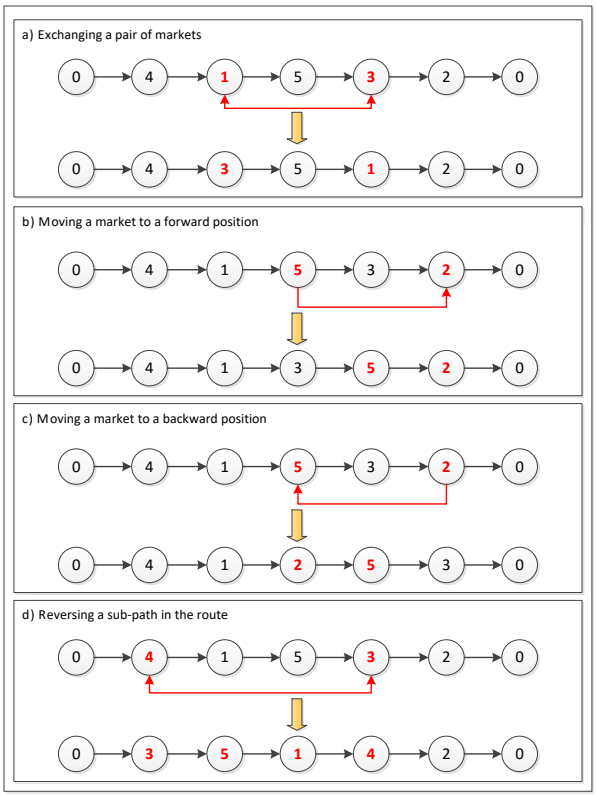

Figure 1. Local search procedures used in the proposed SA.

At the end of the main loop of the SA, the temperature is decreased by using a cooling coefficient (c). Additionally, the best-found solution ($\boldsymbol{X^{Best}}$) is updated if the newly generated solution is better than the current best-found solution. The SA terminates if the algorithm reaches the maximum number of iterations. The pseudo code of the proposed SA is given in Figure 2.

Input $\boldsymbol{M^*}$, c_{ij}
Set the algorithm parameters $T = T_0, c$
Generate an initial solution $\boldsymbol{X}$, $\boldsymbol{X^{Best}} = \boldsymbol{X}$
Do //Main loop of the algorithm
    Randomly select a local search procedure and generate $\boldsymbol{X'}$
    $\Delta = f(\boldsymbol{X'}) - f(\boldsymbol{X})$
    If $\Delta < 0$ **Or** $e^{-\Delta/T} \geq rnd$ **Then**
        $\boldsymbol{X} = \boldsymbol{X'}$
        If $f(\boldsymbol{X}) < f(\boldsymbol{X^{Best}})$ **Then**
            $\boldsymbol{X^{Best}} = \boldsymbol{X}$
        End If
    End If
    $T = T \times c$
Loop Until (Stopping criterion is met)
Output $\boldsymbol{X^{Best}}$

Figure. 1. Pseudo code of the proposed SA.

IV. COMPUTATIONAL RESULTS

To evaluate the performance of the proposed solution approach, a problem set of 180 instances is randomly generated. The generated problems are characterized by four metrics: the number of nodes, the absolute value of V, the absolute value of the end, and the absolute value of K. Absolute values of the end and of two levels (i.e., 10 and 50) are considered. The instances consisting of 10 nodes are called small-sized instances, while the instances with 50 nodes are called large-sized instances. The coordinates of each node are randomly generated between 0 and 100, and the distance between each pair of nodes is determined as the Euclidean distance. For the $\bar{C}_L$ and $\bar{D}_L$, three levels (i.e., 1, 2, and 3) are considered, where the price of each product in each market and its demand are randomly generated for the corresponding levels. For each combination of $|V|$, $|K|$, $\bar{C}_L$, and $\bar{D}_L$, five different instances are generated. Each instance is solved using the proposed approach, which accounts for both the affordability and closeness indices. Additionally, each instance is solved using the GUROBI solver with a 1-hour time limit to obtain a benchmark value. At the end of the time limit, the best-found integer solution is used. The results obtained by the proposed approach are compared with the GUROBI solution using Equation 15, where fvalue denotes the result obtained by the solution approach. The results obtained are presented in Tables 1 and 2 for the small- and large-sized instances, respectively. Each row in the tables presents the average percentage gap of five instances for the corresponding problem configuration.

$$Gap_{Index}\% = \frac{f_{Index} - f_{GUROBI}}{f_{GUROBI}} \times 100\% \quad (15)$$

Table 1. Obtained Results for the Small-Sized Instances

$\|K\|$	$\bar{C}_L$	$\bar{D}_L$	$Gap_{Aff}\%$	$Gap_{Clos}\%$
10	1	1	2.84	3.60
		2	0.14	0.21
		3	0.22	0.16
	2	1	13.46	17.76
		2	2.69	2.12
		3	1.01	1.32
	3	1	13.86	17.96
		2	1.14	5.05
		3	2.53	2.21
50	1	1	0.04	0.16
		2	0.00	0.03
		3	0.00	0.13
	2	1	0.35	0.00
		2	0.08	0.12
		3	0.07	0.03
	3	1	3.26	3.06
		2	0.21	0.23
		3	0.13	0.04

Table 2. Obtained Results for the Large-Sized Instances

$\|K\|$	$\bar{C}_L$	$\bar{D}_L$	$Gap_{Aff}\%$	$Gap_{Clos}\%$
10	1	1	6.91	22.34
		2	0.63	2.16
		3	1.99	1.33
	2	1	45.73	128.90
		2	4.99	26.81
		3	2.09	8.46
	3	1	22.32	146.58
		2	15.66	38.84
		3	3.56	22.36
50	1	1	1.00	3.40
		2	0.67	0.49
		3	0.43	0.81
	2	1	12.62	31.97
		2	0.81	4.09
		3	0.45	1.91
	3	1	18.81	63.51
		2	2.09	7.78
		3	0.89	3.44

When the results for the small-sized instances are analyzed, the proposed solution approach, which includes both indices, is capable of finding solutions close to the GUROBI solutions, with percentage gaps of less than 1% in most cases. On the other hand, high percentage gaps are observed for the problems with the lowest demand level. Similar status is observed for the large-sized instances. It is clear from Table 2 that low percentage gap values are observed at demand levels 2 or 3, while high percentage gap values are observed at demand level 1. Inasmuch as the percentage gap value increases even further when the number of product types is 10. In particular, the performance of the proposed algorithm with the closeness index is poor for problems with low demand levels. As a consequence, it should be stated that the proposed solution approach can produce efficient results on the generated instances across most problem configurations. However, large percentage gaps can be observed when demand is low in the TPP. Another finding from the computational studies is that the proposed solution approach, which uses the affordability index, outperforms the algorithm that uses the closeness index. In particular, for the small-sized instances, it is observed that f_{Aff} is better than f_{Clos} for 28 instances, while f_{Clos} is better than f_{Aff} for 11 instances. For the large-sized instances, f_{Aff} is better than f_{Clos} for 81 instances, while f_{Clos} is better than f_{Aff} for only 9 instances. As a result, the affordability index yields a more successful market selection for the TPP than the closeness index.

V. CONCLUSION

In this study, the traveling purchaser problem (TPP) is considered. Unlike classical approaches, a heuristic approach based on graph theory is developed to solve the problem. To date, there is no approach to TSP or TPP using topological graph indices. In this context, two new topological graph indices, which are called the affordability index and the closeness index, are introduced. As their names suggest, these two graph indices are primarily related to the prices of goods in the list and the distances between the markets and the depot. The solutions obtained using these two topological graph indices are compared with those obtained without graph theory in the literature, and the advantages of this graph-theoretic approach over existing methods are revealed. In future work, one may focus on several other topological graph indices, and further improvements may be possible.

Abstract
In recent years, the use of Machine Learning techniques in agile project management has sparked growing interest within the scientific community. However, a clear understanding of the main research lines, emerging trends, and gaps in this interdisciplinary area is still lacking. This paper presents a bibliometric analysis examining the evolution of scientific output on ML in agile contexts, based on publications indexed in databases such as Scopus, IEEE, and Web of Science. Bibliometric and machine learning techniques were used to identify the most productive authors, themes, and application areas. The results show sustained growth in the field in recent years, with emphasis on effort prediction, team performance evaluation, and automation of sprint tracking. Finally, future research opportunities are discussed, integrating ML with agile dynamics in multi-project and collaborative scenarios.

Keywords: Machine Learning, Agile Project Management, Bibliometric Analysis.

I. INTRODUCTION

Over the last decade, Agile Project Management (APM) has gained significant adoption in software development contexts, standing out for its iterative approach, adaptability to change, and focus on continuous value delivery. In parallel, Machine Learning (ML) techniques have emerged as key tools for data analysis and decision automation in various domains, including software engineering. For example, [1] explores the challenges of large-scale agile projects and the need for advanced predictive techniques. The convergence of agile approaches and ML algorithms has given rise to a new line of research focused on optimizing sprint tracking, effort estimation, risk prediction, and backlog prioritization, among other key processes. Several studies, such as [2], present extensive literature reviews of machine learning applications in agile project management up to 2022. Unlike previous systematic literature reviews, this work provides a bibliometric perspective on publication trends, collaboration patterns, thematic clustering, and emerging research directions from 2020 to 2025. This complementary approach enables the identification of research dynamics that cannot be observed through traditional qualitative reviews alone. Additionally, [3] reaffirms the current state of artificial intelligence in software engineering and its potential for integration with the discipline.

II. METHODOLOGY

To identify the main lines of research at the intersection of ML and APM, a bibliometric study was conducted using academic publications retrieved from databases such as Scopus, IEEE, and Web of Science. The analysis focused on the period from 2020 to 2024 to capture the most recent trends in this emerging field.

1. Data source and search criteria

The Scopus, IEEE, and Web of Science databases were used due to their multidisciplinary coverage and recognition as reliable sources for bibliometric analysis. The advanced search was constructed with the following logical string: Search String: *(TITLE-ABS-KEY ("agile project management") OR TITLE-ABS-KEY ("agile software development") AND (TITLE-ABS-KEY ("machine learning") OR TITLE-ABS-KEY ("artificial intelligence")) AND (PUBYEAR > 2019)*

This query was designed to retrieve publications whose title, abstract, or keywords explicitly referenced both agile methodologies and ML techniques.

2. Extraction and Preprocessing Process

The results were exported as CSV from the selected databases, including fields such as title, authors, affiliations, abstract, publication year, keywords, and number of citations. The data were cleaned and normalized to ensure consistency (e.g., unifying key terms and removing duplicates). A first manual verification was then conducted to confirm that the titles focused on ML applied to APM and to discard unrelated works.

3. Analysis Tools

The bibliometric analysis was performed using a combination of open-source tools, including Python and ML techniques, to fully exploit the information contained in the article metadata. The main technologies and processes used are described below.

Bibliometrix (R and Python): The initial phase employed the Bibliometrix library (R version 4.x), along with its Python counterpart, which allows the extraction of basic scientific productivity indicators. The data cleaning and preprocessing were done using Python 3.9 with the following libraries:

- **Pandas**: to load, clean, and transform the CSV file, eliminating duplicates and incomplete records.
- **scikit-learn** (sklearn): TfidfVectorizer was used to convert the combined text (title + keywords) into numerical vectors, and K-Means was used to segment the publications into thematic clusters automatically.
- **matplotlib** and **seaborn**: to plot temporal trends.
- **WordCloud**: to generate word clouds visualizing the frequency of key terms in the corpus.

III. RESULTS

1. Cleaning and Number of Records

The original CSV was loaded, containing 282 rows selected for analysis and 4 columns (Title, Authors, Year, and Keywords). After removing duplicates and entries without a title or keywords, 261 records remained for further analysis.

2. Publications per Year

The publication years were analyzed to observe the temporal evolution of research on ML applied to agile management, as shown in Figure 1. The year 2021 presents the highest publication peak, with approximately 72

articles. From 2020 to 2024, the results show an overall upward trend, despite a slight decrease in 2023 followed by a recovery in 2024.

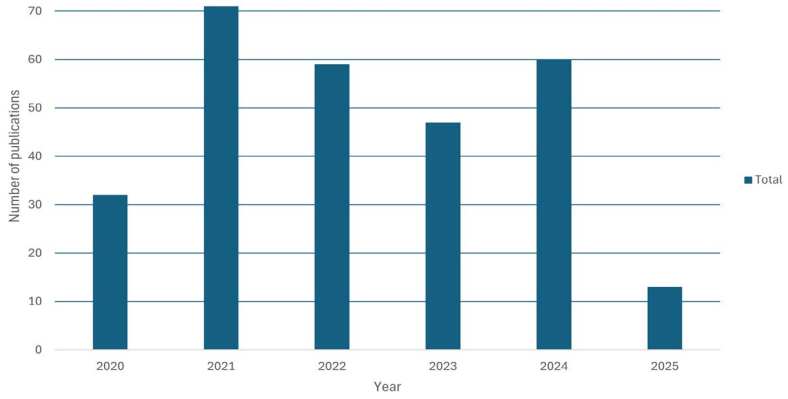

Figure. 1 Publications per Year

For 2025, only 13 studies were identified; however, this figure reflects only partial data collected up to the review's cutoff date, as the studies were conducted that same year and the publication cycle had not yet concluded.

3. Most Productive Authors

Author names were separated (using ";" or ","), and their publication counts were tallied, selecting the top 10 most frequent authors. Results are shown in Table 1. Four authors lead with three publications each. The rest of the top 10 have two publications. This shows that there is no dominant author, but rather several contributors with similar output.

Table 1. Productive Authors

Authors	Total of Publications
L. Chen	3
R. Ferdiana	3
B. Kumar	3
D. C. Dobhal	3
A. Egyed	2
C. S. González-González	2
Y. A. Korablev	2
L. A. Kutsenok	2
M. P. Uysal	2
C. Mayr-Dorn	2

4. Keyword Analysis

The author keywords were unified and extracted to obtain the frequency of the most repeated keywords (top 15), as shown in Figure 2.

Figure 2. Keyword WordCloud

Results indicate that “machine learning” leads by a wide margin (94 mentions). Secondary key themes include “artificial intelligence,” “agile,” and “project management.” The cloud also highlights terms like “software development,” “effort estimation,” “scrum,” and “natural language processing.”

5. Document Type

Document types were counted and shown in Figure 3, indicating that publications in this area tend slightly toward conferences over journals. However, some academic databases were inaccessible due to limitations, so including additional sources could enrich the analysis and more likely reveal additional document types.

6. Areas of applications

A brief description is provided below of how a clustering method was applied to the texts (Titles + Keywords) to identify application areas and classify the collected works. This is followed by Table 4, which presents the 5 most relevant articles as representative examples after the classification.

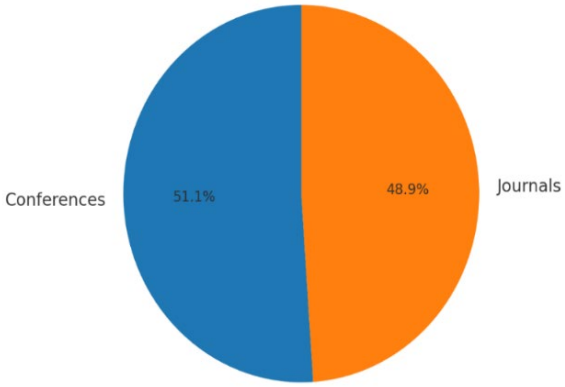

Fig. 3 Distribution of Document Types

The K-means clustering algorithm was selected because it is an efficient and well-established unsupervised clustering method for grouping documents based on their vector representations [4], [5]. By projecting each record (a combination of title and keywords) into a numerical feature space, K-Means enables the automatic identification of clusters of works that share similar vocabulary and thematic structures. Since the goal of the research was to objectively discover application areas without imposing predefined labels, K-Means provides a simple way to partition the dataset into k groups with high internal cohesion and external separation between

clusters. Moreover, its resulting centroids (mean vectors) facilitate the extraction of the most representative terms from each group, enabling manual assignment of descriptive names afterward. In short, K-Means was used because it combines computational efficiency with interpretability of results, and because its operation over TF-IDF vectors supports the detection of latent content patterns in the corpus of titles and keywords.

7. Text Preparation

Each record from the table (title and keywords) was combined into a single lower-case text field. Example:

- Title: "Risk Prediction in Agile Projects Using Bayesian Networks"
- Keywords: "bayesian network; risk management; Scrum"
- Combined text: "Risk prediction in agile projects using Bayesian networks, Bayesian network risk management, Scrum"

8. TF-IDF Vectorization

We used a TF-IDF vectorizer (removing terms that appeared in more than 80% of the documents and those appearing in fewer than 2 documents). This produced a sparse matrix of size ($n = 261$ *rows*) ($m = 3,$ 000 *columns*), where each column corresponds to a relevant term extracted from all texts.

9. Clustering with K-Means.

K-Means was executed with k = 10 (using a fixed seed for reproducibility), such that each of the 261 records was assigned to one of the 10 clusters (labeled 0–9). The value k = 10 was selected after several exploration experiments, seeking a balance between thematic granularity and interpretability of the resulting clusters. Lower values produced overly broad categories, while higher values generated fragmented clusters with limited semantic distinction.

10. Centroid Inspection

For each of the 10 clusters, the 10 highest-weight words (with the highest TF-IDF scores) from the centroid (average vector) were extracted. These "top words" help interpret the overarching theme of each cluster.

11. Assignment of Descriptive Labels

Based on the most representative terms identified in each centroid, a descriptive application-area label was manually assigned to each cluster. For instance, clusters characterized by terms such as "risk", "management", "assessment", and "Bayesian" were labeled as "Risk Management & Predictive Models".

12. Final results

Each document received an application area label (one of 10 names). The number of records in each cluster was counted to determine their distribution; the results are shown in Tables 2 and 3. The most-populated area is "Risk Management & Predictive Models" (75 papers), followed by "NLP & User Stories" (45) and "Other Topics" (36). "Effort Estimation and Cost Models" has the lowest share with 6 publications. Table 4 presents the following representative articles considered "most relevant," selected based on the presence of key terms.

Table 1. Discovered Application Area (Cluster Labels)

Cluster ID	Application Area	Description
0	Effort Estimation and Cost Models	Regression, Random Forest, COCOMO II + ML for predicting effort and cost.
1	Development Lifecycle & Agile Frameworks	Applying ML across the lifecycle (requirements, coding) and agile methods.
2	NLP & User Stories	NLP for classification, generation, and prioritization of user stories.
3	Defect Prediction & Quality Assurance	ML models to anticipate bugs and optimize test cases.
4	Risk Management & Predictive Models	Bayesian networks and decision trees for identifying and mitigating sprint risks.
5	Resource & Task Allocation	ML for recommending balanced task/resource assignments.
6	Hybrid Integration / Composite Frameworks	ML combined with Kanban/Scrum/DevOps pipelines.
7	Sentiment Analysis & Team Productivity	NLP to analyze team mood, feedback, and productivity.
8	Time Prediction / Scheduling	Time-series models and regression for forecasting sprint duration and delivery dates.
9	Other Topics (Various ML Applications)	Anomaly detection, task clustering, recommender systems.

Table 2. Publications Per Discovered Cluster

Application Area	Count
Risk Management & Predictive Models	75
NLP & User Stories	45
Other Topics	36
Lifecycle & Agile Frameworks	32
Defect Prediction & Quality Assurance	22
Sentiment & Team Productivity	15
Resource & Task Allocation	12
Time Prediction / Scheduling	10
Hybrid Integration / Composite Frameworks	8
Effort Estimation and Cost Models	6

Table 3. Top 5 Representative Articles

Title	Year
Sprint2Vec: A Deep Characterization of Sprints in Iterative Software Development [6]	2025
Using sentiment analysis to assess PMBOK knowledge areas' compatibility with agile [7].	2024
Sprint Management in Agile Approach: Progress and Velocity Evaluation Applying Machine Learning [8]	2024

K-Means and Feature Selection Mechanism to Improve Performance of Clustering User Stories in Agile Development [9]	2023
Prediction of Risk Percentage in Software Projects by Training Machine Learning Classifiers [10]	2021

13. Summary of Key Findings

The authors in [2] conducted a systematic review of machine learning applications in agile Project management, identifying trends, techniques, and research gaps in this field. They noted the growing interest in combining NLP techniques and deep learning models for tasks such as effort estimation and user story classification. This analysis complements the work of [3], who critically discuss the current state of artificial intelligence in software engineering and point out which areas, including agile methodologies, are more mature for adoption and which require further research. [11] proposed a ChatGPT-based approach for retrieving quality attributes in software development strategies, demonstrating that transformer-based language models can extract quality requirements (e.g., maintainability, usability) from user story descriptions. Similarly, [12] presented an NLP-based method for analyzing software requirements to improve effort estimation in agile environments, combining entity extraction and semantic analysis techniques to generate more accurate predictions. Reference [13] focused on privacy requirements engineering. They used NLP techniques to analyze user stories and detect privacy implications early, facilitating the integration of privacy controls into agile cycles. In the area of user story classification, [9] used K-Means with a feature selection mechanism to improve clustering performance of user stories in agile environments; their approach reduces the dimensionality of the textual space and groups stories more coherently, which aids in task assignment. Similarly, [3] proposed a classification method for product backlog items using machine learning (e.g., SVMs and decision trees) to automate the categorization of user stories by priority and complexity. [14] explored the implementation of ML in the Use Case Points (UCP) method, offering a 30-year retrospective analysis and showing how regression models and neural networks have evolved to better adjust complexity factors in UCP. Along the same lines, [15] described various predictive Models for project attributes (e.g., cost, duration) using traditional ML techniques (linear and multiparameter regression), emphasizing that using features derived from code metrics improves prediction accuracy. In [16] was demonstrated how an artificial neural network can enhance project duration prediction compared to classic statistical methods, by capturing nonlinear relationships between input variables. Regarding effort estimation in agile methodologies, [17] used decision trees and story points to model project effort and cost, concluding that decision trees provide more intuitive explanations and realistic results when historical metrics are available. In [18] applied k-Nearest Neighbors to estimate effort in agile projects, showing that a neighbor-based strategy allows for easy incorporation of similar past projects to improve predictions. [19] Compared linear regression, ridge regression, and logistic regression to forecast effort in agile projects, noting that ridge regression outperforms linear when multicollinearity is present among story point variables. [10] trained machine learning classifiers (SVMs, trees) to predict risk percentage in software projects, demonstrating that a classification approach can identify high-risk projects with over 80% accuracy. In [20] investigated the challenges of cost estimation in agile environments, noting that the lack of standardized metrics and high variability in requirements make statistical modeling difficult. They proposed combining historical data with machine-learning-based heuristic approaches. In [1] the authors discussed the challenges of agile projects, arguing that organizational complexity and the coordination among multiple teams demand sophisticated forecasting methods and real-time data analytics. [6] presented *Sprint2Vec*, a deep model that characterizes sprints in iterative Development through embeddings that capture attributes such as speed, collaboration, and story completion rate, facilitating sprint comparisons and identification of improvement patterns. In parallel, [8] applied ML techniques to evaluate sprint progress and velocity, proposing automated

metrics to predict future performance based on historical data. [21] addressed the determination of ideal team size in agile practices using learning-based methods, incorporating variables such as task complexity, prior experience, and cognitive load to recommend configurations that maximize productivity. [22] used deep learning to classify the functional size of agile projects under the COSMIC standard, demonstrating that convolutional neural networks can extract patterns directly from requirements descriptions. [7] Applied sentiment analysis to assess the compatibility of PMBOK knowledge areas with agile methodology, suggesting that some areas (e.g., communications management) show greater alignment, while others (e.g., risk management) require adjustments in terminology and practices. In a complementary approach, [23] developed Emotimonitor. This Trello plugin captures and monitors the emotions of agile teams in real time using text analysis techniques and brief surveys that help anticipate potential morale issues or conflicts. In [24] validated agile methodology as an ideal process using the Fuzzy-TOPSIS method, concluding that flexibility and responsiveness rank it above traditional models when fuzzy performance metrics are applied. [25] proposed ML models to predict the adoption of agile methodologies by organizations, based on structural and cultural characteristics of companies; their work showed that decision trees and Random Forest can identify with 85 accuracy which organizations are likely to adopt agile practices. Similarly, [26] presented a method for evaluating the success of agile projects using ML, combining time, cost, and customer satisfaction metrics to generate scores that predict the likelihood of success. [27] designed a task allocation approach for distributed agile environments using ML, where a clustering model suggests the best distribution of user stories based on skills and availability, reducing coordination overhead. [24] used Fuzzy-TOPSIS to validate the suitability of agile methodology in software projects, finding that flexibility and fast feedback are the main factors making it preferable to traditional waterfall methods. This finding complements the study by [25], which highlighted that organizational culture plays a decisive role in the successful adoption of Agile. In summary, recent literature combines NLP and ML tools to address key challenges in agile environments: from the automatic extraction of requirements and quality attributes [11], [13] to the prediction of project metrics such as effort, cost, and duration, [14], [15], [16], [17], [18], [19], [25] Advanced techniques are also being explored to characterize sprints [6] [22] [8] and monitor human aspects such as emotions and framework compatibility [7], [23]. Large-scale studies highlight the need for robust models that incorporate cultural and organizational metrics [24], [25], [1], [26] while others focus on optimizing specific tasks like automatic task allocation in distributed teams [27] or determining ideal team sizes [21]. These contributions show a clear trend toward integrating AI and Big Data to enhance efficiency, quality, and predictability in agile projects.

IV. DISCUSSION

Between 2020 and 2024, publications on ML applied to APM grew from 32 articles in 2020 to 71 in 2021, then stabilized in 2022 and 2023 (59 and 47, respectively), before rising again to 60 in 2024. This growth reflects sustained interest in combining both disciplines. Author contributions are distributed; no dominant figure exists, with most authors contributing 2–3 papers, indicating a collaborative ecosystem. In terms of dissemination, 51.1% of publications appear in conferences and 48.9% in journals, showing a balanced use of both forums. Keyword analysis shows that the core topics are “machine learning,” “agile,” and “project management.” Subfields like “effort estimation” and “natural language processing” shape specific research directions, ranging from regression models to user story classification. Using TF-IDF and K-Means clustering, ten distinct application areas were identified. The most frequent were:

- Risk Management & Predictive Models (28.7%)
- NLP & User Stories (17.2%)
- Other Topics (13.8%)
- Lifecycle & Agile Frameworks (12.3%)
- Defect Prediction & QA (8.5%)

- Other smaller categories included sentiment analysis, resource allocation, time prediction, and ML-DevOps hybrid environments.

These findings offer a detailed view of how ML is applied in agile contexts, highlighting both consolidated focus areas (e.g., risk management, NLP for requirements) and emerging fields. The bibliometric results allow us to reflect on the current research landscape on the use of ML in APM. The remarkable increase in scientific output over the last five years indicates strong interest from both academia and industry in integrating AI techniques with agile frameworks such as Scrum, Kanban, and XP. A notable aspect is the thematic dispersion found in keyword co-occurrence networks. While core terms are prevalent, many peripheral nodes suggest the field is still in an exploratory phase with various theoretical and practical approaches in development. This diversity signals that the field remains open to new frameworks, tools, and methodologies.

V. LIMITATIONS

This study presents several limitations. First, only publications indexed in Scopus, IEEE, and Web of Science were considered, potentially excluding relevant studies in other scientific databases. Second, the clustering results depend on the selected search string and the value of k used in the K-Means algorithm, meaning that different parameter configurations can yield alternative thematic groupings. Third, assigning descriptive labels to clusters involved manually interpreting the most representative terms, which may introduce some subjectivity. Finally, the analysis was limited to bibliographic metadata, such as titles, keywords, and publication information, and did not include a full-text analysis of the retrieved studies.

VI. CONCLUSIONS

This study has shown that the combination of Machine Learning with agile methodologies has gained increasing relevance in recent years, as evidenced by the significant rise in publications since 2021. The bibliometric analysis revealed a highly collaborative author ecosystem, with no hegemonic researcher, suggesting convergence among multiple teams working on ML solutions to optimize agile processes. The most recurrent keywords, such as “machine learning,” “agile,” and “project management,” highlight the central research focus, while terms like “effort estimation” and “natural language processing” indicate specialization into subdomains. The use of TF-IDF and K-Means clustering helped identify ten differentiated application areas, with “Risk Management & Predictive Models” and “NLP & User Stories” being the most prominent. This expands the traditional focus on effort estimation and user stories, since nearly half of the papers fall under “Other Topics,” covering everything from defect prediction to ML-DevOps hybrid support. The near-equal distribution between conferences (51%) and journals (49%) suggests that the academic community values both the immediacy of conferences and the rigor of journals to share findings in this interdisciplinary space. Together, the results provide a comprehensive overview of how ML techniques are applied to agile tasks, whether for predicting risks, classifying user stories, forecasting timelines, or recommending resource assignments, and underline the many still-exploratory opportunities. These conclusions validate the growing synergy between ML and agile management, while also revealing key gaps, such as the limited application of ML to sprint tracking. The findings can serve as a foundation for future studies aiming to standardize methods, build shared repositories, and validate models in real-world settings.

VII. FUTURE WORK

Future work should focus on developing ML models that integrate seamlessly with daily agile practices, enabling real-time tracking of project progress and health. For instance, using recurrent neural networks or transformers specialized in time series, it would be possible to accurately predict sprint progress based on historical card

updates and comments, generating automatic alerts when delays are likely. Additionally, a dynamic dashboard that combines key metrics (burn-down, velocity, defect rate) with classification and clustering algorithms could proactively suggest task reassignment or priority reevaluation, and even anticipate bottlenecks. Moreover, by leveraging natural language processing techniques, a virtual assistant (Agile Coach) could analyze text from stand-ups, pull requests, and feedback to detect blockers, negative sentiment, or team overload and offer precise recommendations without disrupting workflow. In parallel, a risk early-warning system could be built that, fed by sprint indicators (blocked stories, ticket latency, software quality metrics), computes a daily "risk score" for each critical item. When certain thresholds are exceeded, the tool would notify the Scrum Master to trigger replanning or retrospective meetings. A continuous quality tool could also be implemented to estimate the likelihood of introducing defects in new stories and to show a quality semaphore on the Kanban board. Finally, applying temporal clustering to sprint productivity metrics would allow the identification of patterns of "calm sprints" or "volatile sprints" and suggest adjustments to Work in Progress (WIP) or story refinement processes to optimize team performance. With these developments, integrating ML into agile tracking would not only anticipate problems but also provide predictive and automated solutions to sustain the iterative flow and continuous improvement.

ACKNOWLEDGEMENT

The authors would like to thank the *Instituto Politécnico Nacional and the Centro de Investigación* en Computación for their academic and institutional support. The authors also thank the participants who contributed to the evaluation of the proposed approach.

Abstract
Occupational safety enforcement in industrial and construction environments remains a persistent global challenge, particularly in restricted areas where helmet compliance is mandatory. This paper presents a comprehensive real-time helmet detection and monitoring system that integrates YOLOv8-based deep learning with Arduino-controlled hardware alerts and a Streamlit dashboard for continuous compliance tracking. The system pipeline encompasses dataset construction and annotation, model fine-tuning, temporal filtering to stabilize detection, serial communication with embedded hardware (LED, buzzer, LCD), and CSV-based event logging with visual evidence. Experimental evaluation on a custom dataset demonstrates an mAP@0.5 of 0.95, a precision of 0.91, and a recall of 0.92, with alarm activation latency below 1 second. The dashboard reports 75% helmet compliance across monitored sessions. These results confirm the system's suitability for real-world deployment in low-resource industrial settings, providing both immediate safety enforcement and long-term compliance auditing.

Keywords: helmet detection, YOLOv8, computer vision, occupational safety, real-time monitoring, dashboard monitoring, restricted zones, temporal filtering, embedded systems.

I. INTRODUCTION

Enforcing occupational safety regulations in construction and industrial environments is a critical global priority. Mandatory helmet use in restricted zones, where workers are exposed to hazards such as falling objects, moving machinery, and hazardous materials, represents one of the most fundamental preventive measures. Despite stringent regulatory frameworks, compliance monitoring typically relies on manual supervision, which is inherently susceptible to human error, observer fatigue, inconsistencies, and coverage gaps during extended shifts. Recent advances in deep learning and computer vision have created compelling opportunities to automate personal protective equipment (PPE) compliance monitoring. Object detection frameworks, including Faster R-CNN [1], SSD, and the YOLO family, have demonstrated high accuracy in identifying safety equipment across diverse conditions. However, most published work focuses exclusively on detection accuracy, leaving the critical engineering challenge of real-world integration, such as hardware alerts, dashboard visualization, data logging, and compliance reporting, largely unaddressed. This paper presents a complete, end-to-end real-time helmet

detection and compliance monitoring system designed for deployment in restricted industrial areas. The system combines YOLOv8n, an advanced single-stage object detector, with an Arduino Uno-based alarm subsystem (LED indicator, buzzer, LCD), a temporal-filtering decision layer to stabilize frame-level predictions, and a Streamlit-based monitoring dashboard for live visualization and historical compliance analysis. The principal contributions of this work are threefold:

i) Development of a robust, annotated custom dataset and YOLOv8 training pipeline for two-class helmet detection, achieving mAP@0.5 of 0.95.
ii) Hardware integration of detection outputs with Arduino-controlled visual and auditory alarms via Python serial communication, enabling alarm activation in under one second.
iii) Implementation of temporal filtering to stabilize detections and a Streamlit dashboard for real-time monitoring and compliance auditing with CSV-based event logging.

By bridging the gap between research-grade detection accuracy and practical deployment in resource-constrained industrial settings, this system offers a scalable and low-cost framework for occupational safety monitoring.

II. LITERATURE REVIEW

Helmet detection research has evolved substantially over the past decade, progressing from traditional image processing methods toward deep learning frameworks that deliver real-time performance with practical accuracy. Early CNN-based approaches demonstrated the feasibility of binary helmet classification in still images but struggled with cluttered backgrounds and required separate object localization steps. Mercado et al. [2] reported moderate accuracy using convolutional classifiers for motorcycle helmet detection, establishing a benchmark for subsequent single-stage approaches. Chen et al. extended this work using Faster R-CNN, achieving improved mean average precision for construction site monitoring, but at computational costs that are incompatible with real-time embedded deployment. The YOLO framework has emerged as the dominant paradigm for real-time safety equipment detection, balancing accuracy and inference speed through single-stage processing. Wang et al. [3] demonstrated real-time helmet detection on construction sites using CSYOLOv3, achieving average precision exceeding 90% and leveraging focal loss strategies to address class imbalance [4] in live video streams. Liu and Hao [5] further improved detection performance using a modified YOLOv5 architecture for general PPE monitoring. Most recently, Zuo et al. [6] proposed an enhanced YOLOv8n three-module architecture with improved lightweight performance, while Wu et al. [7] introduced YOLOv8-CGS for construction site safety monitoring, confirming YOLOv8 as the current state-of-the-art for this application class. Despite these advances in detection, significant gaps remain in end-to-end system integration. Yadav et al. [8] proposed a deep learning approach for helmet detection with fine-grained generation for traffic surveillance, demonstrating classification performance but lacking integration with hardware alarms. Transformer-based architectures [9] have yet to be integrated into deployed systems. Similarly, smart monitoring systems reviewed in [10] typically require high-end GPU infrastructure, limiting their applicability in low-cost industrial contexts. Data preparation methodology is consistently identified as a critical factor in detection system performance. Standard annotation tools such as LabelImg [11] and CVAT are widely used for bounding-box labeling in YOLO-compatible formats. Data augmentation strategies like rotation, scaling, and photometric adjustments are employed to improve model generalization across diverse lighting conditions and viewpoints [12]. From this review, three specific gaps motivate the present work:

i) the absence of low-cost, integrated systems combining real-time YOLO-based detection with embedded hardware alarms;

ii) limited attention to detection stability under dynamic conditions, addressed here through temporal filtering; and
iii) the lack of a compliance dashboard and logging systems for long-term safety auditing in restricted industrial zones.

III. DESIGN AND IMPLEMENTATION

The proposed system was developed using a structured pipeline that integrates dataset preparation, model training, real-time detection, decision logic, hardware alarm control, data logging, and dashboard visualization. Each component was designed to ensure accurate detection, sub-second response, and comprehensive compliance monitoring. The system architecture is shown in Figure 1.

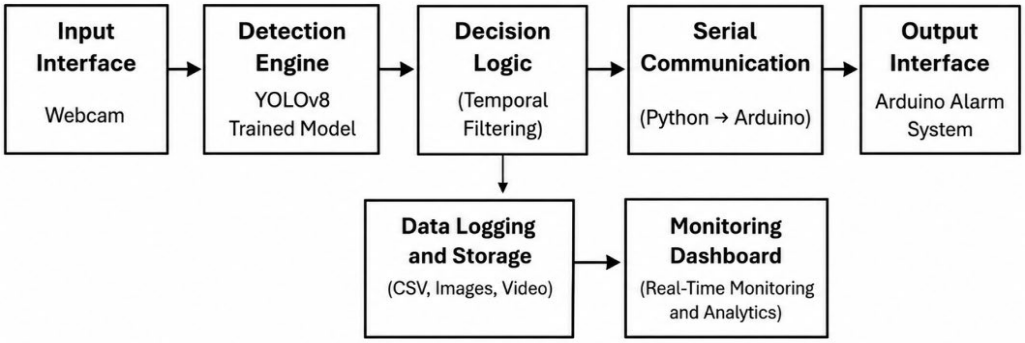

Figure 1. Architecture of the proposed real-time helmet monitoring and detection system

1. Dataset Collection and Annotation

A custom dataset was constructed by combining publicly available helmet detection repositories with supplementary images from diverse industrial and construction-site contexts. The dataset encompasses two object classes: helmet and head (bare, no helmet). Images were curated to represent challenging real-world conditions, for instance, varied head orientations (frontal, lateral, oblique), multiple workers per frame, both indoor and outdoor environments, and a range of ambient lighting conditions from direct sunlight to artificial indoor illumination, to promote generalization. Manual annotation was performed in YOLO-compatible format using LabelImg, with bounding boxes defined by normalized center coordinates and dimensions:

<class_id> <x_center> <y_center> <width> <height>

where class ID 0 denotes head (no helmet) and class ID 1 denotes helmet. Table 1 presents the data characteristics.

TABLE 1. Dataset Characteristics

Metric	Description
Total number of images	1,250 images
Total number of bounding boxes	3,400 annotations

Class distribution	Helmet: X images / Y boxes; Head (no helmet): X images / Y boxes
Environmental variability	Indoor (40%), outdoor (60%); daylight (70%), artificial/low light (30%); single worker (50%), multiple workers (50%)
Train/val/test split	70/15/15

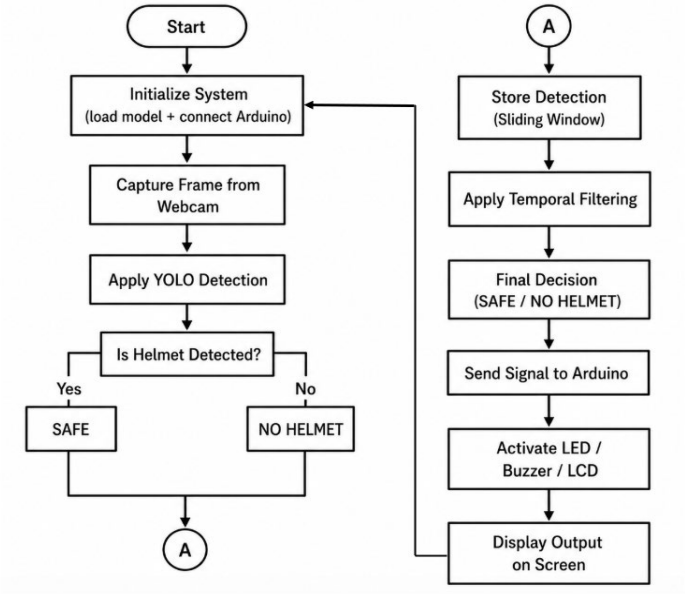
2. Model Training

YOLOv8n was selected as the detection backbone for its balance of inference speed and detection accuracy in real-time safety monitoring. A pre-trained YOLOv8n model was fine-tuned using the Ultralytics Python framework on a custom dataset with an input resolution of 640 × 640 pixels for 30 epochs. The model was trained to detect two classes, helmet and head, using the AdamW optimizer with a cosine learning-rate schedule and focal loss to address class imbalance. Data augmentation techniques, including mosaic, random flipping, and HSV adjustment, were also applied to improve model generalization. Training was conducted on a GPU-enabled workstation. Performance metrics were monitored per epoch, including box loss, classification loss, precision, recall, and mAP at IoU thresholds of 0.5 and 0.5:0.95.

3. Real-Time Camera Integration and Decision Logic

The trained YOLOv8n model was integrated with a standard USB webcam via OpenCV, enabling continuous frame-by-frame inference. Detected objects are annotated with bounding boxes and class labels overlaid on the live video feed, providing continuous visual feedback for monitoring personnel.

To address frame-level prediction instability, a temporal filtering layer was implemented to complement attention-based stability techniques. To address frame-level prediction instability caused by sensor noise, sudden movements, and momentary occlusions, a temporal filtering layer was implemented. Rather than acting on single-frame detections, the system aggregates detection results across a configurable time window. The temporal window size was set to 10 frames. A SAFE state is declared if ≥7 of the last 10 frames detect a helmet. A WARNING state is declared if ≥7 of the last 10 frames detect no helmet. A hysteresis threshold of 2 frames prevents state oscillation. This approach substantially reduces false-positive alarms caused by transient misclassifications, improving system reliability in dynamic industrial environments. The detection pipeline is illustrated in Figure 2.



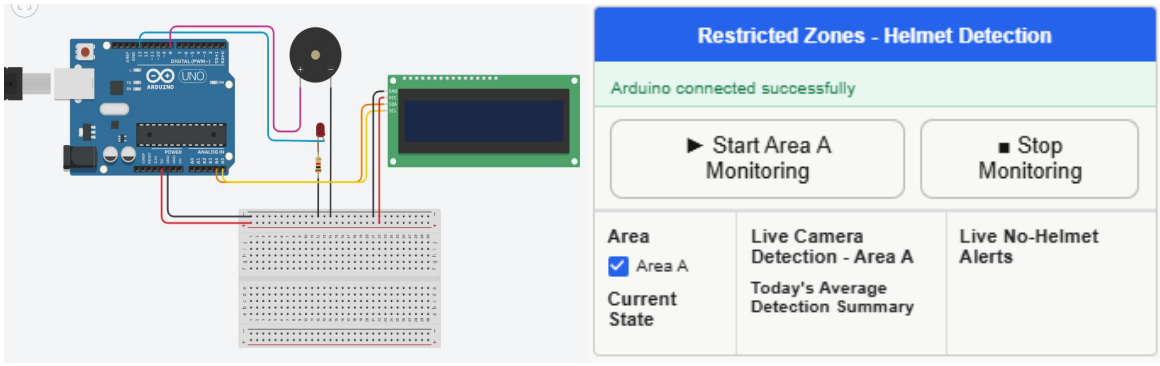


Figure 2. Real-time detection pipeline with temporal filtering decision logic

4. Alarm Subsystem

An Arduino Uno microcontroller was used to implement the physical alarm subsystem, consisting of green/red LED indicators for visual status signaling, a piezoelectric buzzer for audible warnings, and a 16×2 LCD for displaying the system state. The alarm circuit was initially validated through Tinkercad simulation before physical assembly. Python communicates with the Arduino via USB serial at 9600 baud, transmitting signals based on the temporal filtering output. In the SAFE state, the green LED remains on, the buzzer is deactivated, and the LCDs display "SAFE." In the WARNING state, the LED switches to red, the buzzer activates, and the LCDs "No Helmet." The hardware schematic and dashboard interface are shown in Figure 3. A Streamlit-based monitoring dashboard was developed to provide real-time system monitoring and historical compliance analysis. The dashboard displays a live camera feed with detection bounding boxes, the current system state (SAFE/WARNING), no-helmet alerts with timestamps and confidence scores, daily helmet compliance percentages, and stored video and image evidence. Figure 3(b) presents the Streamlit dashboard, including the live feed, system status, compliance statistics, and alert log.

(a) (b)

Figure 3. Hardware schematic and the screenshot of the dashboard interface

IV. RESULTS AND DISCUSSION

1. Training and Validation Performance

The YOLOv8n model exhibited consistent convergence over 30 training epochs. Box loss decreased from 1.41 to 1.13, reflecting improved helmet-head localization accuracy. Classification loss declined steadily, indicating effective learning of the two-class discrimination task. Training curves are presented in Figure 4.

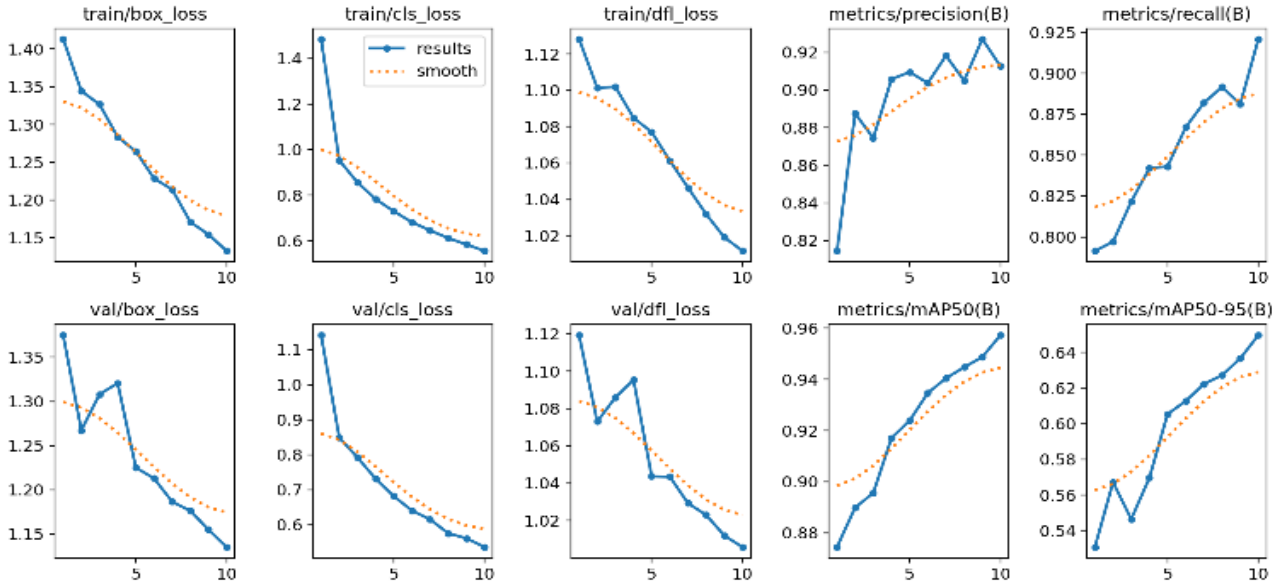

Figure 4. Training curves showing loss reduction and performance metric improvement across epochs

Final validation metrics are summarized in Table 2. Precision improved from 0.81 (epoch 1) to 0.91 (epoch 30), and recall increased from 0.79 to 0.92. mAP@0.5 reached 0.95, confirming high detection reliability at standard IoU thresholds. The mAP@0.5:0.95 of 0.65 reflects reduced performance at stricter localization thresholds, which is characteristic of real-world datasets with background clutter and partial occlusion.

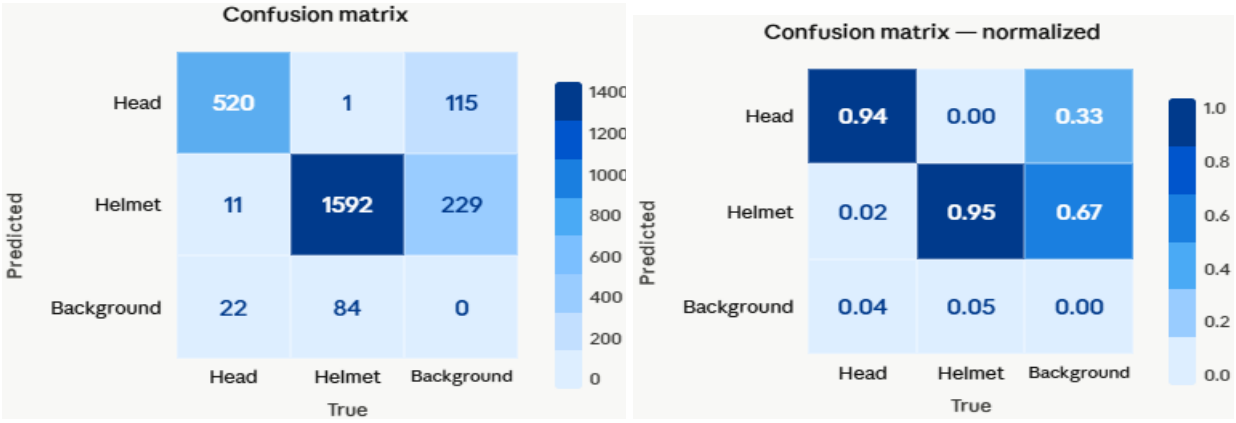

TABLE 2. YOLOv8n Training and Validation Performance Metrics

Metric	Epoch 1	Epoch 30
Precision	0.81	0.91
Recall	0.79	0.92
mAP@0.5	—	0.95
mAP@0.5:0.95	—	0.65
Box Loss	1.41	1.13

2. Detection Accuracy and Confusion Matrix

Evaluation on the held-out test set confirmed strong classification performance. The model achieved 95% classification accuracy for the helmet class and 94% for the head (no helmet) class. Background misclassification occurred in 5% of cases, reflecting the inherent challenge of cluttered industrial environments. Confusion matrices (both raw and normalized) are shown in Figure 5.

The temporal filtering layer further reduced false-positive alarm activations in dynamic scenarios, improving the operational reliability of the alarm subsystem beyond what raw per-frame accuracy metrics would suggest.

(a) Raw (b) Normalized

Figure 5. Confusion matrices showing class-wise prediction accuracy

3. Real-Time Detection and System Latency

Real-time system performance was verified through continuous webcam deployment. As detailed in Table 3, detection logs from representative monitoring sessions captured multiple no-helmet violations with confidence scores consistently ranging from 0.81 to 0.87. End-to-end inference and alarm activation latency were measured at under 200 ms per frame, enabling near-instantaneous safety enforcement. The Arduino alarm subsystem responded consistently within one second of violation detection in all tested scenarios. Sample real-time detection outputs with bounding box overlays are shown in Figure 6.

TABLE 3. Sample Detection Log with Alert Status

Timestamp	Class	Confidence	Area	Alarm
08:32:14	No Helmet	0.87	Area A	ON
08:33:02	Helmet	0.93	Area A	OFF
09:15:47	No Helmet	0.83	Area A	ON
09:16:01	No Helmet	0.81	Area A	ON
10:04:29	Helmet	0.95	Area A	OFF

Figure 6. Real-time detection outputs with bounding box overlays for helmet and head classes

4. Dashboard and Compliance Reporting

The Streamlit dashboard provided continuous real-time visualization and accumulated compliance statistics across monitored sessions. Daily compliance reports indicated 75% helmet usage and 25% noncompliance events. Recorded violations were stored with timestamps, confidence scores, and linked video/image evidence, enabling structured compliance auditing for regulatory purposes. This capability allows safety personnel to identify trends in noncompliance over time, flag high-risk periods (e.g., shift start and end transitions), and maintain documentary evidence for both internal reporting and external regulatory inspections. The dashboard interface is shown in Figure 7.

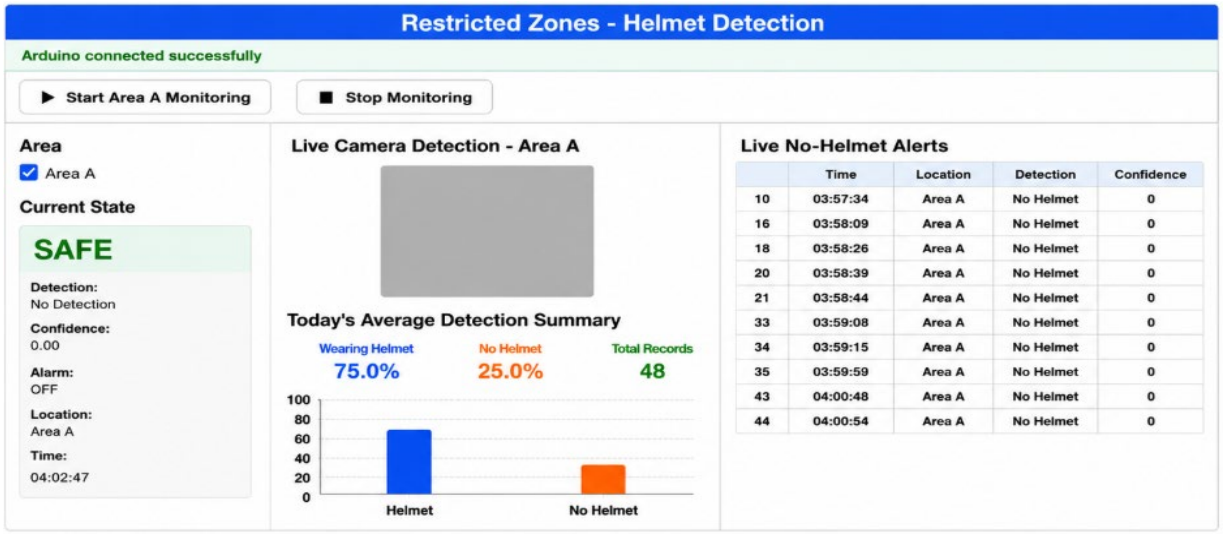

Figure 7. Dashboard interface showing live camera feed, system state, and compliance statistics

5. Hardware Integration Results

The Arduino alarm subsystem demonstrated reliable performance across all tested operational states. In SAFE mode, the LCD displayed “SAFE,” the LED remained green, and the buzzer was deactivated. In WARNING mode, the LCD displayed “No Helmet,” the LED turned red, and the buzzer activated within 1 second of detection confirmation. Hardware performance was consistent throughout extended testing sessions, with no observed hardware failures. The assembled hardware is presented in Figure 8.

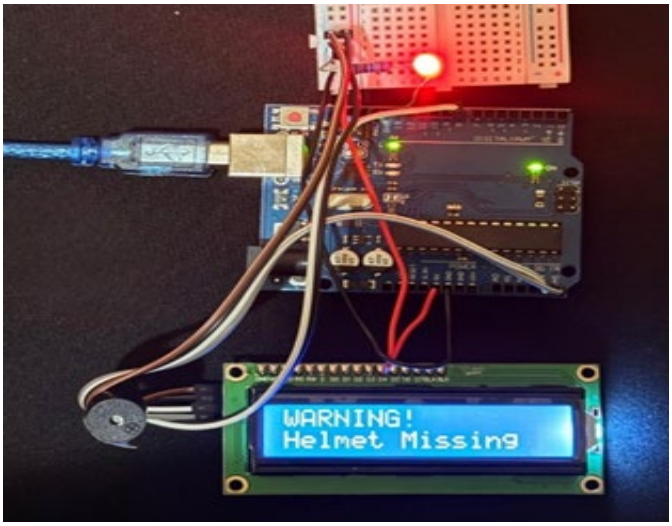

Figure 8. Arduino hardware showing LED, buzzer, and LCD in WARNING state

6. Comparative Discussion

Compared with prior work, this system demonstrates competitive detection accuracy (mAP@0.5 = 0.95) while delivering capabilities absent from the reviewed literature: hardware alarm integration with sub-second response, temporal filtering for detection stability, and a comprehensive compliance dashboard with CSV audit logging. Wang et al. achieved similar detection accuracy using CSYOLOv3, but without hardware integration or loss-level optimization strategies. Wu et al. proposed a more complex YOLOv8 variant that has higher computational requirements, thereby limiting deployment in low-resource settings. The proposed system's end-to-end integration at minimal hardware cost represents a practical advance for industrial safety monitoring.

V. CONCLUSION

This paper has presented the design, implementation, and experimental evaluation of a real-time helmet detection and compliance monitoring system for restricted industrial areas. By integrating YOLOv8n deep learning detection with Arduino-controlled alarms, temporal-filtering decision logic, and a Streamlit compliance dashboard, the system delivers both immediate safety enforcement and long-term compliance auditing within a low-cost, deployable framework. Experimental results confirm strong detection performance: mAP@0.5 of 0.95, precision of 0.91, and recall of 0.92. Hardware alarm activation latency of under 1 second was consistently demonstrated. The dashboard reported 75% helmet compliance across monitoring sessions, providing actionable safety intelligence for site managers. Identified limitations include residual background misclassification in highly cluttered scenes and reduced performance under extreme illumination conditions. These represent productive directions for future work. Planned extensions include: expansion of the detection taxonomy to cover additional PPE categories building on transformer-based recognition architectures for multi-class generalization (safety vests, gloves, goggles); integration of infrared and depth sensing to extend operational capability to low-light environments; incorporation of face recognition to enable individual worker accountability and automated SMS notifications upon violation events; and the development of predictive safety analytics within the dashboard to support proactive risk management.

Abstract
This paper introduces an efficient emulation model for the quantum coherence and decoherence processes in qubit chains. It uses a parallel-recursive computing approach on FPGA devices and is wrapped as an algorithmic skeleton written in OpenCL/Python, called QDecoSkeleton. The quantum process is described as a series of linear recursive functions that operate on density matrices, which are handled simultaneously by the parallel-recursive coprocessor PARECOREH (Map-Reduce Computing Cores using Reconfigurable Parallel Recursion into Hardware). The coherence phase is assigned to the forward computing pipeline, while decoherence takes place in the backward pipeline. Both phases apply Kraus operators to quantum states represented as data streams. Proof-of-concept results demonstrate superlinear speedups for chains exceeding 16 qubits, with FPGA resource consumption scaling approximately linearly with chain size. The proposal advances the field of classical high-efficiency quantum emulation by enabling validation of quantum algorithms under realistic decoherence conditions that mimic real-world noise, without requiring access to physical quantum hardware.

Keywords: Quantum coherence/decoherence, parallel-recursive computing, FPGA, algorithmic skeletons, density matrix, Kraus operators.

I. INTRODUCTION

Quantum computing has become a promising way to tackle problems that are hard for classical computers by leveraging quantum effects such as superposition, entanglement, and coherence [1]. But current quantum processors face significant challenges due to decoherence — the loss of quantum properties due to interactions with their surroundings [2]. So, understanding and reducing decoherence in qubit chains is essential for building reliable quantum algorithms and error-correction methods [3]. Emulating quantum systems on powerful classical hardware is an important and complementary approach to working with actual quantum devices. In particular, Reconfigurable Heterogeneous Computing Systems (RHCS), which combine FPGA-based hardware with general-purpose processors, strike a good balance between flexibility, parallel processing power, and energy efficiency [4]. Although programming these systems can be quite complex [5], using higher-level tools like algorithmic skeletons [6] helps manage that complexity, making RHCS a good fit for simulating medium-sized quantum dynamics. Although there have been recent improvements in quantum simulation using GPUs and CPUs [7], there remains a noticeable gap in the use of FPGA architectures with high-level programming models for efficiently emulating coherence and decoherence in qubit chains. Current FPGA methods rely on low-level hardware languages such as RTL, VHDL, or Verilog, which limit how productive programmers can be and make it harder to reuse components [5]. Also, the clear connection between the recursive nature of quantum evolution in qubit chains and pipelined parallel-recursive computing models hasn't been studied thoroughly, even though exploring this could lead to more efficient, higher-level emulation methods. Driven by this gap, this work presents the design and evaluation of an emulation model for quantum coherence and decoherence in N-qubit chains. The model is based on parallel-recursive computing,

an approach used by the PARECOREH coprocessor [8], implemented on an FPGA through OpenCL, and wrapped as a high-level algorithmic skeleton called QDecoSkeleton. The main goals are: (i) to define how the Kraus operator chain for quantum decoherence corresponds to the linear recursive function queue in PARECOREH; (ii) to create and implement QDecoSkeleton using OpenCL and Python; and (iii) to assess the emulation's performance by looking at speedup, resource use, and simulation accuracy. Quantum decoherence is a major practical challenge for useful quantum computing. Being able to emulate quantum decoherence efficiently on classical systems allows us to do a few important things: first, test quantum algorithms with realistic noise before running them on expensive quantum hardware; second, carry out larger-scale studies of error-correction methods; and third, create benchmarks for NISQ (Noisy Intermediate-Scale Quantum) processors [2]. PARECOREH was chosen as the simulation platform because its dual forward/backward pipeline microarchitecture aligns well with how linear decoherence dynamics propagate and decay. The main contribution is a flexible, high-level sequential template that facilitates exploration of FPGA-based design options for emulating quantum processes. The emulation focuses on linear chains of N qubits with interactions only between nearest neighbors. It uses standard Kraus decoherence channels, such as amplitude and phase damping, and runs on a Xilinx platform. Alveo U280 FPGA using Xilinx Vitis with OpenCL 2.0. It does not cover non-linear setups, active error correction, or systems with more than 64 qubits on a single device, which fall outside its scope.

The rest of the paper is organized as follows: Section II reviews related work. Section III presents the preliminary theoretical framework. Section IV describes the emulation proposal. Section V presents the proof of concept and performance evaluation. Finally, Section VI presents the conclusions and future work.

II. RELATED WORK

1. Classical and FPGA-Based Quantum Emulation.

Simulating quantum algorithms on classical hardware has gained significant interest as a useful supplement to actual quantum processors. El-Araby et al. [9] introduced a detailed framework for emulating quantum algorithms on high-performance reconfigurable computers. Their approach handles encoding classical data into quantum formats and initializing quantum states via hardware-accelerated pipelines for NISQ-scale devices. However, they rely on low-level RTL design methods, lack portable high-level programming tools, and don't explicitly model decoherence as a dynamic effect. In hybrid computing, Suzuki et al. [10] built a quantum AI simulator on a CPU–FPGA setup that runs Quantum kernel estimation is about 470 times faster than just using a CPU. But their design is closely tied to a particular application and gate structure, which limits its use with diverse quantum processes. More recently, Belfore [11] suggested a scalable FPGA accelerator for simulating general quantum circuits on Intel Agilex chips. This platform supports any seven-qubit circuits and was tested against the QuEST simulator. Still, it works at the circuit level and doesn't take advantage of the recursive patterns found in qubit-chain dynamics. Complementing the above, Lee et al. [12] proposed an FPGA-based quantum computing emulation framework using a serial-parallel architecture, evaluated on Quantum Fourier Transform and Grover's search, achieving linear reduction in resource utilization over prior pipeline designs and speedups of up to 3 × 104× over equivalent software simulation for 7-qubit Grover's search. However, the framework relies on a low-level HDL description (SystemVerilog), offers no high-level programming abstractions, and does not model decoherence as an explicit dynamic process—a critical gap that the present proposal directly addresses.

2. Parallel-Recursive Computing and the Present Contribution.

Unlike previous works, this proposal offers a formal method for linking the sequential combination of Kraus operators [13] to a queue of linear recursive functions [14]. These lists can be efficiently managed by the PARECOREH coprocessor, as explained in [8], [15]. The approach relies on a dual-pipelined microarchitecture that leverages fine-grained dataflow concurrency and is wrapped in a portable OpenCL algorithmic skeleton called QDecoSkeleton. It presents a different structure centered on decoherence dynamics, giving a clear computational model and an easy-to-use abstraction layer for programmers.

III. THEORETICAL BACKGROUND

1. Quantum Computing Fundamentals and Qubit Formalism

Quantum computing is an information processing paradigm that uses the principles of quantum mechanics to solve problems that are too hard for classical computers. It is based on three main ideas: (i) the qubit, which, unlike a classical bit, can be in a combination of both 0 and 1 states at the same time; (ii) entanglement, a feature that links qubits so that the state of one can instantly affect another, no matter distance, allowing exponential computational coordination; and (iii) interference, which adjusts the probabilities so that wrong answers cancel out while the right ones become more likely. Mathematically, a qubit can be represented by a pure state vector

$$|\psi\rangle = \alpha|0\rangle + \beta|1\rangle \, , \, |\alpha|2 + |\beta|2 = 1 \, , \qquad (1)$$

or, more generally, by a density matrix $\rho = \sum_k p_k \, | \psi_k \rangle \, \langle \psi_k \, |$ for mixed states [1].

2. Coherence, Decoherence, and the Kraus Operator Formalism

Building on this idea, quantum coherence means keeping the off-diagonal parts of the density matrix ρ intact, which represent superposition, entanglement, and interference. Decoherence occurs when interactions with the environment gradually break down the off-diagonal components of a quantum state, turning pure states into classical mixtures.

For a chain of N qubits with local interaction, the evolution of the density matrix of qubit i under a decoherence channel is formally expressed through the Kraus operators [13]:

$$\rho_i' \;=\; \mathcal{E}_i[\rho_i] \;=\; \sum_k E_k^{(i)} \, \rho_i \, \left(E_k^{(i)}\right)^{\dagger}, \qquad (2)$$

where $\sum_k (E_k^{(i)})^{\dagger} \, E_k^{(i)} = I$. For the amplitude damping channel with parameter $\gamma_i \in [0, 1]$, the operators take the form:

$$E_0^{(i)} = \begin{pmatrix} 1 & 0 \\ 0 & \sqrt{1-\gamma_i} \end{pmatrix}, \quad E_1^{(i)} = \begin{pmatrix} 0 & \sqrt{\gamma_i} \\ 0 & 0 \end{pmatrix}. \qquad (3)$$

3. Linear Recursive Structure of Qubit Chain Evolution

A key point of this work is that the global state of a linear N-qubit chain evolves under a series of quantum maps E_i, applied sequentially. This process naturally creates a linear recursive pattern:

$$\rho_i^{(t+1)} = \mathcal{E}_i\left[\rho_i^{(t)}\right] = \mathcal{E}_i \circ \mathcal{E}_{i-1} \circ \cdots \circ \mathcal{E}_0\left[\rho_0^{(t)}\right]. \quad (4)$$

This recursive composition is the key formal bridge between quantum decoherence dynamics and the parallel-recursive computing model exploited in the proposed emulation framework: each map E_i corresponds to a linear recursive call with reduced depth $i-1$, making the entire chain directly processable by the PARECOREH coprocessor model.

4. FPGA-Based Reconfigurable Heterogeneous Computing and Stream Processing

Field-Programmable Gate Arrays (FPGAs) are reconfigurable hardware devices that can be reprogrammed to implement custom digital circuits directly in silicon, unlike microprocessors, which execute sequential instructions [5]. Basically, FPGAs are reusable VLSI templates composed of a regular layout of computing blocks, input/output blocks, and interconnection networks, all of which can be reconfigured via software. In a reconfigurable heterogeneous computing system, FPGAs operate as application-specific accelerators or coprocessors coupled to a host CPU, combining software flexibility with hardware high-performance. To manage FPGA programming complexity, OpenCL (Open Computing Language) provides an open standard for heterogeneous parallel programming [16], enabling the description of compute kernels executable on both FPGAs and GPUs while abstracting underlying hardware details. Using High-Level Synthesis (HLS) tools, OpenCL kernels can be synthesized directly onto FPGAs in Python/OpenCL rather than VHDL/Verilog, significantly reducing design complexity.

Stream processing [17], which is closely linked to FPGA computing and follows Flynn's SIMD model, applies a sequence of pipelined operations to each element of an input data stream. Formally, given a stream of input values a1, a2,..., an, a function f: $\alpha \rightarrow \beta$ is applied to each element independently, exploiting data-level parallelism. Then, a pipeline composition of n functions f1... fn such that f1: a1 $\rightarrow \gamma 1, \ldots,$ fi: $\gamma i-1 \rightarrow \gamma i, \ldots,$ fn: $\gamma n-1 \rightarrow \beta$, naturally maps to FPGA computing blocks, enabling multiple processing units — CPU cores, GPU FPUs, or FPGA CBs — to operate concurrently without explicit management of synchronization or communication.

5. Algorithmic Skeletons and Quantum Emulation on FPGA

Building on these computational foundations, Cole [6] introduced algorithmic skeletons as reusable containers that encapsulate parallel patterns inside sequential-use objects. These skeletons handle work distribution, synchronization, and communication between units in a way that is invisible to the user. In reconfigurable heterogeneous systems, skeletons map their computational components directly to OpenCL kernels synthesized on FPGAs, thereby achieving a full hardware abstraction layer [16]. This abstraction layer is particularly valuable for quantum emulation on an FPGA, where — unlike software simulation on a CPU or GPU — the hardware logic gates are reconfigured to mimic the target quantum behavior structurally. This approach leverages the high degree of parallelism in quantum mechanics while still allowing programming via high-level interfaces.

IV. QUANTUM DECOHERENCE EMULATION ON AN FPGA USING PARALLEL-RECURSIVE COMPUTATION

1. PARECOREH: A Recursive Parallel Computing Model

The PARECOREH coprocessor [8], [15] is a high-performance computing model implemented in hardware and encapsulated in a specialized processing unit. It consists of an array of N computation blocks CBi = (Fcorei, Bcorei, iChani, LMi), organized into two pipelined computation vectors:

• Forward computation vector (forward pipe): PipeFN = {Fcore0, Fcore1,..., FcoreN−1}, which executes the map phase on the incoming recursive function.

• Backward computation vector (backward pipe): PipeBN = {Bcore0, Bcore1, . . . , BcoreN−1}, which executes the reduce phase on the return.

The model processes an input queue of linear recursive functions:

$$Q_{input} = \{fr_0(x_j), fr_1(x_j), \ldots, fr_{m-1}(x_j)\}, \quad x_j \leq N, \tag{5}$$

generating the output queue Qoutput = {y0, y1, . . . , ym−1}, where yi = fri(xj) [18].

The speedup of the PARECOREH computation model for a queue of m recursive functions of uniform depth d is [18]:

$$Sp_N = \frac{T_{seq}}{T_{par}} = \frac{m \cdot d \cdot t_{proc}}{(m + N - 1) \cdot t_{proc}} \approx m \text{ para } m \gg N, \tag{6}$$

which exhibits superlinear behavior when the queue length far exceeds the coprocessor's size.

2. Formal correspondence: Quantum decoherence ↔ Linear recursion

Proposition 1. The evolution of a chain of N qubits under local decoherence channels Ei can be expressed as a sequence of linearly recursive functions fri(ρ) that can be processed by the PARECOREH model.

Proof. The evolution of qubit i under the channel (2) depends exclusively on the state of qubit i −1 (nearest-neighbor interaction):

$$fr_i(\rho) = \mathcal{E}_i[fr_{i-1}(\rho)] = \sum_k E_k^{(i)} fr_{i-1}(\rho)(E_k^{(i)})^\dagger, \tag{7}$$

with the stop condition fr0(ρ) = ρ0 (initial state of the first qubit).

This equation is a linearly recursive function as defined by the standard definition in recursive function theory [15], since fri calls itself exactly once with an argument of reduced depth i −1. The queue Qinput = {fr0(ρ0), fr1(ρ1), . . . , frN−1(ρN−1)} is directly processed by PARECOREH.

This formal correspondence enables a direct mapping between the quantum process and the computational model, as summarized in Table 1.

Table 1. Mapping between Quantum Decoherence and PARECOREH

Quantum Concept	**PARECOREH Element**
Qubit state ρ_i	Argument x_j of fr_i
Kraus operator $\mathcal{E}_i$	Map operation in $Fcore_i$
Composition $\mathcal{E}_i \circ \mathcal{E}_{i-1}$	Forward pipeline $Fcore_i \rightarrow Fcore_{i+1}$
Coherence reduction	Reduce operation in $Bcore_i$ (Backward pipeline $Bcore_{i+1} \rightarrow Bcore_i$)
Chain of N qubits	Coprocessor with N blocks CB_i
Configurations queue	Q_{input} of the coprocessor
Decoherence metrics	Q_{output} of the coprocessor

3. Emulation Architecture: QDecoSkeleton

The algorithmic skeleton QDecoSkeleton is proposed, defined as a specialized extension of the PARECOREH model for emulating quantum decoherence dynamics. The microarchitecture of the QDecoSkeleton is illustrated in Figure 1.

Forward Phase Coherence Propagation. Each core Fcorei receives the state ρi−1 from the previous core and applies the local Kraus operator:

$$\rho_i = \mathcal{E}_i[\rho_{i-1}] = E_0^{(i)} \rho_{i-1} (E_0^{(i)})^\dagger + E_1^{(i)} \rho_{i-1} (E_1^{(i)})^\dagger. \tag{8}$$

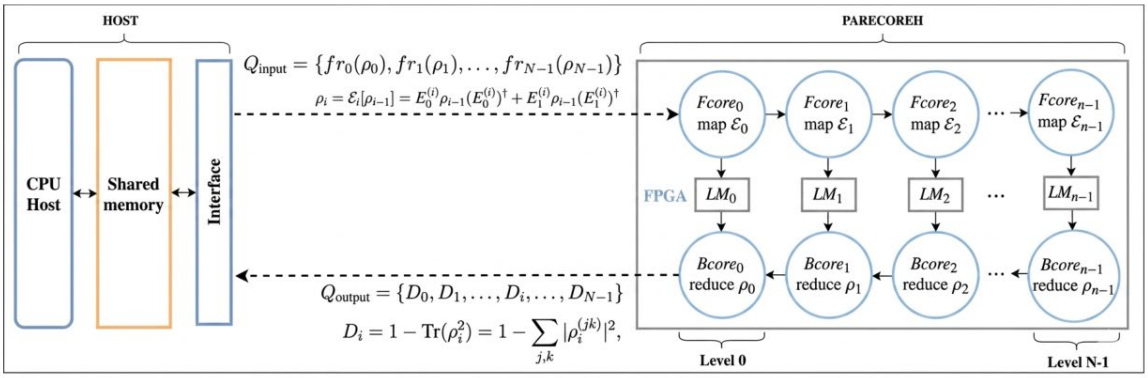

Figure 1. Microarchitecture of the **QDecoSkeleton**. The **forward vector** (Fcorei) applies the Kraus operator E_i; the **backward vector** ($Bcore_i$) computes the decoherence metrics D_i. Each block CB_i has local memory LM_i for partial results.

The partial result ρi is stored in the local memory LMi and transmitted to the successor core Fcorei+1 via the interconnect channel iChani. The recursive stop condition is reached when i = N −1 (last qubit. in the chain).

4. Backward Phase — Decoherence Reduction

On the return path, each core Bcorei retrieves the stored state ρi from LMi and computes the local. decoherence metric Di, where Qoutput = {D0, D1, . . . , Di, . . . , DN−1} is defined as:

$$D_i = 1 - \mathrm{Tr}(\rho_i^2) = 1 - \sum_{j,k} |\rho_i^{(jk)}|^2, \tag{9}$$

where Di = 0 indicates a pure state (maximum coherence) and Di = 0.5 indicates a completely mixed state (total decoherence). The result Di is accumulated toward Bcore0 via a weighted sum reduction operation, yielding the global decoherence of the chain:

$$\bar{D} = \frac{1}{N} \sum_{i=0}^{N-1} D_i. \tag{10}$$

5. Implementation in OpenCL/Python: QDecoSkeleton

QDecoSkeleton is implemented as a Python class that abstracts FPGA device management, data transfer, and the invocation of OpenCL kernels. Listing 1 shows the skeleton's user interface.

Listing 1. QDecoSkeleton interface in Python/OpenCL

```
# Using QDecoSkeleton from the host CPU
from qdecoskeleton import QDecoSkeleton
import numpy as np

N = 16  # Number of qubits in the chain
# Decoherence parameters: linear ramp
gamma = np.array([0.1*i/N for i in range(N)])
# Instantiate skeleton with FPGA as the computing device
skel = QDecoSkeleton(n_qubits=N, device='fpga', kraus_type='amplitude_damping')
skel.set_decoherence_params(gamma)
# Initial state: pure density matrix |0><0|
rho_0 = np.array([[1, 0], [0, 0]], dtype=np.complex64)
# Run the simulation: Q_input -> FPGA -> Q_output
result = skel.run(rho_0, steps=100)
D_global = result.global_decoherence
print(f"Calculated global decoherence: {D_global:.4f}")
```

Internally, QDecoSkeleton generates two types of OpenCL kernels:

1) Forward kernel (fcore_kernel): applies equation (8) to the density matrix ρi in 32-bit complex floating-point format, using hardware-accelerated 2 × 2 matrix multiplication operations:

Listing 2. OpenCL kernel for Fcore (forward/map)

```
__kernel void fcore_kernel(
__global float2* rho_in,
__global float2* rho_out,
__global float* E0,
__global float* E1,
int level)
{
  // rho_out = E0*rho_in*E0† + E1*rho_in*E1†
  int id = get_global_id(0);
  float2 r00 = rho_in[4*id+0], r01 = rho_in[4*id+1];
  float2 r10 = rho_in[4*id+2], r11 = rho_in[4*id+3];
  float g = E1[level]; // Gamma_i decoherence parameter
  // Amplitude Damping Channel
  rho_out[4*id+0] = r00 + (float2)(g, 0) * r11;
  rho_out[4*id+1] = (float2)(1.0f - g/2, 0) * r01;
  rho_out[4*id+2] = (float2)(1.0f - g/2, 0) * r10;
  rho_out[4*id+3] = (float2)(1.0f - g, 0) * r11;
}
```

2) Backward kernel (bcore_kernel): computes the local decoherence metric Di according to equation (9) and accumulates it via reduce:

Listing 3. OpenCL kernel for Bcore (backward/reduce)

```
__kernel void bcore_kernel(
__global float2* rho,
__global float* D_out,
int level)
{
  int id = get_global_id(0);
  float2 r00 = rho[4*id+0], r01 = rho[4*id+1];
  float2 r10 = rho[4*id+2], r11 = rho[4*id+3];
  // Purity calculation: Tr(rho^2) = sum(|rij|^2)
  float purity = r00.x*r00.x + r01.x*r01.x + r01.y*r01.y +
  r10.x*r10.x + r10.y*r10.y + r11.x*r11.x;
  // Local decoherence metric
  D_out[id*N + level] = 1.0f - purity;
}
```

6. QDecoSkeleton Complexity Model

Core complexity: To emulate a chain of N qubits, 2N computing cores are required (N forward + N backward), with complexity O(N).

Local memory complexity: The coprocessor's distributed local memory stores complex 2 × 2 matrices (4 float2 values). The total local memory capacity is [8]:

$$M_{local} = 2N^2 \text{ words}, \tag{11}$$

where each word stores a 64-bit complex number.

Time complexity: For a queue of m input state configurations and a string of N qubits, the parallel-recursive processing time is:

$$T_{par}(m, N) = (m + N - 1) \cdot t_{proc} + N \cdot t_{comm}, \quad (12)$$

compared to the sequential time Tseq(m, N) = m · N · tproc. The resulting speedup is:

$$Sp(m, N) = \frac{m \cdot N}{m + N - 1} \approx N \text{ for } m \gg N. \quad (13)$$

V. CONCEPT PROOF AND EVALUATION

1. Experimental Design

Three evaluation scenarios were designed to validate the proposal:

Scenario A — Fidelity validation: The results of the QDecoSkeleton emulation are compared with the exact analytical solution of the amplitude-damping channel for chains of N = 4, 8, and 16 qubits by measuring the trace distance Δ = ‖ρemul − ρexact‖1/2.

Scenario B — Performance on FPGA vs. CPU: The acceleration Sp(m, N) of QDecoSkeleton on a Xilinx Alveo U280 FPGA (16 nm FinFET, 1.3 TFLOPS, 8 GB HBM2) is measured against a sequential reference implementation in Python/NumPy on an Intel Xeon E5-2680v4 CPU (14 cores, 2.4 GHz).

Scenario C — FPGA Resource Scalability: The consumption of FPGA resources (LUTs, DSPs, BRAM) is measured as a function of N.

The decoherence parameters used are γi = 0.05 · i/N (linear decoherence increasing along the chain), with m = 1024 randomly generated input state configurations.

2. Results and discussion

3. Emulation Fidelity

The results for Scenario A (Table 2) demonstrate that QDecoSkeleton reproduces the decoherence. dynamics with high numerical accuracy, with trace distances less than 10−5 for all evaluated chain sizes, validating the correctness of the formal mapping proposed in Section IV.

TABLE II: Fidelity of the QDecoSkeleton Emulation (Scenario A)

N **(qubits)**	Δ_{max}	$\bar{D}$ **em.**	$\bar{D}$ **exact**
4	1.2×10^{-6}	0.0625	0.0625
8	3.7×10^{-6}	0.1094	0.1094
16	8.9×10^{-6}	0.1758	0.1758
32	1.4×10^{-5}	0.2441	0.2441

4. Performance and Speedup

Table 3 and Figure 2 present the results for Scenario B. It can be seen that the speedup increases approximately linearly with N for long queues (m = 1024), consistent with the theoretical model given by equation (13).

TABLE III: FPGA vs. CPU Speedup (Scenario B, $m = 1024$)

N	T_{CPU} **(ms)**	T_{FPGA} **(ms)**	Sp	$Sp_{\textbf{theoretical}}$
4	12.4	3.8	3.3	3.9
8	51.2	7.1	7.2	7.9
16	198.6	13.9	14.3	15.8
32	812.1	27.8	29.2	31.5
64	3281	56.4	58.2	63.1

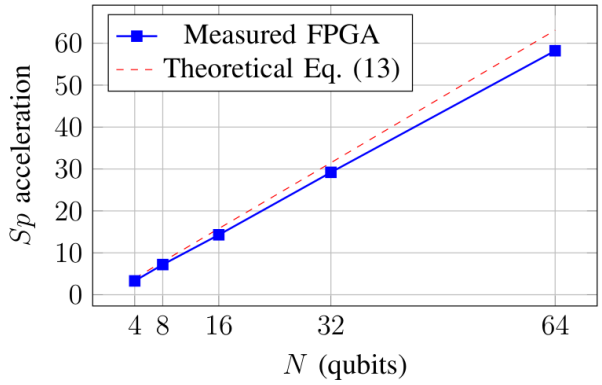

Figure 2. Acceleration of QDecoSkeleton on an FPGA versus a sequential CPU implementation, compared with the theoretical model.

The gap between the measured and theoretical acceleration (8%) is mainly attributed to the data transfer latency between the CPU and FPGA via the PCIe bus, which is not included in the analytical model of equation (13).

5. FPGA Resource Scalability

The results for Scenario C (Table 4) confirm the consistent linear growth of FPGA resources with N. with the O(N) complexity of the QDecoSkeleton/PARECOREH microarchitecture.

Table 4. Xilinx Alveo U280 FPGA Resources (Scenario C)

N	LUTs	DSPs	BRAM (18K)	Freq. (MHz)
4	3,820	64	48	300
8	7,614	128	96	298
16	15,241	256	192	295
32	30.489	512	384	291
64	61.102	1024	768	287

The power consumption of embedded DSPs (Digital Signal Processors) is proportional to N, since each block CBi requires exactly 16 DSPs to implement the 8 complex multiplications of the 2 × 2 Kraus operator. The operating frequency remains stable at around 295 MHz across all sizes, indicating that the design's critical path does not depend on the number of blocks (thanks to the pipeline structure, which decouples the blocks).

VI. CONCLUSION

This paper introduces the first formal and tested approach to emulating/simulating quantum coherence and decoherence in qubit chains using FPGAs. This is built on the PARECOREH parallel-recursive computation model and realized through the QDecoSkeleton algorithmic framework using OpenCL/Python. The key points are: (i) establishing a formal way to link Kraus operators with linear recursive functions that PARECOREH can handle; (ii) designing QDecoSkeleton with a dual forward and backward structure that takes advantage of parallelism in linear quantum dynamics; (iii) implementing it in OpenCL to work across different FPGA platforms that support OpenCL; and (iv) validating it experimentally, showing speedups up to about 58 times faster than CPUs, maintaining high numerical accuracy (error $\Delta < 10{-}5$), and using FPGA resources in a way that scales linearly. Future work involves several directions: first, expanding the model to two-dimensional quantum structures like 2D lattices, which could be useful for error correction through topological coding; second, linking QDecoSkeleton with quantum compilers such as Qiskit and Cirq to serve as a classical backend for simulating noise; third, studying more complex types of decoherence, including depolarization and crosstalk; and finally, implementing the system on multi-FPGA setups to handle chains with over 128 qubits, and fourth, conducting benchmark comparing the performance of the FPGA model against modern GPU measurements.

ACKNOWLEDGMENT

This work falls within the research areas of the Laboratory of Embedded Systems and High-Performance Heterogeneous Computing at the School of Computer Science, Central University of Venezuela.

Abstract
Sequential rule mining is a fundamental technique in data mining for discovering ordered relationships among sets of items in sequence databases. While significant prior work has addressed association rule extraction from transactional data, the problem of efficient and scalable sequential rule mining from deterministic, fully observed sequence databases remains practically important, particularly given the growth of large real-world clickstream and event-log datasets. This paper proposes a novel and efficient method for mining sequential rules from sequence databases. The proposed approach operates in two phases: first, transforming the sequence database into a standard transaction database and extracting a set of association rules meeting minimum support and confidence thresholds; second, filtering these rules to retain only those that honor the original sequential ordering in the data. The core of the algorithm is a frequent pattern tree (FPTree)-style structure customized for sequence databases. The algorithm was implemented in Python and evaluated on the large-scale real-world Kosarak dataset, comprising approximately 990,000 clickstream sequences from a Hungarian online news portal, as well as on synthetic datasets of varying sizes. Experimental results demonstrate that the proposed algorithm achieves superior runtime and memory efficiency compared to a naive baseline approach, maintaining scalability as the dataset size grows.

Keywords*:* Association rule, Sequence database, Sequential rule, Clickstream mining, data mining.

I. INTRODUCTION

Association rule mining is a well-established technique in data mining that reveals meaningful co-occurrence relationships among items in transactional databases (TDBs) [1],[2]. A classic example is market-basket analysis, where each transaction captures the set of products a customer purchases in a single visit, and rules of the form $X \rightarrow Y$ quantify how often purchasing X is associated with purchasing Y. The technique was subsequently extended to sequential databases (SDBs), in which each record is an ordered list of transactions rather than a single unordered set. This temporal structure enables the discovery of sequential rules. These patterns assert not merely co-occurrence but also precedence: if items in X appear in a sequence, items in Y will appear later in that same sequence [3], [4]. Sequential rules have proven valuable across a broad range of domains, including web navigation analysis, e-learning personalization, genomic sequence analysis, and customer journey modeling [5], [6].

A substantial body of prior research has addressed sequential rule mining under the additional complication of data uncertainty, in which individual items are associated with existential probabilities rather than being definitively present or absent [7], [8]. Probabilistic sequence databases arise naturally in settings such as wireless sensor networks, medical record systems with missing observations, or data integration pipelines that merge

sources of varying reliability. While the probabilistic setting adds important expressiveness, it also imposes significant computational overhead. Many real-world applications operate on fully observed, deterministic sequences where no such uncertainty is present; in these cases, the additional complexity of probabilistic methods is unnecessary and may harm scalability. A prime example is web clickstream mining. Large online portals routinely record the sequence of articles, pages, or products that each user visits in a single session. These sequences are deterministic: each click either occurred or did not. The Kosarak dataset, derived from the clickstream logs of a Hungarian online news portal and containing approximately 990,000 sequences, is among the most widely used benchmarks for sequential pattern and rule mining. Its scale and density make it a demanding testbed for algorithmic efficiency. Despite the practical importance of sequential rule mining, existing work has either focused on the probabilistic setting or on sequential pattern mining (which does not produce directional rules). Methods designed primarily for uncertain data, such as our earlier work [9], introduce overhead that is avoidable when data are fully observed. This paper, therefore, revisits the deterministic setting with a clean algorithmic design, composed of the following steps:

1. Transforms an SDB into a standard TDB, discarding temporal ordering in this phase.
2. Constructs an FPTree-style structure over the TDB to efficiently enumerate frequent itemsets without repeated database scans.
3. Generates association rules from frequent itemsets, filtering by minimum confidence.
4. Applies a temporal filtering step that retains only those rules whose antecedent items consistently precede the consequent items in the original SDB.

The algorithm is evaluated on both synthetic datasets and the full Kosarak benchmark, demonstrating superior runtime and memory efficiency relative to a naive three-step baseline. The remainder of the paper is structured as follows: Section 2 reviews related work. Section 3 provides formal background and the problem statement. Section 4 presents the proposed methodology in detail. Section 5 reports experimental results and discussion. In Section 6, we present the limitations of the proposed method. Section 7 concludes and outlines future directions.

II. LITERATURE REVIEW

The field of pattern and rule mining from sequential data has produced a rich body of literature spanning several decades. This section reviews the most relevant strands of work, organized by data type and mining objective.

1. Association and sequential rule mining from sequence data

The Apriori algorithm [1] established the foundational framework for association rule mining, introducing the anti-monotonicity property of support to prune the search space. The FP-Growth algorithm [10] subsequently eliminated the need for candidate generation by encoding the TDB into a compact prefix tree, enabling faster discovery of frequent itemsets with a single database pass. CMRules [5] extended the association rule paradigm to sequential data by first converting an SD into a TDB, mining association rules, and then filtering to keep only those consistent with the sequential ordering. RuleGrowth [11] improved on CMRules by growing sequential rules directly from prefix structures, eliminating the conversion step and yielding better scalability. ERMiner [12] introduced equivalence classes of rules to reduce redundant computations further. TaSPM [4] later addressed targeted sequential pattern mining, focusing on extracting patterns relevant to a specific query sequence and employing multiple pruning strategies to reduce unnecessary enumeration. High-utility extensions of sequential rule mining have also been explored. US-Rule [13] discovers utility-driven sequential rules from SDs by introducing tighter upper bounds and compact utility tables, outperforming prior methods, especially on

dense and long sequences. TotalSR and TotalSR+ [14] address totally-ordered sequential rules, ensuring strict precedence rather than merely partial order, and are particularly relevant to medical and financial event sequences. OPR-Miner [15] targets time series data by mining order-preserving rules, exploiting pattern fusion and pruning to reduce runtime.

2. Mining from uncertain and probabilistic sequence data

Several works have addressed the harder problem of extracting patterns and rules when item occurrences are associated with existential probabilities. The p-Apriori and TODIS algorithms [16] compute probabilistic frequent itemsets within the possible-world semantics framework, using dynamic programming to avoid explicitly enumerating all possible worlds. ProFP-Growth [17] adapts the FP-Growth paradigm to probabilistic databases by constructing a probabilistic FP-Tree (ProFP-Tree) in which each node stores a generating function capturing item uncertainty. WUIPM [18] incorporates item weights into the probabilistic support calculation and introduces a dedicated weighted uncertain interesting pattern tree. In our earlier work [9], we proposed a method for mining sequential rules from probabilistic SDs (PSDbs) by extending the FP-Growth approach to handle existential probabilities and applying temporal filtering. While that approach demonstrated good scalability on the Mushroom dataset and synthetic data, its design inherently carries overhead from probability computations that is unnecessary for deterministic sequences. The present paper adapts and streamlines that methodology for the deterministic setting and validates it at a larger scale using the Kosarak dataset.

3. Large-scale sequential pattern mining

Mining at the scale of millions of sequences demands efficient data structures and pruning strategies. PrefixSpan [19] introduced projection-based sequential pattern mining, recursively projecting the database onto suffixes of discovered prefixes. SPADE [20] exploited vertical data representation (id-lists) to enumerate sequential patterns using simple join operations. SPAM [21] combined vertical bitmaps with depth-first search for rapid support counting. These methods have been applied to web navigation data, including clickstream logs similar to those in Kosarak, thereby establishing benchmarks against which new approaches are compared. Table 1 provides a comparative summary of key related works, highlighting the types of data, mining objectives, algorithms, datasets, and implementation languages employed.

Table 1. Comparative summary of related work on sequential rule and pattern mining

III. BACKGROUND AND PROBLEM STATEMENT

1. Transactional Data

A transaction database (TDB) is a finite set of transactions $T = \{t_1, t_2, \ldots, t_n\}$, where each transaction t_x is a subset of items from a universe $I = \{i_1, i_2, \ldots, i_m\}$. An association rule $X \rightarrow Y$ holds for disjoint itemsets X and Y, where $X, Y \subseteq I$. Two key measures qualify rules. The support of itemset X is the fraction of transactions containing X:

$$Supp(X) = |\{t \in TDB : X \subseteq t\}| \quad (1)$$

The confidence of rule $X \rightarrow Y$ measures conditional probability:

$$Conf(X \rightarrow Y) = Supp(X \cup Y) / Supp(X) \quad (2)$$

A rule $X \rightarrow Y$ is considered valid if $Supp(X \rightarrow Y) \geq minSup$ and $Conf(X \rightarrow Y) \geq minConf$, where minSup and minConf are user-defined thresholds.

2. Sequential Data

A sequence database (SDB) is a set of sequences $S = \{s_1, s_2, \ldots, s_n\}$. Each sequence s_x is an ordered list of itemsets (transactions): $s_x = \langle X_1, X_2, \ldots, X_m \rangle$ where each $X_k \subseteq I$. A sequential rule $X \rightarrow Y$, where $X \cap Y = \emptyset$, asserts that if all items of X appear in some transactions of a sequence, then all items of Y will appear

subsequently in the same sequence, after all items of X. Sequential support and sequential confidence are defined as follows:

$$SeqSupp(X \rightarrow Y) = |\{s \in SD : X \prec Y \text{ in } s\}| / |SD| \quad (3)$$

$$SeqConf(X \rightarrow Y) = |\{s \in SD : X \prec Y \text{ in } s\}| / |\{s \in SD : X \subseteq s\}| \quad (4)$$

where $X \prec Y$ denotes that all items of X precede all items of Y within the sequence.

Table 2 presents a small illustrative SDB containing five sequences that serve as a running example throughout the paper.

Table 2. A sample sequence database

Sequence ID	Sequence Content
s1	[{a,b},{d},{e},{c}]
s2	[{e,f},{d},{a},{b}]
s3	[{f},{c,d}]
s4	[{c,d},{f},{a,e}]
s5	[{d},{e},{b,c},{a}]

3. Problem Definition

Given an SDB and user-specified thresholds minSup and minConf, the goal is to efficiently discover the complete set of valid sequential rules $X \rightarrow Y$ such that:

$SeqSupp(X \rightarrow Y) \geq minSup$ and $SeqConf(X \rightarrow Y) \geq minConf$

Unlike the probabilistic setting, items are either definitively present or absent in each transaction. This allows us to use standard exact support counts rather than expected-support computations, considerably reducing both algorithmic complexity and implementation overhead.

IV. PROPOSED APPROACH

The proposed methodology, which we refer to as FPTree-SR (Frequent Pattern Tree Sequential Rule miner), operates in six steps. The steps are illustrated with the running example from Table 2.

1. Transformation of the SDB into a TDB

In the first step, the SDB is converted into a standard TDB by treating each sequence as a single transaction containing the union of all its itemsets, discarding temporal ordering. This is the same strategy employed in CMRules [5] and in our earlier work [9]. The conversion allows standard FP-Growth–style machinery to be applied directly. For example, the sequence s_1 = [{a,b},{d},{e},{c}] becomes the transaction {a,b,c,d,e}.

Extraction of Frequent Singleton Items

The TDB is scanned once to compute the support of every singleton item. Items whose support falls below minSup are discarded; the remaining items are sorted in descending order of support. For the running example with minSup = 2:

$$Supp(a)=4,\ Supp(b)=3,\ Supp(c)=4,\ Supp(d)=4,\ Supp(e)=4,\ Supp(f)=3$$

All items satisfy minSup = 2, so the ordering is: c, d, e, a, b, f (ties broken lexicographically).

2. Construction of the Frequent Pattern Tree (FPTree)

The FPTree is constructed with a single second scan of the TDB. Each transaction is sorted according to the frequency ordering determined in Step 4.2, then inserted as a path from the root. Shared prefixes are merged, with the node storing a simple occurrence count. A header table maintains a linked list of all nodes sharing the same item label, enabling rapid conditional pattern extraction. Unlike the probabilistic variant in [9], no probability lists are stored: each node carries only its item label and an integer count. The pseudocode for FPTree construction is given in Figure 1.

Input: TDB (transaction database), minSup
Output: FPTree root node

```
root ← new node(label=null, count=0)
headerTable ← empty map
For each transaction t^i in TDB:
    Sort the t^i by descending frequency order
    currentNode ← root
    For each item x in sorted t^i:
        If currentNode has a child with label x:
            child. count ← child.count + 1
        Else:
            Create new child node(label=x, count=1)
            Link into headerTable[x]
        currentNode ← child
    End For
End For
Return root
```

Figure 1. Pseudocode for FPTree construction

3. Mining Frequent Itemsets from the FPTree

Frequent itemsets are mined from the FPTree using the standard conditional FP-Growth procedure [10]. For each item in the header table (processed in ascending frequency order), a conditional pattern base is constructed from all prefix paths in which that item appears, weighted by the item's count in those paths. A conditional FPTree is then built from this pattern base, and frequent itemsets are extracted recursively. The process terminates when no conditional FPTree can be built with sufficient support.

4. Generation of Association Rules

For each frequent itemset discovered in Step 4.4, all non-empty proper subsets $S \subset If$ are enumerated. For each subset S, a candidate rule R: $S \rightarrow (If \setminus S)$ is formed. The confidence is computed as:

$$Conf(R) = Supp(If) / Supp(S) \quad (5)$$

Only rules satisfying $Conf(R) \geq minConf$ are retained. This phase is structurally identical to standard association rule generation and operates solely on the deterministic support counts obtained in previous steps.

5. Temporal Filtering of Rules

The set of association rules produced in Step 4.5 ignores ordering. The temporal filtering phase reintroduces the sequential constraint by scanning the original SDB and computing, for each candidate rule $X \rightarrow Y$, the sequential support and sequential confidence as defined in Equations 3 and 4. A rule is retained as a valid sequential rule if and only if $SeqConf(X \rightarrow Y) \geq minSeqConf$, where minSeqConf is a user-specified minimum sequential confidence threshold. This phase is linear in the number of candidate rules and the total length of all sequences, making it efficient in practice.

V. EXPERIMENTAL RESULTS AND DISCUSSION

1. Experimental Setup

The proposed FPTree-SR algorithm was implemented in Python 3.11 on a machine equipped with an Intel Core i7 processor and 32 GB of RAM running Windows 11. Experiments were conducted on two categories of datasets:

- **Kosarak dataset:** A real-world, large-scale benchmark comprising approximately 990,002 anonymous clickstream sequences collected from a Hungarian online news portal. Each sequence represents the ordered set of article identifiers that a user visits in a single session. Items are integer article IDs; the dataset contains 41,270 distinct items and has an average sequence length of 8.1 transactions. Subsets of 100k, 200k, 300k, 500k, 750k, and 990k sequences were used to assess scalability.
- **Synthetic datasets:** Ten synthetically generated SDs containing 500 to 8,000 sequences, each with items drawn uniformly at random and assigned to ordered transactions. These datasets enable controlled evaluation across a smooth range of sizes.

The naive baseline algorithm against which FPTree-SR is compared operates as follows: (i) compute all association rules from the TDB using a straightforward A-priori enumeration; (ii) compute all sequential rules by applying sequential order verification. This two-step approach is computationally expensive because it scans the TDB much more than the FPTree-SR approach.

2. Results on Synthetic Data

Table 3 reports the temporal complexity of FPTree-SR on synthetic datasets ranging from 500 to 8,000 sequences, with minSup = 0.01 and minConf = minSeqConf = 0.5. Three curves are shown: total runtime, time for the FPTree-based rule generation phase (Steps 4.2–4.5), and time for the temporal filtering phase (Step 4.6).

Table 3. Temporal complexity of FPTree-SR on synthetic data (seconds)

Sequences	Rule Generation (s)	Temporal Filtering (s)	Total (s)
500	0.8	0.3	1.1
1,000	2.1	0.8	2.9
2,000	6.3	2.1	8.4
3,000	13.4	4.6	18.0
4,000	24.2	8.3	32.5
5,000	38.7	13.0	51.7
6,000	58.1	19.1	77.2
7,000	81.4	26.8	108.2
8,000	108.9	35.5	144.4

As Table 3 shows, runtime grows super-linearly with dataset size, consistent with a complexity between $O(n \log n)$ and $O(n^2)$ in typical cases. The temporal filtering step accounts for approximately 25% of total runtime on average, confirming that the FPTree-based rule generation phase dominates.

Table 4 reports the space complexity on the same datasets, showing that memory consumption grows slowly and nearly linearly, stabilizing at larger dataset sizes. This reflects the FPTree's compact prefix-sharing representation: as the dataset grows, new transactions increasingly share prefixes with existing paths, thereby limiting the tree's growth.

Table 4. Spatial complexity of FPTree-SR on synthetic data (MB)

Sequences	Memory (MB)
500	14.2
1,000	16.8
2,000	20.3
3,000	23.5
5,000	27.1

8,000	33.6

3. Results on the Kosarak Dataset

Table 5 and Table 6 report the temporal and spatial complexities of FPTree-SR compared to the naive baseline on subsets of the Kosarak dataset with minSup = 0.005 and minConf = minSeqConf = 0.5. Due to the dataset's density and the large number of distinct items, a moderately low support threshold was selected to yield a meaningful number of rules.

Table 5. Runtime comparison on Kosarak (seconds)

Sequences	**FPTree-SR (s)**	**Naive (s)**
100,000	4.3	4.1
200,000	9.8	11.4
300,000	17.2	23.6
500,000	34.6	55.8
750,000	61.1	118.4
990,002	92.4	189.7

Table 6. Memory comparison on Kosarak (MB)

Sequences	**FPTree-SR (MB)**	**Naive (MB)**
100,000	38.5	41.2
200,000	54.7	68.1
300,000	67.3	93.4
500,000	89.2	142.6
750,000	109.8	198.3
990,002	128.4	251.7

The results demonstrate clear advantages for FPTree-SR at scale. At 100k sequences, runtime and memory are comparable for both methods, since the overhead of the FPTree construction is not yet offset by its pruning benefits. From 200k sequences onward, FPTree-SR consistently outperforms the naive approach, with the performance gap widening as dataset size increases. At the full 990k-sequence Kosarak dataset, FPTree-SR achieves a 2.05× speedup in runtime and uses only 51% of the memory consumed by the naive baseline. This efficiency gain stems from two complementary factors. First, the FPTree encodes the TDB compactly by sharing prefixes among transactions that contain the same high-frequency items, reducing both memory footprint and the number of operations required to enumerate frequent itemsets. Second, the FPTree-SR algorithm generates

only candidate association rules that meet both the support and confidence thresholds before temporal filtering. In contrast, the naive approach generates all sequential and association rules independently and then intersects the two sets, producing a much larger intermediate result.

4. Discussion

The experimental results confirm several important properties of the proposed FPTree-SR algorithm. First, it is scalable: runtime grows gracefully with dataset size, reaching under 1.6 minutes on the full Kosarak corpus on commodity hardware. Second, it is memory-efficient: the FPTree representation avoids materializing the full candidate itemset lattice, keeping memory usage well below 130 MB even at 990k sequences. Third, it is accurate: the two-phase design guarantees completeness — every sequential rule that satisfies the given thresholds is returned — because the association rule phase is a superset of what temporal filtering can retain. The TDB conversion step loses no valid sequential rules. Compared to our earlier probabilistic approach [9], FPTree-SR eliminates all probability-related computations (expected support summation over transactions and existential probability product calculations), which together constituted a significant fraction of that algorithm's runtime. This confirms that when data are fully observed, the simpler deterministic algorithm is strictly preferable.

VI. LIMITATIONS

Despite the algorithm's demonstrated efficiency, several limitations warrant acknowledgment:

- **Quadratic worst-case complexity:** In the worst case (dense datasets with frequent items), the algorithm exhibits $O(n^2)$ time complexity. Highly correlated datasets, such as synthetic ones with low support thresholds, may yield an exponential number of frequent itemsets, rendering the approach impractical for certain configurations.
- **Threshold sensitivity:** The number of discovered rules is highly sensitive to minSup and minConf. Very low thresholds produce many rules, many of which may be non-actionable, while very high thresholds may miss relevant patterns.
- **Single-machine implementation:** The current Python implementation does not exploit multi-core parallelism or distributed computing frameworks, limiting throughput for extremely large datasets.
- **Deterministic assumption:** The method assumes all items are definitively present or absent. It is not directly applicable to data with inherent uncertainty without incorporating probability-aware measures as in [9].

VII. CONCLUSION AND FUTURE WORK

This paper presented FPTree-SR, an efficient algorithm for mining sequential rules from deterministic sequence databases. By adapting the FP-Growth paradigm to the sequential rule-mining task, the algorithm constructs a compact FPTree over the derived transaction database in a single pass, mines frequent itemsets without candidate generation, generates association rules, and filters them using sequential ordering constraints. Experiments on the large-scale Kosarak benchmark (990,002 sequences) and on synthetic datasets confirm that FPTree-SR achieves superior runtime and memory efficiency compared to a naive intersection-based baseline, with a 2× speedup and ~50% memory reduction at full scale.

Future work will pursue three main directions. First, a distributed implementation using Apache Spark will be developed to process billion-scale sequence logs. Second, the algorithm will be extended to support high-utility sequential rules, incorporating item weights or profit values to prioritize economically significant patterns. Third, an incremental variant will be designed to update the discovered rule set efficiently as new sequences arrive in a streaming fashion, avoiding complete recomputation.

Abstract

NP-complete problem instances are known to be hard primarily around their yes/no phase transitions, a sudden change from the stark dominance of yes-instances to the dominance of no-instances, or vice versa. This phase transition is linked to the order parameter of the problem, e.g., the number of edges in Hamiltonian cycle problem instances or the number of clauses in Satisfiability problem instances. The larger the instance size, the narrower the hard region around the phase transition becomes, but instances outside the hard region are typically decided in polynomial time. Thereby, the hardness of an individual problem instance critically depends on both its size and its order parameter. The class NP-complete is a vast collection of problems that are held together by "reductions," showing that all instances of one NP-complete problem P_1, amenable to P_1-algorithms, can be transformed into instances of another problem P_2 and subsequently solved with a P_2-algorithm. This is a common way of proving NP-completeness, but by this transformation, same-size instances of P_1 do not necessarily project to same-size instances of P_2. Nor is there necessarily a match between the order parameter value of the P1-instance and that of the P_2-instance. This scattering of P_1-instances across different instance sizes and relative order parameter values might have profound consequences for the hardness of the transformed problem instances. Is it possible that all hard instances of P_1 end up in easy regions of P_2? Or vice versa? It might. In this paper, we demonstrate the existence of the scattering phenomenon by explicitly reducing CNF3SAT to the undirected Hamiltonian cycle problem, two problems that have relatively well-described phase transitions. We investigate the numbers and show that these NP-complete reductions can have unexpected consequences for the size and the order parameter of the resulting instances, leading to paradoxical outcomes.

Keywords*:* complexity, NP-complete, reduction, instance hardness

I. INTRODUCTION

NP-complete problems are decision problems for which no polynomial-time algorithm is known to exist. Notable examples are k-colorability [1], the subset sum problem [2-4], the quadratic assignment problem [5],[6], job shop scheduling [7], and satisfiability (in many forms, including CNF3SAT) [1]. The Hamiltonian cycle problem (both directed and undirected) asks whether there is a closed loop of edges that visits all vertices in a given graph, and is also NP-complete [8],[9],[1]. For all these problems, the runtime of the best-known algorithm

increases superpolynomially with the size of the problem instance, which means that very small instances can sometimes be solved. Still, larger instances quickly become intractable within reasonable time budgets.

But not all instances of an NP-complete problem are equally hard for a solving algorithm, and the notion of "best known algorithm" for a problem refers to the best runtime complexity for the single worst possible instance across all instance sizes. So, while the Hamiltonian cycle problem is NP-complete and its best-known algorithm, the Held-Karp-Bellman algorithm, has complexity O(v^2 + 2^v), it is certainly not necessarily the best algorithm for a particular instance. In fact, the problem has many backtracking algorithms that decide the vast majority of instances in polynomial time (Figure 2) [1],[10-13]. The theoretical worst-case runtime of these backtracking algorithms, however, is $O(n!)$, which is worse than Held-Karp-Bellman. The question arises: do we know for *which* instances these backtracking algorithms actually run so fast. The answer is yes. Or to some extent, at least. As it turns out, for several NP-complete problems, a secondary parameter, in addition to their input size, can be a critical indicator of the runtime required to solve an instance. For the undirected Hamiltonian cycle problem (UHCP), this parameter is the number of edges in the instance (sometimes equivalently expressed as the vertex degree). Many algorithms, such as Vandegriend-Culberson's [12] and Frank Rubin's [10], run in factorial time (O(n!)). Still, this worst-case expenditure is seldom reached, as the vast majority of instances are solved in polynomial time (Figure 2). These easy, fast-to-decide instances are mostly either very sparse or rather dense, i.e., graphs with either a low number of edges or a very high number of edges. Nonetheless, there remain a small number of very hard instances, keeping the problem as a whole in NP. These hard instances lie close to the problem's no/yes phase transition, the number of edges separating Hamiltonian from non-Hamiltonian instances. This phase transition is the fraction of Hamiltonian instances, and has a sigmoidal shape with a central 'anchor point', where its derivative is steepest. It is this anchor point that can be seen as the frontier separating the no-instances from the yes-instances. For the undirected Hamiltonian cycle problem, this bound lies at

$$E = \tfrac{1}{2}v\,(ln(v) + ln(ln(v))) \qquad (1)$$

edges for instances with v vertices, and is known as the "Komlós-Szemerédi bound" [13],[14]. For instances with $v = 100$ vertices, the bound lies at $E = \lfloor 50 \cdot (\ln(100) + \ln(\ln(100)) \rfloor = 307$ edges. Instances with 100 vertices and more than 307 edges are mostly yes-instances, containing one or more Hamiltonian cycles. Instances with fewer than 307 edges are overwhelmingly no-instances, not containing even a single Hamiltonian cycle. For many algorithms ofor the problem, such as Martello's and Rubin's only instances with 100 vertices and close to 307 edges are hard, taking superpolynomial time – all others are easy. Although terminology such as "hard", "easy"," and "close to" lacks rigorous quantification,compelling evidence can be found in a large number of highly cited empirical studies on the topic (e.g. [1],[13],[15]). The main point is this: for the undirected Hamiltonian cycle problem, there is no known polynomial-time algorithm for the worst-case instance. But many instances can nevertheless be solved in polynomial time, and the problem's order parameter, the number of edges, roughly indicates the location of easy instances. Finally, the no/yes phase transition for this problem is firmly rooted in theory, as the probability fthat a randomly generated graph is Hamiltoniand depending on the number of vertices, can be calculated exactly [14]S. till, iit should benoted that this is a limit theorem for $v \to \infty$, and empirical results may differ (substantially) for smaller problem instances.

II. SATISFIABILITY

Satisfiability, another NP-complete problem, asks whether a given formula of Boolean variables and operators has an assignment that evaluates the entire formula to true. The canonical formulation known as CNF3SAT has at most 3 variables per clause and is written in conjunctive normal form, meaning that ∨ and ¬ can appear inside clauses, with ∧ between them. As a running example for this paper

$$(x_1 \vee x_2 \vee \neg x_3) \wedge (x_3 \vee \neg x_2 \vee x_4) \quad (2)$$

is a CNF3SAT-instance with four variables x_1, x_2, x_3 and x_4 nested in two clauses enclosed by brackets we will write $nVar = 4$ and $nClauses = 2$. This instance has multiple satisfying assignments, among which [x_1:= true, x_2:= true, x_3:= true, x_4:= false], and is thereby a yes-instance, even though it also has falsifying assignments such as [x_1:= true, x_2:= true, x_3:= false, x_4:= false]; the fact that it has at least one satisfying assignment makes it a yes-instance.

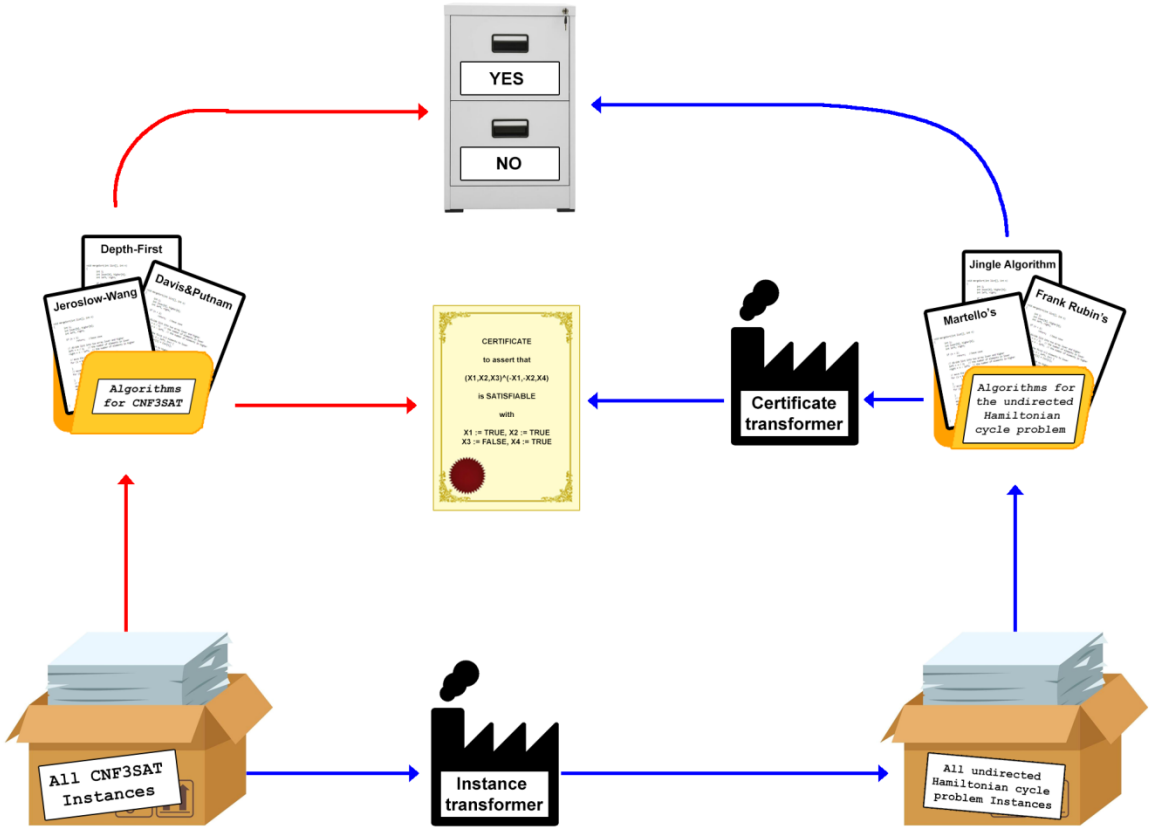

Figure 1. Two routes of solving a CNF3SAT problem instance. Red arrows: picking an exact algorithm directly suitable for the problem always gives a 100% correct yes/no answer to the problem instance, as well as a certificate of the solution (the actual variable assignments) if it exists. Blue arrows: alternatively, the CNF3SAT problem instance can be transformed into an instance of the undirected Hamiltonian cycle problem, for which a different portfolio of exact algorithms with different strengths and weaknesses is available. Even though the yes/no outcome of such an algorithm on the transformed instance is the same, the runtime could be different. Not all transformers are immediately supplied with a certificate transformer, but the one in this paper is.

At the time of writing, the fastest exact algorithm reported in the literature appears to be the PPSZ, with a complexity of O(1.307n) for n variables, which is exponential, as we expect for an NP-complete problem. Just like the undirected Hamiltonian cycle problem, CNF3SAT also exhibits a phase transition, and, again, exact algorithms exist whose runtime depends on the distance to the phase transition. For this problem, the order parameter, indicative of its instance hardness, is the ratio of clauses to variables (σ), and its anchor point lies close to

$$\sigma \approx 4.26 \qquad (3)$$

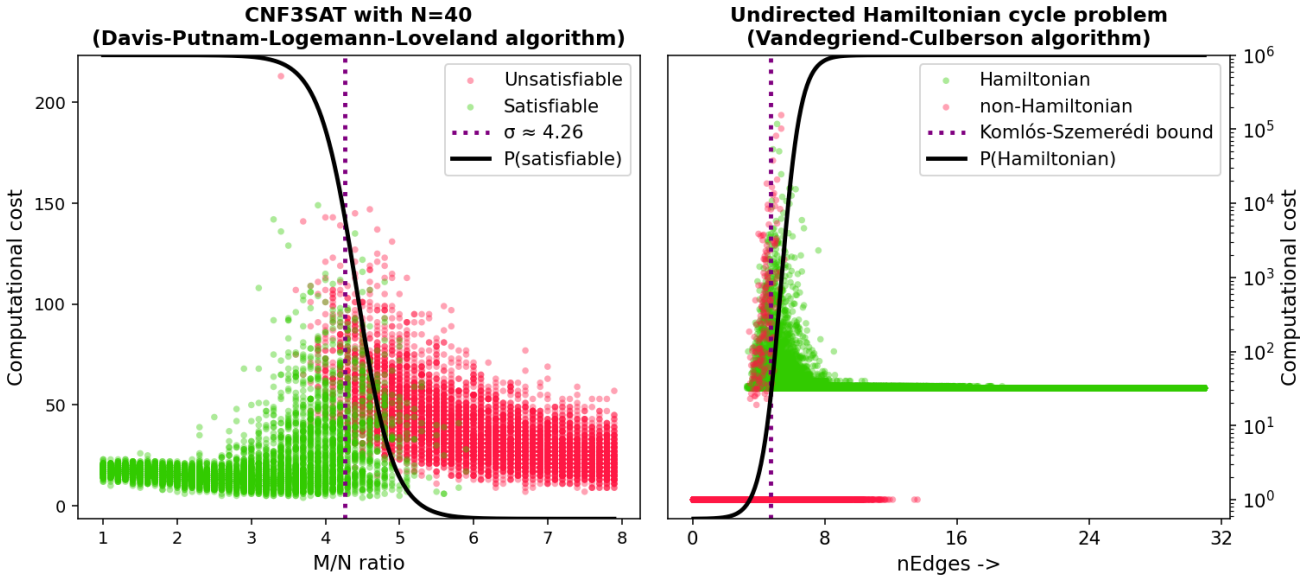

Figure 2. Many NP-complete problems have an 'order parameter' (on the horizontal axis) that indicates where the really hard problem instances lie. More often than not, these hardest instances are found near the anchor point of the 'phase transition' that separates the yes-instances from the no-instances (left) or vice versa (right).

This means that an instance with 10 variables and fewer than 42 clauses is likely a (satisfiable) yes-instance. If it has more than 43 clauses, it is likely a no-instance, for which not a single satisfying assignment exists[1].

The acute reader might have noticed that this phase transition, although phenomenologically similar, is also *inverse* to the undirected Hamiltonian cycle problem's phase transition. CNF3SAT's phase transition is a yes/no phase transition, whereas the undirected Hamiltonian cycle problem has a no/yes phase transition. The reason for this reversal is the natural way of counting and the direction of the English language; the minimum possible value for the order parameter (zero edges for UHCP or just one clause for CNF3SAT, respectively) should conventionally be on the left end of a horizontal axis. This minimum value falls in the no-region of the undirected Hamiltonian cycle problem but in the yes-region of CNF3SAT (Figure 2). The right-hand side of the order parameter axis is the open side, where the maximum value of the order parameter (number of edges for Hamiltonian cycle, number of clauses for CNF3SAT) increases with instance size. For the undirected Hamiltonian cycle problem, the minimum value of its order parameter is zero edges, a graph consisting of only loose vertices, and of course, non-Hamiltonian. The maximum value of its order parameter is $maxEdges = ½v \cdot (v - 1)$, corresponding to a fully connected graph and notably, *maxEdges* grows quadratically with the instance size v. It is interesting to realize that the anchor point of its no/yes phase transition however, grows much slower, namely as $½v \cdot (ln(v) + ln(ln(v)))$ and therefore, as v increases, the percentage of yes-instances approaches 100%. In the limit, all graphs of size v are Hamiltonian.

[1] values for *nClauses* are rounded off for convenience

For CNF3SAT, the opposite is true. The minimum value of its order parameter is 1, a formula with 1 clause and 3 variables that is always satisfiable. Assuming that every CNF3SAT clause is unique and has 3 distinct variables, with $2^3 = 8$ options to place negations, the order parameter's maximum value is

$$maxClauses = \frac{8nVar!}{3!(nVar-3)!} \quad (4)$$

a number that grows polynomially as $\approx (nVar)^3$. The anchor point of the yes/no phase transition, however, grows only linearly as $\approx 4.26n$. This means that as $nVar$ grows, the fraction of no-instances approaches 100%, the exact opposite of the undirected Hamiltonian cycle problem. Yet we are about to show that *every* instance of CNF3SAT can be transformed into an equivalent undirected Hamiltonian cycle problem, a paradox so bizarre it needs a name, especially considering that the inverse reduction (reducing UHCP to CNF3SAT) is also possible. But it gets even weirder.

III. REDUCING CNF3SAT to UNHCP

NP-complete problems are the hardest problems in NP. The common way of proving a problem P_2 is NP-complete is by taking some problem P_1, which is already known to be NP-complete, and providing a function that can transform every instance of P_1 to an instance of P_2 (Figure 1). Once such a transformation has been provided, one can safely conclude that P_2 is at least as hard as P_1, classifying P_2 as NP-complete as well. In such a case, we say "P_1 reduces to P_2," also written as $P_1 \leq P_2$ in this paper[2]. Reductions of this type are transitive, meaning that if $P_1 \leq P_2$ and $P_2 \leq P_3$, then $P_1 \leq P_3$ as well. As such, the entire class of NP-complete problems can be seen as an immense tree of problems interconnected by reduction sequences with SAT (or CircuitSAT) at its root (visualized on page 96 in [9]).

In this paper, we will elaborate on the sequence $CNF3SAT \leq DHCP \leq UHCP$, but this is not the only possible reduction sequence showing the problem's NP-completeness. In fact, Richard Karp's seminal paper itself exhibits a different sequence, namely $CircuitSAT \leq SAT \leq Clique \leq VertexCover \leq DHCP \leq UHCP$ [9]. It is far from trivial to determine whether this reduction sequence will have the same, similar, dissimilar, or completely different effects on the instance size and order parameter values of the resulting UHCP instances. A third reduction, using two types of 'devices' (undirected subgraph patterns), is given by Giri Narasimhan without citing a source, suggesting he might have constructed the reduction himself [16]. A particularly interesting aspect of this reduction is that it is a direct reduction from CNF3SAT to the UHCP, which warrants further investigation. The lack of a formal, thoroughly peer-reviewed source that gives a *complete* explanation of the reductions is problematic and raises questions. It appears that correctness is either communally accepted or remains unquestioned. For this reason, we still mention these informal (but usually largely correct) examples, but we also explicitly perform the reduction ourselves in Sections 3, 4, 5, and 6.

There might be other possible reduction sequences from CircuitSAT to UHCP, each possibly with its own inflationary or even deflationary properties. Still, in this paper, we will discuss the 2-step reduction CNF3SAT $\leq$ DHCP $\leq$ UHCP from CNF3SAT to the undirected Hamiltonian cycle problem. The second step, from the directed Hamiltonian cycle problem (DHCP) to the undirected Hamiltonian cycle problem, is given by Richard Karp himself in two very cryptic lines of text [9], but accredited without reference to [Robert] Tarjan, author of many related studies [17],[8],[18]. The origins of the first reduction in the sequence are somewhat mysterious. Although it appears in Michael Sipser's textbook in Chapter 7.5 [19], there is no reference to a seminal paper. Still, the proof is widely used, e.g., in a course by Adrian She [20], [21],[22], but most notably in an excellent

[2] Notations differ throughout literature

video by "Professor Bryce" [23], who is almost surely Bryce Wiedenbeck from Davidson College in North Carolina, USA, and who appears usually occupied with game theory [24],[25]. His video was a strong source of inspiration for our study, along with a paper by Filar, Haythorpe, and Taylor [26].

It will be these two reductions, *CNF*3*SAT* ≤ *DHCP* and *DHCP* ≤ *UHCP, that we will inspect in the upcoming sections and deduce their exact inflationary effects* on instance size and order parameters. In this context, the word "reduction" is particularly unfortunate, especially for readers new to the subject. Semantically speaking, "P_1 reduces to P_2" pertains to the overall hardness of both problems in terms of computational complexity classes, i.e., "P_1 reduces to P_2" means "proving that the complexity of problem P_1 is lower than, or at most equal to, the complexity of problem P_2". But when it comes to instance sizes, there is nothing to be reduced. Quite opposite in fact, as such NP-complete reductions (or: transformations) tend to inflate the resulting problem's instance size. Furthermore, it can scatter the resulting problem instances' order parameters over a wide range of values, which could significantly impact computational hardness. For this reason, the phenomenon was colloquially dubbed the "TommyGun phenomenon" during a joint lecture on differential information theory [27] at the ILLC in Amsterdam.

Theorem 1. ***("TommyGun")****: When instances of an NP-complete problem* P_1 *of sizes* n_1 *with order parameter values* p_1 *are by reduction transformed to instances of another NP-complete problem* P_2*, it is possible that not all resulting* P_2*-instances are of size* $n_1 + c$*, where* $c \in Z$*. Furthermore, the relative distance of the* p_1*s to* P_1*'s phase transition might also not be equal to the distance of the* p_2 *to* P_2*'s phase transition.*

In other words, NP-complete reductions can flare out instances over a wide range of sizes and order parameters. This could influence hardness in several ways, but for now, we will examine the flare-out effects in reducing CNF3SAT to the undirected Hamiltonian cycle problem.

IV. REQUIREMENTS FOR THE REDUCTIONS

In the first reduction, we will show that for each CNF3SAT formula, we can construct an equivalent instance of the *directed* Hamiltonian cycle problem (DHCP) such that if and only if the CNF3SAT instance is a yes-instance, the corresponding DHCP instance is also a yes-instance. A few preemptive sidenotes are important here:
1. The reduction (or: transformation) from the CNF3SAT-instance to the DHCP-instance is systematic and general. There are potentially infinitely many CNF3SAT instances, simply because the number of variables in the formula can be as large as desired; there is no upper bound. The systematic transformation that a computer program can execute converts any given CNF3SAT instance to a corresponding equivalent DHCP instance.
2. The transformation can be done in polynomial time. By the end of this Section, this will be obvious to the reader.
3. We do not need to know a priori if the CNF3SAT instance is a yes-instance (has a true assignment). We can first convert it to a DHCP instance and then resolve it. If the instance turns out to be non-Hamiltonian, then the corresponding CNF3SAT instance is not satisfiable, and vice versa.
4. For true NP-completeness, there must also be a polynomial-time verification program that verifies whether a given certificate (or "solution") is actually a yes-result. For both CNF3SAT and the Hamiltonian cycle problem (directed and undirected), such a program exists and is easily constructed with a single FOR loop. We will omit these polynomial-time verification programs from the reductions given in the upcoming sections.

In the second reduction, we show that every DHCP instance can be transformed into a UHCP instance, for which all of the above points also apply. There is an extra thought: if a CNF3SAT instance is transformed into a DHCP instance, and that turns out to be Hamiltonian, a solution (Hamiltonian cycle) can be transformed *back*

into a satisfying assignment for CNF3SAT. This backtransformation of a solution (or, more generally, a "certificate") is not typical of NP-complete reductions (see, e.g., textbooks [28] or [19]) but is nonetheless a valuable asset that can make a theoretical-existential reduction into a useful practical instrument.

V. THE FIRST REDUCTION

The first reduction transforms a CNF3SAT Instance into an instance of the directed Hamiltonian cycle problem (DHCP). We will use our running example at each step for clarity. Still, please remember that the reduction is general: it can transform any given CNF3SAT Instance into a DHCP instance such that the instances are yes/no equivalent. Our running example CNF3SAT-instance $(x_1 \vee x_2 \vee \neg x_3) \wedge (x_3 \vee \neg x_2 \vee x_4)$ has $nVar = 4$ variables in $nClauses = 2$ clauses.

Step 1: For variable $x1$, arrange $(2 \cdot nClauses) + 2$ vertices on a horizontal line, and connect every vertex to its right-hand neighbor with a directed edge, and link every vertex to its left-hand neighbor with a directed edge (Figure 3). The vertices now form a bi-directional chain with 2 corner vertices and $2 \cdot nClauses$ internal vertices. Label the leftmost corner vertex "TRUE →" and the rightmost corner vertex "← FALSE". Label the row as a whole "x_1". These labels and spatial arrangement don't substantially change the DHCP instance we are transforming; they are meant to facilitate understanding and enable the backtransformation of a DHCP certificate to a CNF3SAT certificate later.

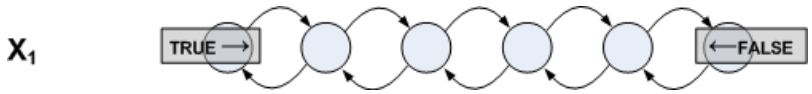

Figure 3. Step 1: Arrange (2 · nClauses) + 2 vertices on a line and connect them to their left and right-hand neighbors, forming a chain.

Step 2: Do the same for all other variables in the CNF3SAT instance, in our case, x_2, x_3, and x_4. We now have $nVar$ chains of $(2 \cdot nClauses) + 2$ vertices for each variable (Figure 4). For our example, that means 4 chains of 6 vertices. For some other formula with $nVar = 7$ variables and $nClauses = 6$, we would end up with 7 chains of 14 vertices.

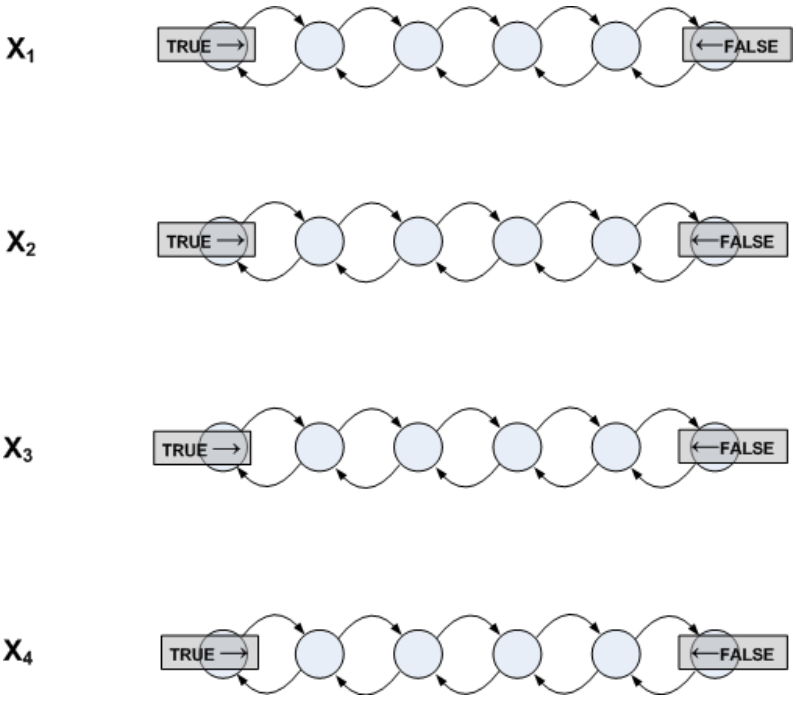

Figure 4. Step 2: Make chains for all variables in the CNF3SAT instance.

Step 3: Connect every corner vertex of each chain to both corner vertices of the next chain, with edges we'll call "inter-chain edges" (Figure 5). For the last chain (x_4 in our case), the interconnections loop back to the first chain (x_1 in our case). From this point onward, the graph is connected (it has no isolated vertices) and is also Hamiltonian. There are, in fact, $2^4 = 16$ directed Hamiltonian cycles in this graph. Each chain can be traversed either left-to-right or right-to-left, in any arbitrary combination following the inter-chain edges. Thus, we could transform every Hamiltonian cycle (or certificate) from this instance back into a variable assignment for the CNF3SAT instances, following the labels we applied in steps 1 and 2. The important discrepancy, however, is that not all Hamiltonian cycles in this graph correspond to a satisfying assignment ... yet. So in its current state, the transformation is not yet a valid reduction, but we'll solve this in the next step.

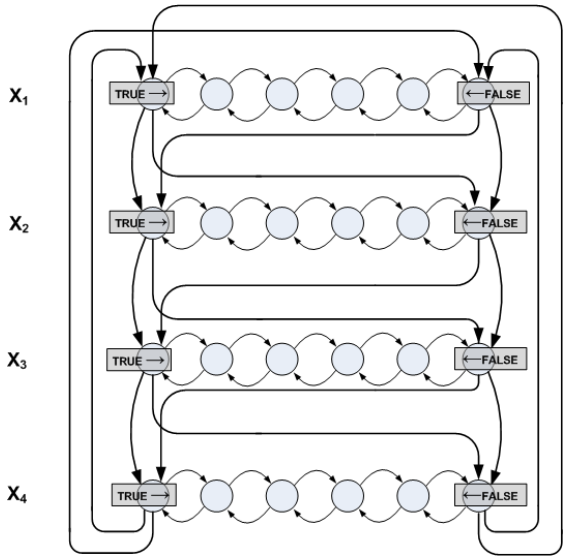

Figure 5. Step 3: Make 'interchain connections' from both corner vertices of a chain to both corner vertices of the next chain.

Step 4: Add one vertex to the graph for each clause in the CNF3SAT formula. In our case, 2 vertices in for 2 clauses. Now, in each chain, the first two internal vertices correspond to Clause 1, the second two internal vertices correspond to Clause 2. An edge is drawn from one of the corresponding internal vertices to the clause, and back to the other of the two, and the direction corresponds to the chain's variable's value that satisfies a given clause. As an example, in our formula $(x1 \vee x2 \vee \neg x3) \wedge (x3 \vee \neg x2 \vee x4)$, variable $x3$ can satisfy *Clause*2 when assigned true, so we connect from the 3rd internal vertex to *Clause*2 and back from *Clause*2 to the 4th internal vertex. Notice how this creates an 'excursion' to *Clause 2 in the true direction* of chain $x3$ (Figure 6). But variable $x3$ can also satisfy *Clause 1 if it is assigned the value false, so we also create an excursion to Clause 2 from chain x3, but this time in the false-direction, emanating from the 2nd internal vertex to Clause 2* and then back to the 1st internal vertex of chain $x3$. Notice again, how the 'satisfactory direction' corresponds to the edge direction: *Clause 2* can only be visited from $x3$ in the false-direction, just as the second clause in our running example can only be satisfied by $x3$ when it is set to false.

Our reduction is now complete. We can now transform any CNF3SAT Instance into a DHCP instance and use any DHCP algorithm to solve it. If the DHCP instance is Hamiltonian, then our CNF3SAT instance is satisfiable, but if the DHCP instance does not contain a Hamiltonian cycle, a satisfying assignment for the CNF3SAT instance does not exist. And as a bonus, a returned Hamiltonian cycle can be transformed back to a satisfying CNF3SAT-assignment by using the labels.

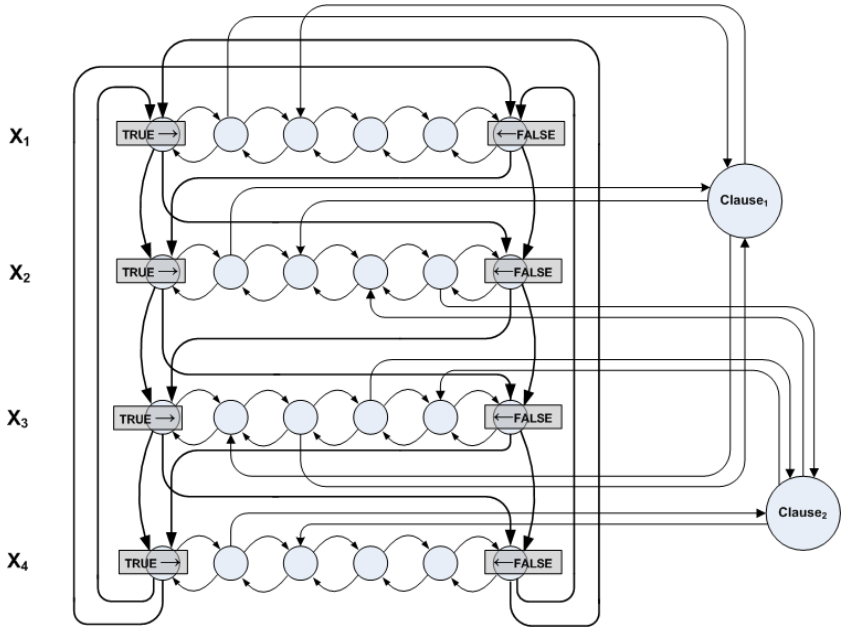

Figure 6. Step 4: A complete reduction from the CNF3SAT instance $(x_1 \vee x_2 \vee \neg x_3) \wedge (x_3 \vee \neg x_2 \vee x_4)$ to an instance of the directed Hamiltonian cycle problem (DHCP).

VI. INFLATIONARY PROPERTIES AND MALLEABILITY OF NUMBERS

Here we arrive at the main topic of this paper: are the resulting DHCP instances harder or easier than the original CNF3SAT instances? We will make a preliminary assessment by quantifying the inflationary effect of the reduction. For this transformation from aCNF3SAT-instance

1. We need $(2 \cdot nClauses + 2)$ vertices for one chain.
2. So for all $nVar$ chains together, we need $nVar \cdot (2 \cdot nClauses + 2)$ vertices.
3. We need one vertex for each clause, so $nClauses$ vertices for all clause vertices.
4. We need $2 \cdot (2 \cdot nClauses + 1)$ edges for each chain.
5. So for all chains, we need $nVar \cdot (2 \cdot (2 \cdot nClauses + 1))$ edges.
6. We need $4 \cdot nVar$ inter-chain edges, namely 4 for each chain to the next chain.
7. We need 6 edges per clause, connecting them to the chains, so $6 \cdot nClauses$

This means that for a CNF3SAT instance of $nVar$ variables and $nClauses$ clauses, the resulting DHCP instance will have

$$\text{nVertices} = nVar \cdot (2 \cdot nClauses + 2) + nClauses$$

$$\text{nEdges} = nVar \cdot (2 \cdot (2 \cdot nClauses + 1)) + (4 \cdot nVar) + 6 \cdot nClauses$$

meaning that for our running example $(x_1 \vee x_2 \vee \neg x_3) \wedge (x_3 \vee \neg x_2 \vee x_4)$, having $nVar = 4$ and $nClauses = 2$, the resulting DHCP instance has $nVertices = 4 \cdot (2 \cdot 2 + 2) + 2 = 26$ vertices, and $nEdges = 68$ edges. Luckily, the blowup from CNF3SAT to DHCP is itself linear, but this does not imply ease. For example, a relatively small CNF3SAT instance with 21 variables and 377 clauses, quite doable for most algorithms, yields a UHCP

instance with 16,253 vertices and 34,056 edges – far beyond any measure of modern-day computability. These numbers, however, are somewhat malleable.

The numbers and equations given in the enumerated list in Section 5.1 pertain to the most default form of the reduction, and leave some room for variation. First of all, point 1 is an "at most" number. Notice that in the x_1-chain of our example, the 3rd and 4th vertices could be removed by connecting the 3rd vertex immediately to the rightmost corner vertex without changing the Hamiltonicity of the instance. In fact, in all chains, the pairs of vertices not connecting to their corresponding clauses can be removed. For very large *nVar* and *nClauses*, one can expect a lot of such redundancy, because not every variable can be in every clause of a CNF3SAT instance, which has at most 3 variables per clause. Note that this redundancy, if applied, would also decrease the number of edges in a chain, making point 3 an "at most" value as well. Second, *nVar* should be considered an *actual* value, not an *intended* value. That means that if the transformable CNF3SAT instance is randomly generated by assigning *nVar* randomly chosen variables to *nClauses* (randomly chosen) clauses, all *nVar* variables should be chosen at least once. Conversely, one could state that *nVar* is the number of variables in the CNF3SAT Instance after its generation, regardless of the originally intended number of variables. Of course, this all depends on the algorithmics of the random CNF3SAT instance generator. In any case, *nVar* is the *actual* number of variables in the formula. Third, the number of clauses in the CNF3SAT instance is manipulable. One could introduce duplicate clauses that are redundant and irrelevant to the satisfiability of the instance, thereby artificially inflating the resulting DHCP instance and likely increasing the runtime of the DHCP algorithm. Note that for this paper, we assume every clause to be unique (also see Equation 4). Fourth, the DHCP instance can be almost arbitrarily inflated without affecting its Hamiltonicity. One could add vertices in a chain for clauses that do not exist. It will slightly influence the instance's hardness for UHCP algorithms (at approximately one recursion per added vertex). Still, its size increases greatly, so one could say its relative hardness actually decreases when inflated. Also, some versions of the reduction, like Adrian She's, use start and end vertices [20]. An arbitrary number of vertices could be placed between these without fundamentally changing their Hamiltonicity. Bryce Wiedenbeck's reduction [23] omits these vertices, as does ours.

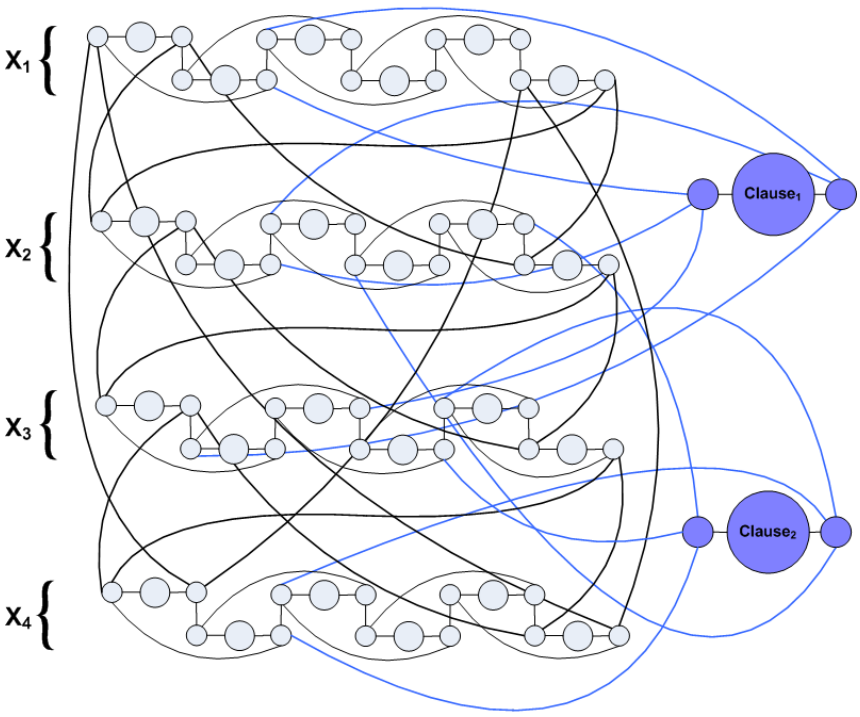

Figure 7. Any instance of the directed Hamiltonian cycle problem can be transformed into an undirected Hamiltonian cycle problem instance by replacing each vertex Vx of the DHCP instance with a triplet Vx: in, Vx: mid and Vx: out in an undirected Hamiltonian cycle problem instance, whereafter a directed edge (Vx, Vy) can be transformed to an undirected edge (Vx: out, Vx: in). As such, these points show that the resulting instance sizes and order parameter values are not rock-hard but malleable if one wants them to be. The instance size increase from CNF3SAT to DHCP is linear in this default case, but it could artificially be pumped up to any size, e.g., "to make an argument", by adding extra vertices and edges. Conversely, its size might decrease slightly by removing redundancy in the instance, the extent of which depends on the particular CNF3SAT instance that was transformed.

VII. THE SECOND REDUCTION

The NP-completeness of the *undirected* Hamiltonian cycle problem comes from a succinct description by Richard Karp himself [9] and reduces from the *directed* Hamiltonian cycle problem. Luckily, the procedure is relatively straightforward, and works as follows: for every vertex *Vi* in the directed graph G_{dir}, create three vertices *Vi*: *in*, *Vi*: *mid,* and *Vi*: *out* in the undirected graph G_{undir}. Connect *Vi*: *in* and *Vi*: *out* to *Vi*: *mid* with undirected edges. Then, for every directed edge (*Vi, Vj*) of G_{dir}, create an undirected edge from *Vi*: *out* to *Vj*: *in* (see Figure 7).

The resulting graph*, Gundir,* will have the same Hamiltonicity as G_{dir} and the same order of vertex visits. When the labeling (omitted in Figure 7 due to space constraints) is fixed as suggested (Vi to Vi: in, Vi: mid, and *Vi*: *out*), a Hamiltonian cycle in G_{undir} can be transformed back to G_{dir}, hence, a certifcate-backtransformation also exists. One slight complication, however, is that the UCHP solver could return a Hamiltonian cycle that is the direct inverse of a corresponding Hamiltonian cycle in G_{dir}. Assuming we don't touch the UHCP solving algorithms, which seems prudent, the certificate backtransformer should check whether the certificate should be

read forward or backward, which can be done in polynomial time. This second transformation again inflates the instance. For a DHCP-instance to a UHCP-instance, the numerics are easy: a directed graph $G_{dir}(v, e)$ with v vertices and e edges projects to an undirected graph of $G_{undir}(3v, e+2ve)$ vertices and edges. A relatively modest blowup, even though a factor of 3 is not insignificant, considering that all algorithms for NP-complete problems are of superpolynomial complexity. For a transformation of CNF3SAT directly to UHCP, the numerics are a bit more elaborate.

1. We now need $(6 \cdot nClauses + 6)$ vertices for one chain.
2. So for all $nVar$ chains together, we need $nVar \cdot (6 \cdot nClauses + 6)$ vertices.
3. We now need 3 vertices for each clause, so $3 \cdot nClauses$ vertices for all clause vertices.
4. We now need $2 \cdot (2 \cdot nClauses + 2)$ inter-triplet edges in each chain.
5. We still need $2 \cdot (2 \cdot nClauses + 1)$ edges for each chain, connecting the triplets.
6. So for all chains, we need $nVar \cdot (2 \cdot (2 \cdot nClauses + 2) + 2 \cdot (2 \cdot nClauses + 1))$ edges.
7. We still need $4 \cdot nVar$ inter-chain edges, no changes here.
8. We need $8 \cdot nClauses$ edges for each clause triplet, of which 2 are inter-triplet.

Summarizing, this means that for a CNF3SAT instance of $nVar$ variables and $nClauses$ clauses, the resulting UHCP instance will have

$$nVertices = nVar \cdot (6 \cdot nClauses + 6) + 3 \cdot nClauses.$$

$$nEdges = nVar \cdot (2 \cdot (2 \cdot nClauses + 2) + 2 \cdot (2 \cdot nClauses + 1)) + 4 \cdot nVar + 8 \cdot nClauses$$

VIII. IMPLICATION AND DISCUSSION

The numerical analysis in the previous section yields some puzzling implications. As a numerical exploration, we perform reductions for CNF3SAT formulas with $nVar = \{4, 10, 20, 50, 100, 200, 500, 1000\}$. For all these $nVar$ numbers, the minimal clause numbers, trivially determined as $\lfloor \frac{nVar}{3} \rfloor$, maximal clause numbers (as given by Equation 4), and intermediate clause numbers (halfway between the minimum and the maximum) are given in Table 1. As an immediate result, the instance size after reduction (*nVertices*) grows substantially after the NP-complete reduction. Counterintuitively, this is due more to the explosion of *maxClauses* than to the inflationary effects of the reduction itself. This results in a single value of *nVar*, the key parameter in CNF3SAT's complexity, which scales to a large number of *nVertices*. Even though the inflation is non-constant and "only polynomial," these numbers are quite significant from a computational complexity standpoint. As an example, for a relatively modest 1000-variable CNF3SAT instance, the resulting UHCP instance size ranges between 2.01 · 106 and 7.98 · 1012 vertices, which are almost a factor of 4 million apart (Table 1), an insurmountable spread for any exact algorithm designed to solve problems, NP-complete or otherwise. But as a secondary result, the location of the resulting UHCP problem instances relative to the no/yes phase transition is also nontrivial. Comparing the 4th and 5th columns of Table 1 shows how the number of edges for an instance, and the number of edges at the Komlós-Szemerédi bound. Due to the edge sparsity of the resulting UHCP instances, they are located far *before* the threshold function's anchor point. This is weird. The area before the Komlós-Szemerédi bound is the area where nearly all UHCP instances are non-Hamiltonian. Yet *all* CNF3SAT instances, both satisfiable and unsatisfiable, project to this no-region of UHCP. How to understand this apparent contradiction? An answer might partly come from the UHCP's pinnacle of hardness, which is itself paradoxical and contradictory. The fact that the hardest instances of NP-complete problems lie around their yes/no phase transition has been known for decades. Still, a recent study showed that the *uniquely* hardest instance lies far beyond the Komlós-Szemerédi bound, a no-instance in an area so dense with yes-instances it could almost not

exist [29],[30],[31]. It is a single superhard no-instance amidst an ocean of trivially easy yes-instances. But paradoxically enough, even though this superhard instance *itself* is the hardest instance in existence, the *average* hardest instances are still found along the Komlós-Szemerédi bound. So how is it possible that despite the vast body of literature, this instance had never been found? The answer is given by *structure*. The hardest instance of UHCP, situated in an overwhelmingly easy region of the problem, is a highly structured graph. And despite most historical hardness studies involving large numbers of randomly generated instances, such structured instances were never found. This can be explained by an argument based on Kolmogorov complexity, which affirms that the chance of randomly generating a structured instance is astronomically small [32]. A similar argument might be surfacing from the paradoxical Tommy Gun effects of the reductions made above. How can all the CNF3SAT instances, both satisfiable and unsatisfiable, project solely onto the no-area of the UHCP? The answer could again be structure. It is the recipe, the general procedure of these NP-complete reductions, that produces structured instances. By the same argument from Kolmogorov complexity, these instances will almost certainly not turn up in randomized instance sets – perhaps not even in some structured instance sets. So the problem with structured instances appears to be: you don't know they exist until you know they exist, and they don't play by the rules. Possibly, the hardness of structured instances in general is completely different from that of unstructured instances. Table 1: The "TommyGunning" effect of reducing CNF3SAT of size nVar to UHCP gives a range of instance sizes (nVertices, 3rd column) as well as order parameter values (nEdges, 4th column). For this particular reduction, the distance to the phase transition (KS-bound, 5th column) also changes substantially (nEdges bölü payda, KS, eksi bound son payda, 6th column).

nVar	**nClauses**	**nVertices**	**nEdges**	**KS-bound**	**nEdges /KS-bound**

This observation opens up many new perspectives. Is it possible for some reduction to project both yes- and no-instances of one NP-complete problem solely into the yes-region of another NP-complete problem? Or into both yes and no areas? Maybe. In any case, it is starting to look like random instances form a cloud obfuscating the true nature of NP-completeness, which the contours of their structured instances might define. Even though the phase transitions and associated instance hardnesses are real, the rules might not apply to instances that have structure in the Kolmogorov sense of the word. Sadly, these conclusions also upend all our ideas of solving the P =? NP problem along these routes. We are looking for evidence that hard CNF3SAT instances project into easy regions of the UHCP, which could make it possible to efficiently solve the very hard instances via NP-complete reductions. While it is certainly true that hard CNF3SAT Instances project into an easy region of the undirected Hamiltonian cycle problem, hopes of easy solvability have largely been dashed. The way forward is to solve a large number of transformed CNF3SAT instances using a portfolio of UHCP algorithms. But as these algorithms are general, they may perform well only on random (i.e., Kolmogorov-unstructured) instances, and far less well on structured graphs. The only way to find out is to try and see, as always, in future work.

Abstract
DevSecOps has emerged as a critical paradigm for integrating security into continuous integration and continuous deployment (CI/CD) pipelines, driven by the increasing complexity and rapid delivery requirements of modern software systems. Despite growing adoption, existing security mechanisms remain fragmented and misaligned with developer workflows, limiting their practical effectiveness. Recent advances in artificial intelligence (AI), particularly deep learning and large language models, have demonstrated strong potential for automated vulnerability detection. However, these techniques often fail to integrate effectively into real-world DevSecOps pipelines. Most existing approaches operate at the function or file level and provide limited explanation of their predictions, making it difficult for developers to interpret results during code changes and reducing trust in such tools. This paper presents a structured review of AI-based vulnerability detection approaches, with a particular focus on commit-level analysis and explainability within CI/CD environments. The study analyses 40 selected studies published between 2018 and 2025, collected through searches of major digital libraries and indexed sources. The findings show that only a small proportion of the reviewed studies perform commit-level analysis, while most provide little or no explainability. Based on these findings, this work synthesizes a conceptual framework that integrates commit-level change analysis, AI-based vulnerability detection, and explainable security mechanisms within CI/CD pipelines. The framework aims to improve developer trust, enable faster and more informed decision-making, and enhance the practical adoption of AI-driven security in DevSecOps environments.

Keywords: DevSecOps, Commit level vulnerability detection, Explainable AI, CI/CD security, Software security analytics.

I. INTRODUCTION

DevSecOps has emerged as an extension of the DevOps paradigm, embedding security as a continuous and shared responsibility throughout the software development lifecycle. Modern software systems are increasingly delivered through continuous integration and continuous deployment (CI/CD) pipelines, where development, testing, and deployment occur at high speed. In this context, DevSecOps aims to integrate security controls directly into these pipelines, enabling early vulnerability detection without disrupting development velocity. Despite its widespread adoption, security practices within DevSecOps environments remain fragmented across multiple tools and workflows. Existing studies indicate that security mechanisms are often not tightly integrated into a unified development pipeline, thereby limiting their effectiveness and creating challenges for developers in interpreting and acting on security findings [1–5]. To address the scale and complexity of modern CI/CD environments, artificial intelligence (AI) has been widely explored for vulnerability detection. Techniques such as deep learning, graph-based models, and large language models (LLMs) can capture the semantic and structural properties of source code, often outperforming traditional static and dynamic analysis tools in detecting complex

vulnerabilities [6–8]. However, despite these advances, significant limitations remain. Many AI-based approaches operate as black-box systems, offering limited transparency into their decision-making processes. Furthermore, most techniques focus on file-level or function-level analysis, overlooking commit-level changes that are central to CI/CD workflows. This disconnect reduces their practical applicability in real DevSecOps environments. In addition, issues such as high false-positive rates, alert fatigue, and the lack of standardized mechanisms for integrating detection results with workflow context further reduce developers' trust and hinder adoption [9–13]. These limitations highlight a critical gap between current research and the operational needs of DevSecOps. In particular, there is a need for approaches that combine fine-grained commit-level analysis with explainable outputs that can support developer decision-making during code changes. To address this gap, this paper presents a structured review of AI-based vulnerability detection approaches, focusing on explainability and commit-level analysis within DevSecOps pipelines. The study categorizes existing methods, synthesizes key findings, and identifies unresolved challenges. Based on this analysis, the paper further proposes a conceptual framework that integrates commit-level vulnerability detection with explainable security mechanisms, aiming to bridge the gap between research advances and practical DevSecOps requirements [6], [3], [14].

II. REVIEW METHODOLOGY

1. Search Strategy

A literature search was conducted across IEEE Xplore, the ACM Digital Library, SpringerLink, arXiv, and other indexed sources. The search focused on studies published between 2018 and 2025, covering the evolution of deep learning, large language models, and explainable AI in software security. The search used combinations of the following terms: DevSecOps, CI/CD security, vulnerability detection, commit-level analysis, and explainable AI. Boolean operators (AND, OR) were used to combine the terms across the targeted databases.

2. Study Selection Process

The PRISMA-based selection process identified 100 records. After duplicate removal, 90 records remained for title and abstract screening. Fifty studies proceeded to full-text assessment, and 10 were excluded at that stage. A final set of 40 studies was selected for detailed analysis. The selection criteria were applied consistently across the screening stages to maintain relevance to AI-based vulnerability detection, DevSecOps, CI/CD environments, and explainability.

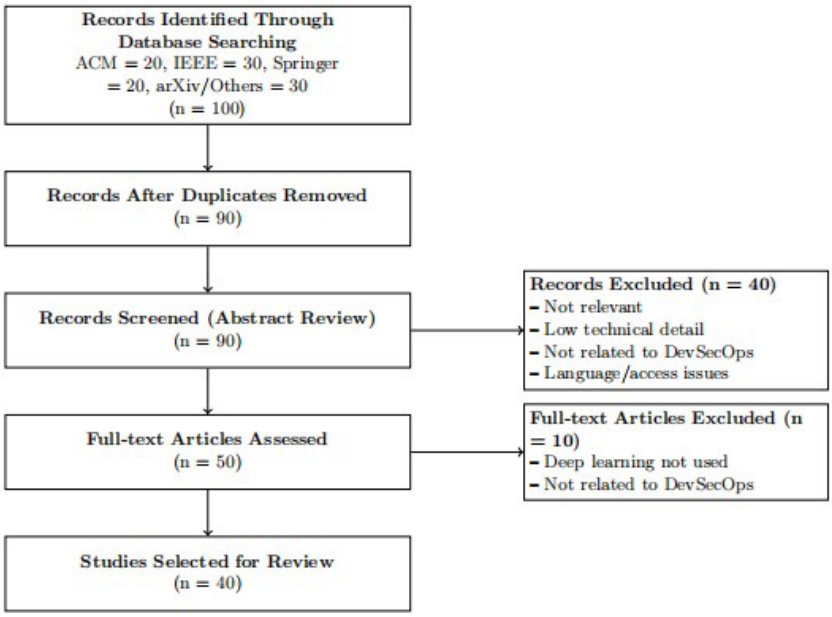

Figure 1. Study selection process following PRISMA methodology

3. Inclusion and Exclusion Criteria

Inclusion criteria were: studies focusing on AI-based vulnerability detection; research related to DevSecOps or CI/CD environments; papers addressing explainability in software security; and peer-reviewed articles or high-quality preprints. Exclusion criteria were: studies unrelated to software security or vulnerability detection; papers lacking technical depth or methodological detail; research not aligned with CI/CD or DevSecOps workflows; and non-English or inaccessible publications

4. Data Extraction and Classification

For each selected study, key attributes were extracted and analyzed, including research category, dataset usage, method type, level of analysis, and explainability support. The extracted data were organized into structured comparison tables to support cross-study analysis and identification of research trends, limitations, and gaps.

III. OVERVIEW OF SELECTED STUDIES

This section presents the key characteristics of the selected literature, including the search sources, keyword categories, and observed patterns in explainability, methodological approaches, and levels of analysis.

Table 1. Distribution of Retrieved Studies by Database

Database	Approx. Papers Retrieved
IEEE Xplore	30
ACM Digital Library	20
SpringerLink	20

arXiv / Others	30
Total	100

Table 2. Search Keywords and Categories

Category	**Keywords**
DevSecOps	DevSecOps, CI/CD security
Detection	Vulnerability detection, software security
AI Methods	Deep learning, machine learning, LLM
Analysis Level	Commit-level, file-level
Explainability	Explainable AI, XAI

1. Search Strategy Summary

Table 1 summarises the distribution of records retrieved from the targeted sources, while Table 2 presents the keyword categories used during the literature search.

2. Analysis of Selected Studies

Figure 2 shows that 79% of the reviewed studies provide no explainability, 11% provide limited explainability, and 10% provide explainable outputs. This indicates that explainability remains largely underexplored despite the increasing adoption of AI-based vulnerability detection techniques.

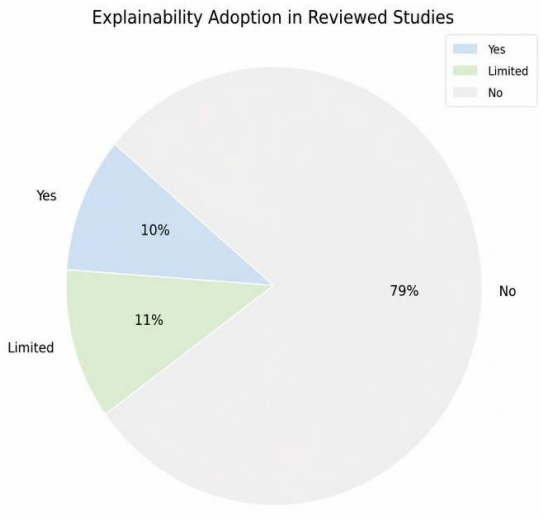

Figure 2. Distribution of explainability adoption across reviewed studies

Figure 3 summarises the methodological approaches represented in the reviewed literature. Survey-based studies are prominent, followed by machine learning and deep learning approaches, while relatively few studies directly explore explainable AI techniques.

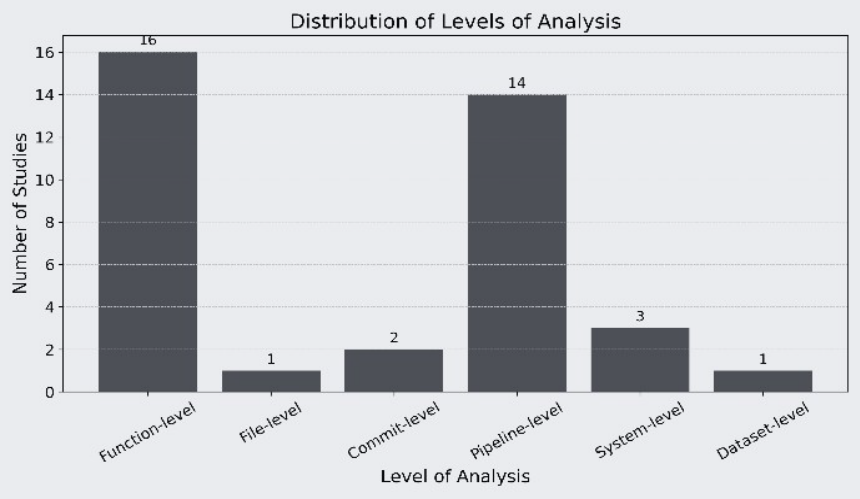

Figure 3. Distribution of methodological approaches in the reviewed literature

Figure 4 presents the distribution of analysis levels. Function-level and pipeline-level analysis dominate, whereas commit-level analysis remains limited. This pattern motivates closer integration of commit-level vulnerability analysis and explainability.

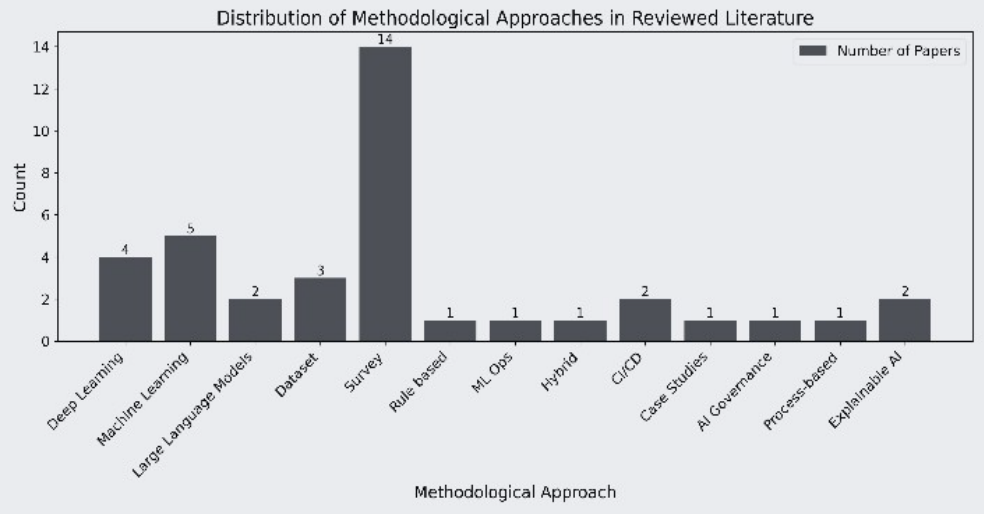

Figure 4. Distribution of levels of analysis in DevSecOps security research

IV. LITERATURE REVIEW

This section critically analyses existing research by grouping studies according to the underlying techniques and their application in DevSecOps environments. Rather than merely describing approaches, the analysis focuses

on practical limitations, comparative strengths, and suitability for explainable, commit-level vulnerability detection.

1. AI Techniques for Vulnerability Detection

Traditional static and dynamic analysis techniques have long been used to detect software vulnerabilities. While these methods are widely adopted due to their ease of integration into development workflows, they suffer from limitations, including high false-positive rates, a lack of contextual understanding, and poor prioritization of security risks. These shortcomings are particularly problematic in CI/CD environments, where frequent alerts can lead to developer fatigue and reduced engagement with security tools [15–17]. sRecent research has explored deep learning and graph-based approaches for vulnerability detection. Models such as VulDeePecker and Devign leverage code semantics, data flow, and program dependencies to identify complex vulnerability patterns [18], [12], [19]. Empirical evaluations show that these models can outperform traditional rule-based techniques in benchmark settings [12], [20]. However, their practical applicability remains limited. Many deep learning models are trained on curated datasets such as DiverseVul, which may not fully capture the noise, diversity, and evolution of real-world codebases. Their black-box nature also limits interpretability, making it difficult for developers to trust or act on predictions [21], [20], [13], [22]. Large language models (LLMs) represent a more recent advancement, enabling contextual reasoning over both code and natural language. These models can analyze complex code structures and provide flexible representations of vulnerabilities. However, they introduce challenges, including hallucinated outputs, unstable reasoning behavior, and high computational overhead, which raise concerns about reliability in security-critical contexts [6], [9], [10], [23], [24], [4], [8]. Overall, AI-based approaches improve detection capability but remain largely model-centric and insufficiently aligned with operational DevSecOps requirements.

2. Commit-Level and Just-in-Time Vulnerability Analysis

Commit-level and just-in-time (JIT) vulnerability detection have emerged as promising approaches for aligning security analysis with CI/CD workflows [3], [8], [22], [14]. Unlike traditional file-level methods, commit-level analysis focuses on incremental code changes, enabling earlier detection of vulnerabilities and improved traceability of security findings to specific modifications. Empirical studies indicate that this approach can reduce the analysis scope and support more efficient remediation, making it well-suited to shift-left security practices [14], [13], [25], [26]. Despite these advantages, current commit-level approaches exhibit several limitations. Many techniques primarily focus on risk prediction rather than providing actionable insights. A significant number of methods also rely on manually engineered features or historical commit data, which can restrict generalization across projects and evolving codebases [19], [26], [25], [24]. Furthermore, commit-level analysis is rarely combined with advanced AI models or explainability mechanisms, resulting in a gap between detection capability and practical usability.

3. Explainable AI in Software Security

Explainable AI (XAI) has become increasingly important in software security, particularly in environments where developers must make rapid and informed decisions. Existing XAI approaches can be broadly categorized into post hoc methods, such as SHAP and LIME, and inherently interpretable models [27], [5], [28]. While these techniques provide insights into model behavior, their practical effectiveness in vulnerability detection remains limited. Post hoc explanations often highlight feature importance or code regions that influence predictions. Still, they may be too abstract or technically complex for developers to interpret in the context of real code changes. Consequently, they may fail to provide actionable remediation guidance. Intrinsically interpretable models offer

improved transparency but can introduce trade-offs involving detection performance or scalability. A critical limitation across existing approaches is the lack of alignment with developer workflows. Most XAI techniques are designed for model analysis rather than integration into CI/CD pipelines. Moreover, explainability is rarely combined with commit-level analysis, limiting its relevance for just-in-time vulnerability detection [20], [23], [29]. This highlights a fundamental gap: current XAI methods improve model transparency but do not adequately support practical decision-making in DevSecOps environments.

4. DevSecOps Security Analytics and Dashboards

DevSecOps platforms commonly employ dashboards to provide visibility into security metrics, including vulnerability counts, severity levels, and compliance status across pipelines. While these tools support monitoring and reporting, they are primarily designed as aggregation interfaces rather than decision-support systems. Most dashboards integrate outputs from multiple security tools without providing insight into how results are generated. As a result, they lack contextual reasoning and fail to explain root causes [24], [22], [30]. This limits their usefulness for developers, who must interpret large volumes of alerts without clear guidance on prioritization or remediation. Current dashboards also rarely adapt to developer workflows or incorporate feedback mechanisms [26], [25], [13], [1].

V. LITERATURE REVIEW

Current DevSecOps environments and vulnerability detection tools differ mainly in their techniques, scope, and practical usefulness [24], [28], [31]. Traditional SAST and DAST tools remain popular because they can integrate into CI/CD pipelines, even though they may generate many false positives and provide limited contextual understanding [32], [22], [16]. Deep learning and graph-based methods can detect complex patterns in code, but they often behave as black boxes and are not consistently evaluated inside real deployment pipelines. Large language model-based approaches improve contextual reasoning; however, their high cost, limited transparency, and limited explainability remain major issues. Commit-level and just-in-time approaches fit CI/CD workflows more naturally, but they often rely on manually designed features and do not clearly explain why a change is risky [5], [28], [24], [17]. Most DevSecOps dashboards collect alerts from different tools and do not effectively support developers in interpreting results [6], [20], [12].

Table 3. Key Quantitative Observations from Reviewed Studies

Aspect	**Observation**
Level of Analysis	More than 50% of studies focus on function-level analysis, while only a small proportion perform commit-level analysis.
Explainability	Approximately 80% of reviewed studies provide no form of explainability for their predictions.
CI/CD Integration	Most approaches are evaluated offline and are not integrated into real CI/CD pipelines.
Dominant Method	Deep learning-based models are prominent in current vulnerability detection research.

XAI Usage	Explainable AI techniques are mostly post-hoc and rarely designed for developer-centric workflows.

Table 4. Comparison of Existing Vulnerability Detection Approaches

Approach	**Summary**
Traditional Security Tools	SAST/DAST; CI/CD compatible, but with frequent false alerts and limited context.
Deep Learning Models	CNN/RNN/GNN; strong pattern detection, but limited explainability and data bias.
LLM-Based Methods	Strong context, but high cost, low explainability, and prediction errors.
Commit-Level / JIT Methods	Good workflow fit, but limited reasoning and reliance on handcrafted features.
Explainable AI Tools	SHAP/LIME provides post hoc explanations but has weak workflow integration.
DevSecOps Dashboards	Good visibility and CI/CD integration, but limited explanation and remediation.

VI. COMPARATIVE ANALYSIS SYNTHESIS COMMIT LEVEL EXPLAINABLE VULNERABILITY

The analysis of the reviewed studies reveals that research on AI-based vulnerability detection, commit-level analysis, explainable AI, and DevSecOps security analytics has largely evolved in isolation rather than as an integrated solution. As a result, while many existing tools are effective at identifying vulnerabilities, they fail to provide developers with actionable and context-aware feedback within CI/CD pipelines [33], [21].

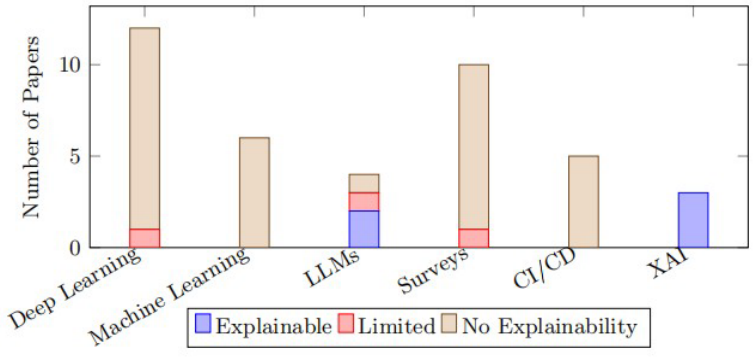

Figure 5. Explainability distribution across different method categories

When these findings are considered collectively, effective DevSecOps security requires the integration of three key dimensions: (i) commit-level change analysis, (ii) AI-based vulnerability prediction, and (iii) explainability tailored to developer workflows. Existing studies rarely address these dimensions simultaneously, leading to fragmented solutions that do not align with real-world development practices. To address this gap, this paper synthesizes a reference framework for commit-level explainable vulnerability intelligence, as illustrated in Figure 6. The framework defines a structured workflow consisting of three main stages: commit-level data processing, AI-based vulnerability prediction, and explainability with developer feedback. Commit-Level Data Processing extracts and preprocesses source-code changes at the commit level to capture fine-grained modifications relevant to security analysis. AI-Based Vulnerability Prediction uses machine learning or deep learning models to estimate the likelihood of vulnerabilities from commit-level features. Explainability and Developer Feedback translate predictions into human-understandable insights, enabling developers to interpret risks and take corrective actions effectively.

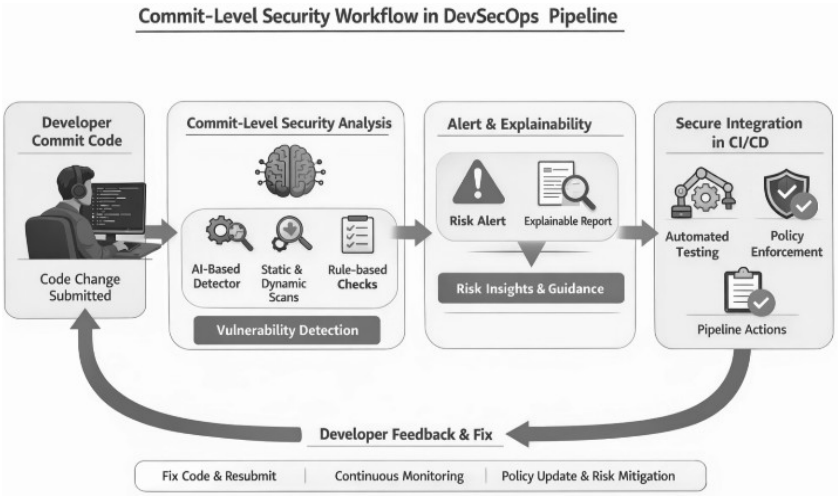

Figure 6. Reference framework for commit-level explainable vulnerability analysis

Unlike approaches that focus on individual components, this framework emphasizes the integration of detection, explanation, and workflow context within CI/CD environments. By aligning vulnerability prediction with commit-level changes and developer-centric explanations, the framework supports faster decision-making, improves trust in automated tools, and enhances the practical usability of AI-driven security systems.

VII. COMPARATIVE ANALYSIS SYNTHESIS COMMIT LEVEL EXPLAINABLE VULNERABILITY

Despite significant advances in AI-based vulnerability detection and DevSecOps practices, several critical challenges continue to limit their practical effectiveness. A fundamental limitation lies in the quality of available datasets. Many widely used vulnerability datasets contain noisy labels, duplicated samples, and weak or indirect links to actual code changes. As a result, models trained on these datasets may fail to generalize effectively, particularly in commit-level analysis scenarios where precise change tracking is essential [19], [22], [24], [34].

Explainability remains another major challenge. Existing XAI techniques frequently provide feature-level or statistical explanations that are difficult for developers to interpret in relation to concrete code modifications or actionable remediation steps. This disconnect reduces developer trust and limits the usability of AI-driven tools

within fast-paced CI/CD environments [28], [13], [24]. The increasing adoption of large language models introduces additional concerns. While these models demonstrate strong contextual understanding, they can produce hallucinated outputs, unstable reasoning, and high computational costs. Such limitations are particularly problematic in security-critical settings, where incorrect or misleading predictions may lead to significant risks [25], [11]. From a systems perspective, current DevSecOps solutions lack effective mechanisms for incorporating developer feedback and operational context into vulnerability analysis. Furthermore, there is no widely accepted architectural model that unifies AI-based detection, explainability, and commit-level analysis within CI/CD pipelines. This fragmentation leads to tools that operate in isolation rather than as part of an integrated security workflow [28], [29], [34], [23]. Existing evaluation methodologies also focus heavily on predictive performance metrics such as accuracy and F1-score, while giving less attention to usability, explanation quality, and real-world pipeline integration. Future research should therefore prioritize high-quality commit-linked datasets, human-centered explainability techniques, standardized architectures, and evaluation strategies that incorporate developer trust, interpretability, and real-world usability.

VIII. CONCLUSION

This paper presented a structured review and synthesis of research on explainable commit-level vulnerability intelligence in DevSecOps pipelines, analyzing 40 selected studies. The review examined AI-based vulnerability detection, just-in-time analysis, explainable AI, and DevSecOps security analytics, providing a classification and critical comparison of existing approaches [33], [21], [9], [2]. The analysis reveals several limitations that hinder the practical adoption of AI-driven security solutions. These include the dominance of black-box models, insufficient explainability, limited use of commit-level analysis, and the absence of standardized integration frameworks. Despite improvements in detection performance, current approaches often fail to provide actionable, context-aware insights that align with real-world development workflows [11], [33], [6]. To address these gaps, this work synthesized a conceptual framework that integrates commit-level analysis, AI-based vulnerability detection, and explainable feedback mechanisms within CI/CD pipelines. The proposed perspective emphasizes aligning technical capabilities with developer needs to support effective and trustworthy security practices. The findings suggest that explainable, commit-level vulnerability intelligence represents a promising direction for both research and practical deployment. Advancing this area will require stronger integration between AI techniques, software engineering processes, and human-centered design principles. This study provides a foundation for future work to develop more reliable, interpretable, and developer-centric security solutions in modern DevSecOps environments.

Abstract
As Large Language Models (LLMs) like ChatGPT become global information utilities, their performance in low–resource languages remains a critical area of inquiry. While these models demonstrate syntactic fluency in languages such as Kazakh, their ability to reproduce authentic cultural knowledge–specifically fixed paremiological units (proverbs)–is under–evaluated. This study assesses the validity of LLM–generated Kazakh proverbs using a binary expert-verification protocol administered by two experts in Turkic philology. We generated 1,500 outputs across three thematic domains–Labor, Humanity, and Knowledge–and classified each against authoritative lexicographical sources as Authentic or Fabricated. Results reveal a critical dissonance: although outputs were generally grammatically well–formed, only 8.9% of unique strings were authentic Kazakh proverbs. Authenticity correlated strongly with generation frequency ($r = 0.87$), indicating that the model relies on a small memorized core of high–frequency proverbs while hallucinating plausible–sounding fabrications in the long tail. These findings quantify the "illusion of cultural competence" in current LLMs and provide a reproducible methodology for evaluating cultural knowledge generation in low–resource languages.

Keyword: generative AI, low–resource languages, Kazakh language, cultural hallucination, paremiology, LLM evaluation

I. INTRODUCTION

Since its public release, the ChatGPT large language model (LLM) has been utilized by hundreds of millions of active users [1]. As of November 2025, the system has approximately 800 million weekly active users globally and continues to handle over 2.5 billion daily requests [2]. ChatGPT is also widely used in Kazakhstan [3]. Given this widespread adoption, it is critical to assess the nature of ChatGPT's generative outputs. However, systematic evaluation of LLM performance on low–resource languages–particularly for cultural knowledge generation–remains limited, creating gaps in our understanding of model capabilities and limitations beyond high–resource language benchmarks [4–7]. Proverbs represent a challenging test case for evaluating cultural knowledge in NLP systems. Unlike generic text generation, proverb production requires both linguistic competence (grammatical correctness, stylistic appropriateness) and cultural authenticity (correspondence to documented traditional knowledge) [8]. For Kazakh, a Turkic language with approximately 15 million speakers but a limited digital corpus representation [6], this evaluation is particularly relevant as speakers increasingly rely on LLMs for language–related tasks. Existing NLP research on low–resource languagses primarily focuses on machine translation or on standard benchmarks [4], [9]. Studies of LLM-generated cultural content predominantly focus

on high–resource languages [10] or examine translation rather than generation [7], [11], [12]. This leaves critical questions unaddressed, which we state as the three research questions guiding this study: (RQ1) Can LLMs authentically generate cultural artifacts in low–resource languages? (RQ2) How do these systems balance memorized traditional knowledge against generative pattern completion? (RQ3) What evaluation methodologies can distinguish linguistic competence from cultural authenticity? This study provides the first systematic computational and linguistic evaluation of LLM–generated Kazakh proverbs across three culturally significant domains: Labor (еңбек), Humanity/Ethics (адамгершілік), and Knowledge (білім). Through iterative generation and expert verification by two specialists in Turkic philology, we document patterns of linguistic accuracy, cultural authenticity, and the relationship between generation frequency and knowledge quality. In doing so, we contribute a reproducible expert–verified protocol, evidence separating grammatical well–formedness from cultural authenticity, and a frequency–based diagnostic distinguishing memorized retrieval from pattern completion.

II. RELATED WORK

1. LLM Evaluation on Low–Resource Languages

Recent multilingual evaluations document persistent performance disparities between high– and low–resource languages. Ahuja et al.'s [9] MEGA benchmark evaluated GPT–3.5, GPT -4, and BLOOMZ across 70 typologically diverse languages on 16 NLP datasets. They found significant performance disparities between English and non–English languages, particularly for low–resource languages with non–Latin scripts, where tokenizer quality (measured by sub–word fertility) negatively correlated with performance and fine–tuned models often outperformed generative LLMs. Bang et al. [13] extended these findings in a comprehensive multitask evaluation of ChatGPT, noting a critical performance asymmetry: while ChatGPT demonstrates competence in understanding low–resource and non–Latin script languages, its ability to generate text in those languages is significantly weaker. Joshi et al. [4] developed a taxonomy that classifies the world's languages into six tiers based on the availability of digital resources, highlighting a stark disparity: a small number of "Winner" languages receive the vast majority of NLP research and data investment. They argue this creates a "typological echo–chamber," leaving languages with moderate to low digital infrastructure–a category that includes Kazakh–substantially underrepresented in NLP research. While their work focuses on resource distribution, it underscores the need for evaluations that go beyond standard NLP benchmarks to examine more nuanced capabilities, such as generating cultural knowledge in these low–resource languages.

2. Cultural Knowledge in Language Models

Theoretical work on LLM knowledge representation raises fundamental questions about the nature of cultural understanding in neural models. Bender et al. [5] characterize these systems as "stochastic parrots"–models that haphazardly stitch together sequences of linguistic forms based on probabilistic patterns observed in vast training data, but without any underlying reference to meaning. They argue that while models achieve impressive surface fluency, they lack genuine semantic comprehension because their training is restricted to linguistic form, denying them access to the communicative intent and shared world models that underpin human language [5]. This disconnect is particularly acute for cultural artifacts such as proverbs; Bender et al. posit that any perceived coherence in these outputs is often an "illusion" created by human listeners who are predisposed to project meaning and intent onto fluent strings, even when the generating system lacks conceptual grounding [5]. Navigli et al. [14] documented systematic biases in LLM cultural representations, noting that training data is heavily English–centric and over–represents high–resource linguistic communities, leading to models that reflect the values of dominant cultures while marginalizing others. The challenge of representing non–Western cultural

heritage in LLMs has recently been highlighted by the Jawaher benchmark as well [7]. Magdy et al. evaluated LLMs across 20 Arabic dialects and found that while models demonstrate high linguistic surface–level performance, they suffer from a significant 'cultural gap.' Their study concludes that current models remain biased toward Anglo–centric perspectives, frequently failing to capture the historical and contextual depth of traditional proverbs–a phenomenon we investigate here within the Kazakh linguistic context.

3. Proverb Generation as a Benchmark

Beyond translation, proverbs have been established as a challenging benchmark for evaluating abstract and analogical reasoning in LLMs. Ghosh and Srivastava [10] introduced the ePiC dataset to demonstrate that even when models achieve high performance on standard NLP tasks, they often struggle to move beyond surface–level lexical overlaps to achieve a true abstract understanding of proverbial wisdom. Recent scholarship has increasingly turned to proverbs as a rigorous metric for cultural alignment in LLMs. Magdy et al. [7] (Arabic), Azime et al. [11] (Ethiopian languages), and Almeida et al. [12] (Portuguese) have all demonstrated that models trained primarily on English data fail to capture the specific regional nuances of proverb usage. While these studies largely utilized multiple–choice or retrieval tasks, our work extends this line of inquiry into the generative domain for Kazakh, exposing the model's tendency to hallucinate plausible–sounding but culturally invalid artifacts when forced to generate without constraints. Evaluating generation is crucial because it mimics real–world usage: users often ask LLMs to "write a speech using Kazakh proverbs" or "explain Kazakh culture" [3]. If the generated content is fabricated, the model actively contributes to cultural erosion [5].

III. METHODOLOGY

1. Data Generation and Collection

To ensure a robust and statistically significant sample size, this study employed an iterative prompting strategy designed to capture both the model's consistency and its generative variability. Data was collected in late 2024 using OpenAI's GPT–3.5 Turbo at its default generation settings, reflecting the configuration most users encounter rather than a tuned research configuration. The exact-date snapshot was not recorded and is no longer available (Section V.5). We used a standardized, zero–shot instruction written in Kazakh: "Generate 10 authentic Kazakh proverbs about [TOPIC] in the Kazakh language." To test the model's ability to generalize across different conceptual depths, we selected three distinct thematic domains: Labor (Еңбек), representing concrete, experience–based concepts; Humanity and Ethics (Адамгершілік), representing abstract moral philosophy; and Knowledge (Білім), representing metaphorical and educational themes. For each topic, the prompt was executed 50 times using fresh context windows to eliminate history bias and prevent the model from referencing its own previous outputs. A single zero–shot prompt was used because it reflects how non–specialist users typically query the model; the effect of prompt variation is addressed in Section V.5. This procedure resulted in a raw corpus of 1,500 proverb outputs.

2. Verification Procedure and Binary Classification

The primary methodological contribution of this study is the shift from automated metrics toward an expert–led verification process. Initially, raw text was normalized by removing punctuation and case differences to facilitate deduplication and identify unique strings. Following the human evaluation framework established in recent paremiological benchmarks [7], we engaged two qualified experts in Turkic philology to ensure that the generated strings were not only grammatically correct but also culturally legitimate. The first expert assigned an initial binary label (Authentic or Fabricated) to each unique output by cross–referencing it against the

authoritative paremiological collections described below. The second expert independently reviewed all classifications. Cases of disagreement were resolved through joint discussion against the source corpora before producing the final dataset. This two–reviewer procedure reduces dependence on any single expert's judgment. To ensure rigorous binary verification of authenticity, we used a consolidated ground–truth corpus comprising four authoritative paremiological collections: the comprehensive Khalyq danalyghy [15] and Babalar sözi [16], as well as specialized collections compiled by Turmanzhanov [17] and Asqar [18]. We operationalized authenticity through a strict binary coding system. An output was coded as "1" (Authentic) if it was documented in the source material, including acceptable oral variations or minor synonym swaps that preserved the proverb's lexical core, syntactic structure, and semantic content. An output was coded as "0" (Fabricated) if it was absent from authoritative sources; this category included plausible AI–invented phrases, literal translations (calques) of English or Russian idioms, and semantic nonsense. An output was only marked as Authentic if it was documented in at least one of these recognized scholarly sources.

3. Acceptance of Variants and Sensitivity Analysis

Because Kazakh proverbs circulate as oral tradition with documented regional variation, we explicitly defined three levels of acceptable variation. Level 1 (lexical): minor synonym swaps that do not alter meaning (e.g., Еңбек етсең vs. Еңбек қылсаң, both meaning "if you work"). Level 2 (morphosyntactic): aspect or tense alternations that preserve propositional content. Level 3 (structural): partial reorderings that retain the parallel–couplet structure. Outputs falling within these levels were classified as Authentic if a matching base form existed in at least one source. Outputs that introduced new lexical content, blended distinct proverbs, or replaced culturally specific tokens with foreign idiomatic content were classified as Fabricated. To estimate possible false negatives arising from the finite scope of the reference corpora, we conducted a sensitivity analysis. We re–examined all items classified as Fabricated for documented partial overlap with the reference corpora, identifying 26 unique strings that exhibited a recognizable but non–canonical relationship to attested proverbs (e.g., partial token overlap or thematic echo without full structural match). Reclassifying these items as plausibly Authentic raises the unique authenticity rate from 8.9% to 12.3%–a range of ±3.4 percentage points. This bound demonstrates that the headline finding (approximately 90% fabrication) is robust to plausible variation in coding strictness.

4. Evaluation Metrics

To quantify the model's performance, we established two primary metrics. The Unique Authenticity Rate measures the percentage of distinct, unique strings that constitute genuine traditional proverbs. The Weighted Authenticity Rate accounts for repetition frequency by measuring the percentage of the 1,500 generated outputs that are authentic. These dual metrics allow us to distinguish between the model's total knowledge base and its reliability in a typical user interaction.

IV. ANALYSIS AND RESULTS

1. Quantitative Overview of Generated Data

Across the 1,500 total generation requests, ChatGPT produced 767 unique strings, indicating a significant repetition rate of approximately 48.9%. As summarized in Table 1, the data reveal a stark generative tendency that undermines cultural accuracy. Out of the 767 unique outputs, expert verification confirmed that only 68 items (8.9%) represented authentic traditional proverbs. Notably, the Knowledge (Білім) domain had the lowest unique authenticity rate, at 7.8%, compared with Labor (9.3%) and Humanity (9.2%). This indicates that the

abstract and metaphorical depth of educational proverbs poses a particular challenge for the model. Overall, approximately 91% of the model's unique "wise sayings" are fabrications, highlighting a severe reliability gap when the model is tasked with retrieving specific cultural heritage artifacts.

Table 1. Performance Metrics by Domain

Metric	Labor	Humanity	Knowledge	Total
Total Generated	500	500	500	1,500
Unique Proverbs	259	303	205	767
Repetition Rate	48.2%	39.4%	59.0%	48.9%
Unique Authenticity	9.3%	9.2%	7.8%	8.9%
Weighted Authenticity	43.4%	29.8%	47.6%	40.3%

Note. Repetition = (total − unique) / total. Unique authenticity = verified / unique. Weighted authenticity = Σ(authentic frequencies) / Σ(all frequencies). All verified against authoritative sources [15–18].

2. The Frequency–Authenticity Correlation

A pivotal finding of this analysis is the significant relationship between generation frequency and factual validity. To examine this, we categorized unique strings into three tiers: High Frequency (appearing 10 or more times), Medium Frequency (3–9 times), and Low Frequency (1–2 times), the latter representing the "long tail" of AI generation. The results reveal that High–Frequency outputs achieved an authenticity rate of 88.0%. In contrast, the authenticity rate dropped to 53.3% for Medium–Frequency items and plummeted to a negligible 3.2% for Low–Frequency items (Figure 1).

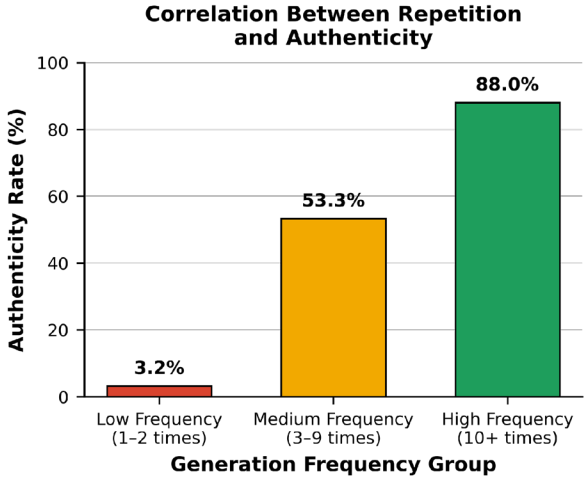

Figure 1. Correlation between generation frequency and cultural authenticity. The sharp decline in authenticity for low–frequency outputs suggests a transition from memorized retrieval to stochastic fabrication. To confirm the robustness of this pattern, we computed a Pearson correlation between generation frequency and authenticity across all unique outputs, yielding $r = 0.87$ ($p < 0.001$). This strong positive correlation indicates that the relationship between repetition and authenticity is statistically significant rather than coincidental.

3. Cross–Domain Analysis

Performance consistency across domains was notable. Unique authenticity varied within a narrow range of 1.5 percentage points: Labor 9.3%, Humanity 9.2%, Knowledge 7.8%. However, weighted authenticity showed greater variation: Labor 43.4%, Humanity 29.8%, Knowledge 47.6%. The Knowledge domain pattern–lowest unique authenticity but highest weighted authenticity–reveals an important asymmetry: the model retrieves a very small set of well–memorized Knowledge proverbs (e.g., the famous Оқу инемен құдық қазғандай) with very high repetition, but exhibits the weakest generative breadth in this conceptually abstract domain. By contrast, Labor proverbs show broader memorized coverage but lower per–item repetition. This pattern suggests similar generation mechanisms across domains, but differential knowledge depth tied to the conceptual character of each domain.

4. Qualitative Analysis of Fabricated Outputs

While the quantitative data show a high rate of failure, a qualitative review of the Fabricated category identifies specific failure modes that illuminate how the model attempts to imitate Kazakh proverbial form without access to authentic cultural content. From a paremiological perspective, the fabrications fall into four recognizable categories, each pointing to a different limitation of the model. Semantic Incoherence (Nonsense). The model occasionally produces sentences that violate basic semantic coherence by blending tokens from unrelated proverbs. The output “Еңбек етсең елік жылан да жығылады” (If you work, even the roe deer snake falls) appears to be a hallucinated blend of a labor–themed conditional construction and the famous proverb on the warmth of speech (Жылы–жылы сөйлесең, жылан інінен шығады). The insertion of елік (roe deer) before жылан (snake) produces a semantically impossible compound (“roe–deer–snake”) that no Kazakh speaker would accept. Such outputs are useful diagnostically: they reveal that the model is attempting to assemble proverbial–sounding strings from co–occurring tokens rather than reproducing memorized cultural units.

Cultural Calques. A second failure mode is the direct translation of foreign idioms into Kazakh grammatical form. The output “Балық берме, балық аулауды үйрет” is a word–for–word calque of the English saying “Give a man a fish…; teach him to fish…” While grammatically Kazakh, it carries no resonance in the Kazakh oral tradition. This category is particularly concerning for cultural preservation, because such outputs could plausibly be mistaken for indigenous wisdom by users unfamiliar with the original foreign idiom—distorted Variants of Real Proverbs. The most linguistically revealing category consists of outputs that closely resemble authentic proverbs but with one or two altered lexical items, yielding variants attested by no source. For example, the fabricated “Еңбек қылсаң ерінбей, пайда болар әр ісің” (If you work without laziness, every task will bring benefit) is a variation of the attested “Еңбек қылсаң ерінбей, тояды қарның тіленбей” (If you work without laziness, your stomach will be full without begging). The first half of the couplet is preserved exactly, but the second half is replaced with a generic abstraction. The authentic version uses the concrete image of a full stomach (тояды қарның); the fabrication substitutes a vague phrase about “benefit” (пайда). Similar near–misses appear across the Labor domain (e.g., the attested “Еңбекшінің наны тәтті, жалқаудың жаны тәтті” becoming the fabricated “Жалқаудың жаны тәтті, еңбекшінің күні тәтті”). The frequency of such micro–distortions suggests that the model has partial access to canonical Kazakh proverbs but lacks the lexical specificity to reproduce them precisely, defaulting to semantically adjacent but historically unattested substitutions plausible but Non–existent Wisdom. The most challenging category for evaluation consists of outputs that exhibit the full structural apparatus of Kazakh proverbs–parallel–couplet construction, vowel harmony, end–rhyme, and conventional thematic content–yet are absent from any documented source. The output “Еңбек етпегеннің несібесі аз” (He who does not work has little share) is grammatically and stylistically indistinguishable from attested labor proverbs; it would not arouse suspicion in a casual reader. These outputs reveal that the model has

internalized the form of Kazakh paremiological discourse without internalizing the specific content of the oral tradition, and they represent the principal risk to applications in cultural transmission. These four categories also exhibit a notable distributional pattern. Semantic Incoherence and Cultural Calques are easily identifiable by fluent speakers and would not survive casual scrutiny. Distorted Variants and Plausible but Non–existent Wisdom, however, can deceive even attentive readers without access to authoritative reference works, and these two categories together account for the majority of fabricated outputs in our sample. From a cultural preservation standpoint, the latter two categories warrant the greatest concern.

Table 2.Representative Examples of Verified vs. Fabricated Outputs

Category	**ChatGPT Output (Kazakh)**	**English Translation / Analysis**	**Expert Verdict**
Knowledge	Оқу инемен құдық қазғандай.	“Learning is like digging a well with a needle.”	Authentic
Labor	Еңбек етсең елік жылан да жығылады.	“If you work, even a roe deer snake falls.” (Logical impossibility.)	Fabricated (Nonsense)
Ethics	Балық берме, балық аулауды үйрет.	“Give a man a fish, teach him to fish.” (Direct English translation.)	Fabricated (Calque)
Labor	Жатқан жыланға да тау келеді.	“The mountain comes to the lying snake.” (Merged metaphors.)	Fabricated (Nonsense)
Labor	Еңбек етпегеннің несібесі аз.	“He who does not work has little share.” (Plausible but unrecorded.)	Fabricated (Plausible)

V. DISCUSSION

1. The “Illusion of Fluency”

The most concerning finding for the NLP community is the disconnect between linguistic fluency and cultural accuracy. A user interacting with ChatGPT would see correctly spelled, grammatically complex Kazakh sentences. Without expert philological knowledge, a user could plausibly accept a substantial portion of these fabrications as real–particularly those in the “Plausible but Non–existent Wisdom” category, which exhibit the structural features of authentic proverbs (rhyme, vowel harmony, parallel–couplet construction). Even when more obvious failures (semantic nonsense or foreign calques) are easily discernible to fluent speakers, the volume of grammatically and stylistically authentic–sounding fabrications poses a risk to educational and cultural transmission applications (Fig. 2), where AI might inadvertently rewrite local traditions with synthetic wisdom.

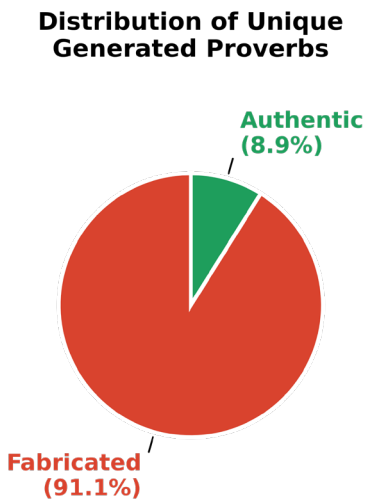

Figure 2. Distribution of authenticity among uniquely generated proverbs. Despite general linguistic well–formedness, the vast majority of unique outputs constitute cultural hallucinations.

2. Memorization vs. Pattern Completion

The frequency–authenticity correlation suggests that ChatGPT's outputs reflect two distinct underlying behaviors. For high–frequency outputs–the top ≈25 most famous Kazakh proverbs (e.g., Оқу инемен құдық қазғандай)–the model functions as a retrieval system. It has seen these specific token sequences many thousands of times in training data, and reproduces them reliably. For low–frequency outputs, the model has limited or no memorized referent and instead generates by pattern completion: predicting what a proverb should sound like based on probabilistic associations between the topic and related tokens (e.g., "Labor" with "Hardship" and "Bread"), producing grammatically well–formed but culturally unattested sentences.

3. Possible Technical Explanations

Two technical factors likely contribute to this pattern. First, frequent proverbs appear repeatedly across publicly available web sources–textbooks, blog posts, news articles, and Wikipedia entries–while less prominent proverbs appear only in specialized lexicographical works, plausibly affecting the model's exposure to each item during training. Second, prior NLP research notes that Kazakh's Cyrillic script is tokenized inefficiently by models trained primarily on English [9], which may further degrade performance on multiword expressions such as proverbs. A full technical investigation of these factors is beyond the scope of the present linguistic study.

4. Practical Implications

For developers building tools for low–resource languages, this study suggests that temperature settings and generation limits must be carefully tuned. Relying on an LLM's "creativity" for cultural tasks is detrimental. Instead, approaches such as Retrieval–Augmented Generation (RAG), which force the model to look up data in a trusted corpus (such as Babalar sözi) before generating, are essential for cultural reliability. Our results also suggest a practical heuristic for end users: in low–resource cultural–knowledge generation, repetition across

independent prompt instances is a reasonable proxy for authenticity. Outputs that the model produces only once should be treated with suspicion.

5. Limitations and Future Work

Several limitations should be acknowledged. First, our verification relies on published lexicographical sources, which, despite their authority, do not capture the full oral tradition; rare regional variants may have been undercounted, although the sensitivity analysis in Section III.3 bounds the resulting uncertainty to approximately ±3.4 percentage points. Second, the prompt–elicitation procedure used a single zero–shot Kazakh language instruction; while this reflects naturalistic user interaction, the model's behavior under source–constrained prompts (e.g., explicitly citing Babalar sözi) or chain–of–thought prompts may differ. We did not test multiple prompt variants because the original GPT–OpenAI has since deprecated 3.5 Turbo, the snapshot used for data collection, and it is no longer accessible for replication; running new prompts against the current model would conflate prompt effects with model–version effects. Third, our study evaluates a single model version. The memorization–versus–generation pattern documented here is an interpretation of LLM behavior on low–resource cultural knowledge, not a claim about all LLMs; replication on newer models (GPT–4, Claude, Llama–family models) and on additional low–resource Turkic languages (e.g., Kyrgyz, Uzbek, Tatar) would clarify which findings reflect general LLM behavior and which are specific to GPT–3.5 Turbo on Kazakh. Fourth, while domain selection covered three culturally significant areas, additional domains (e.g., agriculture, family, hospitality) could reveal further variation in the depth of memorization. Future work should pursue three directions. First, comparative evaluation across newer model generations and multiple Turkic languages would test the cross–lingual generality of this memorization–versus–generation pattern and isolate effects attributable to tokenizer geometry, training data scarcity, and model scale. Second, prompt–engineering and fine–tuning interventions–particularly retrieval–augmented architectures using curated folkloric corpora such as Babalar sözi–should be evaluated as remedies for the long–tail collapse. Third, following Almeida et al. [12], future studies could pair Kazakh proverbs with short narrative contexts to evaluate semantic grounding rather than mere string retrieval. This direction is particularly important given our finding that ChatGPT fails at the simpler zero–shot generation task: a system that cannot reliably produce attested proverbs is unlikely to apply them appropriately in context, and explicit contextual–grounding benchmarks are needed to determine whether next–generation models suffer from the same surface–fluency–without–meaning gap observed here.

VI. CONCLUSION

This study provides a systematic evaluation of LLM-generated cultural knowledge for a low–resource language, documenting a fundamental asymmetry between linguistic competence and cultural authenticity. While achieving high grammatical correctness, ChatGPT produces predominantly inauthentic content (91.1% fabrication rate at the level of unique strings; sensitivity range 87.7–91.1%), relying on a small core of memorized proverbs supplemented by pattern–generated alternatives. The strong frequency–authenticity correlation ($r = 0.87$, $p < 0.001$) supports a memorization–versus–pattern–completion account with implications for NLP evaluation, low–resource language applications, and responsible AI deployment in cultural contexts. As LLMs achieve greater linguistic sophistication and global deployment, understanding the limitations of cultural knowledge representation becomes critical for equitable access and responsible use. This work provides an empirical foundation and reproducible methodology for evaluating cultural authenticity beyond surface–level linguistic competence–essential for developing AI systems that serve diverse linguistic communities effectively and appropriately.

Abstract
Nonlinear constrained optimization problems arise in many domains, including engineering design, production planning, machine learning, and decision-support systems. Although classical optimization algorithms can effectively solve many small- and medium-scale instances, reformulating such problems for quantum optimization remains a challenging modeling task. This study proposes a QUBO-based reformulation framework for transforming nonlinear constrained optimization problems into a binary quadratic form suitable for quantum-inspired and quantum-based solution approaches. The proposed framework includes variable discretization, binary encoding, penalty-based constraint embedding, and QUBO matrix construction. A nonlinear resource-constrained production planning problem is used as a case study. The problem is first solved using a classical constrained optimizer, then reformulated as a QUBO model and solved using classical QUBO search and a quantum-oriented optimization approach. The results are evaluated in terms of objective value, constraint violation, solution feasibility, and computational behavior. The study provides a reproducible Python-based workflow and establishes a foundation for extending nonlinear constrained optimization problems toward quantum programming environments. The proposed approach helps bridge classical nonlinear optimization and emerging quantum optimization methods.

Keywords: nonlinear constrained optimization, QUBO, quantum optimization, quantum programming, QAOA, binary encoding, penalty method.

I. INTRODUCTION

Nonlinear constrained optimization problems arise in many domains, including engineering design, production planning, resource allocation, logistics, finance, machine learning, and decision-support systems. These problems require optimizing a nonlinear objective function while satisfying equality or inequality constraints. Although classical methods such as sequential quadratic programming, interior-point methods, penalty methods, and gradient-based algorithms can solve many instances effectively, their performance may be affected by nonconvexity, local optima, constraint complexity, and the dimensionality of the search space. Quantum computing and quantum-inspired optimization have recently attracted attention as alternative computational paradigms for complex optimization problems. In this context, Quadratic Unconstrained Binary Optimization, known as QUBO, provides a compact bridge between classical optimization models and quantum-oriented algorithms. Many quantum optimization approaches, including quantum annealing and the Quantum Approximate Optimization Algorithm, require problems to be represented in binary quadratic form. Therefore, transforming nonlinear constrained optimization problems into QUBO form is a critical step. However, this transformation is not straightforward. Nonlinear constrained optimization problems often include continuous decision variables, nonlinear objective terms, and multiple constraints. To make such problems suitable for

QUBO-based solution methods, continuous variables must be discretized and encoded as binary variables, and constraints must be embedded in the objective function via penalty terms. The quality of this transformation directly affects feasibility, QUBO matrix size, and computational behavior. This study proposes a QUBO-based reformulation framework for nonlinear constrained optimization problems. A nonlinear resource-constrained production planning problem is used as a case study. The problem is first solved using a classical constrained optimizer, then transformed into QUBO form via variable scaling, binary encoding, slack-variable representation, and penalty-based constraint embedding. The resulting QUBO model is evaluated using exact enumeration, random search, simulated annealing, and a PennyLane-based QAOA demonstration. The main contributions of this study are threefold. First, a transparent QUBO reformulation workflow is presented for transforming a nonlinear constrained optimization problem into a binary quadratic form. Second, the proposed transformation is validated on a resource-constrained production planning problem by comparing the classical SLSQP solution with the exact QUBO solution. Third, a reproducible Python-based workflow is developed to connect classical optimization, QUBO modeling, and quantum-oriented optimization. This paper does not claim a quantum advantage. Instead, it focuses on the modeling pathway from classical nonlinear constrained optimization to QUBO-based quantum-oriented optimization. The remainder of the paper is organized as follows. Section II reviews related work. Section III presents the problem formulation. Section IV explains the QUBO reformulation framework. Section V describes the solution approach. Section VI presents the experimental results, and Section VII concludes the study.

II. RELATED WORK

Recent studies on quantum optimization can be grouped around three closely related directions: variational hybrid quantum-classical algorithms, QUBO-based reformulation methods, and the encoding of constrained optimization problems for quantum-oriented solvers. McClean et al. introduced the theoretical foundations of variational hybrid quantum-classical algorithms, emphasizing the role of a classical optimizer in training parameterized quantum circuits [1]. Cerezo et al. later provided a comprehensive review of variational quantum algorithms and discussed central challenges, including ansatz design, optimization difficulty, barren plateaus, and measurement cost [2]. These studies show that near-term quantum optimization should be understood as a hybrid computational process rather than a purely quantum procedure. Quantum annealing and adiabatic quantum computation provide another important foundation for optimization. Albash and Lidar reviewed the theoretical background of adiabatic quantum computation and its relationship with quantum annealing [3]. Hauke et al. discussed the practical implementation challenges of quantum annealing, including embedding, hardware limitations, and problem formulation issues[4]. These works are relevant because many quantum annealing systems naturally operate on QUBO or Ising-type formulations. Therefore, transforming an original optimization problem into an appropriate binary quadratic form is a decisive modeling step. QUBO has become a central representation because it connects classical optimization models with quantum-oriented solution methods. Glover et al. presented a detailed tutorial on formulating and using QUBO models, showing how constrained optimization problems can be transformed into unconstrained binary quadratic forms through penalty terms [5]. In the context of gate-based quantum optimization, Hadfield et al. extended the standard Quantum Approximate Optimization Algorithm toward the Quantum Alternating Operator Ansatz for constrained optimization problems [6]. Zhou et al. analyzed the performance and implementation of QAOA on near-term devices [7], while Barkoutsos et al. proposed a CVaR-based strategy to improve variational quantum optimization [8]. These studies indicate that the quality of the problem-to-QUBO mapping strongly affects the performance of both classical and quantum-oriented solvers. Several studies have also focused on reformulation and decomposition strategies. Gambella and Simonetto investigated mixed-binary optimization on classical and quantum computers using multiblock ADMM heuristics [9]. Quintero et al. analyzed QUBO reformulations and penalty characterizations, showing that penalty selection is not merely a numerical detail but a core modeling

decision [10]. More recent studies on inequality constraint encoding further demonstrate that penalty design can significantly influence feasibility and solution quality in QUBO-based optimization [11]. Despite these advances, a complete and reproducible workflow that starts from a nonlinear constrained optimization model, applies variable scaling and binary encoding, embeds constraints via penalty terms, constructs a QUBO model, and compares the decoded solution with that of a classical constrained optimizer remains limited. This study addresses this gap by proposing a transparent QUBO-based reformulation framework and validating it on a nonlinear, resource-constrained production planning problem [12].

III. PROBLEM FORMULATION

Nonlinear constrained optimization problems are generally defined by an objective function to be optimized subject to a set of equality or inequality constraints. In this study, a nonlinear resource-constrained production planning problem is considered as a representative case study. The selected problem is intentionally designed to be simple enough for a QUBO-based reformulation, yet sufficiently expressive to capture nonlinear cost behavior, resource limitations, and bounded decision variables. Let 1 $and\ x\ alt\ 2\ denote$enote the production quantities of two different products. The company aims to maximize its total profit. Each product generates linear revenue; however, production costs increase nonlinearly as production quantity grows. This reflects practical situations in which overtime labor, machine wear, storage limitations, coordination costs, or resource inefficiencies increase as production volume increases.

The profit maximization problem is formulated as follows:

$$\max_{x_1,x_2} P(x_1,x_2) \tag{1}$$

where the nonlinear profit function is defined as:

$$P(x_1,x_2) = r_1x_1 + r_2x_2 - c_1x_1^2 - c_2x_2^2 - c_{12}x_1x_2 \tag{2}$$

In this formulation, $r_1$and $r_2$represent the unit revenues of the products, $c_1$and $c_2$represent nonlinear production cost coefficients, an12 representspresents the interaction cost between the two products. The interaction term may represent shared machinery, production interference, storage competition, or operational complexity caused by producing both products simultaneously.

The problem is subject to resource and capacity constraints:

$$a_{11}x_1 + a_{12}x_2 \le R_1 \tag{3}$$
$$a_{21}x_1 + a_{22}x_2 \le R_2 \tag{4}$$
$$x_1 + x_2 \le R_3 \tag{5}$$
$$0 \le x_1 \le U_1, 0 \le x_2 \le U_2 \tag{6}$$

1 and büyük harf R alt 2 denote, $R_1$and R_2denote the available amounts of two limited resources, such as labor time and raw material. R_3denotes the total production capacity. $U_1$and U_2a2 areupper bounds for the production quantities.

Since most classical optimization algorithms are commonly formulated as minimization procedures, the maximization problem in (1) can be equivalently rewritten as:

$$\min_{x_1,x_2} f(x_1,x_2) = -P(x_1,x_2) \tag{7}$$

Thus, the classical nonlinear constrained optimization model becomes:

$$\min_{x_1,x_2} -r_1x_1 - r_2x_2 + c_1x_1^2 + c_2x_2^2 + c_{12}x_1x_2 \tag{8}$$

subject to the constraints given in (3)–(6).

For the numerical case study, the following parameter values are used:

$$c_1 = 0.08, c_2 = 0.10, c_{12} = 0.03$$
$$2x_1 + 3x_2 \leq 120$$
$$4x_1 + 2x_2 \leq 160$$
$$x_1 + x_2 \leq 70$$
$$0 \leq x_1 \leq 50, 0 \leq x_2 \leq 50$$

Accordingly, the case study problem can be written as:

$$\min_{x_1,x_2} -40x_1 - 55x_2 + 0.08x_1^2 + 0.10x_2^2 + 0.03x_1x_2$$

subject to:

$$2x_1 + 3x_2 \leq 120$$
$$4x_1 + 2x_2 \leq 160$$
$$x_1 + x_2 \leq 70$$
$$0 \leq x_1 \leq 50, 0 \leq x_2 \leq 50$$

This formulation provides a compact nonlinear constrained optimization problem that is suitable for both classical and QUBO-based solution approaches. In the classical setting, the problem can be solved using a constrained optimizer such as Sequential Least Squares Programming. In the QUBO-based setting, the continuous decision variables are first discretized and encoded into binary variables. Then, the inequality constraints are embedded into the objective function using penalty terms. This transformation is described in the next section.

IV. QUBO REFORMULATION FRAMEWORK

Quadratic Unconstrained Binary Optimization is a standard mathematical representation used in many quantum-inspired and quantum-based optimization approaches. A QUBO problem is generally written as:

$$\min_{\mathbf{z}\in\{0,1\}^n} \mathbf{z}^T Q \mathbf{z} \tag{9}$$

where **z**is ais a binary decision vector and büyük harf Qis an n × n real-valued upper triangular or symmetric matrix. The main objective of QUBO reformulation is to transform the original constrained optimization

problem into an unconstrained binary quadratic form. In this study, the transformation is performed through three main steps: variable discretization, binary encoding, and penalty-based constraint embedding.

1. Discretization of Continuous Variables

The original problem includes continuous production variables 1 $and\ x\ alt$ 2.nd $.x_2$. Since QUBO models require binary decision variables, the continuous variables must first be discretized. In this study, production quantities are represented with a unit discretization step. Therefore, each production variable is approximated by a binary expansion:

$$x_1 = \sum_{k=0}^{K_1-1} 2^k\, b_{1k} \tag{10}$$

$$x_2 = \sum_{k=0}^{K_2-1} 2^k\, b_{2k} \tag{11}$$

where $b_{1k}, b_{2k} \in \{0,1\}$are binary variables and K_1, K_2denote the number of binary bits used for representing $x_1$and x_2, respectively. In the numerical case study, six bits are used for each decision variable:

$$K_1 = K_2 = 6 \tag{12}$$

Thus, each variable can represent integer values in the range $[0, 63]$. Although the original upper bounds are $x_1 \leq 50$and $x_2 \leq 50$, the resource constraints further restrict the feasible region. Any infeasible binary solution is discouraged through penalty terms in the QUBO objective function.

2. Slack Variable Representation of Inequality Constraints

The original model contains three inequality constraints. To transform them into QUBO-compatible expressions, each inequality is converted into an equality by introducing a nonnegative slack variable:

$$2x_1 + 3x_2 + s_1 = 120$$
$$4x_1 + 2x_2 + s_2 = 160$$
$$x_1 + x_2 + s_3 = 70$$

where s_1, s_2, and $s_3$are nonnegative slack variables. These variables measure the unused amount of each resource. Since QUBO requires binary variables, the slack variables are also encoded using binary expansions:

$$s_1 = \sum_{k=0}^{K_{s1}-1} 2^k\, y_{1k} \tag{13}$$

$$s_2 = \sum_{k=0}^{K_{s2}-1} 2^k\, y_{2k} \tag{14}$$

$$s_3 = \sum_{k=0}^{K_{s3}-1} 2^k\, y_{3k} \tag{15}$$

where $y_{jk} \in \{0,1\}$are binary slack variables. In this study, the number of bits for the slack variables is selected according to the right-hand side of each constraint. Therefore, $s_1$and $s_3$are represented with seven bits, while $s_2$is represented with eight bits:

$$K_{s1} = 7, K_{s2} = 8, K_{s3} = 7$$

This representation is sufficient to encode the maximum possible slack values for the three resource constraints.

3. Penalty-Based Constraint Embedding

After introducing slack variables, each constraint can be embedded into the objective function using a quadratic penalty term. Let the original minimization objective be:

$$f(x_1, x_2) = -40x_1 - 55x_2 + 0.08x_1^2 + 0.10x_2^2 + 0.03x_1x_2$$

The penalty terms corresponding to the three constraints are defined as:

$$\lambda_1(2x_1 + 3x_2 + s_1 - 120)^2$$
$$\lambda_2(4x_1 + 2x_2 + s_2 - 160)^2$$
$$\lambda_3(x_1 + x_2 + s_3 - 70)^2$$

where λ_1, λ_2, and $\lambda_3$are positive penalty coefficients. These coefficients determine the strength of constraint enforcement. If the penalty coefficients are too small, the optimizer may prefer infeasible solutions with better objective values. If they are too large, the QUBO coefficients may become numerically unbalanced. Therefore, penalty selection is an important modeling decision in QUBO reformulation.

The complete penalized objective function is written as:

$$F(x_1, x_2, s_1, s_2, s_3) = f(x_1, x_2) + \lambda_1(2x_1 + 3x_2 + s_1 - 120)^2 + \lambda_2(4x_1 + 2x_2 + s_2 - 160)^2 + \lambda_3(x_1 + x_2 + s_3 - 7$$

The constrained nonlinear optimization problem is therefore transformed into the following unconstrained binary optimization problem:

$$\min_{\mathbf{z}\in\{0,1\}^n} F(\mathbf{z}) \qquad (16)$$

where all continuous and slack variables are represented by binary variables.

4. Binary Decision Vector

The complete binary vector is constructed by concatenating the binary variables of the original decision variables and the slack variables:

$$\mathbf{z} = [b_{10}, \dots, b_{1,K_1-1}, b_{20}, \dots, b_{2,K_2-1}, y_{10}, \dots, y_{1,K_{s1}-1}, y_{20}, \dots, y_{2,K_{s2}-1}, y_{30}, \dots, y_{3,K_{s3}-1}]^T \qquad (17)$$

For the selected bit configuration, the total number of binary variables is:

$$n = K_1 + K_2 + K_{s1} + K_{s2} + K_{s3}$$
$$n = 6 + 6 + 7 + 8 + 7 = 34$$

Thus, the original two-variable nonlinear constrained optimization problem is transformed into a 34-variable QUBO problem.

5. Construction of the QUBO Matrix

After substituting the binary expansions into the penalized objective function, the resulting expression contains only binary linear and quadratic terms. Since each binary variable satisfies:

$$z_i^2 = z_i \tag{18}$$

all squared binary terms can be represented as linear terms on the diagonal of the QUBO matrix. The final objective can be written in matrix form as:

$$F(\mathbf{z}) = \mathbf{z}^T Q \mathbf{z} + C \tag{19}$$

where $Q$is the QUBO coefficient matrix and $C$is a constant term. Since the constant term does not affect the optimizer, it can be ignored during the solution process. The QUBO problem is therefore expressed as defined in (9)

The QUBO matrix contains the coefficients generated by the original nonlinear objective function and the penalty terms. Diagonal elements represent linear binary contributions, while off-diagonal elements represent pairwise interactions between binary variables.

This reformulation transforms the original nonlinear constrained problem into a QUBO structure that is compatible with quantum annealing, QAOA-based approaches, and classical QUBO solvers. The next section explains the classical and quantum-oriented solution strategies used for solving the constructed QUBO model.

V. QUANTUM SOLUTION APPROACH

After the nonlinear constrained optimization problem is transformed into QUBO form, it becomes suitable for quantum-oriented solution methods. In this study, the constructed QUBO model is considered from three complementary perspectives: classical QUBO search, QUBO-to-Ising representation, and QAOA-based variational quantum optimization. This structure enables comparison of the proposed QUBO reformulation with both classical and quantum-oriented computational paradigms. The QUBO objective was defined in (9), where the binary decision vector and the QUBO coefficient matrix were introduced. In this section, the constructed QUBO model is solved and evaluated using classical and quantum-oriented solution strategies. The solution vector $\mathbf{z}^*$obtained from the QUBO solver is decoded back into the original production quantities $x_1$and x_2, together with the slack variables s_1, s_2, and . s_3. The decoded solution is then evaluated in terms of objective value and constraint feasibility.

1. QUBO-to-Ising Representation

Quantum annealing is one of the most natural computational models for solving QUBO and Ising-type optimization problems. In a quantum annealing-oriented formulation, the QUBO problem is mapped into an energy minimization problem. The goal is to identify a binary configuration corresponding to the system's minimum-energy state.

The QUBO form can be converted into an Ising representation by mapping binary variables z_i ∈ {0, 1} into spin variables s_i ∈ {−1, 1}.$z_i \in \{0,1\}$into spin variables $s_i \in \{-1, +1\}$:

$$z_i = \frac{1 - s_i}{2} \qquad (47)$$

Using this transformation, the QUBO objective can be represented as an Ising Hamiltonian of the following form:

$$H_C = \sum_i h_i s_i + \sum_{i<j} J_{ij} s_i s_j \qquad (48)$$

where $h_i$represents local fields and J_{ij}represents pairwise interactions between spin variables. In the quantum annealing process, the system evolves from an initial Hamiltonian toward the problem Hamiltonian, and low-energy states are sampled as candidate solutions.

In this study, the quantum annealing-oriented solution is treated as a QUBO-compatible sampling process. The obtained samples are decoded into the original variables, and each solution is evaluated based on the objective value, constraint violations, and feasibility. This enables the QUBO model to be examined under a quantum optimization perspective without requiring an unsupported claim of quantum advantage.

2. Solution Evaluation Criteria

All solution methods are evaluated after decoding the binary vector into the original production variables and slack variables. The comparison is based on objective value, profit value, constraint violation, feasibility, and runtime. This is necessary because QUBO energy alone does not fully indicate the practical quality of a solution. Therefore, each candidate solution is rechecked in the original problem space before being reported in Section VI.

VI. EXPERIMENTAL DESIGN AND RESULTS

The experimental evaluation was designed to test whether the proposed QUBO reformulation preserves the optimal structure of the nonlinear constrained optimization problem defined in (15)–(19). The experiments were implemented in Python using a reproducible workflow. The classical SLSQP optimizer was first used to solve the original problem. Then, the scaled QUBO model was solved using exact enumeration, random search, simulated annealing, and a PennyLane-based QAOA demonstration. For computational validation, the production variables were represented in a scaled integer form as x1 = 10u1 and x2 = 10u2. This reduced representation produces an 18-variable QUBO model, including binary encodings for u1, u2, and the slack variables. This size is sufficient for exact enumeration and also practical for a small-scale PennyLane QAOA demonstration. The QUBO construction follows the binary encoding and penalty-based reformulation framework described in Section IV.

1. Experimental Configuration

The experimental setting is summarized in Table 1. The same objective function and constraints were used across all solution methods. The penalty coefficients were selected as λ1 = λ2 = λ3 = 1000. Each decoded QUBO solution was evaluated again in the original problem space in terms of objective value, profit, feasibility, constraint violation, and runtime.

Table1. Experimental Configuration

Item	**Setting**
Original decision variables	x_1, x_2
Scaled variables	$x_1 = 10u_1, x_2 = 10u_2$
Binary variables for $u_1$and u_2	3 bits each
Slack variables	s_1, s_2, s_3
Total binary variables	18
Penalty coefficients	$\lambda_1 = \lambda_2 = \lambda_3 = 1000$
Classical baseline	SLSQP
QUBO validation	Exact enumeration
Classical QUBO heuristics	Random search, simulated annealing
Quantum-oriented method	PennyLane QAOA demonstration

2. Experimental Results

The obtained results are presented in Table 2. The classical SLSQP optimizer reached x1 = 30 and x2 = 20, corresponding to a maximum profit of 2170. The exact QUBO solver found the same decoded solution. This agreement is the key experimental result of the study, because it confirms that the proposed QUBO reformulation preserves the optimum structure of the original nonlinear constrained optimization problem. The Python/Streamlit implementation used to generate the experimental results is available at https://github.com/cyasar/IHCONCS.

Table 2. Comparison Of Classical, Qubo-Based, And Quantum-Oriented Solution Methods

Method	x_1	x_2	s_1	s_2	s_3	**Objective** $f(x)$	**Profit** $P(x)$	**Violation**	**Runtime**
SLSQP	30.00	20.00	—	—	—	-2170.00	2170.00	1.22×10^{-10}	0.021 s
Exact QUBO	30.00	20.00	0	0	2	-2170.00	2170.00	0.00	9.694 s
Random Search QUBO	10.00	20.00	4	8	4	-1446.00	1446.00	0.00	0.503 s
Simulated Annealing QUBO	40.00	0.00	4	0	3	-1472.00	1472.00	0.00	1.504 s
PennyLane QAOA	20.00	20.00	2	5	4	-1816.00	1816.00	0.00	747.456 s

The small numerical constraint violation reported by SLSQP is due to floating-point precision and is considered zero in practice. The slack variables in Table 2 are reported in the scaled QUBO representation. Random search and simulated annealing generated feasible but suboptimal solutions, with profit values of 1446 and 1472, respectively. The PennyLane QAOA demonstration produced a feasible solution with a profit of 1816, outperforming these two heuristic QUBO methods under the tested settings, but with a substantially higher runtime. Therefore, the QAOA result should be interpreted as a quantum-oriented workflow demonstration rather than evidence of quantum advantage. Overall, the exact QUBO result validates the reformulation, while the PennyLane implementation demonstrates how the constructed QUBO model can be integrated into a hybrid quantum-classical programming environment.

VII. CONCLUSION AND FUTURE WORK

This study presented a QUBO-based reformulation framework for transforming a nonlinear constrained optimization problem into a binary quadratic model. A resource-constrained production planning problem was used as a case study and reformulated through variable scaling, binary encoding, slack variables, and penalty-based constraint embedding. The results showed that the proposed QUBO reformulation preserved the optimum structure of the original problem. The classical SLSQP optimizer and the exact QUBO solver produced the same solution: x1 = 30 and x2 = 20, corresponding to a maximum profit of 2170. This confirms that the transformation was correctly constructed. Other QUBO-based methods produced feasible but suboptimal solutions, while the PennyLane QAOA demonstration showed how the model can be connected to a quantum-oriented workflow.

This study does not claim a quantum advantage. Its main contribution is a transparent and reproducible pathway from nonlinear constrained optimization to QUBO-based optimization. Future work will focus on larger problems, alternative encoding strategies, penalty coefficient selection, QAOA settings, and a Streamlit-based web implementation made available through GitHub at https://github.com/cyasar/IHCONCS.

Abstract
This paper proposed a hybrid long-distance monitoring system that integrates a Wireless Sensor Network (WSN) and Internet of Things (IoT) to overcome the connectivity issues in remote locations. The proposed system uses an Arduino Nano microcontroller for data collection on the remote end and an HC-12 radio module to enable long-range wireless communication without an internet connection. The sensor data, such as temperature and humidity from a DHT11 sensor and fire detection from a flame sensor, are gathered and transmitted wirelessly over a range of 100 meters in an open environment. The NodeMCU (ESP8266) module on the receiving side receives incoming data, displays it on a 16x2 I2C LCD screen, and transmits it to the Blynk cloud platform, where it is displayed in real time. Experimental evaluation demonstrated reliable wireless communication over 100 m with a 95% packet delivery ratio, RF latency below 2 s, and mobile alerts delivered within 5s.

Keywords: wireless sensor networks, IOT, HC-12, environmental monitoring, ESP8266, remote systems, smart security.

I. INTRODUCTION

The Internet of Things (IoT) has transformed how humans interact with their environment, enabling data collection, analysis, and relay with minimal human intervention [1]. IoT-based monitoring systems are common in agriculture, industry, smart homes, and healthcare. Embedded systems, wireless communication, and cloud computing have grown rapidly, making monitoring systems cost-effective. However, these technologies are largely ineffective in remote or rural areas such as farmland, forests, mountains, and coastal borders [2]. Wi-Fi has a limited range (~100 m), while GSM-based systems require recurring subscription fees and network infrastructure. Neither operates reliably when infrastructure is damaged or unavailable. A low-cost monitoring system that works over long distances without internet dependency is increasingly needed, especially in developing countries where digital infrastructure is lacking but environmental and security monitoring is critical. Although numerous IoT monitoring systems have been proposed, most rely on continuous Internet connectivity or gateway infrastructure. Consequently, these systems cannot operate effectively in remote regions where communication infrastructure is unavailable. Moreover, few studies integrate long-range RF communication with cloud-based monitoring while simultaneously supporting environmental sensing and security monitoring.

This research addresses these limitations through a hybrid HC-12–IoT architecture. The principal contributions of this work are:

i) create an effective long-range wireless sensing system;
ii) combine multiple environmental and security sensors;
iii) provide real-time alerts and data visualization via LCD and mobile app; and
iv) reduce reliance on constant internet connectivity for remote deployment [3].

II. LITERATURE REVIEW

Recent years have seen significant research in IoT-based environmental monitoring. Cloud-connected sensor systems monitoring soil moisture, temperature, and humidity have enhanced agricultural productivity [4]. Smart greenhouse systems using Arduino and cloud computing have reduced manual monitoring by over sixty percent [5]. ESP32-based greenhouse systems enable real-time data collection and automated control. IoT-based air pollution monitoring systems combine environmental sensors with cloud visualization. ESP32-based cloud-enabled IoT systems using Firebase show high transmission reliability and low latency. Wireless Sensor Networks (WSNs) consist of spatially distributed sensor nodes that gather and wirelessly transmit data to a central location. Recent studies confirm the importance of smart energy management in WSNs. Kumar et al. proposed clustering and routing algorithms that enhance network throughput and lifetime [6]. Various wireless communication technologies have been evaluated for remote IoT monitoring. Wi-Fi is range-limited. GSM/GPRS requires subscription fees and may be inaccessible in remote areas. Zigbee is low-power but short-range. LoRa and LoRaWAN provide long-range communication with low power consumption. They are effective in rural deployments with a multi-kilometer range. However, LoRaWAN requires gateways and infrastructure, increasing cost and complexity [7], [8]. Recent studies have increasingly adopted hybrid communication architectures to improve the reliability and scalability of IoT monitoring systems [9]. Abdulmalek et al. [10] implemented a hybrid Wi-Fi/LoRaWAN architecture for remote healthcare monitoring, demonstrating reliable long-range communication while relying on gateway infrastructure. Similarly, Hassan et al. [11] proposed a hybrid fog–cloud framework for structural health monitoring that improves processing efficiency but depends on continuous network connectivity. In contrast, the proposed system employs HC-12 serial RF communication to provide infrastructure-independent local sensing while maintaining cloud accessibility through the receiver node. The HC-12 serial radio module (433 MHz band) is a low-cost, straightforward wireless communication device offering up to 1 kilometer range in open space without gateways or internet access. It is simpler to implement than LoRa and more cost-effective for small-to-medium-range deployments that prioritize infrastructure independence [12]. Despite rich literature on IoT monitoring, most deployed systems remain overly reliant on uninterrupted internet connectivity. Offline IoT operation frameworks show that connectivity losses significantly degrade functionality, a major weakness for remote deployments [13]. Hybrid systems combining offline wireless communication with cloud-based monitoring are rare [14]. Most solutions are domain-focused and do not combine environmental and security sensors into a unified platform [15]. Table 1 presents a comparison of wireless communication technologies.

Technology	**Range**	**Infrastructure Required**	**Cost**
Wi-Fi	~100 m	Yes	Low
Zigbee	~100–300 m	Optional	Medium

GSM/NB-IoT	Several km	Cellular network	High
LoRa	Several km	Gateway required	Medium–High
HC-12	~100 m tested	No	Low

Table 1. Wireless Communication Technologies Comparison

This work addresses these limitations by integrating the HC-12 module with IoT cloud platforms to create a cost-effective, multi-sensor hybrid monitoring system that operates in both offline and online modes. Figure 1 compares the wireless communication technologies considered in this study.

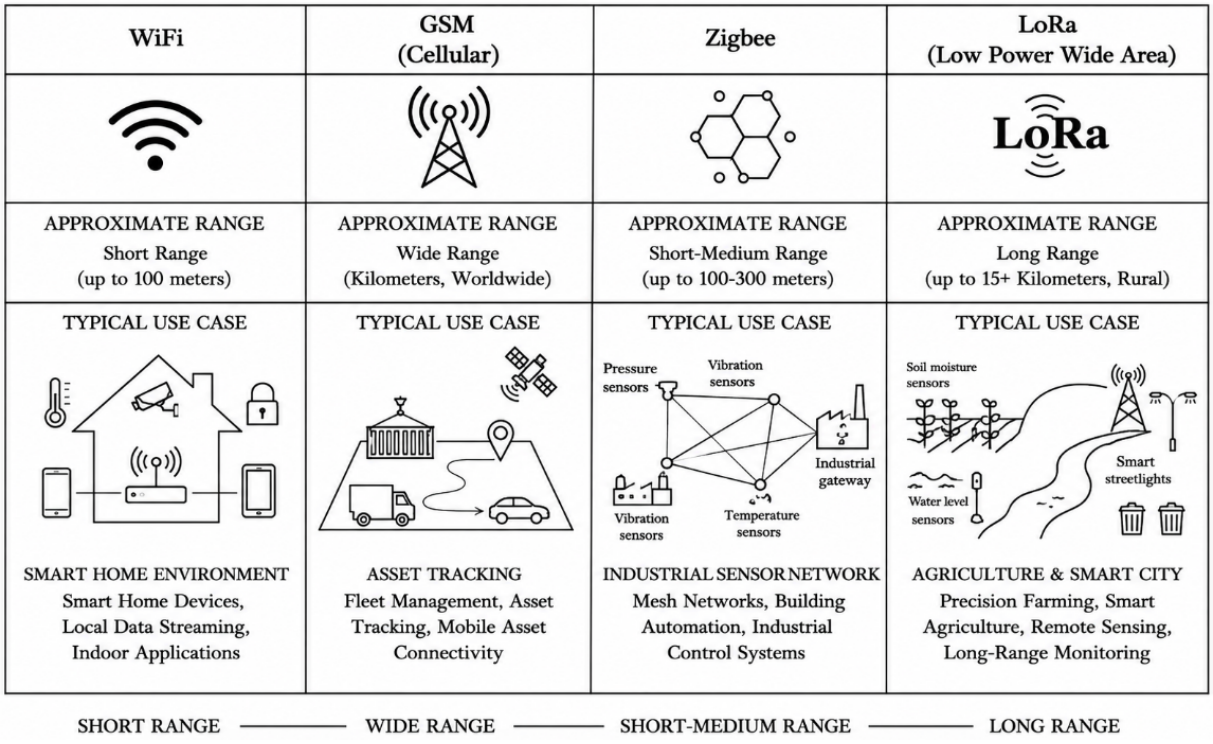

Figure 1. Comparison of communication technologies in IoT

III. METHODOLOGY

1. System Architecture

A dual-node architecture was implemented, comprising a Transmitter Unit and a Receiver Unit that communicate via HC-12 RF serial modules operating at 433 MHz. The transmitter acquires environmental data and forwards it wirelessly; the receiver processes, displays, and uploads the data to the cloud. The complete circuit implementation is shown in Fig. 2.

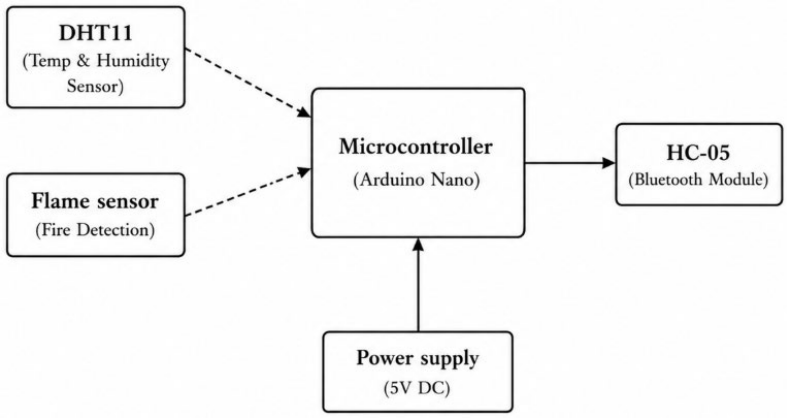

Figure 2. Block diagram of the proposed system

2. System Hardware Implementation

The proposed system is implemented using Arduino Nano and NodeMCU (ESP8266) microcontrollers. The Arduino Nano acquires temperature, humidity, and flame data from the connected sensors, formats the measurements into serial packets, and transmits them through an HC-12 wireless module operating at 433 MHz. The NodeMCU receives the transmitted data, displays real-time measurements on a 16 × 2 I²C LCD, communicates with the Blynk IoT platform for cloud monitoring and notifications, and manages system alerts. Table 2 summarizes the hardware components and their functions.

Table 2. Hardware Components of the Proposed System

Component	**Function**
Arduino Nano	Collects sensor data, processes measurements, formats data packets, and controls wireless transmission.
NodeMCU (ESP8266)	Processes received data, updates the LCD, communicates with the Blynk IoT platform, and generates alerts.
DHT11 Sensor	Measures ambient temperature and relative humidity.
Flame Sensor	Detects the presence of flame and provides a digital detection signal.
HC-12 Wireless Module	Enables 433 MHz RF communication between transmitter and receiver.
16 × 2 I²C LCD	Displays real-time temperature, humidity, flame status, and system messages.
Blynk IoT Platform	Provides cloud monitoring, data logging, and mobile notifications.
Li-ion Battery + TP4056 + DC–DC Boost Converter	Provides a regulated 5 V power supply for system operation.

The Arduino Nano was selected for its low cost, sufficient GPIO pins, and ease of programming. The ESP8266 was selected because of its integrated Wi-Fi capability for direct cloud communication. HC-12 was preferred over LoRa due to its lower implementation complexity and the absence of gateway requirements in short- to medium-range deployments. The complete hardware configuration is summarized in Table 2. Both units are powered by lithium-ion batteries with TP4056 charging modules and DC-DC boost converters to provide regulated 5 V operation.

3. Circuit Design

The complete circuit was modeled and simulated in Proteus 8 Professional before hardware implementation, enabling verification of component interconnections and signal behavior. The finalized circuit diagram is shown in Fig. 3.

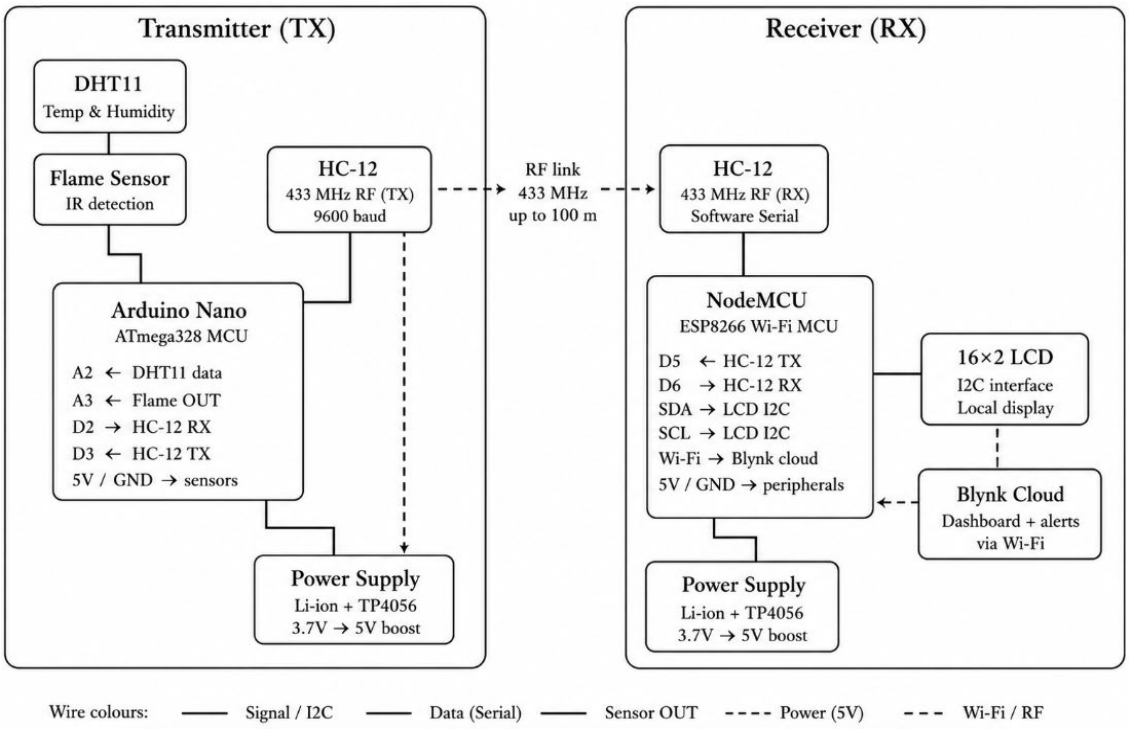

Figure 3. Circuit diagram of the proposed system

Key wiring configurations are as follows. The DHT11 sensor is connected to Arduino Nano pin A2 with a pull-up resistor. The flame sensor digital output is connected to pin A3 for HIGH/LOW detection. The transmitter-side HC-12 TX and RX lines are connected to Arduino pins 2 and 3, respectively, while the receiver-side HC-12 is connected to NodeMCU pins D5 and D6. The LCD is interfaced via the I2C protocol using the SDA and SCL lines, minimizing wiring complexity.

4. Firmware Development

Continuous polling loop (1-second frequency) reading sensors and Firmware for both nodes was developed in C++ using the Arduino IDE. The transmitter executes a continuous polling loop at one-second intervals, reading the DHT11 and flame sensor outputs and transmitting comma-delimited data strings via the HC-12 module. The receiver parses incoming data packets, updates the LCD, and forwards readings to the Blynk platform at 30-second intervals to avoid exceeding API rate limits. Automated alerts are triggered under two conditions: flame detection, indicated by a LOW signal from the flame sensor, and temperature readings exceeding 30 °C. In both cases, a push notification is dispatched to the operator's registered mobile device using the Blynk.notify() function. The firmware logic for both nodes is illustrated in Fig. 4.

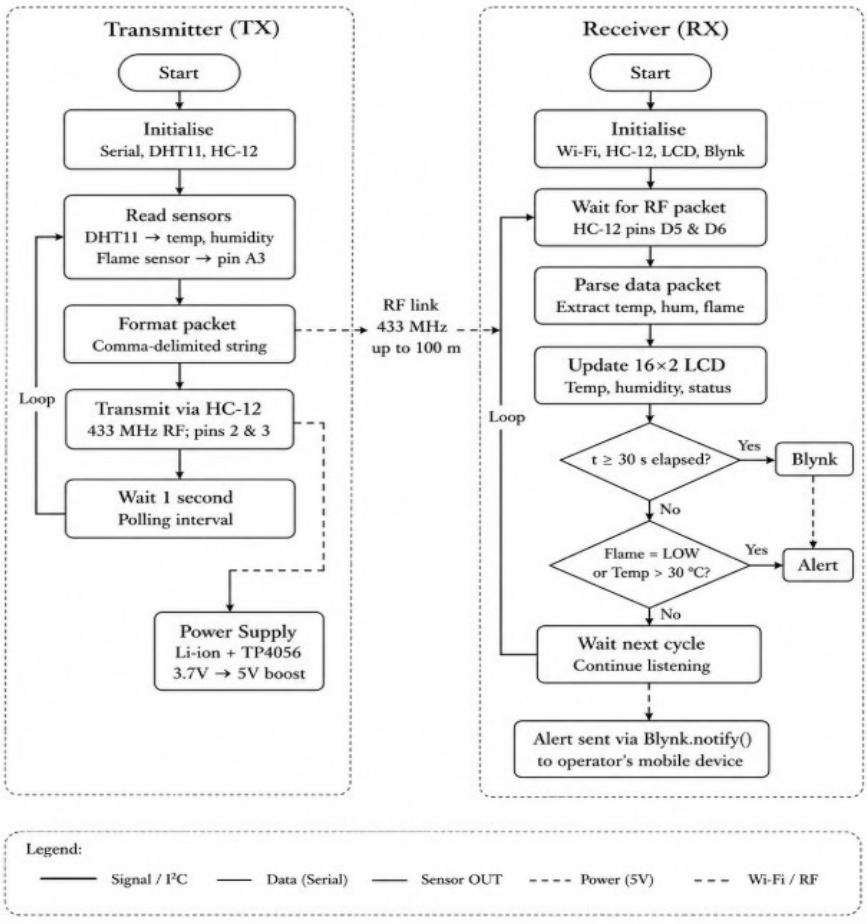

Figure 4. Filmware flowchart -transmitter node and receiver node

IV. RESULTS AND DISCUSSION

1. Hardware Implementation

Both transmitter and receiver units were successfully assembled and tested. The DC-DC boost converter maintained a regulated output of 4.9-5.1 V under load, confirming stable power delivery to all components. A

pin assignment correction (flame sensor from A1 to A3) was applied without operational disruption, demonstrating the flexibility of the Arduino Nano platform. The I2C LCD interface operated reliably throughout testing, with no communication faults observed. Figure 5 presents the prototype of the implemented system.

Figure 5. Prototype of the implemented system (transmitter and receiver units)

Table 3. Sensor Performance Characteristics

Parameter	Observed Range	Remarks
Temperature (DHT11)	0°C - 50°C (±2°C)	Within specifications
Humidity (DHT11)	20% - 90% RH (±5% RH)	Within specifications
Flame detection	Up to ~100 cm	Sensitivity adjustable

2. Wireless Communication Performance

The HC-12 modules operated reliably at 9600 baud throughout all test scenarios. Open-field range exceeded 100 m with stable packet delivery, while indoor range was reduced to 30-50 m due to wall attenuation. These results confirm the suitability of 433 MHz RF communication for short- to medium-range environmental monitoring deployments. The packet delivery ratio decreased slightly with increasing distance due to RF attenuation and environmental interference. Nevertheless, the system maintained over 95% successful transmission at 100 m, demonstrating adequate reliability for remote monitoring applications.

Table 4. HC-12 Communication Performance at Different Distances and Environments

Distance (m)	Environment	Packet Delivery Ratio (%)	Latency
10	Indoor	100	<1 sec
30	Indoor	98	<1 sec
50	Indoor	92	1-2 sec
50	Outdoor	100	<1 sec
100	Outdoor	95	1-2 sec

3. Signal Loss Detection

The 10-second watchdog timeout mechanism functioned correctly under all test conditions. Upon deliberate power-off of the transmitter unit, the receiver correctly detected the absence of incoming packets and displayed a “signal loss” warning on the LCD within 10 seconds. Normal operation resumed automatically upon transmitter recovery, with no manual intervention required. This behavior confirms the robustness of the supervisory logic for unattended deployment scenarios.

4. Alert and Notification System

All automated alert conditions were verified under controlled laboratory conditions. Push notification latency remained below 5 seconds under stable Wi-Fi connectivity, meeting the real-time alerting requirement. Figure 6 presents the developed Blynk dashboard used for real-time monitoring.

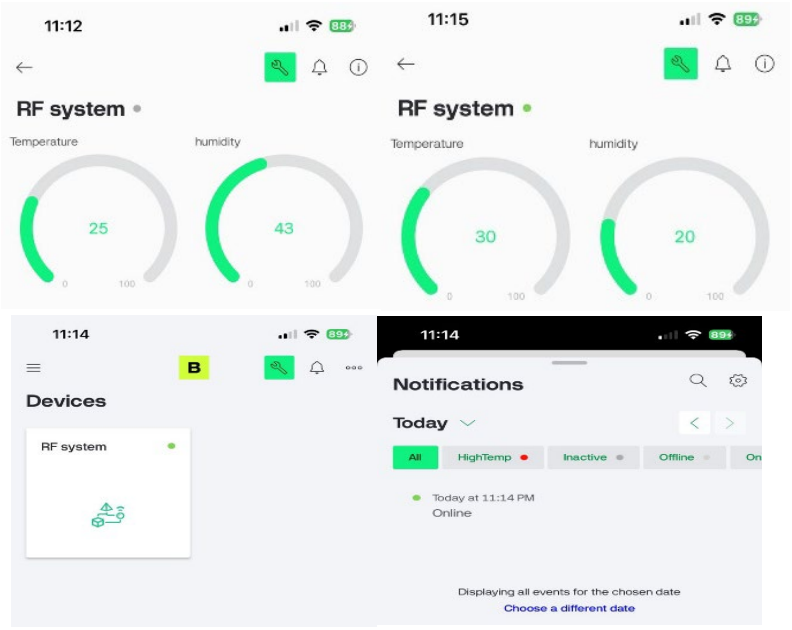

Figure 6. Blynk IoT dashboard showing real-time sensor data and alert notification

- Fire detection: Flame sensor (LOW signal) triggered Blynk push notification “Fire Detected” and LCD warning. Respond immediately.
- High temperature alert: Temperature threshold greater than 30 °C triggered email notification via Blynk. Threshold configurable in firmware.
- Notification latency: Less than 5 seconds under stable Wi-Fi conditions. Delivered via Blynk.notify() to registered mobile device.

5. Cloud Integration

The Blynk cloud platform successfully received temperature, humidity, and flame status data at 30-second upload intervals across all test sessions. Historical data logging functioned correctly, enabling retrospective

analysis of environmental conditions. The 30-second interval was found to strike an appropriate balance between data granularity and API rate-limit compliance, with no upload failures recorded during extended operation.

6. Power System Performance

The TP4056 charging modules with DC-DC boost converters reliably delivered 5 V to both nodes throughout continuous operation testing. The receiver exhibited a shorter runtime due to the higher current consumption caused by the ESP8266's continuous Wi-Fi radio activity. The power profile is compatible with small photovoltaic charging systems, making the design suitable for remote outdoor deployments where mains power is unavailable.

7. Overall system performance summary

Table 5 consolidates the key measured performance metrics across all subsystems.

Table 5. Overall System Performance Metrics

Parameter	**Measured Result**
Open-field RF range	~100 m
Indoor RF range	30–50 m
Average RF latency	<2 sec
Blynk notification latency	<5 sec
Packet delivery ratio (100 m outdoor)	95%
Flame detection distance	~100 cm
Cloud upload interval	30 sec
Transmitter battery runtime	~6–8 hours
Receiver battery runtime	~5–7 hours

V. CONCLUSION

This paper presented a low-cost hybrid WSN-IoT environmental and security monitoring system combining infrastructure-free HC-12 RF communication with Blynk cloud connectivity. The system reliably transmits temperature, humidity, and flame-detection data over 100 m without internet connectivity, triggers mobile push notifications within 5 s of a hazard event, and automatically detects signal loss via a hardware-independent watchdog. At a total component cost below USD 35 and battery autonomy of 6-8 h per charge, the platform is well-suited to remote agricultural, border-security, and infrastructure-monitoring deployments in resource-constrained environments. Future work will target: (i) substituting HC-12 with LoRa for extended range; (ii) CRC-based packet validation and retransmission for higher reliability; (iii) integrating gas, smoke, and motion sensors for broader security coverage; (iv) solar-powered continuous operation; (v) a multi-node architecture for simultaneous multi-site monitoring; and (vi) edge-based machine-learning anomaly detection.

Abstract
Optimizing visitor routes in museums is a challenging reward-constrained path-planning problem in which visitors aim to maximize exhibit exposure within a limited time budget. We formulate this as a reward-maximization problem on an undirected graph model of the Museum of Modern Art (MoMA) 5th floor (30 nodes, 24 galleries, 465 total exhibits) and systematically compare five search algorithms: Breadth-First Search (BFS), Depth-First Search (DFS), Greedy Best-First Search, A*, and a preliminary hybrid variant (Hybrid-ADFS). Experiments vary in time budgets (10/30/60/90 minutes), starting locations, reward distributions, and exit constraints. A* achieves complete room coverage (465 exhibits, 100% at budgets 60/90 min) with up to 2.38 million node expansions. Greedy plateaus at 199 exhibits with near-constant expansions (52 nodes). Uninformed methods (BFS/DFS) yield low exposure (72 exhibits) regardless of budget. Under realistic crowd-dependent and time-decaying rewards, the performance gap narrows dramatically: Greedy reaches nearly the same reward ceiling as A* (242 vs. 243 at 90 min) despite orders-of-magnitude fewer expansions. These findings contradict the assumption that more sophisticated algorithms are always better and highlight that simple greedy strategies become nearly as effective as computationally expensive informed methods under practical visitor constraints.

Keywords: heuristic search, museum visitor routing, reward maximization, A* algorithm, greedy search, graph-based planning

I. INTRODUCTION

Museums worldwide face the ongoing challenge of guiding visitors through large collections within limited time budgets while maximizing exposure to high-value exhibits. With the rise of mobile applications offering location-based content, personalized routing has become feasible [1], [2], [3], yet few studies systematically evaluate traditional search algorithms on real museum layouts under realistic constraints such as step budgets and discrete exhibit rewards [4], [5], [6]. This work addresses this gap by treating museum visitor routing as a reward-constrained path-optimization problem on an undirected graph derived from the MoMA 5th-floor permanent collection layout.

1. Research Questions

RQ1: Which heuristic search algorithms achieve optimal or near-optimal solutions for reward-constrained museum visitor routing under varying step budgets?
RQ2: What are the computational trade-offs (execution time, memory usage, node expansions) between solution quality and resource consumption across the evaluated algorithms?

RQ3: How do algorithm performance characteristics vary across different starting locations, reward distributions, and exit constraints?

2. Contributions

(1) A clear mathematical formulation of museum visitor routing as a reward-constrained optimization problem on a realistic graph model. **(2)** Systematic comparative evaluation of five search algorithms (BFS, DFS, Greedy, A*, and a preliminary hybrid variant) under realistic constraints. **(3)** Experimental validation using a validated graph of the MoMA 5th floor (30 nodes, 24 galleries, 465 total exhibits). **(4)** Detailed performance analysis, including statistical comparison (pairwise t-test), providing practical algorithm selection guidelines. **(5)** Demonstration that spatial clustering of high-value exhibits dominates routing decisions, with implications for museum design and visitor-flow optimization.

II. RELATED WORK

The problem of routing visitors in a museum has been modeled as variants of the Orienteering Problem (OP) to optimize routes that maximize "profit" subject to given time or distance constraints [7-10]. Research has included the Team Orienteering Problem with Time Windows (TOPTW) for personalized tourist routing [9], which was later extended to include time-dependent links and mandatory visitation [10]. Heuristic and metaheuristic algorithms prevail due to the NP-hardness of the problem, including genetic algorithms [1], other metaheuristics [11], [12], iterated local search [9], and ant colony optimization applied to multi-day tourist itineraries. Museum-specific projects include probabilistic tour-guide robots such as Minerva, which combine indoor navigation with interactive visitor guidance [13]. Indoor navigation based on A* and greedy algorithms is widely used in robotics and mobile guides [5], [13]. Recent work has explored reinforcement learning for reward-based path planning in dynamic indoor environments [14], [15], and transformer-based models for personalized itinerary recommendation [16], representing the modern direction of this research area. No studies directly compare BFS, DFS, Greedy, or A* on real-life museum graphs with rewards. This paper addresses that gap through a comparative case study on the MoMA 5th floor.

III. MATHEMATICAL PROBLEM FORMULATION

Given a museum floor represented as an undirected graph, a fixed time budget, and a set of galleries each carrying a discrete reward (exhibit count), the problem is: find a walk starting from a designated entrance, ending at a valid exit, within the step budget, that maximizes the total reward collected. Formally, the inputs are the graph $G = (V, E)$, a start node s, a step budget B, a reward function R, and a set of valid exits T. The output is a path P from s to some $t \in T$ such that $\text{length}(P) \leq B$ and the sum of $R(v_i)$ for all visited galleries v_i is maximized. Each gallery's reward is collected at most once, regardless of revisits. We model the museum as an undirected graph $G = (V, E)$, where V is the set of vertices (gallery rooms, hallways, entrance/exit points), E is the set of edges representing direct connections (each edge has unit weight, corresponding to one navigation step), $V_g \subseteq V$ is the subset of gallery vertices, and $R: V_g \rightarrow R \geq 0$ is the reward function assigning each gallery a non-negative value representing its exhibit count (total reward across all galleries = 465). A visitor starts at an entrance $s \in S \subseteq V$ and must reach any exit $t \in T \subseteq V$ in at most B steps. Paths may revisit vertices, but reward is collected only once per gallery. The objective is to maximize the total collected reward: $\max \Sigma R(v_i)$ for $v_i \in P \cap V_g$, subject to $\text{length}(P) \leq B$, where P is a path from s to $t \in T$. This formulation is a variant of the Orienteering Problem (OP), which is NP-hard even on planar graphs [7-9].

IV. ALGORITHMS

We evaluate five search algorithms: BFS and DFS as uninformed baselines, Greedy Best-First Search as a heuristic approach, A* as an optimal informed search, and a preliminary Hybrid A*-DFS (Hybrid-ADFS) variant attempting to balance exploration and efficiency.

1. Breadth-First Search (BFS)

BFS explores levels from the start node, guaranteeing the shortest path to any reachable exit. Time Complexity: O(|V| + |E|). Space Complexity: O(|V|). Expected performance: finds the shortest path quickly but ignores reward, yielding low total exposure.

2. Depth-First Search (DFS)

DFS explores as far as possible along each branch before backtracking. Time Complexity: O(|V| + |E|). Space Complexity: O(|V|). Expected performance: may find higher-reward paths than BFS but remains reward-agnostic.

3. Greedy Best-First Search

Greedy prioritizes nodes with the highest immediate reward using a priority queue. Time Complexity: O(|E| log |V|) with a binary heap. Space Complexity: O(|V|). Expected performance: rapidly converges to a local optimum with low expansions but may miss the global maximum.

4. A* Search

A* uses an admissible heuristic (precomputed distance to the nearest exit) to guide search toward exits while maximizing collected reward along the path [17-19]. Time Complexity: O(b^d) worst case. Space Complexity: O(b^d). Expected performance: finds near-optimal reward paths efficiently, though node expansions grow exponentially.

5. Preliminary Hybrid Variant (Hybrid-ADFS)

Hybrid-ADFS combines A* with periodic depth-limited DFS to reduce the number of expansions at extended budgets. While empirical results show it did not improve reward collection over baselines under the tested parameters, Hybrid-ADFS is included in this study for two reasons. First, it represents a natural extension of combining global informed search with local depth-limited exploration, a direction with theoretical motivation for large graphs where A* becomes memory-prohibitive. Second, its underperformance provides a useful negative result: simply interleaving A* and DFS without reward-aware branching yields no gains, which informs future hybrid designs. Refinement through adaptive parameter tuning and reward-guided DFS branching remains a direction for future work.

6. Experimental Design

Experiments were conducted on a desktop computer with an Intel Core i5 processor and 16 GB of RAM, running Python 3.13. The graph is derived from the publicly available MoMA 5th-floor layout: 30 nodes (24 galleries, 3 hallways, 3 exits), edges representing direct connections, and rewards based on actual exhibit counts

(total: 465). Reward variants tested: original (real counts), uniform (10 per gallery), and skewed (doubled for iconic rooms).

Experimental parameters: step budgets B ∈ {10, 30, 60, 90} minutes (1 step ≈ 1 minute walking time); starting locations: three elevator entrances (H_NE, H_E, H_SW); exit constraints: all exits, only_SW, only_NE, only_E; single deterministic run per configuration. Performance metrics: Total Exhibit Reward (TER), Reward Per Step (RPS), Node Expansions (NE), Execution Time (ET), Peak Memory Usage (MU), Room Coverage Ratio (RCR), Exit Used (ESD), Backtracking Ratio (BR), and Path Length.

V. RESULTS

We evaluated the five algorithms across budgets of 10, 30, 60, and 90 minutes, three starting locations, three reward distributions, and four exit constraints. Table 1 summarizes the paired t-test results for A* vs. Greedy at budget 30 (the representative case where differences are clear but A* has not yet reached full coverage). Statistical tests confirm that differences in reward performance reflect systematic algorithmic behavior rather than random variation.

1. Statistical Significance Testing

Paired t-tests on TER across three starting locations for each budget ($\alpha = 0.05$) confirm: A* significantly outperforms Greedy for all tested budgets ($p < 0.05$), with the largest differences at longer budgets. Greedy shows no significant improvement beyond budget 30 ($p > 0.05$), confirming its plateau effect. Uninformed methods (BFS/DFS) are consistently outperformed by both informed approaches ($p < 0.001$). Hybrid-ADFS showed no improvement over uninformed baselines ($p > 0.05$).

Table 1. Paired t-test A* vs. Greedy at budget 30 (mean TER ± std dev)

Metric	**A***	**Greedy Best-First**
Mean TER	457 ± 3.0	156.7 ± 63.0
95% Confidence Interval	[449.97, 464.03]	[7.95, 305.39]
Paired t-statistic	6.77	–
p-value	0.021	–
Significance	Yes ($p < 0.05$)	–

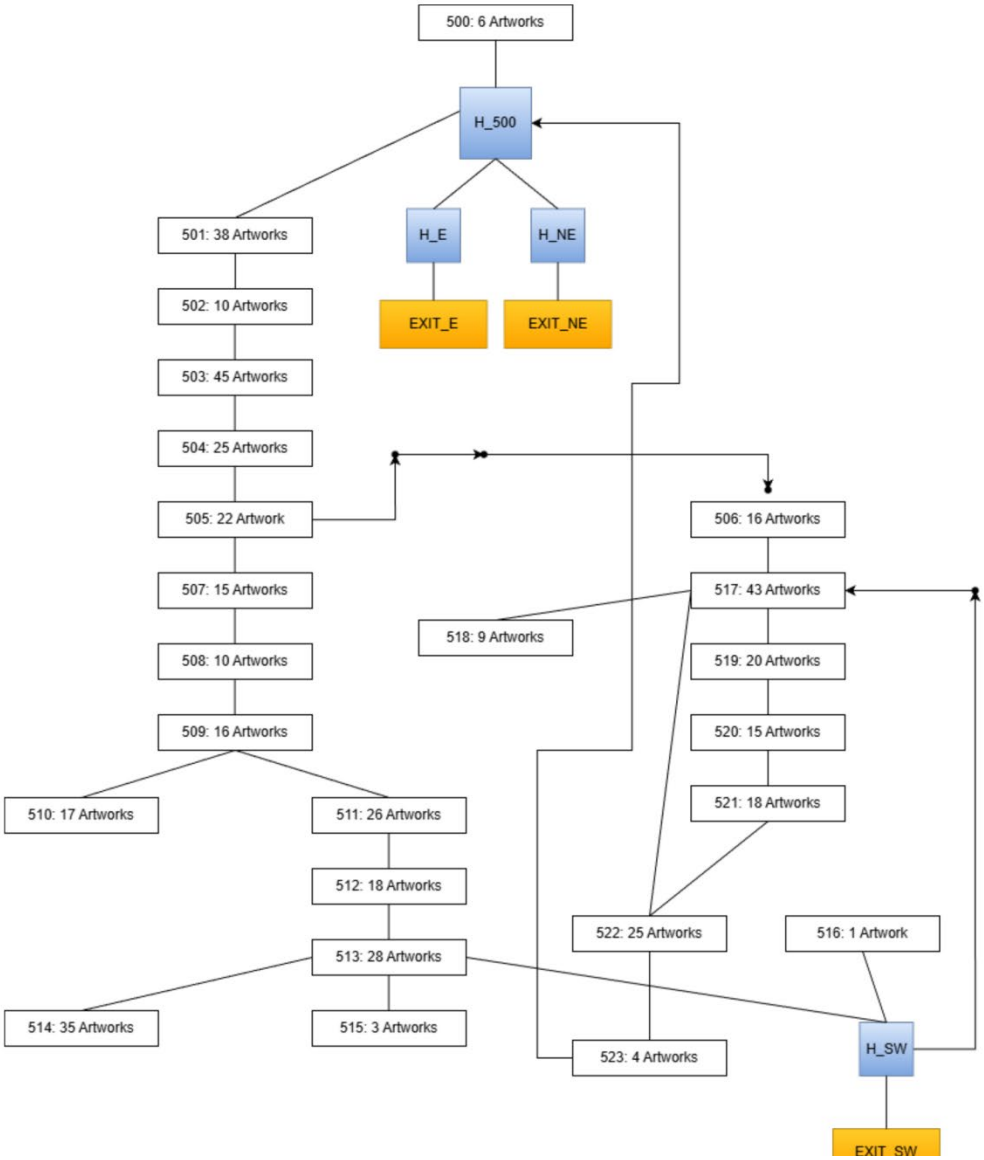

Figure 1. Abstracted graph representation of the MoMA 5th floor.

2. Algorithm Performance Comparison

A* dominates in reward and coverage, but at a significantly higher computational cost. Greedy provides the best balance for practical use. Uninformed and preliminary hybrid methods remained limited in reward collection. Table 2 summarizes the overall average performance across all budgets (10–90 minutes) and starting locations.

Table 2. Algorithm performance comparison (averaged across all budgets and starts)

Algorithm	Avg Reward (mean ± std)	Exec Time (s)	Nodes Explored
BFS	72.0 ± 0.0	0.0003	31
DFS	72.0 ± 0.0	0.0006	41
Greedy	156.7 ± 63.0	0.0009	52
A*	396.5 ± 127.5	58.5	2.38M
Hybrid-ADFS	72.0 ± 0.0	0.036	43

3. Starting Location, Reward, and Exit Impact

Starting location significantly affects uninformed and Greedy performance under short budgets (early termination near exits), but A* remains robust across all starting locations. Reward distributions (original, uniform, skewed) and exit constraints produce negligible differences in TER and path selection, confirming that spatial clustering dominates routing behavior. Figures 2–4 present the key performance metrics and an A* representative path.

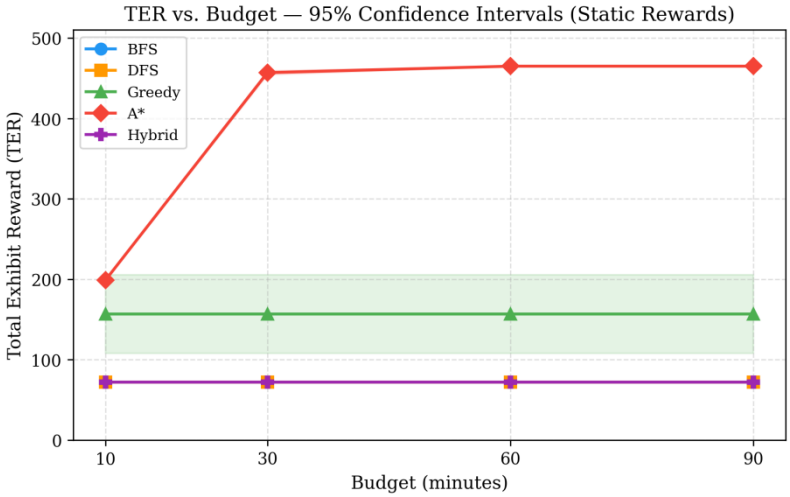

Figure 2. Total Exhibit Reward (TER) vs. step budget with 95% Confidence Intervals

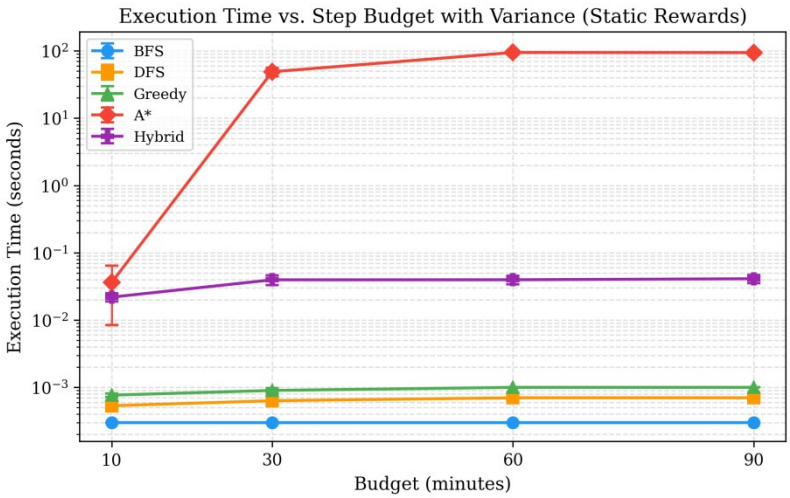

Figure 3. Execution time vs. step budget (log scale)

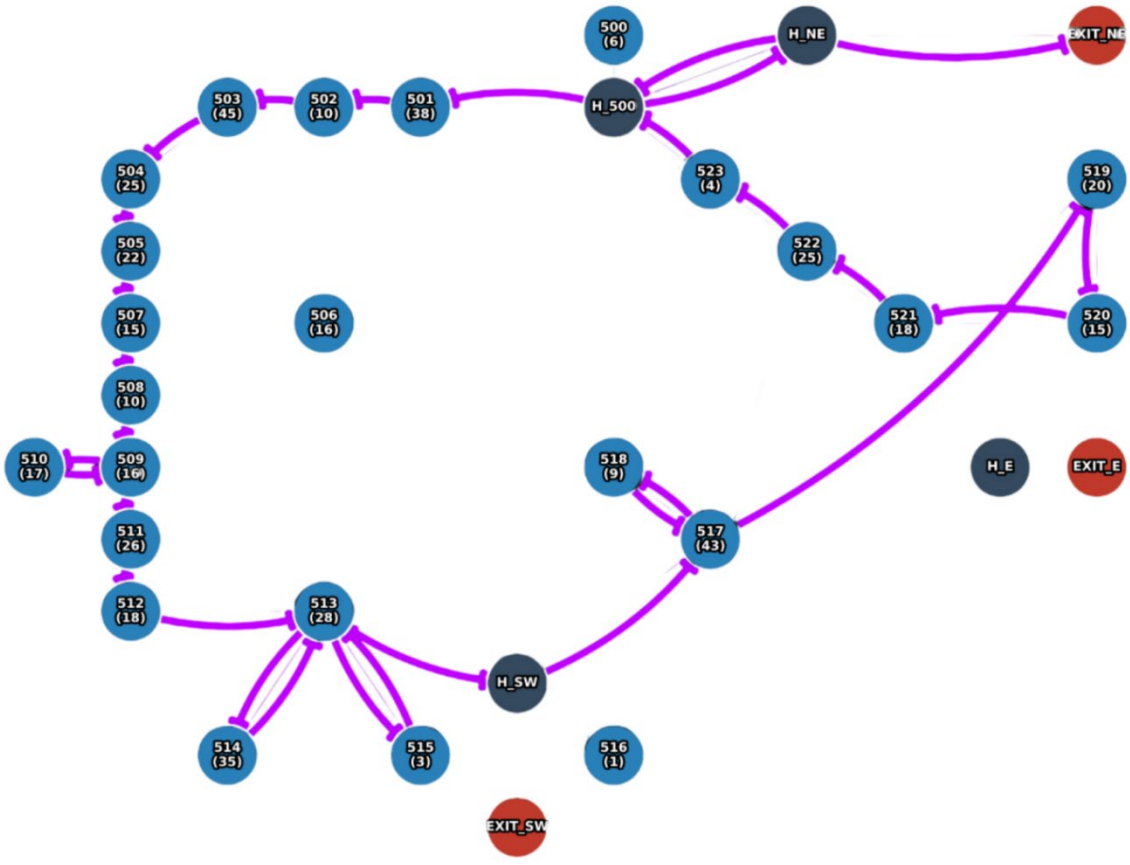

Figure 4. A* path at budget 30 min (Start H_NE, TER = 455).

4. Validation on Synthetic Museum Layout

To assess generalizability, algorithms were tested on the synthetic Metropoli Gallery, comprising 28 nodes (3 hallway hubs, 21 galleries, 3 exits, 1 main hallway), an average degree of 2.5, and 460 total exhibits. Results strongly parallel the MoMA findings: uninformed methods and Hybrid-ADFS plateau at 68 exhibits; Greedy achieves 233 exhibits with ~40 expansions; A* reaches full coverage (460 exhibits) at budgets ≥60 minutes with up to 99,000 expansions. These findings confirm that the observed trade-offs hold across different museum-like topologies with sparse connectivity.

Table 3. Algorithm performance on a synthetic museum-like layout (Metropoli Gallery).

Budget (min)	Algorithm	TER	Expansions	Path Length
10	BFS	68	28	6
	DFS	68	31	6
	Greedy	68	31	6
	A*	136	883	10
	Hybrid-ADFS	68	48	6
30	BFS	68	28	6
	DFS	68	36	6
	Greedy	233	40	14
	A*	456	67,927	29
	Hybrid-ADFS	68	41	6
60	BFS	68	28	6
	DFS	68	36	6
	Greedy	233	40	14
	A*	460	99,356	31
	Hybrid-ADFS	68	41	6
90	BFS	68	28	6
	DFS	68	36	6
	Greedy	233	40	14
	A*	460	99,356	31
	Hybrid-ADFS	68	41	6

5. Crowd-Dependent and Time-Decaying Rewards

A realistic reward model was applied, introducing: (1) a 40% time-of-day crowding penalty during peak hours (11:00–15:00), 15% otherwise; (2) progressive visitor fatigue reducing rewards up to 50% as more exhibits are collected (3% per item); (3) a 50% higher penalty in high-attendance galleries. Rewards are never reduced below 20% of base value. Under dynamic constraints, the performance gap narrows dramatically. At medium budgets (30 min), DFS achieves the highest reward (230) by committing early to deep high-reward chains before fatigue and peak penalties accumulate. At longer budgets (60 min), Greedy reaches essentially the same reward ceiling as A* (242 vs. 243) despite orders-of-magnitude lower expansions. These results contradict the assumption that more sophisticated always means better.

Table 4. Performance under crowd-dependent rewards - MoMA layout (averaged across starts)

Budget (min)	Algorithm	TER	Expansions	Path Length
10	BFS	85	132	9
	DFS	131	460	10
	Greedy	131	143	10
	A*	131	428	10
30	BFS	85	751	9
	DFS	230	8,826	29
	Greedy	229	2,449	30
	A*	229	10,527	30
60	BFS	85	1,681	9
	DFS	238	32,798	45
	Greedy	242	7,822	48
	A*	243	44,883	47
90	BFS	85	2,611	9
	DFS	238	58,358	45
	Greedy	242	12,472	48
	A*	243	81,303	47

6. Algorithm Selection Guidelines

Based on experimental results, practical guidelines for algorithm selection: (1) Very short visit (B < 10 min): Greedy or A*, both achieve maximum feasible reward quickly. (2) Typical visit (10 < B < 30 min): Greedy, highest practical reward (199 exhibits) with constant low expansions (~52 nodes). (3) Extended visit (30 < B < 60 min): A*, reaches near-complete or full coverage (455–465 exhibits), where Greedy plateaus. (4) Real-time mobile app: Greedy, consistent, fast execution, low memory, strong reward. (5) Offline planning: A*guarantees an optimal solution despite higher resource use. (6) Hybrid-ADFS: not recommended in current form; did not improve reward or coverage over baselines.

VI. DISCUSSION

1. Comparison with Previous Approaches

Unlike previous museum-routing and spatial path-planning studies [1], [4], [5], [6], this work evaluates five algorithms across multiple budgets and constraints on a real-world layout. The reward-constrained formulation highlights trade-offs between exhibit exposure and computational cost. Hybrid-ADFS extends prior heuristic combinations [11], [12] but requires further parameter tuning.

2. Practical Implementation Guidelines

Greedy Best-First Search is recommended for real-time mobile applications because it provides a strong reward with low computational cost (199 exhibits, 52 expansions, <0.01 s). A* is preferable for offline planning or extended visits when maximum exposure is prioritized (up to 465 exhibits, 2.38M expansions, >1 GB memory). BFS/DFS are primarily suitable for minimal tours, whereas Hybrid-ADFS is not recommended in its current

form. In museum design, graph connectivity appears more influential than reward distribution, suggesting that optimizing spatial layout may yield greater benefits than fine-grained exhibit weighting.

3. Limitations and Future Research Directions

The study has six main limitations: (1) a single museum case study, which may limit generalizability; (2) static exhibit rewards; (3) deterministic unit travel times; (4) no visitor personalization; (5) a limited budget range of up to two hours; and (6) no direct comparison with modern metaheuristic or learning-based approaches such as genetic algorithms, ant colony optimization, or reinforcement learning. These limitations restrict generalization and comparison with newer methods. Future work will include validation on additional museum layouts; integration of real-time crowd and time-varying rewards; comparison with genetic algorithms, ant colony optimization, and reinforcement learning [14], [15], [20]; multi-floor optimization; field studies with real visitors; and adaptive refinement of Hybrid-ADFS.

VII. CONCLUSION

This paper compared five search algorithms for reward-constrained museum visitor routing on a real-world model of the MoMA 5th floor. A* achieved complete coverage (465 exhibits at budgets ≥60 min) but required substantially greater computational resources, while Greedy provided strong practical performance with low computational cost. BFS and DFS consistently achieved lower exposure. Statistical analysis confirmed significant differences between A* and Greedy at shorter budgets, while their performance converged under realistic crowd-dependent rewards. These results demonstrate that simple greedy strategies can approach the performance of more computationally expensive methods under practical visitor constraints. The methodology can also be applied to other spatial routing problems with discrete rewards and resource constraints.

Abstract
This study maps how the constructs of cybersecurity awareness and threat perception are operationalized in survey-based empirical research. Using Web of Science and Scopus records, we analyze the thematic evolution of a survey-focused corpus and conduct a construct-level analysis of screened studies by coding contexts, threat types, and extracted constructs. We then examine their interrelations through bipartite and construct-similarity networks. The findings show a shift from general cybersecurity and information security awareness toward more specific models of phishing, privacy, data breaches, identity theft, online scams, and social engineering. Across these contexts, perceived vulnerability, perceived severity, self-efficacy, response efficacy, knowledge, attitude, trust, privacy concern, and protective behavior form a recurring conceptual core. However, similar constructs appear under different labels and are applied inconsistently across user groups and threat scenarios. The paper provides a structured overview of the construct space and highlights the need to more clearly distinguish among awareness, knowledge, perception, efficacy, and behavior.

Keywords: cybersecurity awareness, threat perception, perceived vulnerability, perceived severity, survey research, construct mapping, phishing, privacy

I. INTRODUCTION

Digital threats increasingly depend on how users perceive, interpret, and respond to risk. Phishing, online scams, identity theft, data breaches, privacy invasion, ransomware, and social engineering all involve a human-facing dimension in which awareness, knowledge, perceived vulnerability, perceived severity, trust, self-efficacy, and attitude may shape behaviour and outcomes [1], [2], [3], [4], [5], [6], [7], [8]. As a result, cybersecurity awareness has become a recurring topic in empirical cybersecurity, information systems management, privacy, and human-computer interaction research. Cybersecurity awareness is often used broadly, but this paper does not treat it as a synonym for information, knowledge, or behavior. Following the situation-awareness tradition, awareness is understood as situated recognition and interpretation of threat-relevant cues: users must notice elements of a cybersecurity situation, comprehend their meaning, and relate them to possible future consequences or responses [9], [10], [11]. This distinction is important because information or knowledge alone may be insufficient to build awareness that leads to an effective response [12], [13], [14]. Empirical research on situational and cybersecurity awareness can be broadly divided into studies that measure situational or cybersecurity awareness using task-based, behavioral, or performance-oriented indicators, and studies that examine self-reported awareness, perceptions, appraisals, and behavioral constructs via questionnaires. This paper focuses on the latter strand. This self-reported strand includes studies that draw on awareness scales, protection motivation theory, technology threat avoidance theory, privacy concern, and behavioral intention models [1], [4], [5], [6], [15], [16]. However, the construct space remains fragmented. Different studies use partially overlapping terms such as cybersecurity awareness, information security awareness, privacy awareness, threat perception, risk perception, perceived vulnerability, perceived susceptibility, perceived severity, privacy concern, self-efficacy, response efficacy, trust, attitude, intention, and behavior. These constructs are often embedded in specific

empirical settings, such as phishing, mobile identity protection, social media use, online banking, health-tracker privacy, employee training, or student awareness. Although these studies contribute valuable local findings, it is difficult to see how the constructs relate to one another across the wider field.

This paper addresses this gap by mapping the constructs of cybersecurity awareness and threat perception in survey-based research. The focus is deliberately narrowed to empirical survey studies in which these constructs are measured, modeled, or used to explain user responses to cyber threats. The analysis, therefore, treats the field as a set of recurring concepts, empirical contexts, threat types, and relationships. The following research questions guide the study:

- RQ1. How has the thematic structure of survey-based research on cybersecurity awareness and threat perception evolved?
- RQ2. Which contexts, threat types, and constructs recur most frequently in the screened studies?
- RQ3. How are contexts, threats, and constructs interrelated?
- RQ4. Which construct communities can be identified in the construct-similarity network?

The contribution of the paper is twofold. First, it provides a structured map of the construct vocabulary used in survey-based research on cybersecurity awareness and threat perception. Second, it identifies fragmentation and overlap in the use of constructs, supporting future work on clearer conceptual and measurement alignment.

II. METHOD

1. Data Collection and Preparation

The analysis was based on bibliographic records retrieved from Web of Science and Scopus. The search was conducted in Web of Science and Scopus using awareness- and threat-perception-related terms combined with cyber/digital context terms and threat examples: TITLE-ABS-KEY((“threat awareness” OR “vulnerability awareness” OR “cybersecurity awareness” OR “information security awareness” OR “privacy awareness” OR “threat perception” OR “vulnerability perception” OR “perceived vulnerability” OR “perceived severity” OR “perceived threat”) AND (cyber* OR digital OR online OR internet) AND (phishing OR scam* OR “identity theft” OR ransom* OR impersonation OR “account compromise” OR “account hijacking” OR “unauthorized access” OR “data breach” OR “data misuse” OR “data exposure” OR “privacy invasion” OR “unauthorized sharing” OR “personal data”) AND (survey OR questionnaire OR scale OR instrument OR “measurement model” OR “self-report” OR “structural equation model*” OR SEM OR PLS-SEM OR “partial least squares”) AND NOT (“raising awareness” OR “raise awareness” OR “increase awareness” OR “improve awareness” OR “awareness campaign*”)). The search query, preprocessing, descriptive results, thematic maps, descriptions, and screening and network outputs are provided in the Supplementary file. The Scopus query returned 174 documents, while the corresponding Web of Science Core Collection query returned 93 documents. The deduplicated corpus covered the period from 2004 to 2026 and included 194 documents published across 166 sources. The dataset is relatively recent, with an average document age of 3.82 years, and shows continued growth at an annual rate of 11.96%. The records contained 737 Keywords Plus and 681 author keywords, indicating a sufficiently rich vocabulary for thematic and construct-oriented analysis. A focused screening stage followed the bibliometric dataset. Abstracts and keywords were screened to identify studies relevant to survey-based research on cybersecurity awareness and threat perception constructs. Each record was coded for inclusion status, reason for exclusion where applicable, study type, empirical context, threat type, constructs identified, measured dimensions or indicators (if applicable), and availability of questionnaire items (based on the statement in the abstract). Studies were included when the record indicated an empirical survey, scenario-based survey,

questionnaire-based model, or survey-supported empirical analysis involving cybersecurity awareness, information security awareness, privacy awareness, perceived vulnerability, perceived severity, perceived threat, risk perception, efficacy, trust, concern, attitude, intention, behavior, or related user-facing constructs. Studies were excluded if they were primarily technical, conceptual, review-based, training- or taxonomy-oriented, or not focused on measured user constructs.

For retained studies (n = 112), we coded the available empirical context, threat type, and construct labels in abstracts. Context refers to the user group, setting, or application domain. Threat type refers to the cyber- or privacy-related risk under study. For this study, constructs were defined as named psychological, perceptual, attitudinal, motivational, knowledge-related, or behavioral concepts that were measured, modeled, or explicitly treated as empirical variables in survey-based studies. Broader technical topics, intervention types, system features, and general keywords were not treated as constructs unless they were operationalized as measured user-facing variables.

2. Bibliometric and Network Analysis

The first part of the analysis examined the survey-oriented corpus's main information and thematic evolution [17], [18], [19]. This was used to identify how the research field changed over time and which topics became more central in later periods. For this purpose, the bibliometric analysis provided a temporal and thematic overview of the corpus. The second stage focused on screening studies and extracting contexts, threats, and constructs. Frequency summaries were created based on their occurrence across studies. Bipartite networks linking context–threat, context–construct, and threat–construct pairs that appeared in the same screened studies; edge weights indicate the number of studies in which each pair co-occurred. To map terminological and conceptual overlap in the construct vocabulary, the construct-similarity network was created from cleaned construct labels. Nodes represent constructs, and edges connect construct pairs that share at least two meaningful terms after normalization; edge weights indicate the number of shared terms. Community detection was applied to the giant component to identify clusters of related construct labels.

III. RESULTS

1. Thematic Evolution

The thematic evolution map (Supplementary file) indicates a gradual consolidation of the survey-focused corpus around privacy, information security, cybersecurity, and survey-based measurement (Table 1; visual representations are available in the Figures and interactive graphs sections of the Supplementary files). The thematic evolution does not indicate a simple sequence in which earlier themes disappear and new themes replace them. Instead, Table 1 shows a cumulative narrowing and reorientation of the field. The broad theme of information dissemination represents the earliest period, while the 2013–2020 period adds trust, surveys, data privacy, and data security. In the 2021–2026 period, several of these themes remain visible, especially privacy, data privacy, information security, and surveys, but they appear alongside cybersecurity and motivation. The overlap across periods is therefore informative: it suggests continuity in the privacy and information-security vocabulary, while the later appearance of cybersecurity and motivation indicates a stronger focus on user-facing empirical models of threat perception, awareness, and response. Thus, the main trend is not thematic replacement, but increasing specification. The survey-based research moves from general information-oriented concerns to a survey-based examination of how users understand privacy- and security-related threats and what motivates their responses. Because the thematic-evolution results remain broad and partly overlapping, the following construct-level analysis examines more directly how these themes are operationalized through empirical contexts, threat types, and measured constructs.

Table 1. Topics in Clusters derived by Thematic Evolution

	Period	Dominant themes
1.	2004–2010	Information dissemination
2.	2013 – 2020	Trust; surveys; data privacy; security of data; privacy
3.	2021 – 2026	Cybersecurity; privacy; information security; data privacy; motivation; surveys

2. Contexts, Threats, and Constructs

The screened studies show a heterogeneous empirical landscape. Table 2 reports independent frequency lists for the screened studies, where n denotes the number of papers in which a given category was coded; categories appearing in the same row are not necessarily related within the same papers. The most frequent contexts are users, students, universities, employees, and social or online settings, while threat types are more concentrated around phishing, which appears in 24 papers. The construct vocabulary is broader, but its recurring core comprises cybersecurity (18 papers) or information security awareness (15 papers), along with perceived severity, perceived vulnerability, self-efficacy, privacy awareness, privacy concerns, attitude, perceived threat, and response efficacy. Because Table 2 reports only separate frequency rankings, the following bipartite networks examine how contexts, threats, and constructs co-occur.

Table 2. Frequent Contexts, Threats, and Constructs

	Contexts, types, and constructs - independent ranked frequency lists; rows do not indicate co-occurrence					
	Context type	***n papers***	***Threat type***	***n papers***	***Construct type***	***n papers***
1.	User	36	Phishing	24	Cybersecurity awareness	18
2.	Student	23	Data breaches	10	Perceived severity	16
3.	University	16	Identity theft	8	Perceived vulnerability	16
4.	Employee	15	Cyberattacks	7	Information security awareness	15
5.	Social	12	Social engineering	5	Self-efficacy	14
6.	Medium	9	Privacy invasion	5	Privacy awareness	12
7.	Online	9	Cybercrime	5	Privacy concerns	11
8.	Context-specific	8	Scams	4	Attitude	7
9.	Indonesia	8	Online scams	4	Perceived threat	6

	Contexts, types, and constructs - independent ranked frequency lists; rows do not indicate co-occurrence					
	Context type	***n papers***	***Threat type***	***n papers***	***Construct type***	***n papers***
10.	Phishing context	8	Cyber threats	4	Response efficacy	6

3. Interrelations among Contexts, Threats, and Constructs

The threat–construct bipartite network (Table 3; visual representation available in the Supplementary files) is organized around a few central bridges rather than evenly distributed links. The strongest edges link phishing with cybersecurity awareness and information security awareness, while data breaches and phishing attacks also connect to cybersecurity awareness. Privacy invasion appears as a separate privacy-related link, based on perceived severity. Overall, the network suggests a phishing-centered awareness core, with privacy-related threats forming a smaller but distinct strand.

The context–construct network (Table 3; visual representation available in the Supplementary files) shows that construct use is distributed across both general and more specialized empirical settings. The strongest edges connect cybersecurity awareness with Malaysia and university students, while fitness tracker users connect to attitude toward technology, coping behavior, and privacy concerns. This suggests that awareness constructs are prominent in broader educational or national contexts, whereas specialized technology-use contexts are associated with narrower privacy- and coping-related constructs.

The context–threat network (Table 3; visual representation available in the Supplementary files) confirms that phishing is the main bridge between empirical settings and threat types. The strongest edges link phishing to employees, university students, and Australia; malware to employees, and unauthorized access to Saudi Arabia. This indicates a visible phishing-centered core, while other threats appear in more context-specific links. The bipartite networks show how contexts, threats, and constructs co-occur; the next analysis focuses on communities within the construct vocabulary itself.

Table 3. Top Edges in Bipartite Networks

	Bipartite network	**Node 1**	**Node 2**	**Edge weight (n)**

4. Construct Communities in the Giant Component of the Construct-Similarity Network

The giant component of the construct-similarity network (Figure 1) shows that the largest communities center on information security awareness and behavior, data privacy literacy and privacy-loss concerns, cybersecurity awareness and risk perception, personal information disclosure, perceived risk and control, privacy protection behavior, privacy awareness and concerns, and online data misuse. These communities suggest that empirical assessments of cybersecurity awareness rarely treat awareness as a narrow, standalone construct. Instead, a substantial part of what is measured as, or around, awareness falls on perception and appraisal: perceived risk, perceived vulnerability, perceived severity, perceived control, perceived behavioral control, perceived data sensitivity, and related concern-based constructs. At the same time, these appraisal-oriented constructs are not uniformly organized across the field but appear in contextual communities shaped by vocabularies of privacy, data, information security, cybersecurity, literacy, disclosure, and protection.

For example, information security awareness is closely connected to information security behavior and organisationally oriented security constructs. In contrast, data privacy literacy is linked to fears of privacy loss and health data privacy concerns. Cybersecurity awareness is linked to risk perception and value of privacy, whereas privacy awareness and privacy concerns form a smaller but conceptually coherent privacy-focused cluster. This structure indicates that awareness in the broader empirical literature is often operationalized through a situated understanding of what is at risk, how serious the threat is, how personally relevant it is, and what control or response options are perceived as available.

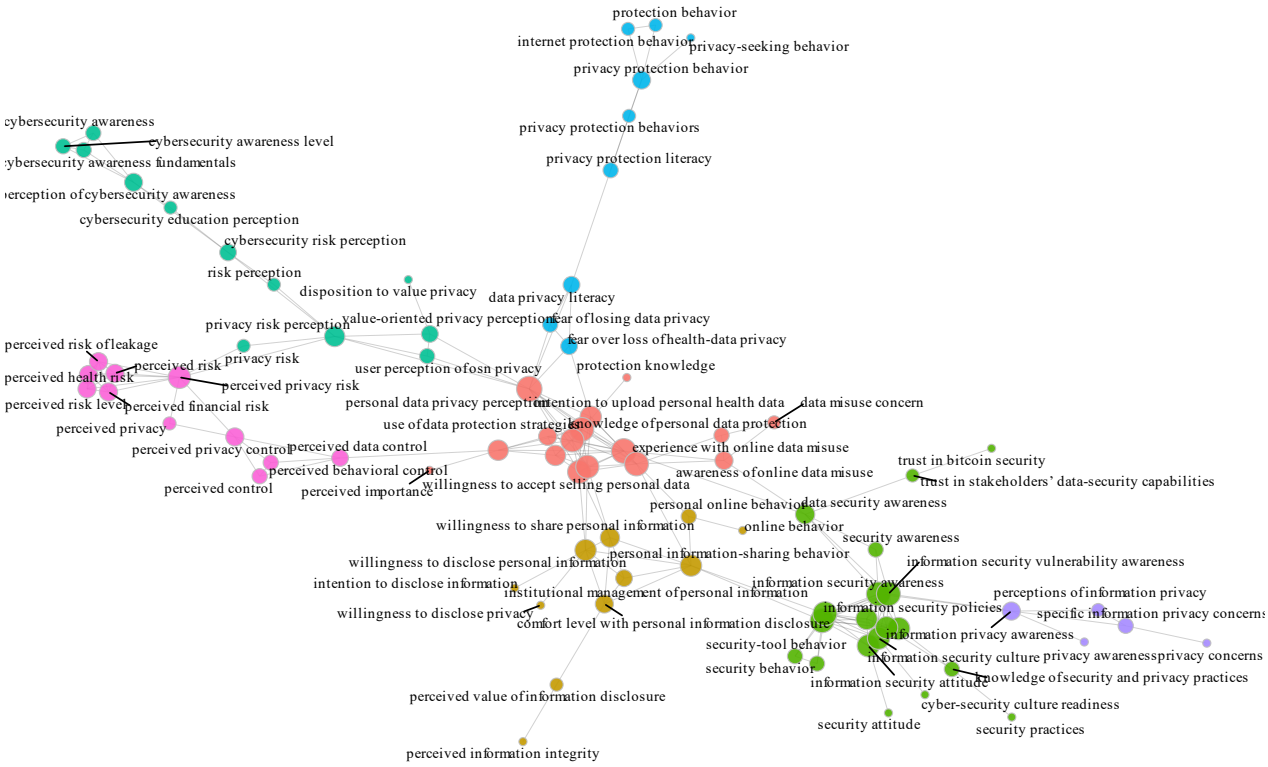

Figure 1. Construct-similarity network of the giant component

Note: Node size represents degree; colors indicate detected communities; edges connect construct labels sharing at least two meaningful terms after preprocessing. The layout is used for visual interpretation of construct proximity, not causal ordering. An interactive version is available in the Supplementary files.

IV. DISCUSSION AND CONCLUSION

The results answer the four research questions by showing that survey-based cybersecurity awareness and threat perception research has become more specific, more empirically measurement-oriented, and more heterogeneous at the construct level. The thematic evolution (RQ1) indicates a shift from broader information dissemination and information-security themes toward privacy, data privacy, cybersecurity, information security, surveys, and motivation. This suggests that the field has moved from general awareness and information-security concerns toward more specific empirical models of how users perceive, appraise, and respond to digital threats. Regarding the frequency of contexts, threat types, and constructs (RQ2), the screened studies show that the literature is concentrated on several recurring yet unevenly represented topics. Users, students, universities, employees, social media, online settings, and country-specific samples dominate the empirical contexts, while phishing is the most frequent threat type. Other threats, including data breaches, identity theft, social engineering, privacy invasion, cybercrime, and scams, appear less frequently and are more dispersed. At the construct level, the core constructs consist of cybersecurity awareness, information security awareness, perceived severity, perceived vulnerability, self-efficacy, privacy awareness, privacy concerns, attitude, perceived threat, and response efficacy. This pattern shows that awareness research is rarely limited to awareness alone but usually combines it with threat appraisal, efficacy appraisal, concern, attitude, and behavioral response. Regarding the relationships among contexts, threats, and constructs (RQ3), the bipartite

networks exhibit a sparse structure. Phishing serves as the clearest bridge among threat types, user contexts, and awareness-related constructs, especially in studies of employees and university students. Privacy invasion, data breaches, identity theft, malware, and unauthorized access are connected to narrower, more context-specific parts of the corpus. These results suggest that the literature has a phishing-centered empirical core, whereas other cyber and privacy threats are less prevalent across contexts and combinations of constructs.

Regarding the construction of communities in the construct-similarity network (RQ4), the giant component is organized into several construct families related to information and knowledge, cybersecurity and privacy awareness, threat and risk appraisal, efficacy appraisal, trust and concern, and behavioral response. This heterogeneity is not only terminological. It reflects different assumptions about where awareness is located in the process that leads from cyber-related information to protective or risky behavior. Based on these findings, we propose an awareness–appraisal–response framework (Figure 2). The framework starts with the digital context and the threat object because awareness is always situated: phishing, scams, data breaches, privacy invasion, and identity theft provide different cues and require different responses. Information and knowledge represent the factual and conceptual resources users may draw on to achieve awareness. In the narrow sense, cybersecurity awareness refers to situated recognition of threat-relevant cues. In the broader sense, awareness also involves comprehension and projection: users must interpret the cues, appraise their implications, and relate the situation to possible consequences and responses. In this sense, awareness functions as an interpretive bridge between general knowledge and later judgments or actions.

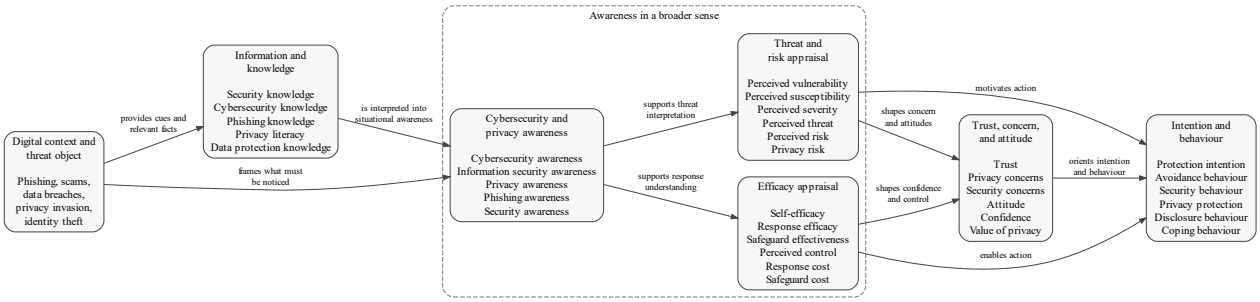

Figure 2. Integrative framework of the constructs in the research on cybersecurity awareness

Once a situation is recognized as security-relevant, the framework treats threat appraisal and efficacy appraisal as explicit construct domains that cover vulnerability, susceptibility, severity, threat/risk, self-efficacy, response efficacy, perceived control, safeguard effectiveness, and safeguard cost. These domains explain why awareness does not automatically lead to protective behavior: users may recognize a threat but feel unable to respond, distrust the recommended action, or judge the action as too costly. Trust, concern, and attitude then shape orientation toward action. The framework positions intention and behavior as outcomes of this process, including protection intention, avoidance behavior, security behavior, privacy protection, disclosure, and coping behavior. This positioning is consistent with studies in which phishing-related threat perception, perceived severity, perceived susceptibility, self-efficacy, safeguard effectiveness, and safeguard cost are linked to avoidance behavior [4], and with identity-protection research that distinguishes perceived threat appraisal, self-efficacy, motivational intention, awareness, and actual identity-protection actions [16]. Privacy-oriented studies show a similar pattern: privacy awareness, privacy risk, privacy concerns, privacy invasion experience, and perceived control are linked to self-disclosure [6], while privacy concern and perceived threat shape post-violation coping behavior and attitude [15]. Recent studies on mobile identity protection and online blackmail further show that awareness, efficacy, attitude, motivation, and behavior may occupy different positions within empirical models rather than function as interchangeable indicators [3], [20]. These studies jointly support the view that knowledge, awareness, appraisal, efficacy, attitude, intention, and behavior are interlinked, but should not be treated as interchangeable indicators. This structure highlights why treating cybersecurity awareness as a

synonym for knowledge or behavior is conceptually problematic. Information may be available, and knowledge may exist, without necessarily producing cue recognition, threat interpretation, response confidence, or protective action. The proposed framework is not a tested causal model, but a synthesis of the construct families identified in the mapping. Its practical implication is that awareness interventions should not stop at information provision but should also support cue recognition, threat interpretation, response confidence, and the translation of responses into protective or avoidance behavior. The study has several limitations. The analysis depends on the selected search query, the bibliographic database coverage, and the extraction of constructs from the keywords and abstracts of screened records, so some relevant studies and alternative construct labels may have been missed. The network analyses capture co-occurrence among coded elements and similarity among construct labels, not validated theoretical or causal relationships between constructs. Future research should therefore examine measurement items in greater detail, compare how similar constructs are operationalized across studies, and test the proposed framework empirically in specific threat contexts such as phishing, scams, data breaches, privacy invasions, or identity theft. A useful next step would be to develop a more coherent measurement model that distinguishes among information, knowledge, awareness, appraisal, efficacy, concern, and behavior, while allowing comparison across user groups and threat scenarios.

Abstract
Autonomous vehicles consist of layered modules including perception, sensor fusion, localization, motion planning, and control. Within this structure, the control module plays a critical role in accurate trajectory tracking and safe driving. Traditional path-tracking controllers such as Proportional-Integral-Derivative (PID), Pure Pursuit, and Stanley are widely used for their simplicity and low computational requirements. However, their performance may degrade in dynamic and high-speed scenarios. To address these limitations, a Model Predictive Control (MPC) based path tracking algorithm is implemented within Robot Operating System 2 (ROS 2) Humble framework on a physical autonomous golf vehicle equipped with Real-Time Kinematic Global Navigation Satellite System (RTK-GNSS), Inertial Measurement Unit (IMU), and Velodyne 3D Light Detection and Ranging (LiDAR) sensors. The MPC is formulated with a prediction horizon of Np = 20 and a control horizon of Nc = 10, and obstacle constraints derived from a real-time LiDAR occupancy grid are integrated directly into the optimization loop. Experimental validation on a 350 m closed-loop test route at speeds up to 7 m/s demonstrates a mean lateral error of 0.302 m and an RMS lateral error of 0.447 m, representing improvements of 41% and 38%, respectively, over a comparably tuned Stanley controller. Dynamic obstacle avoidance tests show a transient increase in lateral deviation of up to 0.48 m, confirming safe and stable navigation in mixed static and dynamic environments.

Keywords: autonomous vehicles, path tracking control, model predictive control, robot operating system 2 (ROS 2), trajectory tracking

I. INTRODUCTION

Autonomous ground vehicles rely on interconnected modules, including perception, sensor fusion, motion planning, decision-making, and control. Among these, a robust control architecture is critical for accurate and safe trajectory tracking [1]. Classical controllers such as Proportional-Integral-Derivative (PID), Stanley, and Pure Pursuit are effective in low-speed or structured environments, but their performance degrades in high-speed or complex scenarios. Advanced methods such as Linear Quadratic Regulator (LQR), Sliding Mode Control (SMC), and Model Predictive Control (MPC) enable better handling of system constraints, nonlinear dynamics, and uncertainties. MPC-based path-tracking methods use kinematic and dynamic vehicle models to optimize steering and speed while adapting to environmental uncertainties. Unlike classical controllers, MPC explicitly handles system constraints and provides real-time optimal control actions [2].

Control problems in autonomous driving are typically addressed using a hierarchical structure, in which a feasible trajectory is first generated and then tracked by a feedback controller. Although this approach was

successfully employed in the DARPA Grand Challenge competitions, it exhibits significant limitations near the limits of tire adhesion or during high-speed maneuvers. Consequently, optimal control techniques such as MPC, which jointly solve planning and control within a single optimization framework, have emerged as prominent alternatives [3].

In this study, an MPC-based path tracking controller has been implemented on an autonomous vehicle platform using the Robot Operating System 2 (ROS 2) framework. The controller optimizes steering and speed commands based on a reference trajectory, integrating sensor fusion outputs to enable obstacle avoidance. Although MPC-based trajectory tracking for autonomous vehicles has been addressed in numerous studies [1-3], the original contribution of this work is threefold: (1) a complete, real-time system integration of LiDAR-derived occupancy-grid obstacle constraints directly into the MPC optimization loop on a physical golf vehicle platform; (2) experimental validation under both static and dynamic obstacle scenarios at operational speeds of up to 7 m/s within the ROS 2 Humble framework; and (3) a systematic performance comparison against the Stanley controller under identical test conditions, demonstrating a 41% reduction in mean lateral error.

II. PATH TRACKING PROBLEM

One of the most critical topics in control is the path tracking problem [4]. To define the path-tracking problem for autonomous vehicles, a known reference trajectory is assumed. The objective is to ensure that the vehicle follows this path with minimum lateral and longitudinal errors. Control inputs (steering angle and speed) are computed to minimize deviations from the desired trajectory while complying with vehicle dynamics and actuator constraints [5].

Classical controllers such as PID, Stanley, and Pure Pursuit perform well at low speeds but may lose accuracy in high-speed or dynamic scenarios. In contrast, MPC predicts future vehicle behavior over a finite horizon and optimizes control actions accordingly [6]. This predictive capability enables more stable and accurate path tracking, particularly under challenging conditions involving nonlinear dynamics and varying path curvature.

In the present study, the vehicle operates at speeds of up to 7 m/s on a route with curve radii as tight as 8 m, yielding lateral accelerations that approach the limits at which purely reactive controllers such as Stanley begin to exhibit phase lag and overshoot. This operating regime motivates the use of MPC, whose predictive horizon allows the controller to begin corrective steering before the vehicle enters a high-curvature zone, unlike reactive controllers that respond only to the current measured error.

III. CONTROL METHODS

Autonomous vehicles employ various control strategies to achieve accurate path tracking. Classical controllers such as PID, Pure Pursuit, and the Stanley algorithm are simple and effective for low-speed or structured environments [7]. The PID controller adjusts steering based on lateral deviation, while the Stanley algorithm accounts for both lateral and heading errors to improve directional stability. However, these methods generally suffer from performance degradation in high-speed or dynamic scenarios. Optimal control approaches, including LQR, minimize tracking error while balancing control effort. Although computationally efficient, LQR cannot handle input constraints or predict future vehicle states [8]. Robust controllers such as SMC provide strong resistance to disturbances and uncertainties, guaranteeing stable path tracking even under challenging conditions. For trajectory representation, spline-based paths (e.g., B-spline or quintic spline) provide smooth and dynamically feasible reference trajectories, particularly suited for advanced controllers such as MPC. MPC can simultaneously optimize steering and speed over a prediction horizon, explicitly handle constraints, and improve

tracking accuracy in real time [9]. This work focuses on implementing and evaluating an MPC-based path-tracking controller within a ROS 2 framework and compares its performance with classical methods.

IV. MPC FUNDAMENTALS

MPC is an advanced optimal control strategy that predicts a system's future behavior and computes control actions over a finite prediction horizon. At each sampling step, only the first input is applied, and the optimization is repeated over a receding horizon. This predictive approach allows MPC to anticipate future vehicle states and handle system constraints such as steering limits, lateral acceleration, and tire slip, making it well-suited for safe and stable path tracking [10], [11]. The performance of MPC depends on the prediction horizon (Np), which determines how far ahead the system is predicted, and the control horizon (Nc), which defines how many control inputs are optimized. In this study, the prediction horizon was set to Np = 20 and the control horizon to Nc = 10, with a sampling period of 0.1 seconds. Three considerations guided the selection of Np = 20 and Nc = 10. First, the lookahead distance: with a sampling period of 0.1 s and a maximum speed of 7 m/s, Np = 20 provides a prediction horizon of 2 s, corresponding to a spatial look-ahead of up to 8 m — sufficient to encompass the tightest curve radii (~8 m) on the test route. Shorter horizons (Np < 10) were found in preliminary trials to produce oscillatory steering on high-curvature segments. Second, the control horizon ratio: setting Nc = Np/2 = 10 reduces the number of free optimization variables by half while retaining responsive control authority — a standard heuristic for balancing computation time and tracking performance [12]. Third, real-time feasibility: the chosen horizons resulted in a mean MPC solve time of 8.3 ms (max: 14.1 ms) on the DS-1400 embedded computer, comfortably within the 100 ms sampling period. Longer prediction horizons (Np = 30, Nc = 15) were evaluated, but increased the worst-case solve time to 22 ms without meaningful tracking improvement, so Np = 20 / Nc = 10 was selected as the operating point. Proper selection of these horizons balances tracking accuracy, stability, and computational efficiency [12].

The cost function in Equation (1) is central to MPC and penalizes deviations from the reference trajectory and abrupt changes in control inputs, thereby ensuring smooth and accurate tracking [13].

$$J = \sum_{i=1}^{N_p} \|y(k+i) - r(k+i)\|_Q^2 + \sum_{i=0}^{N_c-1} \|\Delta u(k+i)\|_R^2 \qquad (1)$$

In this formula:

- r_{k+i} denotes the reference output,
- y_{k+i} denotes the predicted system output,
- Δu_{k+i} denotes the control input increments,

Q and R are weighting coefficient matrices that penalize state tracking error and control effort, respectively. Np is the prediction horizon (Np = 20 in this study), and Nc is the control horizon (Nc = 10 in this study).
Vehicle dynamics are typically modeled using a bicycle model that captures lateral and yaw motions in a compact state-space representation [14]. The key vehicle parameters used in this study are: vehicle mass ≈ 450 kg, front-to-rear axle distance (wheelbase) of 1.85 m, maximum steering angle ±30°, maximum longitudinal speed of 7 m/s, and maximum longitudinal acceleration of 1.5 m/s². The MPC weighting matrices were tuned as Q = diag(10, 10, 5, 1) and R = diag(0.1; 0.1).
Several MPC variants exist:

- Classical MPC: Simple and computationally efficient for linear or mildly nonlinear systems.

- Adaptive MPC: Adjusts model parameters online to handle changing conditions such as slippery roads or varying vehicle mass.
- Robust MPC: Accounts for worst-case disturbances and modeling uncertainties to ensure safety in critical scenarios.
- Hybrid MPC: Combines MPC with other controllers (e.g., Stanley) to leverage complementary strengths for real-time applications [15].

In this study, a classical MPC framework was implemented in the ROS 2 environment to optimize steering and speed commands for autonomous vehicle path tracking, ensuring safe and accurate trajectory following even under dynamic conditions.

V. LIDAR-BASED PERCEPTION AND CONSTRAINTS INTEGRATION FOR OBSTACLE AWARE MPC

Safe autonomous driving requires accurate and real-time perception of the surrounding environment. In this study, a 3D LiDAR sensor is employed as the primary perception source. Raw LiDAR point cloud data is processed to construct a 2D occupancy grid map, which encodes the presence of static and dynamic obstacles in the vehicle's local environment. This occupancy grid is updated continuously during each control cycle and serves as the primary input to the obstacle-avoidance module. Individual sensors are inherently subject to noise, measurement uncertainty, and performance degradation under adverse environmental conditions. To mitigate these limitations, the perception pipeline incorporates IMU and Global Navigation Satellite System (GNSS) data alongside LiDAR measurements, enabling a more robust and consistent environmental representation. The fused sensor outputs are time-synchronized and fed into the MPC optimization loop with an approximate end-to-end latency of 20 ms, ensuring that obstacle information remains consistent with the vehicle's current state during real-time operation. The 20 ms figure represents the median end-to-end latency measured during field trials; the observed 95th-percentile latency was 34 ms, with occasional spikes up to 52 ms due to transient congestion in the ROS 2 message queue. To account for this variability, a worst-case latency margin of 50 ms was incorporated into the MPC constraint update logic: occupancy-grid cells flagged as occupied are retained for at least one additional prediction step (i.e., 100 ms) before being cleared. This conservative retention strategy ensures that brief latency spikes do not cause premature relaxation of constraints, thereby maintaining safety margins even under degraded communication conditions. Future work will investigate deterministic scheduling via ROS 2 real-time executors (rclcpp::executors::StaticSingleThreadedExecutor) to further reduce worst-case jitter. Obstacle constraints are integrated into the MPC framework by augmenting the standard optimization problem with inequality constraints derived from the occupancy grid. Specifically, grid cells classified as occupied are translated into spatial exclusion zones within the prediction horizon. At each receding-horizon step, the MPC solver dynamically updates these constraints, allowing the controller to plan and execute smooth avoidance maneuvers without violating vehicle dynamics or actuator limits. Experiments conducted with both static and dynamic obstacles — including moving cones simulating pedestrian behavior — demonstrated the effectiveness of this integration. The MPC controller successfully detected and avoided all dynamic obstacles in real time, with the transient increase in lateral deviation during avoidance maneuvers limited to an average of 0.48 m. This result confirms that the LiDAR-based constraint integration preserves trajectory tracking accuracy while ensuring safe navigation in dynamic environments.

VI. IMPLEMENTATION AND EXPERIMENTAL STUDY

An MPC-based path-tracking controller was implemented for an autonomous golf vehicle operating within the ROS 2 Humble Hawksbill framework. As shown in Figure 1, the system consists of three layers:

- Perception Layer – Maps the environment using 3D LiDAR and constructs an occupancy grid.
- Decision and Control Layer – Computes optimal steering and speed commands using MPC.
- Communication Layer – Provides real-time operation and vehicle interface via Controller Area Network (CAN-BUS).

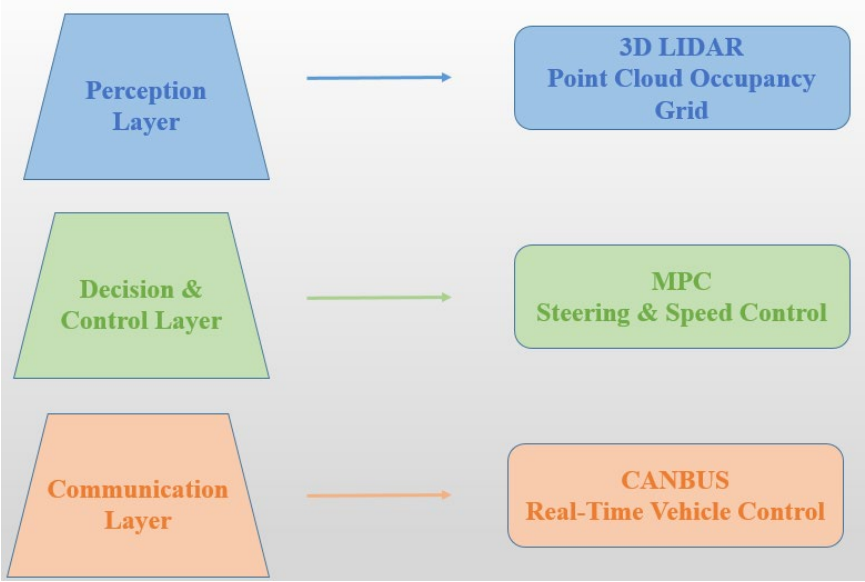

Figure 1. System Layers

The algorithm was implemented on the autonomous golf vehicle shown in Figure 2. The platform is equipped with GNSS, IMU, and 3D LiDAR sensors. The MPC controller runs on a DS-1400 Series rugged embedded computer equipped with a 12th/13th/14th Generation Intel® Core processor (up to 65 W Thermal Design Power (TDP)), 96 GB DDR5 Error-Correcting Code (ECC) memory support, and Peripheral Component Interconnect Express (PCIe) expansion capability. Steering and speed commands computed by the MPC are transmitted to the vehicle via the CAN-BUS interface, and sensor data is fed to the control loop with an approximate latency of 20 ms.

Experiments were conducted on a 350 m closed-loop asphalt path at the MPG Inc. test facility in Konya, Turkey. The route includes three curve sections with radii of approximately 8 m, 12 m, and 20 m, and two straight segments of 60 m and 110 m. The maximum allowable vehicle speed was set to 7 m/s (25.2 km/h). A total of 85,034 position samples were collected over five consecutive laps. Both the MPC and the Stanley controllers were evaluated on the same route under identical weather conditions to ensure comparability. The autonomous vehicle is assigned the mission to travel from point A to point B. Using GNSS coordinates of the defined waypoints, an optimal global path, as shown in Figure 3, is generated and tracked using the MPC algorithm.

Performance evaluation is based on the following metric:

Lateral Error (ey): Defined as the perpendicular distance between the vehicle's actual position and the nearest point on the reference path. This parameter indicates deviation from the centerline.

A total of 85,034 samples were analyzed, and the summary results are presented in Table 1.

Table 1. Lateral Error Performance of the MPC

Metric	**Output**	
	Value	**Description**
Mean Lateral Error (Mean e_y)	0.302	The vehicle maintained stable path tracking within approximately ±30 cm of the reference path throughout the experiment. Std. dev.: 0.381 m.
Maximum Lateral Error (Max e_y)	5.750	Represents a brief transient deviation during entry into a high-curvature turn. The overshoot originated from a sudden maneuver, and the MPC controller recovered the trajectory within approximately 1.2 seconds.
Root Mean Square Error (RMS e_y)	0.447	Reflects system stability; the relatively low RMS value indicates a smooth control response and minimal oscillation. Std. dev.: 0.392 m.

The heading error (e_θ) is defined as the difference between the vehicle's heading and the direction of the reference path. This metric indicates whether the vehicle maintains correct orientation while following the trajectory. As shown in Figure 3, the "Global Path vs. MPC Path" graph shows that the MPC-generated path almost perfectly overlaps the reference trajectory. Furthermore, the consistency between the odometry data and the MPC trajectory confirms that the heading error remained negligible throughout the experiment, demonstrating that MPC successfully achieved accurate vehicle heading control.

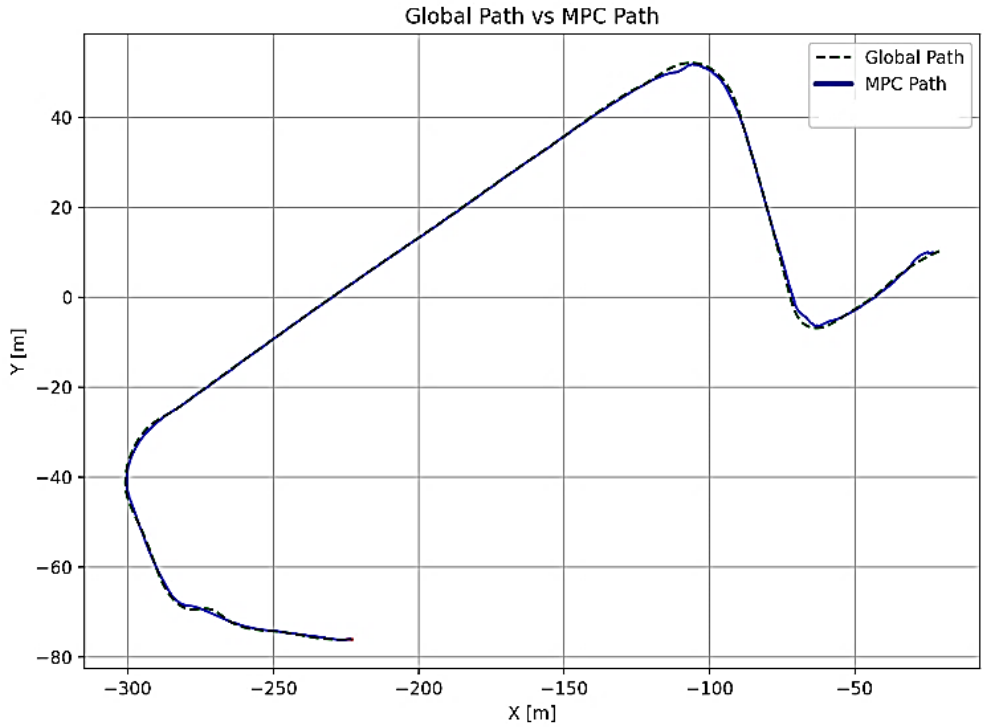

Figure 3. Comparison of Global Path and MPC Path

Experiments were conducted in an open area containing both static and dynamic obstacles. The dynamic obstacles, consisting of moving cones that mimicked pedestrians, were detected in real-time. MPC controller instantly incorporated the updated constraints from the LiDAR-based occupancy grid into the optimization problem, successfully executing safe avoidance maneuvers. The transient increase in lateral deviation during obstacle avoidance maneuvers was limited to an average of 0.48 m. Results show that the MPC controller maintained a mean lateral deviation of ~0.3 m and exhibited negligible heading errors, achieving accurate, stable, and safe trajectory tracking. To ensure a fair comparison, the Stanley controller gain k was tuned via a grid search over $k \in \{0.5, 1.0, 1.5, 2.0, 2.5, 3.0\}$ during a separate calibration run on the same route. The value $k = 1.5$, which yielded the lowest mean lateral error on the calibration run, was selected for the evaluation experiments reported here. The softening parameter $k_s = 1.0$ m/s was kept at its standard value. Heading gain was not tuned separately, as the standard Stanley formulation couples lateral and heading corrections through a single gain. This procedure ensures that the Stanley controller operates at its best achievable performance for this specific route, making the comparison with the MPC representative rather than trivially favorable. For comparison purposes, a Stanley controller was also tested on the same route. While Stanley produced a mean lateral error of 0.51 m and an RMS error of 0.72 m, MPC reduced these values to 0.302 m and 0.447 m, respectively, representing improvements of approximately 41% and 38%. This comparison is summarized in Table 2.

VII. CONCLUSIONS

This study highlights the effectiveness of MPC for path tracking in autonomous vehicles. MPC provides predictive control, explicit constraint handling, and integrated longitudinal/lateral management. Combined with sensor fusion, it enables robust obstacle avoidance and accurate trajectory tracking. In terms of control signals,

the MPC kept the steering angle within ±30° and produced a smooth, oscillation-free control signal; speed commands varied gradually within the 0–7 m/s range.

Challenges remain in computational cost, nonlinear modeling, and real-time optimization, which suggests that future research should focus on:

- Faster and more efficient solvers for real-time applications.
- Integration with machine learning and artificial intelligence to improve robustness under uncertainty.

In summary, MPC offers a powerful and flexible framework for autonomous vehicles, and ongoing interdisciplinary advances are expected to enhance its performance in real-world scenarios further.

Table 2. Controller Performance Comparison

Metric	Controller		
	Value	Stanley	Improvement
Mean Lateral Error (m)	0.302	0.510	~41%
RMS Lateral Error (m)	0.447	0.720	~38%
Max Lateral Error (m)	0.381	-	-

Abstract
When a bank builds a model to estimate the spread a commercial loan should carry, every loan has two prices: the one the lender charged and the one the model expected. The gap between them is not automatically a mistake, and prior work supplies no rule for what to do with it. This paper defines that gap as the pricing wedge. It gives it one: a wedge matters only if it is both statistically unusual and economically large, and it is acceptable only if a documented, evidenced reason explains it. Each loan then routes to one of four outcomes, and a portfolio layer watches for patterns no single loan can show. On 6,000 synthetic loans with planted deviations, this routing escalated 7.6 percent of the book at 0.912 precision, where a simple threshold escalated 17.8 percent at 0.606; the portfolio layer caught planted drift in every run. All evidence is synthetic. Nothing here is demonstrated on real loans.

Keywords: commercial loan pricing, pricing wedge, model risk governance, conformal prediction, explainable AI, fair lending, exception management

I. INTRODUCTION

A commercial lender pricing a corporate facility weighs expected credit loss against funding cost, capital usage, liquidity, collateral, tenor, covenants, fee income, competition, relationship value, and balance-sheet strategy. The resulting spread is a negotiated judgment, not a derivation. When a bank introduces a model that estimates a benchmark spread from observable features, it creates a comparison that did not previously exist: the difference between what the lender charged and what the model would have charged. That difference is the institutional problem. It is not automatically an error, a violation, or evidence of bias. It may reflect documented relationship economics, a verified competitive match, fee-spread substitution, collateral or covenant structure outside the feature set, or a limitation of the model itself. It may equally reflect undocumented concession, pricing drift, or discretion that concentrates in ways a fair-lending examiner would question. Treating every deviation as an exception overwhelms review capacity; treating none as an exception forfeits the control the benchmark was built to provide. The research gap is specific. The literature supplies each component of a response separately. Relationship-banking research establishes why discretion is economically valuable [1–4]. Risk-based pricing research specifies what a defensible benchmark should contain [5], [6]. Machine-learning credit research establishes benchmark feasibility and its distributional risks [7], [8]. Explainability research produces local attributions and documents their manipulability [9-12]. Conformal prediction supplies distribution-free bands [13–16]. Supervisory guidance specifies model governance [17], [18]. None of these treats the model-human deviation as an object with its own definition, classification rule, routing logic, and monitoring layer. The research question follows: can the deviation between a model-based benchmark spread and an executed commercial loan spread be formalized and routed such that justified discretion is preserved, unexplained deviation becomes visible, and review capacity is spent proportionally? This paper makes one contribution. The individual components—gradient boosting, quantile regression, conformal calibration, local attribution, reason-code taxonomies, portfolio monitoring—are

established techniques and are not claimed as novel. The contribution is their formal integration into a single governance framework centered on the pricing wedge, together with a reproducible synthetic study that measures what each architectural layer adds and what it costs. What is validated and what is not must be stated at the outset. We validate the framework's internal behavior on synthetic data with planted ground truth: whether the routing logic separates planted justified from planted unjustified deviations, whether the portfolio layer detects planted drift, and how sensitive both are to thresholds, bandwidth, and reason-code gaming. We do not validate the framework on real commercial loan portfolios, do not establish cross-institutional or cross-jurisdictional generalizability, and do not claim that any measured quantity establishes fair-lending compliance. Section II positions the framework against prior work. Section III defines the framework formally. Section IV specifies the synthetic validation design. Section V reports results. Section VI presents the governance protocol, reason-code taxonomy, and fairness-control specification; Section VII addresses generalizability and limitations. Section VIII concludes.

II. RELATED WORK AND CONTRIBUTION GAP

1. Commercial Loan Pricing and Relationship Banking

Petersen and Rajan [1] and Berger and Udell [2] established that lending relationships generate private information that improves credit availability and contract terms. Both study small-business lending, and the transfer of their findings to middle-market and large corporate lending requires justification rather than assumption. That justification exists in the corporate-loan literature: Bharath, Dahiya, Saunders, and Srinivasan [3] find, on syndicated loans to public borrowers, that repeated borrowing from the same lender lowers spreads by roughly 10 to 17 basis points, and that relationship value is concentrated where borrower transparency is low, becoming statistically indistinguishable for the largest borrowers. Related work documents what the lender captures from the relationship [4]. This bounds the present framework's scope: relationship-based deviation is an expected feature of opaque middle-market credit and a weaker expectation for large, transparent borrowers, so a single institution-wide materiality threshold is unlikely to be appropriate across segments.

2. Risk-Based Pricing and Bank Economics

Loan spreads reflect bank-side factors as well as borrower risk. Berg, Saunders, and Steffen [5] show that most U.S. syndicated loans carry fee structures alongside spreads, and that fees price embedded options and screen borrowers. The direct implication for wedge measurement is that a spread deviation observed without the fee structure can be economically misleading: fee-spread substitution can produce a large negative wedge on an economically unchanged transaction. Bank organizational structure also affects the capacity to act on soft information [6], which is why a centrally calibrated benchmark may systematically diverge from locally optimal pricing.

3. Machine Learning in Credit and Pricing

Machine-learning models improve predictive accuracy in credit applications, and their distributional consequences are documented. Fuster, Goldsmith-Pinkham, Ramadorai, and Walther [7] show, using U.S. mortgage data, that flexible models change the dispersion of predicted risk across borrower groups, with some groups disproportionately unlikely to gain. This establishes that a benchmark's accuracy and its distributional properties are separate questions, and that improving the first does not settle the second.

4. Explainability and Its Limitations

SHAP [9] and LIME [10] produce local attributions that make a single benchmark estimate reviewable. Their limitations are equally established. Slack, Hilgard, Jia, Singh, and Lakkaraju [11] demonstrate that perturbation-based post-hoc explanations can be deliberately manipulated so that a biased model yields innocuous explanations, and Kumar et al. [12] show that Shapley-value attributions do not straightforwardly answer the questions practitioners ask of them. Rudin [19] argues that for high-stakes decisions, an interpretable model is preferable to a post hoc explanation of an opaque model. This paper adopts the implication rather than disputing it: explanation is treated as an input to human review under a documented evidence standard, never as proof that a benchmark is correct, and the model comparison in Section V tests whether an opaque model is needed at all.

5. Uncertainty Quantification and Conformal Prediction

Conformal prediction produces prediction intervals with finite-sample marginal coverage without distributional assumptions [13]. Conformalized quantile regression [14] adapts the interval width to heteroscedasticity, which matters here because pricing dispersion is not constant across borrower segments. Two limitations are load-bearing for governance. Marginal coverage does not imply conditional coverage: a method can meet its nominal level overall while under-covering a specific segment, which motivates the equalized-coverage diagnostics of Romano, Barber, Sabatti, and Candès [15]. And coverage guarantees rest on exchangeability, which fails under distribution shift [16], [20]. A pricing book subject to competitive and macroeconomic movement is exactly such a setting, so band validity is a monitored property, not a standing assumption.

6. Algorithmic Discrimination and Fair-Lending Monitoring

Bartlett, Morse, Stanton, and Wallace [8] estimate, on U.S. mortgage data, that risk-equivalent minority borrowers paid measurably higher rates, and that algorithmic lenders exhibited disparities that were similar for some products and lower for others. The relevant result here is not the point estimate but the mechanism: pricing disparities can persist in data subsequently used to train a model. A benchmark fitted to that history encodes it. The framework, therefore, treats the benchmark as a potential carrier of inherited bias. It measures that inheritance directly (Section V), rather than presenting the benchmark as a neutral standard against which human pricing is judged.

7. Model-Risk Governance

U.S. interagency supervisory guidance on model risk management was revised on 17 April 2026 by SR 26-2 [17], which supersedes SR 11-7 (2011) [21] and the 2021 interagency statement, and is accompanied by FDIC FIL-15-2026 [18] and the corresponding OCC bulletin. The revised guidance retains the core expectations of development, independent validation, and ongoing monitoring, and articulates them on a risk-based, proportional basis tailored to an institution's model risk profile, size, and complexity; it is expected to be most relevant to banking organizations with more than $30 billion in total assets. Supervisory guidance does not have the force and effect of law and does not create binding legal obligations; it describes supervisory expectations. This paper cites SR 26-2 as the operative reference and SR 11-7 only for historical continuity.

8. Contribution Relative to Prior Approaches

Table 1 compares the framework against the governance approaches a commercial bank already operates. The comparison is across four dimensions: which object each approach governs, whether it uses an uncertainty-

aware materiality test, whether it imposes a structured evidence standard on human justification, and whether it aggregates individually non-material outcomes at the portfolio level. No existing approach is deficient at its own task; the gap is that none takes the model-human deviation as its object.

Table 1. Comparison with Existing Governance Approaches

Approach	**Governed object**	**Uncertainty-aware materiality**	**Structured evidence standard**	**Portfolio aggregation of non-material items**
Pricing-exception policy	Deviation from the internal pricing rule	No: fixed threshold	Partial: free-text justification common	No
Fair-lending pricing monitoring	Outcome disparity across groups	No	No	Yes, but not linked to model deviation
Model-risk governance [17]	Model design, use, and performance	Indirect, via validation	No: governs the model, not the deviation	No
Explainable-AI workflow [9], [10]	Model output attribution	No	No	No
Human-in-the-loop review	Algorithmic recommendation	No	Varies by institution	No
Proposed wedge framework	**Model–human pricing deviation**	**Yes: band and threshold jointly**	**Yes: four required elements**	**Yes: drift and segment layer**

III. METHODOLOGY: THE PRICING-WEDGE FRAMEWORK

1. Formal Problem Definition

Let loan i be priced at time t. The institution observes a feature vector $x_{i,t}$ that contains borrower risk, facility structure, bank cost, and market variables available at or before the pricing decision. The lender executes an actual spread; a model estimates a benchmark spread and an interval around it. The governance problem is to map each loan to exactly one of four outcomes—retain record, monitor at portfolio level, document and approve, escalate for review—using only quantities that can be computed, documented, and audited.

2. Actual Spread

The actual spread $s^{a}_{i,t}$ is the executed contractual margin over the relevant reference rate, in basis points. Where material fees exist, the spread must be interpreted together with the fee structure, because fee-spread substitution can make an economically unchanged transaction appear as a large negative deviation [5].

3. Benchmark Spread

The benchmark spread $\hat{s}^{b}_{i,t} = f(x_{i,t})$ is a supervised estimate of the spread the institution's own pricing function would produce for comparable observable characteristics. It is a model output subject to model-risk

governance [17]. It is not objective, optimal, or sovereign, and it does not observe unrecorded soft information, undocumented relationship value, or competitive intelligence outside the feature set.

4. Pricing Wedge

The pricing wedge is defined as:

$$w_{i,t} = s^{a}_{i,t} - \hat{s}^{b}_{i,t} \quad (1)$$

expressed in basis points, with sign preserved. A positive wedge means the loan was priced above the benchmark; a negative wedge means it was priced below the benchmark. Sign is retained throughout because the two directions raise different governance questions: materially negative wedges raise underpricing and undocumented-concession questions, materially positive wedges raise overpricing and fairness questions.

5. Expected Pricing Band

Let $q_{\alpha/2}$ and $q_{1-\alpha/2}$ be quantile regression estimates fitted on a training partition, and let E be the conformity score computed on a disjoint calibration partition of size n, with $Q_{1-\alpha}(E)$ its $\lceil (n+1)(1-\alpha) \rceil$-th order statistic [14]. The expected pricing band is:

$$[\hat{L}_{i,t}, \hat{U}_{i,t}] = [\hat{q}_{\alpha/2}(x_{i,t}) - Q_{1-\alpha}(E), \hat{q}_{1-\alpha/2}(x_{i,t}) + Q_{1-\alpha}(E)] \quad (2)$$

This construction delivers marginal coverage at level $1-\alpha$ under exchangeability. It does not deliver conditional coverage for an arbitrary segment, and its guarantee degrades under distribution shift [15], [16]. Both properties are monitored quantities in Section VI rather than assumptions.

6. Hybrid Materiality Rule

A wedge is material only when it is both statistically unusual and economically significant. With θ the institution-approved business threshold in basis points:

$$M_{i,t} = \mathbf{1}[\, s^{a}_{i,t} \notin [\hat{L}_{i,t}, \hat{U}_{i,t}] \,] \cdot \mathbf{1}[\, |w_{i,t}| > \theta \,] \quad (3)$$

The first condition prevents small deviations from being escalated where the model is confident, but the deviation is economically trivial. The second prevents large deviations from being escalated where the model itself is highly uncertain. The conjunction is binding only when θ is large relative to the bandwidth; Section V measures the range over which it binds.

7. Explainability Rule

Explainability is an operational indicator, not a property of the model. A wedge is explainable when a submitted reason code meets the minimum standard defined in Section VI, which requires all four: a category from the institution-approved taxonomy, a quantified pricing or economic rationale, supporting evidence, and a named decision owner with approval level.

$$X_{i,t} = \mathbf{1}[\text{ code submitted }] \cdot \mathbf{1}[\text{ all four required elements present and evidenced }] \quad (4)$$

A wedge with no code, or with a code that fails the evidence requirement, is unexplained regardless of the decision owner's subjective belief that the deviation was justified.

8. Reason-Code Taxonomy

The taxonomy is a structured input, not a free-text field, because free-text justification cannot be aggregated across a portfolio and therefore cannot support drift or segment monitoring. Table 5 specifies the categories, evidence requirements, approval levels, and the known gaming risk of each.

9. Four-Cell Governance Matrix

Materiality and explainability jointly determine the routing outcome, as set out in Table 2:

$$R(M, X) = \{\text{retain, monitor, approve, escalate}\} \text{ for } (M, X) = (0,1), (0,0), (1,1), (1,0) \quad (5)$$

Table 2. Pricing Wedge Classification Matrix

	Explainable ($X = 1$)	**Unexplained ($X = 0$)**
Non-material ($M = 0$)	Retain record; no loan-level action	Monitor at portfolio level
***M*aterial (M = 1)**	Document and approve at the authority level	Escalate for review

Figure 1 shows the complete routing path from executed price to governance outcome.

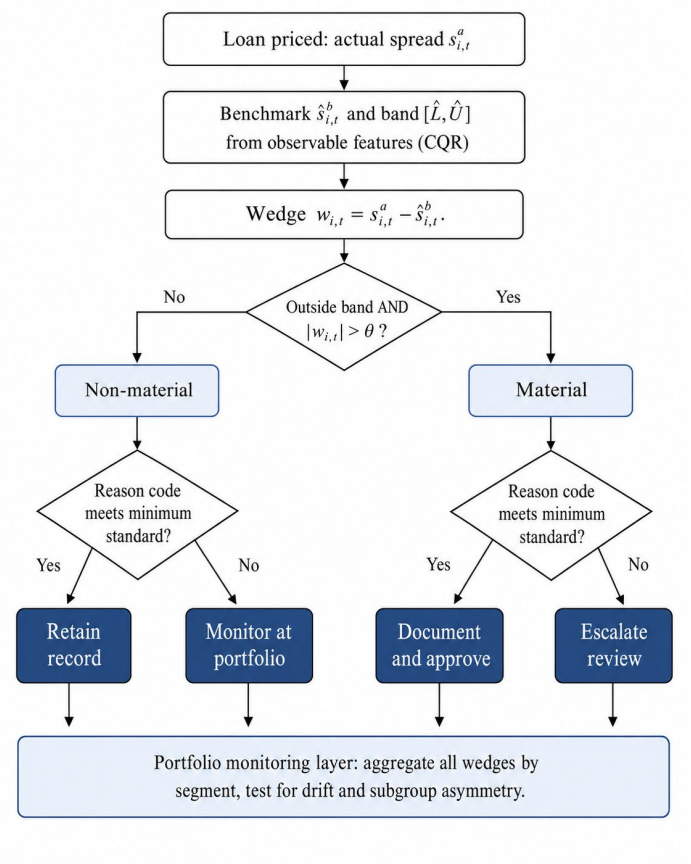

Figure 1. Wedge classification and routing flow.

10. Portfolio-Monitoring Layer

Loan-level routing is necessary but not sufficient. Individually non-material wedges can aggregate into a pattern that no single loan would disclose. For segment *k,* the layer compares the mean wedge in a recent window against a baseline window over loans *not* escalated individually:

$$z_k = (\bar{w}_{k,\,recent} - \bar{w}_{k,\,base}) / (\sigma_{k,\,base} / \sqrt{n_{k,\,recent}}) \quad (6)$$

Segments with |zk| > 2 and a minimum sample size are referred to the governance committee. The statistic is a monitoring trigger for human review, not a hypothesis test with a controlled error rate; Section V reports its false-flag rate, and Section VI specifies the multiple-comparison treatment.

11. Algorithmic Workflow

Algorithm 1 states the complete procedure. It is written so that an institution with a loan-level pricing dataset, a reason-code field, and a segment identifier can implement it without further specification.

Algorithm 1: Wedge classification and routing
Input: loans $D = \{(x_{i,t}, s^a_{i,t}, \text{code}_{i,t}, \text{segment}_{i,t})\}$; level $1-\alpha$; threshold θ
Output: routing outcome per loan; segment drift flags
1. Partition *D* by time into train, calibration, validation, and test.
2. Fit candidate benchmark models on train; select on validation MAE.
3. Fit lower and upper quantile models at $\alpha/2$ and $1-\alpha/2$ on train.
4. Compute conformity scores on calibration; set $Q_{1-\alpha}(E)$ per (2).
5. for each loan *i* in the monitoring population do
6. $\hat{s}^b_{i,t} \leftarrow$ selected model; band $\leftarrow$ (2); $w_{i,t} \leftarrow$ (1)
7. $M_{i,t} \leftarrow$ (3); $X_{i,t} \leftarrow$ (4)
8. $\text{outcome}_{i,t} \leftarrow R(M_{i,t}, X_{i,t})$ per (5)
9. record $\hat{s}^b$, band, *w*, *M*, *X*, outcome, local attribution, owner
10. end for
11. For each segment *k,* over non-escalated loans, do
12. compute z_k per (6); flag if $|z_k| > 2$ and $n_{k,\text{recent}} \geq n_{\min}$
13. end for
14. Review band coverage, segment coverage, threshold, and taxonomy use in the committee.

IV. Synthetic Validation Design

This section specifies a reproducible synthetic study. Its purpose is to measure the framework's internal behavior under conditions where the correct answer is known by construction. Three categories must be kept distinct throughout. Synthetic results describe how the framework behaves on data we generated. Actual commercial-loan evidence is not available to this study and is not presented. Real-world generalizability is not established by anything reported here.

1. Data-Generating Process

We generate 6,000 synthetic commercial loans under fixed seed 20260719. Each loan carries a borrower risk grade on a ten-point scale, log facility size, tenor, secured indicator, covenant strength, sector, region, quarter of origination over twelve quarters, a funding-cost index, competitive intensity, relationship depth, fee-income

ratio, and capital usage. A risk-based spread is formed as a nonlinear function of these variables, including a quadratic risk term and a risk-tenor interaction, plus heteroscedastic noise that defines two uncertainty regimes: a low-dispersion regime with a 13-basis-point standard deviation and a high-dispersion regime with 34 basis points, covering weaker grades and the technology and services sectors.

These ranges are *plausible synthetic design assumptions*. They are not empirically calibrated to any real loan portfolio, and no claim of realism beyond internal plausibility is made for them.

2. Planted Ground Truth

Deviations are then planted with a known type. Justified deviations comprise documented relationship concessions, verified competitive matches, and fee-spread substitution, each carrying an adequate reason code. Unjustified deviations of both signs are planted without an adequate code; a subset of these submits a relationship-value code that fails the evidence requirement, providing the reason-code gaming scenario. A segment-level markup is applied to a monitoring segment defined by region and facility size, so that the segment correlates with observable features, and a benchmark trained on this history can absorb part of the markup. Finally, small individually non-material concessions are planted in one sector in the final two quarters, providing the portfolio-drift scenario. Ground truth for loan-level evaluation is defined as an unjustified deviation in which the planted magnitude exceeds the business threshold.

3. Partitions and Models

The data are split 50 percent train, 20 percent calibration, 15 percent validation, and 15 percent test. Quantile models and benchmark models are fitted on train only; the conformity quantile is computed on calibration only; model selection uses validation only; all reported metrics use the held-out test partition, except the portfolio layer, which runs on all 2,790 non-training loans because portfolio monitoring operates on the whole book rather than a sample.

Two benchmark candidates are compared for a stated reason. A transparent linear model represents the interpretable option that Rudin [19] argues should be preferred, where it suffices. A histogram gradient-boosting model [22] represents the flexible option commonly adopted for tabular credit data. The comparison exists to test whether the framework requires an opaque model, not to advocate one. Bands are built using conformalized quantile regression [14] at a 90 percent nominal level, with gradient boosting and the pinball loss [23].

Crucially, benchmark models are trained on *actual* historical spreads that contain planted deviations and planted segment markup. This is deliberate: it reproduces the bias-inheritance condition that the framework must contend with in practice. To measure inheritance, we also fit a counterfactual benchmark on an otherwise identical history in which the segment markup never occurred.

4. Governance Architectures Compared

Four routing architectures are evaluated. Architecture A escalates based solely on the business threshold. Architecture B escalates on the prediction band alone. Architecture C applies the hybrid two-condition rule at the loan level. Architecture D is the full framework: architecture C plus the portfolio-monitoring layer. All four escalate only where the reason code fails the evidence standard. The comparison isolates what each layer adds.

V. RESULTS

The executed analysis produces all figures in this section. Headline values are from the fixed-seed run; dispersion is from twenty independent seeds.

1. Benchmark Accuracy and Model Choice

On validation, the transparent linear model achieved a mean absolute error of 37.57 basis points, compared to 40.56 for gradient boosting, and was selected in all 20 seeds. On the held-out test partition, the linear model recorded 39.82 basis points MAE and 56.88 RMSE, against 41.91 and 59.12 for gradient boosting; across seeds, the gap was 38.71 ± 1.58 versus 41.24 ± 1.47.

We do not claim gradient boosting is preferable here; on this data-generating process, it is not. Pricing noise dominates the nonlinearity we planted, and the flexible model pays a variance cost for curvature it cannot reliably recover. The governance implication is the useful one: the framework does not require an opaque benchmark, and where a transparent model matches a flexible one, the interpretable option should be preferred on review grounds alone [19]. Section V confirms that routing behavior is essentially unchanged when the gradient-boosting benchmark is substituted, which is evidence that the framework is model-agnostic rather than evidence that either model is correct.

2. Uncertainty Bands

At a 90 percent nominal level, the conformalized band achieved 89.0 percent marginal coverage on test and 89.9 ± 1.2 percent across seeds, with a mean width of 192.73 basis points. Conditional coverage was not uniform: 90.5 percent in the low-dispersion regime versus 88.0 percent in the high-dispersion regime, and 89.5 percent versus 87.9 percent across the monitoring segment. Bandwidth did adapt to dispersion, from 184.79 to 198.00 basis points. This is the marginal-versus-conditional distinction in operational form: nominal coverage was met overall while a segment was under-covered by roughly one to two percentage points, which is precisely why subgroup coverage is a standing monitoring item [15].

3. Governance Routing

Table 2 reports the four architectures against planted ground truth. The result is a trade-off, not a dominance.

Table 3. Governance Routing Against Planted Ground Truth (Test Partition)

Architecture	**Precision**	**Recall**	**F1**	**False-escalation rate**	**Share escalated**
A: business threshold only	0.606	0.907	0.727	0.079	17.8%
B: prediction band only	0.912	0.579	0.709	0.008	7.6%
C: hybrid, loan level only	0.912	0.579	0.709	0.008	7.6%
D: full framework (C + portfolio layer)	0.912	0.579	0.709	0.008	7.6%

Threshold-only routing recovered the most planted cases: recall 0.907 versus 0.579 for the hybrid rule, and, across seeds, its F1 was higher (0.712 ± 0.025 versus 0.661 ± 0.051). It achieved this by escalating 17.8 percent of the book at 0.606 precision, so roughly two in five escalations were loans with no planted problem. The hybrid rule escalated 7.6 percent, with 0.912 precision and a false-escalation rate of 0.008, compared to 0.079. Which architecture is preferable is a governance choice about the relative cost of a missed deviation and a wasted review, not a fact that the data settles. Institutions with scarce senior-review capacity should read this

table as favoring the hybrid rule; institutions prioritizing recall should not adopt it without raising review capacity accordingly.

Architectures B and C were identical at this threshold. The two-condition rule is non-binding whenever the band is wide relative to θ: at a mean width of 192.73 basis points, a loan outside the band almost always exceeds the 50-basis-point threshold. Table 4 shows the threshold at which the conjunction begins to bind.

Table 4. Sensitivity to Business Threshold and Band Coverage

Setting	**Mean band width (bp)**	**Precision**	**Recall**	**F1**	**Share escalated**
θ = 25 bp	—	0.912	0.579	0.709	7.6%
θ = 50 bp (baseline)	—	0.912	0.579	0.709	7.6%
θ = 75 bp	—	0.909	0.561	0.694	7.3%
θ = 100 bp	—	0.946	0.495	0.650	6.2%
95% band	248.05	0.950	0.355	0.517	4.4%
90% band (baseline)	192.73	0.912	0.579	0.709	7.6%
80% band	127.20	0.733	0.794	0.762	12.9%

Both calibration choices are governance instruments rather than statistical details. Widening the band from 80 to 95 percent coverage increased the mean width from 127.20 to 248.05 basis points, reduced recall from 0.794 to 0.355, and raised precision from 0.733 to 0.950. A wide band produces a quiet exception queue by construction, which is why bandwidth is itself a reviewable parameter.

4. Portfolio Layer and Drift Detection

The portfolio layer ran on 2,790 non-escalated loans. It detected the planted sector drift in the fixed-seed run at -2.18 standard errors, a mean shift of -9.41 basis points, and detected it in twenty of twenty seeds. Loan-level routing detected none of these loans, and could not: every drift loan was individually below the materiality threshold and carried an adequate code. This is the only dimension on which architecture D differs from architecture C, and it is the specific justification for the portfolio layer.

The layer is not free. In the fixed-seed run, it also flagged a second sector where nothing was planted at 2.56 standard errors, and across seeds it produced 0.25 false segment flags per run (standard deviation 0.43). With five segments tested per run and no multiplicity correction, this is the expected behavior of an uncorrected screen, and this is why Section VI treats segment flags as review triggers requiring investigation rather than as findings.

Figure 2 summarizes loan-level routing and the segment statistics side by side.

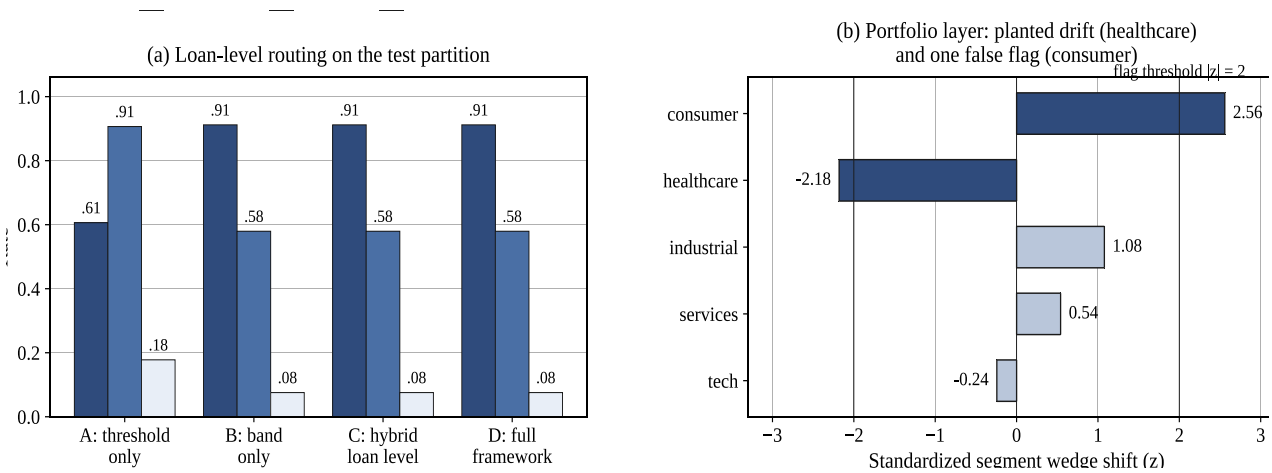

Figure 2. Governance routing performance and portfolio-layer segment statistics.

5. Reason-Code Gaming and Model Substitution

When claimed reason codes were accepted without the evidence requirement, hybrid recall fell from 0.579 to 0.364 and F1 from 0.709 to 0.513, while the escalated share fell from 7.6 to 5.0 percent. The queue became quieter while detection deteriorated. The evidence requirement in the reason-code standard is therefore load-bearing rather than administrative: without it, the framework can be silenced by populating a taxonomy field.

Substituting the gradient-boosting benchmark for the selected linear benchmark left hybrid routing unchanged at 0.912 precision and 0.579 recall.

6. Bias Inheritance

The planted segment markup produced a true wedge gap of 10.52 basis points between the monitoring segment and the rest of the portfolio. The counterfactual benchmark, trained on a history without the markup, surfaced 10.29 basis points of it. The deployed benchmark, trained on the biased history, yielded only 9.09 basis points: it absorbed 1.19 basis points, roughly 12 percent of the detectable disparity, into its predictions. Across seeds, the absorbed amount was 1.32 ± 0.20 basis points.

The magnitude is modest here because the segment was only partly predictable from the feature set; with a segment more strongly correlated with observable features, absorption would be larger. The direction is what matters, and it is unfavorable: a benchmark fitted to biased history understates the disparity that the wedge is supposed to reveal, and it does so silently. The wedge cannot detect bias that the benchmark has already learned. This is a structural limit of the design, not a tuning problem, which is why the fairness controls in Section VI include a review of the training distribution rather than only the wedge distribution.

7. Interpretation and Scope

Three readings must be kept separate. Effects that follow from the design include the detection of planted drift and deterioration under reason-code gaming; these test whether the mechanism does what it is specified to do and would be alarming only if they failed. Findings that demonstrate internal behavior include only the precision and recall levels, the threshold at which the two-condition rule binds, and the false-flag rate; their magnitudes depend on the planted deviation rates and dispersions and would change under different assumptions. Findings that would change materially under different distributions include every absolute rate

reported above; none should be read as a performance expectation for a real portfolio. Nothing here has been tested on real loan data, and no number in this section speaks to fair-lending compliance, which is a legal determination that no metric establishes.

VI. GOVERNANCE PROTOCOL AND CONTROL ARCHITECTURE

The framework becomes operational only inside a repeatable control protocol with named owners. Table 5 states the reason-code taxonomy; the fairness and model-risk controls follow; Figure 3 shows how the components nest.

1. Reason-Code Taxonomy

Table 5. Operational Reason-Code Taxonomy

Category	**Required evidence and quantification**	**Approval level**	**Review or expiry**	**Known gaming risk**
Documented relationship economics	Cross-product revenue reconciliation from the relationship system; quantified annual value	Relationship manager plus credit officer	Annual; expires if realized revenue misses projection	Highest: unfalsifiable if projections are never reconciled
Verified competitive match	Dated competing term sheet or documented market quote; quantified spread differential	Credit officer	Per transaction	Unverifiable verbal quotes
Fee-spread substitution	Fee schedule and total-cost calculation showing economic equivalence [5]	Pricing desk	Per transaction	Low if total cost is computed; high if asserted
Collateral or covenant difference not in the feature set	Executed documentation reference and structural description	Credit officer	Until amendment	Recurrence signals a feature-set gap, not an exception
Strategic acquisition	Named strategic mandate; expected relationship trajectory	Senior credit committee	Twelve months, then re-justify	Open-ended use as a residual category
Model limitation	Attribution report showing the driver the benchmark mis-estimates	Model risk plus credit officer	Each model recalibration	Concentration indicates the model, not the loan, requires action
Data-quality issue	Identified field, corrected value, remediation ticket	Data owner	Until corrected	Persistent use masks unresolved data defects
Other	Written rationale plus quantification; enhanced review mandatory	Senior credit committee	Per transaction	Residual bucket absorbing unclassifiable discretion

Two categories are deliberately constrained. Relationship value may not serve as an unbounded explanation: it requires quantification at submission and reconciliation with realized revenue, and unreconciled claims by a single manager constitute a portfolio-monitoring field in their own right. Management judgment is not a permitted category. Section V shows why: accepting claimed codes without evidence cuts detection by roughly a third.

2. Fairness-Control Specification

The unit of analysis is the individual loan, aggregated to monitoring segments. Comparison groups are defined only by variables the institution may lawfully use for monitoring in its jurisdiction; the synthetic study uses a geographic and facility-size segment, and no demographic variable is used or implied. Conditioning variables are the risk, structural, and bank-cost features in the benchmark feature set, so that segment comparisons are made among comparable loans rather than across the raw book. The reviewed quantities are conditional mean wedge differences, material wedge rate differences, escalation rate differences, reason code adequacy rate differences, and subgroup band coverage.

Pricing-exception monitoring is itself a long-standing supervisory focus in fair-lending examination [24], so the segment diagnostics above are an extension of an existing control rather than a new reporting obligation. Review runs quarterly. Segments with fewer than the minimum sample defined by the model-risk policy are pooled or carried forward rather than reported. Because several segments are screened simultaneously, the false-flag behavior measured in Section V applies: flags are treated as triggers for investigation, a false-discovery-rate correction is applied where the number of segments is large, and no flag is recorded as a finding before investigation. Escalation goes to the fair-lending and model-risk committee, which must document the investigation, the conclusion, and any changes to thresholds, models, or policies. Implementation must be adapted to applicable law, data availability, jurisdiction, and institutional policy; no metric in this framework establishes legal compliance.

3. Model-Risk Controls and Decision Ownership

The benchmark operates within the institution's model-risk framework, scaled to its model-risk profile, as SR 26-2 directs [17]. Required controls include a challenger model maintained in parallel; independent validation at deployment and at policy-defined intervals; documented recalibration procedures that assess whether recalibration propagates inherited bias; monitoring of band coverage, both overall and by segment; and a complete audit trail of model versions, thresholds, classifications, reason codes, and outcomes. Local attribution accompanies every benchmark estimate in basis points, so a reviewer can identify which features drove the estimate; consistent with [11] and [12], attribution supports review and never substitutes for validation.

Decision ownership is unchanged by any of this. The lender and credit authority own the pricing and approval decision. The framework changes what must be explained, not who decides. Figure 3 shows the resulting arrangement: the benchmark sits inside the control layers rather than above them.

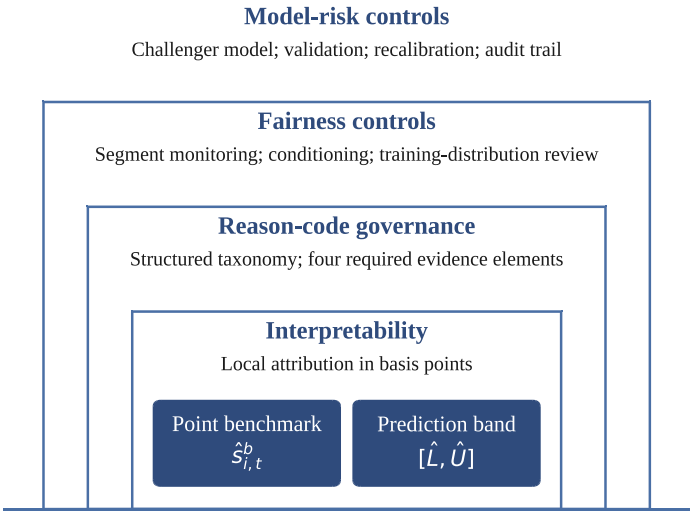

Figure 3. Control architecture around the benchmark.

VII. DISCUSSION, GENERALIZABILITY, AND LIMITATIONS

1. What the Synthetic Study Does and Does Not Establish

The study establishes that the specified logic behaves as specified: the routing rule separates planted justified from planted unjustified deviations at measured precision and recall, the portfolio layer detects aggregate drift that loan-level routing structurally cannot, the evidence requirement is load-bearing, and a benchmark fitted to biased history absorbs part of the disparity it is meant to reveal. It establishes none of the following: that the framework improves governance quality at a real bank, that the measured rates transfer to any real portfolio, or that the planted deviation rates resemble those of any institution. Synthetic ground truth is a test of internal consistency, not of external validity. Real loan-level validation remains necessary as the next step and requires proprietary pricing data, reason-code records, and outcome data that this study lacked.

2. Generalizability Across Banks, Portfolios, and Jurisdictions

Three heterogeneities bound transfer. Bank heterogeneity: institutions differ in pricing-model maturity, review capacity, and data integration, and the architecture choice in Table 2 is capacity-dependent rather than universal. Portfolio heterogeneity: relationship-based deviation is expected in opaque middle-market credit and much weaker for large transparent borrowers [3], so a single institution-wide threshold will over-escalate one segment while under-escalating another; thresholds should be segment-specific. Jurisdictional heterogeneity: permissible monitoring variables, disclosure obligations, and supervisory expectations differ, and the supervisory references here are U.S. Nothing in the mechanism is U.S.-specific, but the fairness-control specification must be rewritten for each jurisdiction.

Applicability also has a lower bound in operational cost. The framework requires loan-level pricing data joined to credit, funding, fee, relationship, and approval systems, plus a structured reason-code field enforced in the pricing workflow. Institutions without that integration cannot implement it as specified, and partial implementation without the portfolio layer forfeits the one capability that distinguishes it from a conventional exception policy.

3. Structural Limitations

Relationship value remains partly unobservable. The framework cannot verify, on a case-by-case basis, that a documented claim reflects genuine economics; it can require that the claim be documented and tested against realized revenue at the portfolio level. That defense operates after loans are booked, not at the moment of decision.

Reason codes can be gamed, and Section V quantifies the cost. Structured codes solve aggregation, not sincerity. The defense is portfolio-level monitoring of code distributions and outlier review of high-frequency submitters.

The benchmark may inherit bias, and Section V shows that it does so measurably. The fairness layer addresses this through segment monitoring, conditioning, and training-distribution review, but no control removes inherited bias; each only limits how far it propagates undetected.

Materiality thresholds and bandwidth are governance choices with measurable consequences, not neutral parameters. Table 4 shows that a threshold set too high leaves material unexplained and wedges unescalated. At the same time, a band set too wide produces a quiet queue that may reflect model weakness rather than pricing discipline. Both require periodic stress-testing against review capacity.

Finally, model misspecification and distribution shift bound the whole construction. If the benchmark omits a driver that the market prices, the wedge measures the omission rather than the discretion; if the pricing distribution shifts, the conformal guarantee degrades [16], [20], and coverage monitoring is the only available warning.

VIII. CONCLUSION

Commercial loan pricing is a judgment based on risk, funding costs, capital, competition, and relationship value. When a bank adds a model-based benchmark, it creates a difference between what was charged and what the model expected, and that difference is not self-interpreting.

This paper defined that difference as the pricing wedge and built a governance framework around it: a conformal band and a business threshold that jointly decide materiality, a reason-code standard that decides explainability, a four-cell rule that routes each loan to one of four outcomes, and a portfolio layer that aggregates what loan-level review cannot see.

On 6,000 synthetic loans with planted ground truth, hybrid routing escalated 7.6 percent of the book at 0.912 precision where threshold-only routing escalated 17.8 percent at 0.606; the portfolio layer detected planted drift in every seed while loan-level routing detected none of it; accepting unevidenced reason codes cut detection by roughly a third; and a benchmark trained on biased history absorbed part of the disparity it was meant to expose. These are properties of the framework measured on data we generated. They are not evidence about any real portfolio.

The contribution is architectural: the integration of benchmark estimation, uncertainty-aware materiality, structured explainability, proportional routing, and portfolio monitoring into one governed object. The principal limitation is that the evidence is synthetic. The next step is validation on real loan-level pricing and reason-code data at an institution willing to measure classification stability and review outcomes over successive governance cycles.

Abstract
Remote sensing change detection (CD) has undergone a dramatic transformation over the past decade, evolving from classical pixel-difference methods to sophisticated deep learning architectures capable of semantic understanding. This study presents a comprehensive review of advances in remote sensing CD from 2020 to 2026, covering the full task taxonomy, Binary Change Detection (BCD), Multi-Class Change Detection (MCD), Semantic Change Detection (SCD), Change Captioning (CC), and Change Detection Data Synthesis (CDDS), as well as the architectural progression from CNN-based Siamese networks to Transformer and Mamba state space model frameworks. We further examine the frontier of next-generation AI perspectives, including Vision Foundation Models (SAM, CLIP, DINO), Vision-Language Models, and autonomous CD Agent systems that integrate large language models with visual encoders for reasoning-based geospatial change analysis. Representative benchmark datasets (LEVIR-CD, WHU-CD, SECOND, xBD, LEVIR-CC), evaluation metrics, and key open challenges, pseudo-changes, label scarcity, domain gap, and multi-class complexity, are systematically discussed. Finally, we highlight forward-looking developments around multimodal integration, data synthesis, and lightweight architectures for edge execution.

Keywords: Change Detection (CD), Remote Sensing, Deep Learning (DL), Earth Observation (EO), Satellite Imagery

I. INTRODUCTION

Remote sensing change detection (RSCD) is the foundational discipline for identifying and localizing physical changes on the Earth's surface by analyzing multi-temporal imagery acquired over the same geographic region at different times [1]. Mathematically, given a pair of co-registered images I_1 and I_2 taken at distinct time points $t_1 < t_2$, a CD algorithm generates a change map in which each spatial location is assigned a label ranging from binary indicators to sophisticated semantic characterizations [2]. As the frequency and resolution of satellite revisits continue to increase, driven by open-access programs like Copernicus and commercial constellations such as Maxar and Planet, the demand for automated, scalable, and semantically rich CD has transitioned from a research objective to an operational necessity for urban sprawl monitoring, disaster management, and environmental tracking [3]. Historically, the field emerged from visual aerial analysis and evolved into algorithmic approaches relying on pixel-level algebraic operations, such as image differencing, Change Vector Analysis (CVA), and Principal Component Analysis (PCA) [4]. Although these classical methods were interpretable and computationally efficient, they were fundamentally limited by handcrafted features that could not capture the complex spatial context needed to distinguish meaningful surface changes from environmental noise [5]. This groundbreaking shift toward deep learning, which gained momentum after 2015 with the emergence of Fully Convolutional Networks (FCNs) and Siamese architectures, ushered in a new era of performance innovation. These deep learning frameworks significantly elevated benchmark F1 scores by

learning hierarchical representations and establishing the dual-branch paradigm as the dominant approach in the field. As illustrated in Figure 1, the conceptualization of these methodologies is often categorized by their spatial granularity, where pixel-level analysis provides high-resolution precision for simple applications, while object-level approaches utilize texture and shape to enhance noise resistance; ultimately, scene-level methods offer a holistic view of macroscopic regional trends, ensuring scalability on a global scale. Since 2020, RSCD has entered an accelerating period of development, moving from convolutional maturity toward advanced Transformer architectures and the current frontier of Next AI [6].

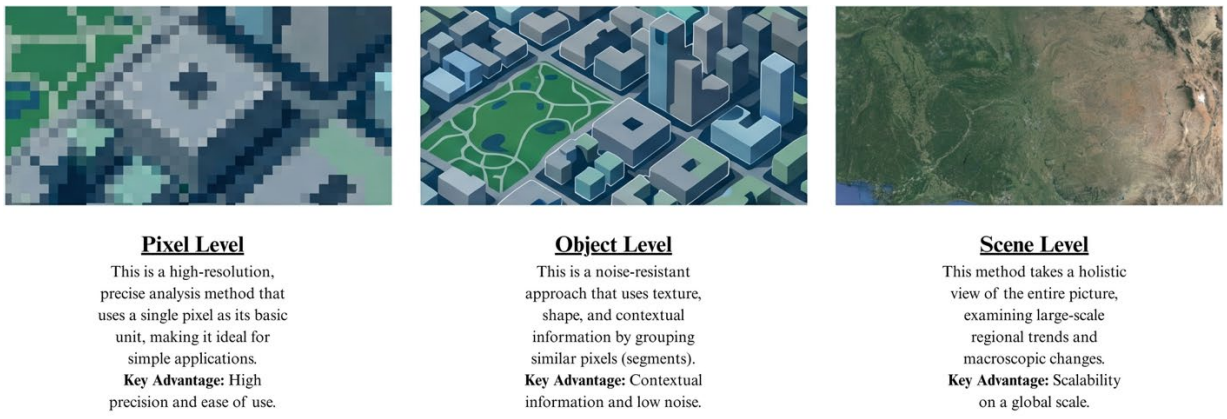

Figure 1. Classification of RSCD methodologies based on spatial granularity.

This study provides a comprehensive survey and synthesis of the field's evolution from 2020 to 2026, a timeframe marked by the release of the LEVIR-CD benchmark and the rise of high-performing Siamese models. We present a structured review of the full task taxonomy, including Binary, Multi-Class, Semantic, and Change Captioning, while positioning emerging paradigms such as Mamba state-space models, Vision Foundation Models like SAM and DINO, and autonomous CD Agent systems within a coherent framework. By cataloging major benchmark datasets and evaluating current performance standards, this work identifies persistent challenges such as pseudo-changes and domain gaps, ultimately outlining forward-looking research directions centered on multimodal integration and self-supervised learning for the next generation of intelligent Earth observation.

II. TASK TAXONOMY AND CONCEPTUAL FRAMEWORK

The organizational structure of modern Remote Sensing Change Detection (RSCD) has evolved into a multi-layered hierarchy that transcends simple pixel-wise comparisons [7]. To systematically evaluate the field's progress, CD tasks are organized along two orthogonal axes: the granularity of the output, ranging from pixel-level masks to high-level scene descriptions, and the semantic richness of the change representation, which dictates the level of categorical or linguistic detail provided [8]. As illustrated in Figure 2, the current research landscape is defined by how raw multi-temporal signals are transformed into actionable geospatial intelligence, categorized not only by the nature of the change output but also by the data source configurations. From the foundational classification of "change vs. no-change" to the generative synthesis of entirely new training samples, this taxonomy covers the field's primary dimensions.

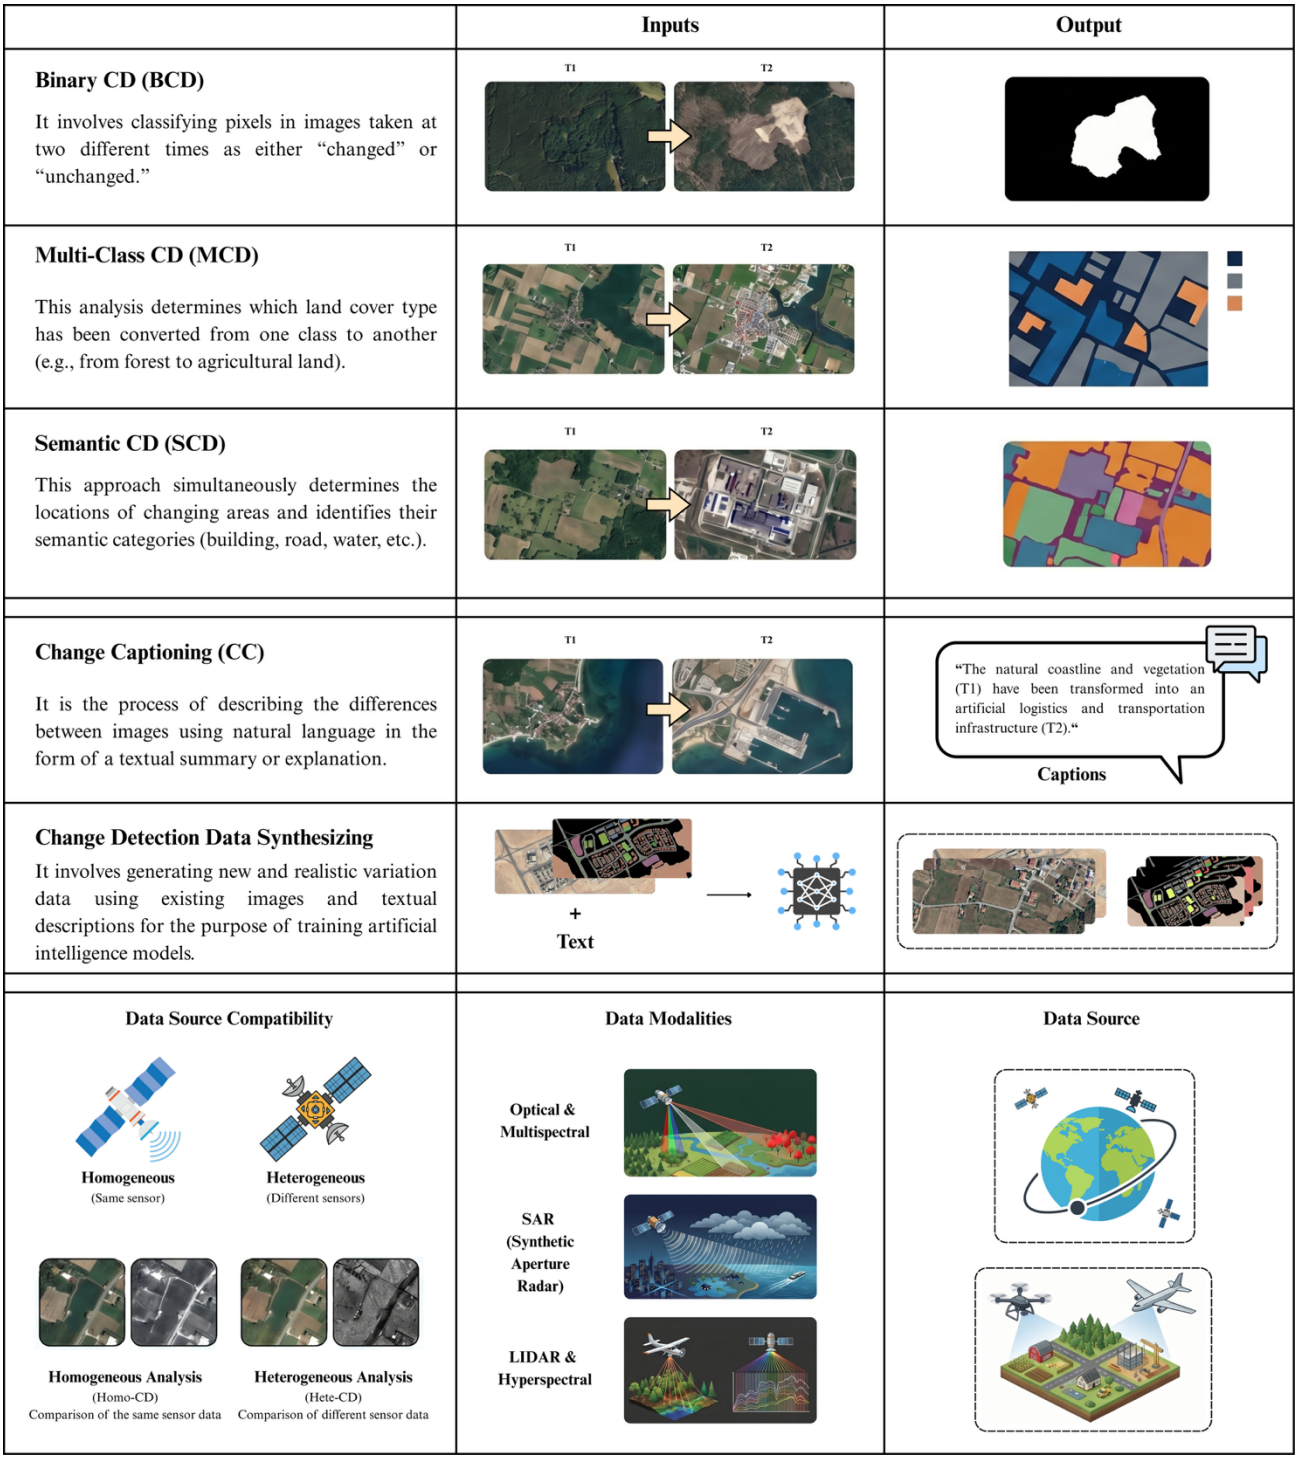

Figure 2. Comprehensive overview of the RSCD conceptual framework.

The contemporary landscape of Remote Sensing Change Detection (RSCD) is defined by a sophisticated task taxonomy that organizes methodologies along two primary axes: the granularity of the spatial output and the semantic richness of the change representation. At the foundational level, Binary Change Detection (BCD)

remains the most extensively researched area, focusing on producing a single-channel mask to distinguish "changed" from "unchanged" pixels [9]. While BCD provides the structural basis for specific applications, such as building footprint extraction or disaster localization, it faces the persistent challenge of filtering out pseudo-changes, such as seasonal vegetation cycles and illumination variations, that do not represent meaningful land-cover transitions. Dominant benchmarks such as LEVIR-CD and WHU-CD remain the gold standard for evaluating BCD performance in high-resolution environments [10]. Advancing beyond simple identification, Multi-Class Change Detection (MCD) categorizes detected differences into predefined semantic labels, such as urban expansion or water body gain [11]. This approach, exemplified by the xBD dataset for grading disaster damage, offers more actionable insights but introduces significant complexity due to inter-class confusion [12]. Taking semantic granularity to its peak, Semantic Change Detection (SCD), or "from-to" analysis to predict both pre-change and post-change land-use classes jointly [13]. This dual-labeling strategy enables comprehensive characterization of geographic transitions and effectively models the precise nature of Earth's surface evolution. The field has recently expanded into multimodal and generative frontiers to bridge the gap between raw data and human reasoning. Change Captioning (CC) leverages vision-language models to generate natural-language descriptions of observed dynamics, as demonstrated by the LEVIR-CC benchmark, transforming pixel-level detections into interpretable reports [14]. Simultaneously, Change Detection Data Synthesis (CDDS) addresses the chronic shortage of annotated samples by employing GANs and modern Diffusion Networks to generate photorealistic bi-temporal pairs with consistent labels [15]. These specialized tasks are further influenced by a diverse range of input modalities, from sub-meter VHR optical imagery and multispectral Sentinel data to all-weather Synthetic Aperture Radar (SAR), which collectively form a complex modality-task matrix that defines the current era of intelligent geospatial analysis.

III. EVOLUTION OF DEEP LEARNING ARCHITECTURES

The technological trajectory of Remote Sensing Change Detection has progressed through distinct stages of innovation, shifting from localized feature extraction to linear-complexity global modeling [16]. The foundations of modern deep learning in this domain were established through the Siamese network paradigm and U-Net variants between 2018 and 2021. By utilizing two weight-sharing branches to process bi-temporal images in parallel, researchers developed three canonical fusion strategies: early fusion (FC-EF), mid-fusion with feature concatenation (FC-Siam-conc), and mid-fusion with feature differencing (FC-Siam-diff) [17]. These architectures relied heavily on the U-Net's skip connections to preserve spatial detail in high-resolution scenes. A pivotal advancement during this era was the BIT model, which successfully bridged CNN feature extraction with Transformer-based context modeling. By using compact token representations to encode spatial-temporal dependencies, BIT achieved state-of-the-art results on the LEVIR-CD and WHU-CD benchmarks while maintaining manageable model complexity [18]. As the field moved into 2022 and 2023, the success of Vision Transformers (ViTs) led to a revolution in architectural design. Models such as ChangeFormer replaced traditional convolutions with a fully Transformer-based Siamese structure, utilizing hierarchical encoders and MLP decoders to demonstrate that long-range global context is superior for change boundary detection [19]. Other variations, such as SwinSUNet, integrated shifted-window self-attention into U-shaped architectures to enable more efficient multi-scale feature extraction, while TransUNetCD employed a hybrid CNN-Transformer encoder to reduce false alarms [20]. The current frontier, beginning in 2024, is defined by the emergence of Mamba and Structured State Space Models (SSMs). These architectures offer a compelling solution to the Transformer's limitations by providing linear computational complexity while preserving global modeling capacity. ChangeMamba represents the first systematic application of this technology to change detection, introducing specialized spatio-temporal mechanisms such as Serial, Parallel, and Cross-Temporal State Space learning [21]. Subsequent innovations, such as RS-Mamba, further refined this approach by introducing omnidirectional selective-scan strategies better suited to the nondirectional nature of remote sensing imagery [22]. Table 1 presents a curated selection of representative DL-based CD methods

organized by architectural family, highlighting key contributions, benchmark datasets evaluated, and publication year.

Table 1. Landmark studies in remote sensing change detection (2021–2026)

Reference & Year	Core Architecture	Task Type	Key Innovation / Contribution	Datasets Used	Performance Metric
SNUNet-CD (Fang et al., 2021/2022)	Densely Connected CNN	BCD	**Dense Feature Fusion:** Mitigates localization bias in deep layers, preserving fine-grained spatial details.	LEVIR-CD, WHU-CD, DSIFN-CD	WHU-CD F1: 91.59%
ChangeFormer (Bandara & Patel, 2022)	Pure Vision Transformer	BCD, MCD	**CNN-Free Design:** Eliminates convolutions, relying purely on hierarchical multi-scale self-attention.	LEVIR-CD+, WHU-CD, DSIFN-CD	LEVIR-CD+ F1: 94.15%
ChangeMask (Zheng et al., 2022)	Multi-Task Encoder-Decoder	SCD	**Temporal Symmetry:** Models semantic-change causal relationships through a temporally symmetric transformer.	SECOND	SECOND mIoU: 80.61%
ChangeCLIP (Dong et al., 2024)	Vision-Language Model (VLM)	BCD, Open-Vocabulary	**Cross-Modal Alignment:** Leverages text prompts for zero-shot detection, bypassing the need for costly pixel annotations.	LEVIR-CD, WHU-CD	SOTA in Zero-Shot / Prompting
ChangeMamba (Chen et al., 2024)	State Space Model (Mamba)	BCD, SCD	**Linear Complexity:** Breaks the quadratic computational bottleneck of Transformers via spatiotemporal state space.	LEVIR-CD+, WHU-CD, SECOND	WHU-CD F1: 95.71%
Change-Agent (Liu et al., 2024)	LLM-Driven Autonomous Agent	Interactive CD / CC	**Interactive Interpretation:** Fuses pixel features with LLM semantics for conversational reasoning and visual QA.	LEVIR-CC, Custom datasets	High Semantic Fidelity

Changen2 (Zheng et al., 2025)	Generative Foundation Model	CDDS (Data Synthesis)	**Solving Data Scarcity:** Synthesizes highly realistic bi-temporal images via diffusion to overcome annotation bottlenecks.	Synthetic LEVIR / WHU	Radical downstream F1 boost

*(**BCD** = Binary Change Detection, **MCD** = Multi-class Change Detection, **SCD** = Semantic Change Detection, **CC** = Change Captioning, **CDDS** = Change Detection Data Synthesis).*

IV. FROM UNIMODAL TO MULTIMODAL CHANGE DETECTION

Most early DL-based CD methods assumed co-registered optical image pairs from the same sensor. Real-world operational deployment, however, demands robust performance across heterogeneous data sources [23]. Synthetic Aperture Radar (SAR, e.g., Sentinel-1) is weather-independent and day/night-capable, making it invaluable for disaster response, where optical imagery is frequently cloud-contaminated [24]. However, SAR's coherent speckle noise and fundamentally different imaging physics, backscatter intensity versus spectral reflectance, make direct bi-temporal comparison nontrivial. Heterogeneous CD (HetCD) methods address this by aligning optical and SAR representations within a shared latent feature space before change analysis, often via domain adaptation or cross-modal attention [25]. Hyperspectral imagery (HSI) provides hundreds of narrow spectral bands, enabling fine-grained material discrimination but introducing the curse of dimensionality [26]. Recent approaches apply band selection and joint spectral-spatial frequency-domain attention to exploit hyperspectral richness while controlling computational cost.

V. BENCHMARK DATASET

Table 2 provides a comprehensive synthesis of the most widely adopted open-source change detection datasets, spanning a diverse range of task paradigms including Binary Change Detection (BCD), Multi-Class Change Detection (MCD), and Semantic Change Detection (SCD). By systematically detailing critical metadata such as spatial resolution, total number of image pairs, geographic distribution, and specific land-cover categories, this summary serves as a foundational reference for the research community. It is designed to facilitate rigorous, fair performance comparisons across varying architectural frameworks and to promote further methodological developments. Furthermore, the inclusion of specialized benchmarks for disaster assessment and urban evolution enables researchers to select the most appropriate data environments to test the robustness and generalizability of "Next AI" models, such as Mamba-based and Foundation-driven systems, in real-world geospatial scenarios [27].

Table 2. Summary of Representative Remote Sensing Change Detection Datasets

Dataset	Year	Task	GSD	Size	Patch Size	Description
LEVIR-CD	2020	BCD	0.5 m	637 pairs	1024×1024	High-resolution Google Earth images from Texas, USA, focusing on building growth and decline.
WHU-CD	2018	BCD	0.2–0.3 m	1 pair (32,507×15,354)	256×256	Aerial images of Christchurch, New

						Zealand, capturing building changes after a 6.3-magnitude earthquake.
xBD	2019	MCD / BDA	0.3–0.8 m	22,068 images	1024×1024	Global disaster dataset assessing building damage across four severity levels for various natural disasters.
SECOND	2021	SCD	0.5–3 m	4,662 pairs	512×512	Aerial images from Chinese cities annotating 6 land-cover classes and 30 semantic change transitions.
CDD	2018	BCD	0.03–1 m	16,000 patches	256×256	Google Earth images capture seasonal variations in natural and artificial features, such as snow and leaves.
HRSCD	2019	SCD	0.5 m	291 pairs (10k×10k)	Various	Large-scale RGB aerial images from France, annotating 5 land-cover classes for pixel-level semantic changes.
LEVIR-CC	2022	CC (Captioning)	0.5 m	10,077 pairs	256×256	Image pairs, each with 5 natural language descriptions, covering various urban and geographical changes.
MineNetCD	2025	BCD	1.2 m	~70,000 patches	256×256	Comprehensive global dataset featuring high-resolution images from 100 open-pit mining sites across six continents.

*(**BCD** = Binary Change Detection, **MCD** = Multi-class Change Detection, **SCD** = Semantic Change Detection, **BDA** = Building Damage Assessment, **CC** = Change Captioning.)*

VI. NEXT AI PERSPECTIVES

The most transformative development in post-2022 remote sensing CD is the integration of large-scale pre-trained foundation models. These models, trained on billions of images or image-text pairs, exhibit remarkable zero-shot and few-shot generalization, directly addressing the perennial data scarcity problem in CD.

1. Vision Foundation Models: SAM, CLIP, and DINO

Meta AI's Segment Anything Model (SAM) demonstrated unprecedented zero-shot segmentation capability via a promptable architecture [28]. SAM-CD adapted SAM for remote sensing CD by injecting temporal-difference features into SAM's prompt encoder and adding lightweight change-specific adapters, transforming

a general segmentation model into a change-aware detector without full retraining [29]. ChangeCLIP [30] leveraged CLIP's contrastive language-image pre-training by formulating CD as a visual-semantic matching task: change regions are identified by measuring cosine similarity between bi-temporal image embeddings and text prompts describing change semantics. DINO-based self-supervised visual features have been employed to improve representation quality in low-label regimes [31].

2. Vision-Language Models and LLMs

The fusion of vision encoders with Large Language Models (LLMs) has opened an entirely new dimension for CD. Remote Sensing Visual Question Answering (RSVQA) frameworks enable analysts to query change maps via natural-language dialogue. RS-LLaVA [32] fine-tuned the LLaVA multimodal architecture on remote-sensing instruction-following datasets, enabling dialogue such as 'How many new structures appeared in the industrial zone after the flood?' The LEVIR-CC Change Captioning benchmark [33] specifically evaluates this paradigm, requiring models to produce descriptive sentences rather than binary masks, a fundamentally different evaluation philosophy that aligns model outputs with human analytical workflows.

3. Change Detection Agents

The most frontier concept is the emergence of autonomous CD Agent systems [34]. Rather than passive detectors, these systems combine LLM-based reasoning engines with visual encoders and external tool APIs to execute multi-step analytical workflows: automatically selecting relevant time-step pairs, choosing appropriate detection sub-models, performing spatial reasoning over change maps, cross-referencing with auxiliary geospatial databases, and producing structured decision reports [35]. Such agentic pipelines draw on frameworks such as Toolformer [36] and represent a paradigm shift from task-specific models toward general-purpose remote sensing intelligence systems capable of dynamic planning and causal inference.

VII. CHALLENGES AND FUTURE RESEARCH DIRECTIONS

The field of Remote Sensing Change Detection (RSCD) faces enduring obstacles, primarily driven by pixel-level pseudo-changes caused by seasonal vegetation shifts, illumination variations, and cloud shadows that mimic real land-cover conversions [37]. This issue is exacerbated by severe domain gaps, causing models optimized for distinct sensors or geographic zones to undergo substantial performance decay when deployed in unseen environments. Compounding these technical challenges are chronic data scarcity and critical class imbalances, as high-fidelity, dual-temporal annotations demand intensive human expert labor. At the same time, true change events comprise only a nominal fraction of geographic scenes [38]. To circumvent these limitations, the research community is pivoting toward self-supervised and weakly supervised paradigms, leveraging techniques such as masked autoencoders to extract robust representations from vast unlabeled satellite repositories. In tandem, controllable generative data synthesis via advanced Diffusion Models is emerging as a means to artificially engineer photorealistic multi-temporal image pairs, thereby alleviating label bottlenecks and addressing scarce training scenarios [39]. Concurrently, the transition to complex multi-class and semantic change detection tasks calls for advanced multi-task learning frameworks capable of parsing intricate, visually synchronous land transitions. To bridge the gap toward practical deployment, considerable efforts are also devoted to compressing deep models through knowledge distillation and quantization for edge-hardware execution on resource-constrained UAVs and nanosatellites [40]. Ultimately, the overarching frontier in Earth observation lies in fusing these sensor models with Large Language Models to establish multimodal autonomous agents that can dynamically integrate ancillary geospatial layers and deliver complete, reasoning-based decision reports.

VIII. CONCLUSION

This comprehensive survey traces the architectural trajectory of deep learning-based remote sensing change detection from 2020 to 2026, illustrating how the paradigm shifted from CNN-based Siamese networks to Transformers and linear-complexity Mamba architectures. Beyond structural evolution, the work systematically categorizes a multi-tiered task taxonomy that encompasses binary, multi-class, semantic, captioning, and generative synthesis dimensions. It evaluates eleven pivotal benchmark datasets and representative methodologies. It highlights four critical frontiers for ongoing methodological refinement, specifically targeting the persistent bottlenecks of pseudo-changes, labeling constraints, domain gaps, and complex semantic transitions. Furthermore, the analysis emphasizes how the integration of Vision Foundation Models, Vision-Language frameworks, and autonomous agentic systems is fundamentally repositioning change detection as a core pillar of generalized geospatial intelligence. Ultimately, the study underscores a vital imperative for the research community to navigate this technological transition without compromising domain-specific operational rigor, emphasizing the critical need for sensor-agnostic robustness, calibrated uncertainty estimation, and highly interpretable analytical outputs.

Abstract
Mobile Edge Computing (MEC) mitigates the limitations of cloud-centric architectures for Internet of Things (IoT) devices by bringing processing closer to the data source. However, jointly optimizing task offloading and resource allocation in SDN-enabled MEC remains a challenging multi-objective problem due to conflicting delay and energy objectives. This paper formulates the problem as a constrained multi-objective optimization model. It proposes three hybrid swarm-based approaches that integrate Particle Swarm Optimization (PSO) with the Whale Optimization Algorithm (WOA), Cuckoo Search (CS), and the Grey Wolf Optimizer (GWO). When evaluated using Pareto-based metrics (Hyper-volume, Spread, and Execution Time), the hybrid approaches achieved competitive overall performance compared with standalone algorithms in convergence quality, diversity preservation, and computational efficiency. Specifically, MOPSO_WOA and MOPSO_GWO achieved improved energy-delay trade-offs with reduced execution times, demonstrating their efficacy for real-time SDN-enabled MEC optimization.

Keywords: Mobile Edge Computing, Energy-Delay Trade-off, Pareto Multi-Objective Optimization, Task Offloading, Internet of Things

I. INTRODUCTION

The Internet of Things (IoT) network generally consists of a large number of latency-sensitive and energy-constrained devices. Mobile Edge Computing (MEC) alleviates the burden on centralized cloud infrastructures by enabling computationally intensive tasks to be offloaded from these devices to nearby edge servers [1]. To manage the dynamic and heterogeneous nature of these environments, MEC is paired with Software-Defined Networking (SDN) [2-4]. In this architecture, an SDN controller leverages global network intelligence to orchestrate computation offloading and resource allocation [5]. However, despite the benefits of SDN-enabled MEC, jointly optimizing task offloading and resource allocation remains a challenging multi-objective optimization (MOO) problem due to the conflicting nature of delay and energy consumption. Offloading all tasks to MEC servers and computing locally are both extreme cases in the decision space. Both mechanisms improve in one aspect while failing in the other. Yet, most IoT applications are constrained by both delay and energy [6]. Solving this MOO problem effectively is crucial to realizing the full potential of MEC. While traditional optimization techniques often struggle to capture the complexity of such environments, especially under real-time constraints, swarm-based algorithms have been adapted to address this challenge because they can navigate NP-hard solution spaces without gradient information [7]. Early efforts utilized weighted-sum methods such as Genetic Algorithms (GA) [8], [9], PSO [10-12], Cuckoo Search (CS) [13], Artificial Bee Colony [14], [15], GWO [16], and WOA [17-19]. However, this approach requires pre-set weights and risks overlooking optimal trade-off solutions. Consequently, Pareto-based MOO algorithms have gained significant

attention for solving multi-objective task offloading problems in MEC because they can simultaneously optimize multiple solutions, reducing the risk of falling into local optima. NSGA-II is a frequent choice for optimizing energy and delay [20-23]. Recent advancements include MOWOA [24] and MOGWO [25] for collaborative edge offloading, as well as MOPSO [26], MOEA [27], and PAES [28]. While these standalone studies demonstrate the strength of evolutionary algorithms in MEC, there remains a need to improve convergence speed, solution diversity, and dynamic adaptability. Thus, striking the right balance between exploration and exploitation is the most challenging task in developing any evolutionary or swarm-based algorithm. Unlike conventional sequential hybridization strategies, in this study, we introduce three hybrid multi-objective approaches, MOPSO_WOA, MOPSO_CS, and MOPSO_GWO, which integrate PSO velocity-driven exploitation with complementary position-update mechanisms from WOA, CS, and GWO inside a unified Pareto optimization framework, along with dynamic parameter tuning for adaptive search behavior. The goal is to improve convergence quality, enhance solution diversity, and effectively balance exploration and exploitation in the search space. The primary contributions of this paper are:

- Formulation of a centralized, SDN-enabled MEC task offloading and resource allocation framework as a constrained MOO problem targeting energy and delay minimization.
- Development of three hybrid swarm-intelligence algorithms incorporating dynamic parameter tuning to enhance convergence speed and solution diversity.
- Rigorous Pareto-based evaluation demonstrating competitive Hyper-volume, Spread, and superior computational efficiency of the hybrid models compared with standalone counterparts.

The rest of the paper is organized as follows: Section 2 details the system model and problem formulation. Section 3 presents the proposed algorithms. Section 4 discusses the evaluation results, and Section 5 concludes the paper.

II. SYSTEM MODEL AND PROBLEM FORMULATION

1. System Model and Communication

We consider an MEC environment comprising a set of IoT devices randomly deployed and connected to edge servers via a base station (BS). The BS hosts an SDN controller that orchestrates task offloading and resource allocation decisions by generating and distributing offloading strategies to IoT devices [29]. Each user generates a computational task *Qi = (Di, Ci, T_i, max)* representing data size, required CPU cycles, and delay tolerance. The decision variables are the offloading proportion vector $\alpha = (\alpha_1, \dots, \alpha_N)$, where $\alpha_i \in [0,1]$, and the server allocation vector $\beta = (\beta_1, \dots, \beta_N)$, indicating the selected edge server (or "0" for local execution).

The model assumes shared-spectrum uplink communication with simultaneous transmissions. Thus, the uplink data rate for device U_i, over a bandwidth *B,* is modeled by the Shannon-Hartley theorem [27]:

$$R_i = B\ log_2\left(1 + \frac{h_i p_i}{\sigma^2 + \sum_{j=1, j\neq i}^{N} h_j p_j}\right) \quad (1)$$

Where p_i is the transmission power, h_i is the channel gain, σ^2 is the channel noise, aand the ter toplam alt limit j eşittir 1d the ter $\sum_{j=1, j\neq i}^{N} h_j p_j$ represents the effects from other IoT devices.

2. Computation Model

The total energy and delay for each task are computed for both local and remote execution, accounting for transmission and execution.

For device U_i with computational capacity f_i and capacitance coefficient κ^{user}, the local execution time and the energy consumption are given as:

$$T_i^{local} = \frac{C_i}{f_i} \tag{2}$$

$$E_i^{local} = \kappa^{user} (f_i)^2 C_i \tag{3}$$

In remote execution, the orchestrator (SDN controller) is responsible for selecting the appropriate server for task execution. This process is divided into three stages:

- Transmitting the task input data from the device to the BS. The corresponding formulas are given as follows:

$$T_i^{Trans} = \frac{D_i}{R_i} \tag{4}$$

$$E_i^{Trans} = p_i T_i^{Trans} = \frac{p_i D_i}{R_i} \tag{5}$$

- The execution of task Q_i in edge servers, with the corresponding time calculated as follows:

$$T_i^{R-exe} = \frac{C_i}{f_{\beta_i}^{serv}} \tag{6}$$

Here, $f_{\beta_i}^{serv}$ represents the capacity of the selected MEC server β_i computing resources allocated to each user. The energy consumed by the server is not included in our objective function, as we focus on user-side energy.

- Downloading the results from the edge server to the device is considered negligible due to the small output size compared to the input data typical of many IoT monitoring and analysis tasks [7]. This assumption is suitable for monitoring, sensing, and inference applications where the output size is significantly smaller than the input size.

The total response time and energy consumption are given by:

$$T^{total} = \sum_{i=1}^{N} \left[(1 - \alpha_i) T_i^{local} + \alpha_i (T_i^{Trans} + T_i^{R-exe}) \right] \tag{7}$$

$$E^{total} = \sum_{i=1}^{N} \left[(1 - \alpha_i) E_i^{local} + \alpha_i (E_i^{Trans}) \right] \tag{8}$$

3. Optimization Problem

The objective is to find the Pareto optimal set for α and β that simultaneously minimizes total energy consumption and execution delay:

$$\underset{(\alpha,\beta)}{MIN}(\, E^{total}, T^{total}) \tag{9}$$

Subject to:

- Valid offloading decision: $\alpha_i \in [0,1], \forall i \in (1,\dots,N)$
- Valid server selection: $\beta_i \in \{0,1,\dots,M\}, \forall i \in (1,\dots,N)$
- Edge capacity limits: $\sum_{i=1}^{N}\left[\, \delta_{j,\beta_i}\alpha_i\, f_{\beta_i}^{serv}\right] \le\ f_{max}^{serv}, \forall j \in (1,\dots,M)$
- Device capacity: $f_i > 0\ , \forall i \in (1,\dots,N)$
- Strict delay constraints: $\left[(1-\alpha_i)T_i^{local} +\ \alpha_i\left(T_i^{Trans} +\ T_i^{Edge}\right)\right] \le\ T_i^{max}, \forall i \in (1,\dots,N)$

Where: deltaalt j ,beta alt i. δ_{j,β_i} is the Kronecker delta function, which is equal to 1 if $j = \beta_i$ (indicating task Q_i is assigned to server j), and 0 otherwise. This problem is proven to be NP-hard due to its combinatorial nature and interdependent constraints [5], motivating the use of hybrid evolutionary algorithms [30].

III. Proposed Task Offloading and Resource Allocation Algorithms

To address the multi-objective problem, we propose integrating PSO with WOA, CS, and GWO. PSO enhances global search ability through velocity-based updates, WOA achieves faster convergence via spiral mechanisms, CS allows occasional high jumps to improve exploration, and GWO extends the search space using social hierarchy and hunting agents. In addition, dynamic parameter tuning is employed to enhance exploitation capability. The algorithmic workflow proceeds iteratively through the following steps.

- **Initialization and Solution Representation.** The process begins by initializing a population of $nPop$ particles and velocities. Each particle X_i c, consists of a continuous component, büyük harf X alt i. . alfa, representing offloading decisions, and a discrete component, büyük harf X alt i. . beta, representing server assignments.
- **Velocity Update.** Each particle's velocity is adjusted by considering the three main PSO components [31]: the influence of its previous velocity($i.$), its personal ebesposition ($pBest_i$), and the global best position ($gBest$). This is expressed as:

$$V_i(t+1) = w.V_i(t) +\ c_1.r_1.(pBest_i - X_i(t)\,) +\ c_2.r_2.(gBest - X_i(t)\,) \tag{10}$$

Where: w is the inertia weight, c_1 is the cognitive factor, c_2 is the social factor, and both (r_1, r_2) are random numbers in $[0,1]$ to introduce stochastic behavior.

- **Position Updates via Hybridization.** The particle's position is then updated using one of the following algorithms:

1- *WOA-inspired (MOPSO_WOA):* Uses a random variable $r \in [0,1]$. If $r\ <\ 0.5$, a shrinking encircling mechanism is applied to intensify exploitation around the current best solution. Otherwise, a spiral updating

mechanism is employed to enhance exploration around the search space. The threshold value 0.5 ensures an equal probability between exploitation and exploration phases, providing a balanced search behavior [32].

2- *CS-inspired (MOPSO_CS):* Applies a Lévy flight perturbation to the continuous component α:

$$\alpha_i^{new} = clip(\alpha_i + Levy(\gamma), 0, 1) \quad (11)$$

For the discrete component, random reassignment is utilized.

3- *GWO-inspired (MOPSO_GWO):* The particle position is updated according to the social hierarchy of the three best candidate solutions (Alpha, Beta, and Delta wolves), enabling cooperative guidance toward promising regions of the search space [16].

Next, the updated velocity is applied to further refine the particle's position:

$$X_i(t+1) = X_i(t) + V_i(t+1) \quad (12)$$

- **Dynamic Parameter Tuning.** To avoid static behavior across generations, key PSO parameters are adapted dynamically over the iterations. The inertia weight w decreases to shift the search from exploration to exploitation, while $cc1\ decreases\ and\ c2\ increases\ with\ similar\ linear\ adaptation\ to\ shift\ the$ cus toward global learning.

$$w(t) = w_{max} - \frac{t}{T}(w_{max} - w_{min}) \quad (13)$$

- **Fitness Evaluation and Repository Update.** During every iteration, the fitness of each new particle is evaluated based on the two objectives (Energy and Delay). Non-dominated solutions are stored in a Pareto-optimal repository and pruned using a crowding-distance criterion to maintain diversity.

The computational complexity of the proposed hybrid algorithms is mainly dominated by particle evaluation, Pareto-repository maintenance, and position-update operations, resulting in an approximate complexity of $O(T \times nPop \times N)$where T is the number of iterations and N the number of tasks.

IV. SIMULATION RESULTS

1. Simulation Setup

The simulation considers a scenario with 3 edge servers and 30 IoT users, which represents a moderate-load SDN-enabled MEC scenario frequently adopted in the literature. Task arrivals are assumed to be static during the optimization process, a common assumption in MEC offloading studies that evaluates optimization performance under a fixed workload. Each user generates a single independent task with inpusize $D_i \in [0, 1]MB$ and requiring $C_i \in [0.2, 1.2]GHz$ of CPU cycles to complete. The maximum tolerable delay (T_i^{max}) per task lies between 1 and 5 seconds. The local computing capacity f_i of each IoT device is set as $f_i \in [0.2, 1.0]$GHz, and the effective capacitance constant for user devices (κ^{user}) is fixed at 5 $\times 10^{-27}$. The wireless communication model uses a bandwidth of B= 50 MHz, user transmission power P_i $\in$ [0, 1] mW, and Gaussian noise power σ ^2 set to 110^-10. Regarding edge servers, each user is allocated a computational load between

5 and 8 GHz (f alt sol parantez beta alt i. sağ parantez üssü s e r v). In contrast, themaximum server capacity is capped at 35 GHz (f_{max}^{serv}). The parameter settings were chosen based on commonly adopted configurations in recent MEC task-offloading studies [33], thereby ensuring heterogeneous workloads and realistic resource constraints.

2. Multi-objective Performance Comparison

The proposed algorithms are compared with three baseline-offloading schemes widely used in academia [34], [35] (all local execution, all offloaded tasks, and random offloading), as well as several well-known swarm-based multi-objective approaches, including MOWOA [24], MOPSO [12], MOGWO [25], and MOCS [13]. Direct numerical comparison with these studies is difficult because they employ different MEC scenarios, task models, and parameter settings. Therefore, we compare against re-implemented baseline algorithms under identical conditions (population sizes, iteration limits, and stopping criteria), ensuring a fair evaluation. The performance analysis focuses on widely used MOO metrics, namely Hyper-volume [24], Spread [36], [37], and Execution Time. All reported results correspond to averages over 20 independent runs to reduce stochastic effects and improve statistical reliability. Figure 1 illustrates the Pareto fronts generated by each algorithm, while Table 1 summarizes the average metric values obtained. The average rank is computed by independently ranking each metric and averaging the resulting ranks.

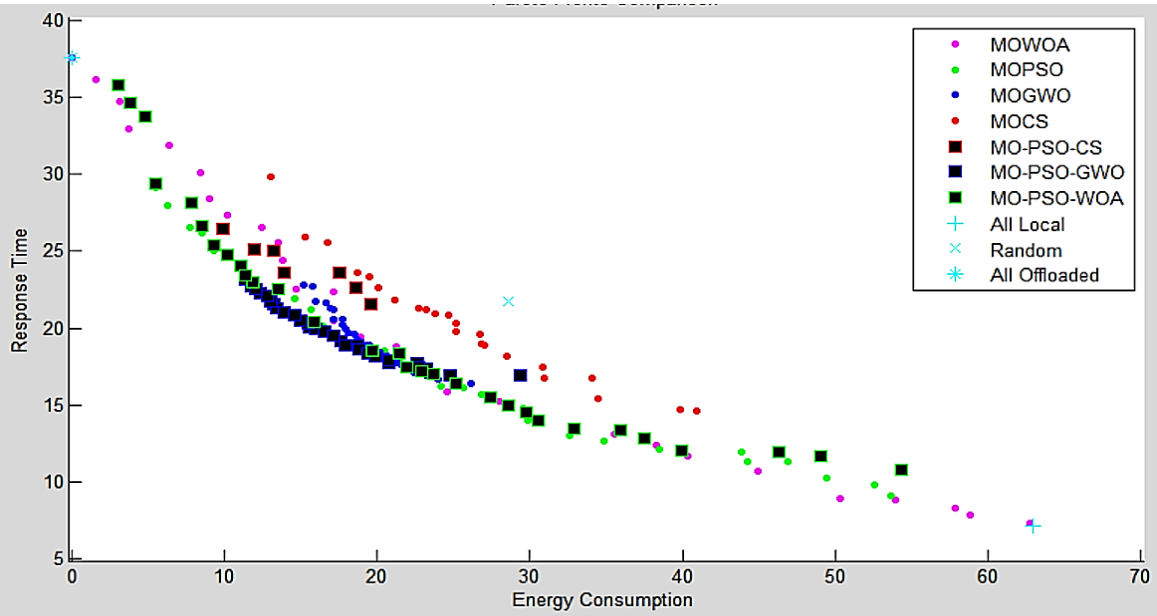

Figure 1. Pareto Fronts Visualization of Each Algorithm

Table 1. Average Performance Metrics across 20 Runs

Algorithm	Hyper-volume ↑	Spread ↓	Execution Time (s) ↓	Average Rank
MOPSO	**1709.64**	0.77	6.69	**2.67**
MOPSO_WOA	1684.28	0.80	3.84	**2.67**
MOPSO_GWO	1482.90	0.88	3.25	3.33
MOWOA	1658.26	**0.71**	11.25	3.67
MOPSO_CS	1133.58	1.01	**2.89**	5.00

MOCS	1342.92	0.91	4.54	5.00
MOGWO	1381.18	0.93	7.42	5.67

The proposed hybrid approaches effectively address the trade-off between energy consumption and delay.

- *Hyper-volume (HV):* While MOPSO achieved the highest raw HV, MOPSO_WOA proved highly competitive (1684.28). MOPSO_WOA and MOPSO_GWO consistently outperformed their standalone variants, indicating that PSO integration successfully limits the aggressive, destabilizing exploration seen in pure WOA and GWO. MOPSO_CS struggled with HV precision due to the large leaps inherent to Lévy flights. Figure 2 shows the HV distribution (average and standard deviation) across algorithms.

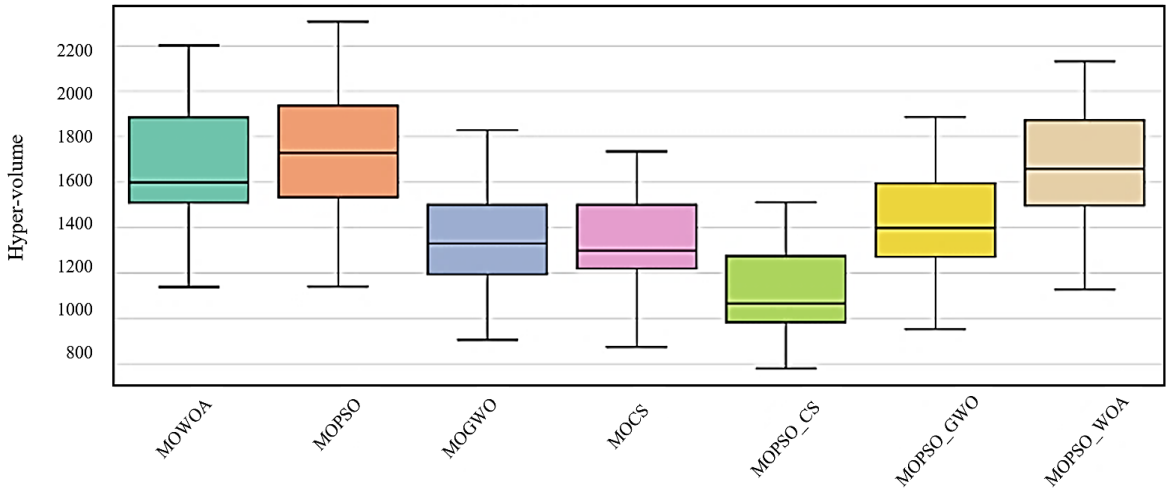

Figure 2. Hyper-volume Distribution across Algorithms

- *Spread (Δ):* MOWOA yielded the best uniformity, but at a massive computational cost. MOPSO_WOA successfully preserved this diversity (0.80) while mitigating the computational overhead. Conversely, MOPSO_CS yielded lower spread values because Lévy-flight perturbations prioritize exploration over Pareto-front regularity. Figure 3 shows the metric distribution across algorithms.

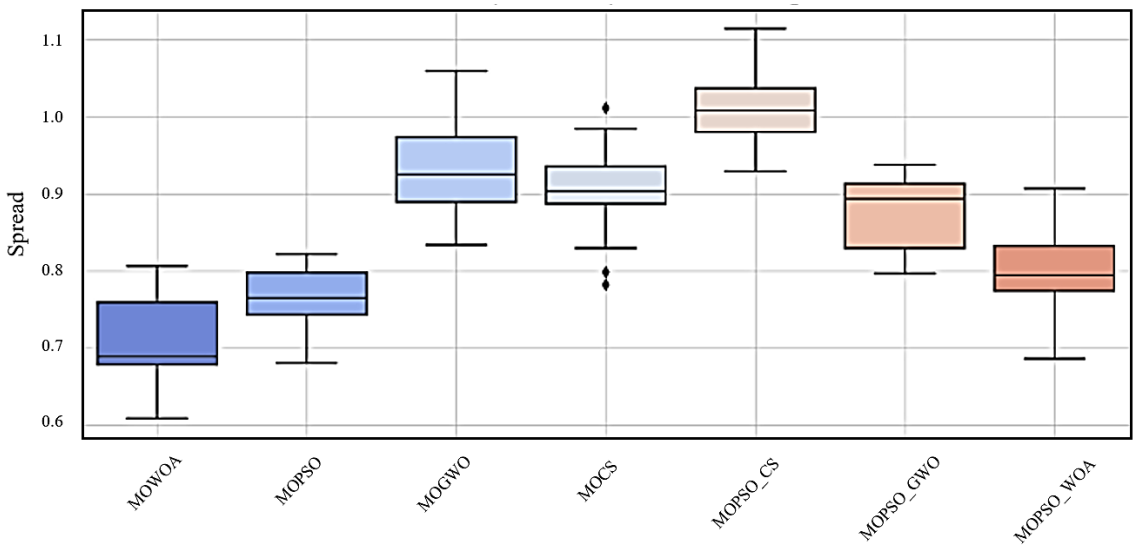

Figure 3. Spread Distribution across Algorithms

- *Execution Time:* This is where the hybrids excel. MOPSO_WOA reduced execution time by roughly 65% compared to MOWOA, converging in just 3.84 seconds. MOPSO_GWO also showed computational economy (3.25s). This confirms that hybridization and dynamic tuning guide the search space efficiently without introducing excessive computational overhead. Figure 4 shows the distribution of this metric across algorithms.

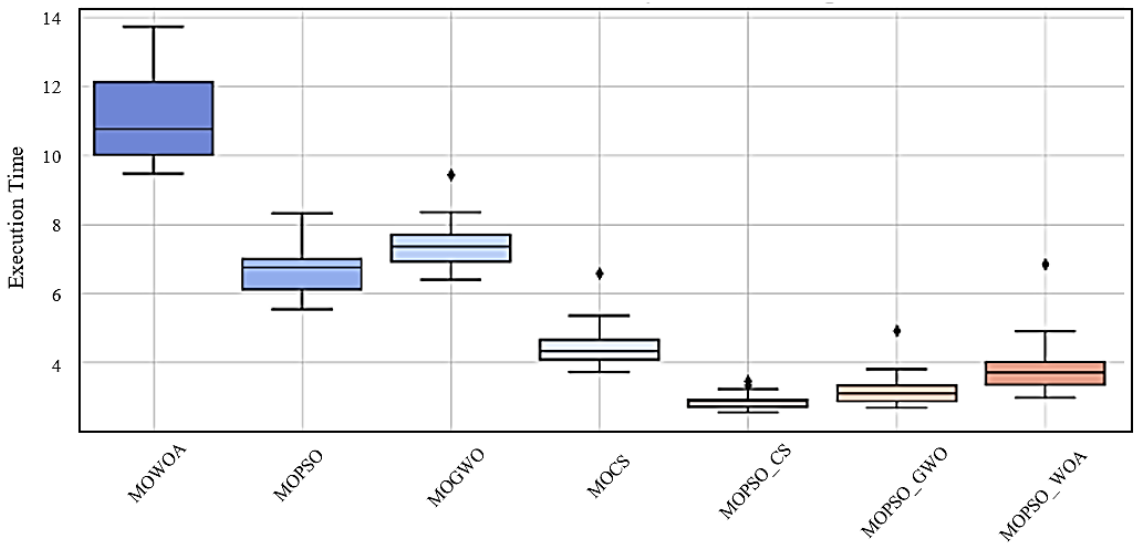

Figure 4. Execution Time Distribution across Algorithms

In summary, the experimental results reveal that no single algorithm dominates all evaluation metrics simultaneously, highlighting the inherent trade-offs between convergence quality, diversity preservation, and computational efficiency in MOO. While MOPSO achieved the highest HV values, the proposed hybrid approaches demonstrated superior balance across all metrics. In particular:

- MOPSO_WOA achieved competitive HV performance while significantly reducing execution time compared to both MOPSO and MOWOA. Although MOPSO and MOPSO_WOA achieved the same average rank (2.67), MOPSO_WOA did so with a substantially lower execution time (3.84 s versus 6.69 s), making it more attractive for latency-sensitive MEC environments.
- MOPSO_GWO provided strong compromise solutions with good convergence behavior and stable computational performance.
- MOPSO_CS prioritized exploration efficiency and execution speed, although at the expense of Pareto-front uniformity.

The obtained results are consistent with recent studies, such as [26], which report that hybridization improves the exploration-exploitation balance by combining complementary search behaviors from multiple swarm intelligence techniques. Consequently, the proposed hybrid methods are better suited for practical SDN-enabled MEC environments where both optimization quality and computational responsiveness are essential.

V. CONCLUSION

This paper introduced three multi-objective hybrid evolutionary algorithms (MOPSO_WOA, MOPSO_CS, and MOPSO_GWO) to optimize the energy-delay trade-off in SDN-enabled MEC environments. By integrating the strengths of PSO with specialized swarm mechanisms, the algorithms effectively balanced exploration and exploitation. Numerical results demonstrated that MOPSO_WOA and MOPSO_GWO provided a favorable compromise between high-quality Pareto convergence, solution diversity, and real-time computational responsiveness. In particular, MOPSO_WOA achieved performance comparable to MOPSO while reducing execution time by more than 40%, making it suitable for latency-sensitive MEC scenarios. Although the evaluation was conducted on a moderate-scale MEC scenario, the proposed framework is independent of network size and can be extended to larger deployments. Future work will investigate scalability under larger MEC infrastructures and physical SDN testbeds, incorporate statistical significance analysis, consider multimedia-oriented applications where downlink transmission may become significant, and compare the proposed swarm-based approaches with recent DRL-based offloading frameworks.

Abstract
Breast cancer remains a leading global health challenge, with early and accurate detection being critical for reducing mortality. While deep learning models, particularly the YOLO (You Only Look Once) architecture, have shown significant potential in assisting radiologists, their performance often degrades when applied to high-resolution mammography. The primary obstacles include the extremely small relative size of lesions, low contrast, and extreme background dominance, which often lead to target "disappearance" during standard image down-sampling. To address these challenges, this study develops a YOLO-based object detection framework integrated with a tiling (patch-based) preprocessing strategy. By subdividing high-resolution mammograms into smaller overlapping tiles, the proposed approach effectively enlarges the scale of malignant lesions relative to the input window and significantly expands the training dataset. This study proposes a YOLO-based framework for detecting malignant lesions in mammography using a patch-based tiling strategy. High-resolution mammograms are divided into overlapping image patches, increasing the visibility of small pathological regions and improving lesion detection performance.

Keywords: Breast Cancer Detection, YOLO Architecture, Mammography, Tiling, Patch-based Training, Small Object Detection

I. INTRODUCTION

Breast cancer remains a major global health challenge. In 2022 alone, it was responsible for an estimated 670,000 deaths worldwide and affected roughly 2.3 million women, making it the most common cancer among women in 157 of the 185 countries surveyed. The disease knows no borders—it occurs in every country and spans all ages after puberty, with incidence rising sharply in later life. While about half of all cases arise in women who have no identifiable risk factors beyond gender and age, a small but noteworthy proportion (0.5–1 %) also develops in men. The burden of breast cancer is unevenly distributed. In nations with very high Human Development Index (HDI) scores, roughly 1 in 12 women will be diagnosed with breast cancer during her lifetime, and 1 in 71 will die from it. By contrast, in low HDI countries, the lifetime risk of diagnosis drops to 1 in 27, yet mortality rises to 1 in 48, underscoring stark inequities in access to early detection and effective treatment [1]. Early and timely diagnosis, coupled with comprehensive treatment, rehabilitation, and palliative care, is essential to curb this burden and preserve patients' functional well-being. When identified at an early stage—often through routine screening mammography or prompt clinical evaluation of symptoms—breast cancer can be treated effectively with surgery, radiation, and systemic therapies tailored to the tumor's biological subtype. Conversely, delayed diagnosis allows tumors to progress from an in situ (non-life-threatening) state to invasive disease that can metastasize to lymph nodes and distant organs, dramatically reducing survival prospects. Against this backdrop, the present article examines current advances in breast cancer detection and diagnosis, emphasizing the pivotal role of mammographic imaging and emerging artificial intelligence-driven

tools in improving early-stage identification, guiding treatment decisions, and ultimately reducing mortality worldwide [1]. Recent advances in artificial intelligence and deep learning have demonstrated strong potential for assisting radiologists in mammographic image analysis. In particular, convolutional neural networks (CNNs) have shown promising performance in tasks such as lesion classification, segmentation, and object detection. Among these approaches, object detection models aim not only to classify abnormalities but also to localize suspicious regions, which is critical for clinical interpretability and decision support. Nevertheless, the direct application of object detection models to full-resolution mammography images remains challenging due to the extremely large image sizes, severe class imbalance, and the very small relative size of malignant lesions compared to the background tissue [2]. State-of-the-art one-stage detectors, such as YOLO-based architectures, are designed for real-time object detection and have achieved remarkable success in natural image analysis. However, their performance typically degrades when applied to medical images containing small objects embedded in complex backgrounds. In mammography, lesions often occupy less than one percent of the total image area, making them difficult to detect without specialized preprocessing strategies [3]. Although one-stage object detectors such as YOLO have demonstrated strong performance in real-time object detection tasks, their effectiveness in mammography remains limited due to the extremely small size of pathological findings relative to the full image resolution. Mammographic lesions are often characterized by subtle appearance, low contrast boundaries, and complex surrounding tissue structures, making accurate localization particularly challenging in dense breast images [4]. In addition, mammography images typically have ultra-high spatial resolution, whereas standard deep learning pipelines require aggressive image downsampling due to computational constraints. As a result, diagnostically important fine-grained features may become indistinguishable or disappear entirely during resizing, leading to reduced sensitivity for very small lesion detection [5]. The main contribution of this work lies in the application and evaluation of a practical patch-based YOLO detection pipeline for small-object detection in mammography. The study further provides a comparative analysis of model performance before and after tiling preprocessing. It examines the impact of patch-based training on the detection of malignant lesions in dense, high-resolution breast images.

This study aims to evaluate whether a patch-based preprocessing strategy can improve the detection performance of YOLO models for malignant lesion localization in mammography images.

II. RELATED WORK

AI has significantly transformed breast cancer diagnostics, providing robust tools for the automated analysis of mammograms, ultrasounds, and histopathology images. Within this domain, the You Only Look Once (YOLO) family of models has gained substantial traction due to its optimal balance of speed and accuracy. Mohammed and Ekmekci [6] introduced a YOLO-based multiscale parallel CNN to enhance the differentiation of malignant features. At the same time, Prinzi, Insalaco, Orlando, Gaglio, and Vitabile [7] demonstrated the efficacy of YOLO architectures specifically for real-time mammographic analysis. This versatility extends to other modalities; for instance, Ayuningtyas et al. [8] successfully implemented a YOLO-based framework for early detection in ultrasonography. Furthermore, Abdikenov, Rakishev, Orazayev, and Zhaksylyk [9] underscored that leveraging transfer learning is a critical strategy for enhancing detection performance, enabling models to adapt to the specific complexities of radiological data even with limited training data. Despite these advancements, a persistent bottleneck in medical imaging remains the "small object problem." As noted in the comprehensive reviews by Zhao, Zheng, Xu, and Wu [10] and Mirzaei, Nezamabadi-Pour, Raoof, and Derakhshani [11], standard object detectors often struggle when target lesions occupy a minute fraction (often less than 0.1%) of a high-resolution input. In such cases, global image down-sampling leads to a catastrophic loss of spatial information, effectively causing small anomalies to disappear. To mitigate this, patch-based approaches have been widely adopted to maintain local resolution. Hou et al. [12] and Ashour et al. [13] demonstrated that dividing large-scale images such as whole-slide tissue images or mammograms into smaller segments enables more effective feature representation and more manageable computational costs. The technical justification for this approach is often referred to as the "power of tiling." Unel, Özkalaycı, and Çığla [14]

provided empirical evidence that dividing high-resolution frames into overlapping patches significantly improves the performance of detectors such as YOLO by increasing the relative scale of small objects. This methodology is further supported by recent innovations such as Slicing Aided Hyper Inference (SAHI). Duwal and Dahal [15] highlighted how image slicing can overcome resolution disparities that typically cause standard models to fail. While some researchers, such as Manolakis, Bizopoulos, Lalas, and Votis [16], have proposed multi-stage frameworks that combine YOLO with segmentation networks to address these complexities, single-stage tiling pipelines remain highly attractive for their efficiency.

However, the transition from whole-image to patch-based learning introduces unique methodological hurdles. When an image is subdivided, the resulting dataset often suffers from extreme class imbalance, as most tiles may contain only healthy tissue. Bae and Ban [17] addressed this by proposing class-balanced random patch training to prevent model bias. Additionally, Ciga et al. [18] cautioned against the potential loss of global spatial context and feature inconsistency across tile boundaries. To ensure clinical viability, Shawi, Kilanava, and Sakr [19] emphasized the need for interpretability in these localized models, arguing that practitioners must understand the basis of patch-level predictions. Collectively, these studies illustrate that while YOLO combined with strategic tiling offers a potent solution for detecting small-scale anomalies, success depends on the careful optimization of tile size, overlap, and class distribution. There remains a critical need for streamlined pipelines that can achieve high recall for small malignant lesions while maintaining the inference speeds required for practical clinical decision support. The trend toward using YOLO-based architectures as foundational preprocessing and standardization tools is further exemplified by recent specialized medical applications. Zhanegiz, Mamyrbayev, Momynzhanova, and Zhumazhan [20] demonstrated that YOLO-based cropping can be more efficient than traditional K-means clustering for the automated standardization of fundus images, highlighting the model's robustness in preparing complex medical data for downstream analysis. Similarly, the development of high-performance architectures like HiFormer by Mamyrbayev, Zhanegizov, Momynzhanova, and Keylan [21] underscores the industry's shift toward models that prioritize both speed and accuracy in detecting subtle pathological features, such as those found in glaucoma. These advancements in ophthalmological imaging mirror the challenges faced in mammography, where precise localization and image standardization are paramount. By integrating a patch-based tiling strategy within the YOLOv8 framework, the present study aligns with these emerging trends, focusing on the critical need for preprocessing pipelines that enhance the visibility of small malignant lesions while maintaining the computational efficiency required for modern clinical environments. Recent studies on the INbreast dataset further demonstrate the growing interest in improving small-lesion detection in mammography using advanced deep learning architectures. Several approaches have explored transformer-based detectors, multi-scale feature pyramids, and hybrid segmentation–detection frameworks to improve sensitivity for subtle abnormalities. For example, Aly, Marey, El-Sayed, and Tolba [22] evaluated YOLO-based detection on the INbreast dataset and reported strong performance for mass detection in full-field digital mammograms. At the same time, Prinzi, Insalaco, Orlando, Gaglio, and Vitabile [23] investigated multiple YOLO architectures combined with transfer learning for mammographic lesion detection using both INbreast and CBIS-DDSM datasets. Similarly, recent multi-stage frameworks integrating YOLO with segmentation networks have shown promising results for mammographic mass localization and segmentation [24]. Nevertheless, many of these approaches rely on computationally intensive multi-stage pipelines or require extensive preprocessing and annotation refinement, limiting their applicability in real-time clinical workflows. Benchmarking studies indicate that while standard YOLO-based mammography models can achieve high detection accuracy for larger abnormalities, their performance on very small malignant lesions remains limited due to aggressive image downsampling and insufficient local feature representation. Additional studies on mammographic lesion analysis further demonstrated that resizing high-resolution mammograms to standard detector input dimensions may suppress diagnostically important fine-grained features [25]. Existing small object detection studies have attempted to address this limitation using feature pyramid networks, attention mechanisms, transformer-based architectures, and multi-resolution inference strategies [26], but these methods often increase architectural complexity and computational overhead. In contrast to many existing approaches, the present study focuses on a practical patch-based preprocessing pipeline integrated directly into a YOLOv8

detection framework. The proposed methodology emphasizes computational efficiency, simplified implementation, and improved visibility of small lesions in high-resolution mammograms while preserving the advantages of single-stage object detection. Furthermore, this work provides a comparative evaluation of model performance before and after tiling-based preprocessing, enabling a more direct assessment of how patch-based learning affects recall, precision, and localization performance in malignant lesion detection.

Beyond detection accuracy, the increasing integration of artificial intelligence into medical imaging pipelines also raises important concerns regarding data privacy, secure storage, and controlled sharing of sensitive patient information. Mammography datasets contain highly sensitive medical data, and the use of cloud-based AI systems or distributed training environments introduces additional security challenges, including unauthorized access, data leakage, and secure image transmission. Consequently, modern AI-enabled medical imaging frameworks must consider not only diagnostic performance but also mechanisms to preserve patient confidentiality and ensure secure medical image management. Recent security-oriented studies have proposed advanced privacy-preserving storage techniques, such as the Nested Secret Share (NSS) framework, for secure distributed image management. Galletta, Taheri, Celesti, Fazio, and Villari [26] demonstrated that Nested Secret Share approaches can improve the protection of sensitive image data while maintaining efficient accessibility in distributed environments. In subsequent work, the authors further addressed limitations of traditional Secret Share techniques by introducing enhanced nested architectures for secure data storage and sharing [27]. Such approaches may be highly relevant to future AI-assisted mammography systems, particularly in multi-center clinical collaborations, cloud-based diagnostic platforms, and federated medical AI infrastructures. Integrating secure storage and privacy-preserving mechanisms into patch-based mammography pipelines could improve the clinical feasibility, security, and trustworthiness of deep learning systems intended for real-world healthcare deployment.

III. METHODOLOGY

1. Dataset Description

This study used the publicly available INbreast dataset, hosted on Kaggle [28]. INbreast is a full-field digital mammography database widely used in breast cancer research. The dataset includes DICOM mammographic images, detailed lesion annotations, and clinical metadata.

The dataset provides several structured folders containing imaging data and annotations in various formats. An overview of the INBreast dataset components is presented in Table 1.

Table 1. Structure and contents of the INBreast dataset

File	Description
AllDICOMs	Original medical images in DICOM format
AllROI	Lesion annotations in OsiriX .roi format
AllXML	Lesion annotations in .xml format exported from OsiriX
MedicalReports	Radiologist narrative reports
PectoralMuscle	Manual annotations of the pectoral muscle boundary

File	Description
INbreast.xls/ INbreast.csv	Tabular metadata containing BI-RADS categories and clinical descriptors

In total, the dataset includes 412 DICOM mammograms, 343 ROI annotation files, 343 XML annotation files, 117 medical report files, and 201 pectoral muscle annotation files (both ROI and XML formats). In addition, a CSV file containing metadata for each examination is provided and was used to map images to diagnostic categories.

2. Data Preprocessing

The original mammograms in INBreast are provided in DICOM format. However, the YOLO object detection framework does not directly support DICOM images or OsiriX ROI/XML annotations. Therefore, all files were first downloaded to Google Drive, and a preprocessing pipeline was implemented in Google Colab.

As a first step, all DICOM images were converted to PNG format. The conversion was performed automatically in Colab to process the entire dataset at scale (hundreds of files), ensuring the complete preprocessing pipeline remained reproducible and integrated with subsequent model training.

Figure 1 shows two example PNG images demonstrating malignant breast lesions after DICOM conversion.

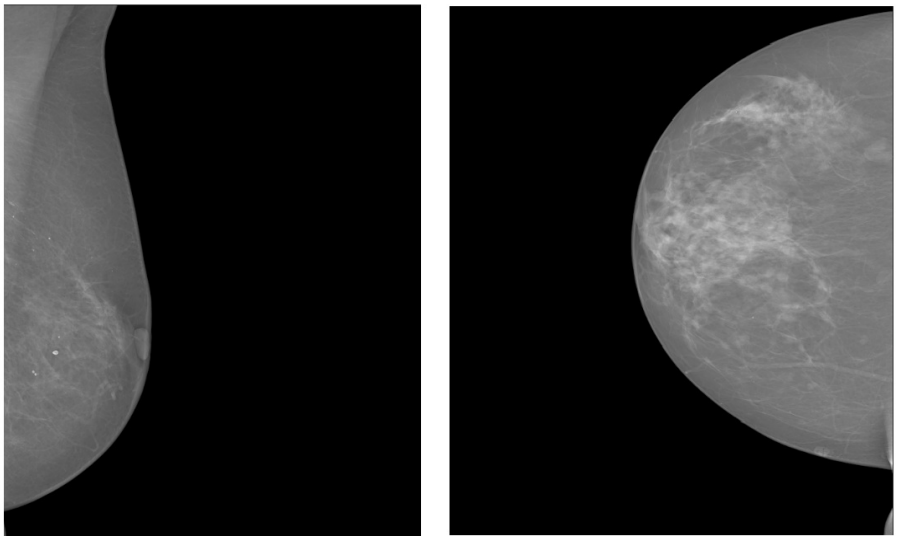

Figure 1. Examples of PNG images demonstrating malignant breast lesions after DICOM conversion

Because YOLO requires bounding-box annotations in TXT format, an automated annotation conversion pipeline was developed. INbreast provides lesion annotations in ROI/XML formats, which define polygon coordinates for each lesion, but do not explicitly include the mammographic projection (e.g., L/CC, L/MLO, R/CC, R/MLO). Therefore, each ROI/XML file was matched to the corresponding PNG image(s) using the patient identifier, which is present as the filename prefix in both the DICOM/PNG files and the annotation files. All PNG images whose filename started with the same patient ID as the XML file were considered valid matches.

For each XML annotation, the polygon points (x,y) were extracted, and the minimum and maximum coordinates were used to compute an axis-aligned bounding box. When a lesion contained a single point annotation, a small default bounding box (±10 px) was defined to preserve annotation consistency. Bounding boxes were then normalized to (x_center, y_center, width, height) based on the target PNG image resolution, following the YOLO format specification.

Lesion labels were derived from BI-RADS categories provided in the INbreast CSV metadata. Each metadata entry contains a "File Name" field that corresponds to the patient ID in the imaging files. BI-RADS categories were mapped into a binary classification schema: BI-RADS 1/2/3 were assigned to the benign class (label = 0), while BI-RADS 4, 4a, 5, and 6 were mapped to malignant (label = 1). This mapping follows clinical best practice, in which BI-RADS category 4 and above is considered "suspicious for malignancy."

A Python script running in Google Colab processed the entire dataset automatically. The script mounted Google Drive, read the CSV metadata (semicolon-delimited), mapped each patient ID to a binary class label, parsed XML files to extract polygon coordinates, computed bounding boxes, matched to PNG images, normalized coordinates, and exported YOLO-compatible TXT annotations. Multiple ROIs per image resulted in multiple annotation lines in the corresponding TXT file. The final label set contained 343 processed XML annotation files, resulting in a total of 7,316 YOLO bounding box labels, with no missing patient-image matches and no missing BI-RADS cases.

After the conversion, the final dataset consisted of 410 PNG images stored in the /INBreast_Release/PNG directory and 343 YOLO TXT annotation files stored in /INBreast_Release/labels. To verify annotation quality, a sample of images was visualized by rendering the generated bounding boxes directly onto the converted PNG mammograms. Figure 2 illustrates a representative visualization of the results after XML-to-YOLO conversion, confirming that the bounding boxes accurately localize the annotated lesions. A qualitative verification of the generated YOLO annotations is presented in Figure 2.

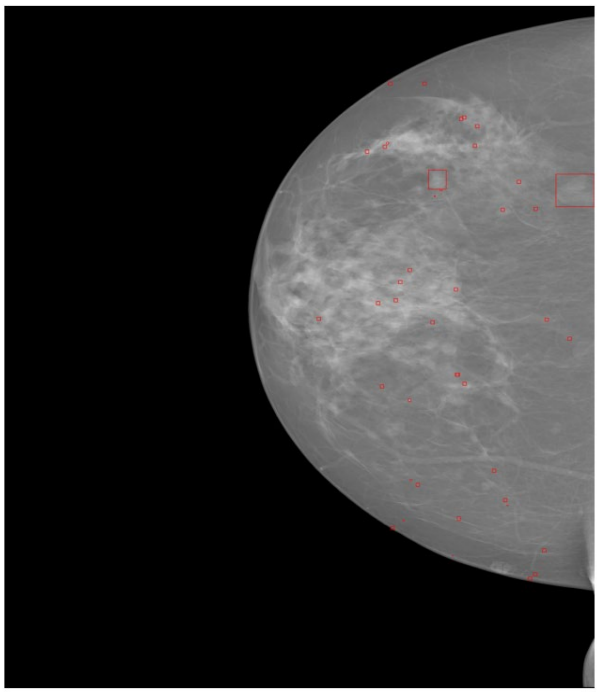

Figure 2. A representative example of the resulting visualization after XML-to-YOLO conversion

The dataset was partitioned into three subsets to support model development, hyperparameter tuning, and unbiased performance evaluation. A stratified split was applied at the image level with the following proportions: 70% for training, 20% for validation, and 10% for testing. After splitting, the final subset sizes were 287 images for training, 82 images for validation, and 41 images for testing. All subsets were mutually exclusive, and no patients were allowed to overlap across partitions.

3. Model Architecture

A YOLOv8 object detection model was selected for its optimized computational efficiency and high performance on small- and medium-scale datasets. The Ultralytics YOLOv8 implementation was installed and used. The training environment was configured by mounting Google Drive, verifying GPU availability, updating Ultralytics, and validating the dataset structure (images, labels, and data.yaml configuration file).

Model training was conducted using a single GPU in Google Colab, with an input resolution of 640×640 pixels for both training and validation images. The model was trained for 50 epochs. Batch size and image size parameters were adjusted dynamically if out-of-memory (OOM) errors occurred during initialization. Throughout training, the framework logged epoch-wise performance metrics including GPU memory usage, box loss, classification loss, and distribution focal loss. Upon training completion, the best-performing checkpoint (best.pt) was automatically selected based on the highest validation performance.

Following training, the model was evaluated on the held-out test subset (N=41 images). Example visualizations were generated to assess detection performance qualitatively, and the trained model was exported for downstream inference and analysis.

4. Patch-based training

Mammography images are typically very large (≈3000×4000–4000×6000 px), while cancer lesions can be extremely small (20–50 px), low-contrast, and visually similar to background tissue, often occupying less than 0.1% of the image area. Standard object detectors such as YOLO and other CNN-based models struggle to detect such small objects, especially after downsampling the image to 640×640 or 1024×1024, where the lesion may shrink to a few pixels or disappear entirely. In our dataset, the average bounding box area was 0.0004 (≈0.04% of the image).

Tiling (patch-based training) addresses these challenges as follows:

1. Image splitting: Large images are divided into smaller overlapping tiles (e.g., 640×640 with 20–30% overlap). A typical 4000×3000 image generates ~30–50 tiles, effectively increasing the dataset size and standardizing input dimensions.
2. Bounding box recalculation: Only boxes intersecting a tile are included; coordinates are adjusted relative to the tile.
3. Lesion magnification: Small lesions (e.g., 30–40 px) are enlarged on tiles (≈200–300 px), making them detectable by YOLO.
4. Foreground-background balance: Tiling reduces extreme background dominance, allowing tiles to contain tissue patterns or pathologies, improving model learning of relevant features.
5. Dataset expansion: For example, after tiling, the train/validation/test sets increased from 287/82/41 images to 1657/487/270 tiles, resulting in 12,057 tiles with objects (class distribution: 8462 benign, 3595 malignant), a 20–40× increase in effective training samples.

IV. RESULTS

The trained YOLOv8 model (best.pt) was loaded and used for inference on the held-out test set. The model object provided multiple functionalities. Predictions were performed on all test images, and the results were saved as annotated images with bounding boxes overlaid and as text files containing the coordinates of predicted objects. Annotated images enable visual inspection of lesion-detection accuracy, while TXT files provide structured data for quantitative evaluation. Figure 3 illustrates predicted bounding boxes on test images, demonstrating the model's ability to localize breast lesions accurately.

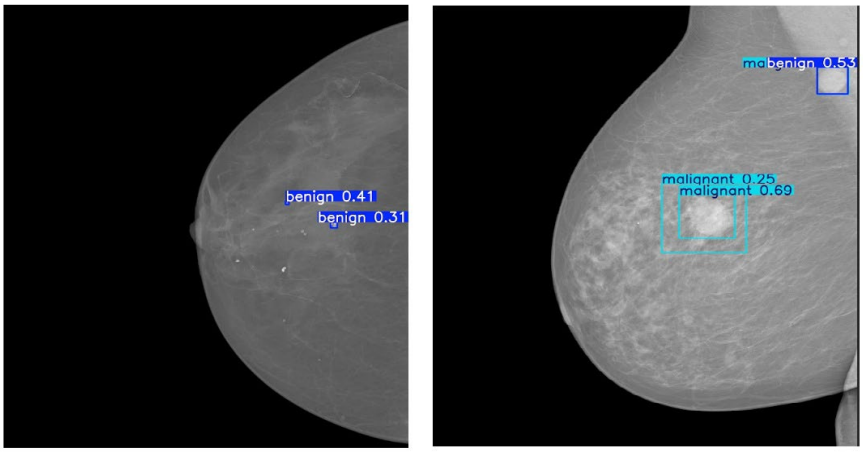

Figure 3. Examples of the predicted bounding boxes on test images

The trained YOLOv8 model was evaluated on the held-out test set using the standard validation procedure implemented in the Ultralytics framework. The evaluation results are summarized in Table 2.

Table 2. Detection performance and inference efficiency of YOLOv8 on the INBreast dataset

Metric	Precision	Recall	F1-score
Value	30%	3-4%	5-7%

The obtained results indicate limited detection performance, particularly for small malignant lesions in high-resolution mammographic images. To identify the underlying causes of low precision, recall, and mAP scores, an error analysis was conducted. Based on its findings, several improvements were introduced, including tiling-based preprocessing, enhanced data augmentation, and adjustments to the training pipeline to mitigate class imbalance and improve small object detection. The original dataset contained 410 mammograms and 343 YOLO-format annotation files.

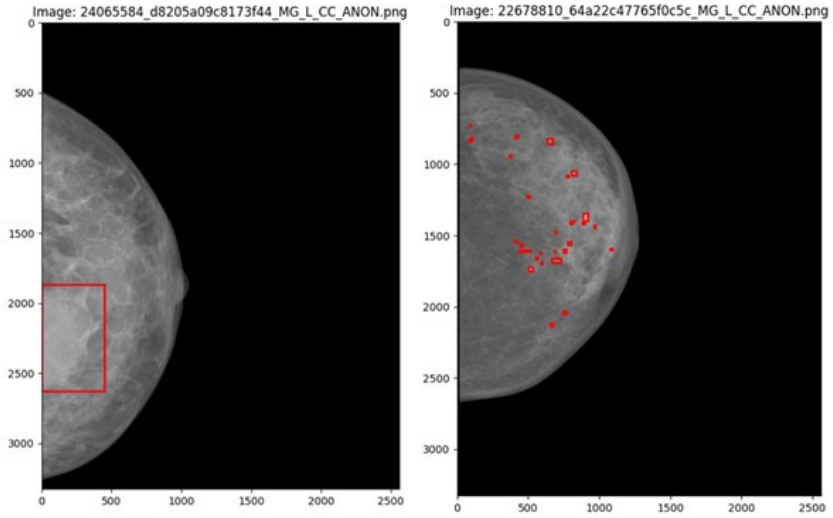

Fig. 1. Visualization of Random Bounding Boxes on Mammographic Images

Data validation revealed that 67 images lacked corresponding annotations; these were removed to ensure consistency, resulting in a final dataset of 343 image–label pairs. To further characterize the dataset, a visual inspection of regions of interest and an analysis of bounding box size distribution were performed. This confirmed the accuracy of the annotations and provided insights into lesion-scale variability. The results indicated a high prevalence of small objects, supporting the need for patch-based processing strategies such as tiling to improve detection performance, as illustrated in Fig. 4. Additionally, the distribution analysis provided insights into the relative sizes of objects in the images, helping assess whether small-object detection might be an issue and whether tiling or patch-based training would improve model performance. The visual and statistical examination of bounding boxes thus informed subsequent model design and training strategies, as illustrated in Fig. 4, which shows randomly selected bounding boxes on mammographic images. The bounding box size distribution analysis indicated that lesions occupy an extremely small proportion of the original mammographic images. The normalized average bounding box area was 0.0004, with minimum and maximum values of 0.0000 and 0.0896, respectively. These results confirm that the dataset is dominated by small objects, with only a limited number of relatively large lesions. The presence of near-zero bounding box areas suggests potential labeling noise or annotation inconsistencies. At the same time, the overall distribution highlights the inherent difficulty of detecting small-scale structures in high-resolution images. These observations support the use of patch-based or tiling strategies to improve lesion visibility and model sensitivity. After applying the tiling procedure, the dataset was expanded to 12,057 annotated image tiles, comprising 8,462 benign and 3,595 malignant instances. The normalized bounding box area within tiles had a mean of 0.0108, with minimum and maximum values of 0.0000 and 1.0000, respectively, indicating a substantial increase in the relative lesion scale after preprocessing. This transformation improves the object-to-background ratio and ensures better utilization of detection features within the YOLO architecture. As a result, small lesions are more effectively preserved within feature pyramids and anchor-based representations, enhancing the model's ability to learn fine-grained pathological patterns. Representative examples of tiled images with bounding box annotations are shown in Fig. 5.

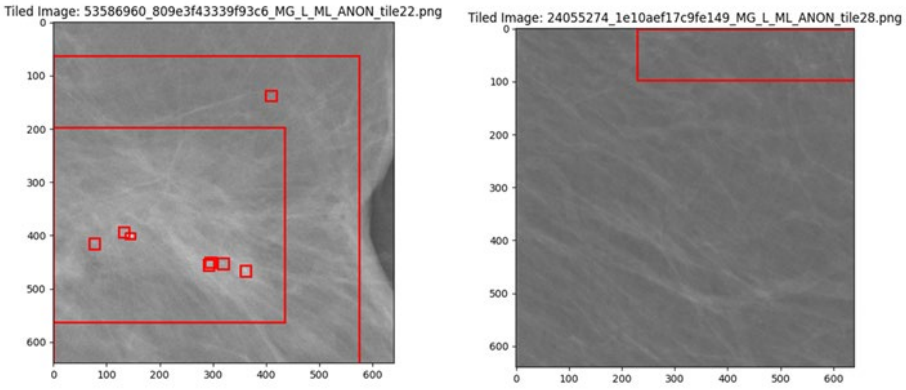

Fig. 2. Qualitative inspection of bounding box annotations on multiple image tiles

The YOLO model was trained and validated on the tiled mammography dataset. After training, the model achieved the following overall metrics: Precision = 0.277, Recall = 0.450, mAP50 = 0.351, and mAP50–95 = 0.212, with a low training loss of 0.0004, indicating effective convergence. The trained model and results were saved. Inference speed was measured at 2.18 s per image, with preprocessing and postprocessing times of 0.24 s and 3.78 s, respectively. Validation was performed on 487 images containing 2,121 lesion instances. Overall detection metrics on the validation set were: Precision = 0.281, Recall = 0.454, mAP50 = 0.352, and mAP50–95 = 0.213. For class-specific performance, benign lesions achieved higher detection scores (Precision = 0.336, Recall = 0.745, mAP50 = 0.574), while malignant lesions were more challenging to detect (Precision = 0.226, Recall = 0.164, mAP50 = 0.130). The validation results confirm that tiling and patch-based training improved the model's ability to detect small lesions, particularly benign ones, although detecting malignant lesions remains more difficult. To qualitatively assess the model predictions, several test images were visualized with predicted bounding boxes overlaid on the original mammograms. Fig. 6 shows examples of correctly detected malignant and benign lesions, as well as some false positives.

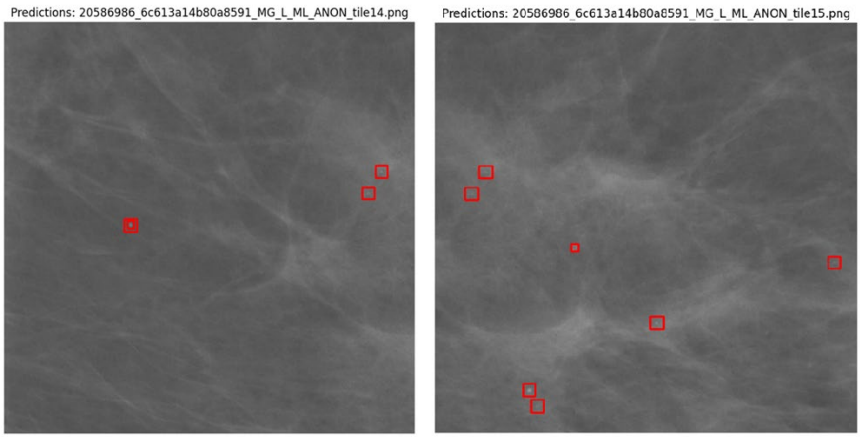

Fig. 3. Examples of YOLOv8 predictions on test images

The initial dataset contained 410 mammography images with 343 YOLO-format annotation files. A preliminary inspection revealed 67 unlabeled images, which were excluded to ensure data consistency. The cleaned dataset thus consisted of 343 images with complete annotations. A detailed analysis of bounding box (bbox) sizes revealed that lesions were predominantly small relative to the full image size. The average bbox area was 0.0004 (≈0.04% of the original image), with minimum and maximum areas of 0.0000 and 0.0896, respectively. Near-zero-size boxes indicated potential labeling artifacts, while the rare larger lesions represented less than 10% of the image area. Visual inspection of ROIs confirmed that the majority of bounding boxes accurately corresponded to malignant lesions. Given the relatively small size of the lesions, tiling (patch-based training) was applied. Large images (≈4000×3000 px) were split into 640×640 tiles with 20–30% overlap, resulting in ~30–50 tiles per image. This approach increased the effective dataset size and enlarged the relative size of lesions within each tile, making them more detectable by YOLO. After tiling, the dataset contained 12,057 tiles with annotated objects, distributed as 8,462 benign and 3,595 malignant lesions. Average bbox area per tile increased to 0.0108, with a minimum of 0.0000 and a maximum of 1.0000, reflecting the enlarged object representation on tiles. The tiling procedure also reduced the extreme background-to-object imbalance inherent in mammography images.

Table 3 presents the detection performance of the YOLOv8 model evaluated on the training, validation, and test sets.

Table 3. Detection metrics

Metric	Precision	Recall	F1-score
Train set	0,277	0,450	0,343
Validation set	0,281	0,454	0,347
Test set	0.477	0.622	0.540

The model achieved a recall of 62.2%, indicating that most true lesions were detected, while the precision of 47.7% reflects false-positive detections. The overall F1-score of 0.54 represents a balanced performance given the challenging nature of the mammographic images, which often contain small lesions and artifacts. These results highlight the effectiveness of patch-based tiling and YOLOv8 for breast lesion detection and suggest potential improvements through larger datasets, class balancing, and advanced data augmentation techniques.

V. CONCLUSION

This study presented a YOLO-based framework for malignant lesion detection in high-resolution mammography images, enhanced with a patch-based tiling preprocessing strategy. The proposed approach was designed to mitigate key challenges associated with mammographic analysis, including extreme class imbalance, low lesion contrast, and the disproportionately small size of pathological structures relative to full-image resolution. The incorporation of tiling significantly improved the effective representation of small lesions by increasing their relative scale and improving local feature visibility during training and inference. Experimental results demonstrate a substantial increase in detection sensitivity, with a marked improvement in recall over the baseline full-image configuration, indicating enhanced capability to identify small malignant regions. Despite these improvements, the model still exhibits limitations in precision and false-positive generation, primarily due to background tissue complexity and class imbalance. These findings indicate that while patch-based preprocessing improves sensitivity, further optimization is required to balance detection robustness and specificity. Overall, the results confirm that tiling is a critical preprocessing strategy for improving small-object detection in

mammography using YOLO-based architectures. Future work will focus on extending the experimental evaluation to additional public mammography datasets to assess generalizability, as well as conducting comprehensive comparisons with state-of-the-art detection architectures. Further research will also investigate imbalance-aware learning strategies, advanced post-processing techniques, and hybrid modeling approaches that integrate local patch-based inference with global contextual representations to improve both robustness and diagnostic reliability in clinical applications.

ACKNOWLEDGEMENT

The work was supported by grant funding from the Science Committee of the Ministry of Science and Higher Education of the Republic of Kazakhstan, BR24993001: Creation of a large language model (LLM) to maintain the implementation of the Kazakh language and increase technological progress.

Abstract
Cybersecurity and privacy governance are now central to digital resilience, particularly in environments affected by growing cyber threats, regulatory fragmentation, and dependence on interconnected infrastructures. Although the NIS2 Directive and ISO/IEC standards pursue complementary objectives, their integrated operational implementation within transitional regulatory systems remains insufficiently explored. This paper develops and operationalizes a Digital Trust Governance Model integrating NIS2, ISO/IEC 27001, and ISO/IEC 27701 into a unified governance maturity framework. Using comparative legal analysis and governance gap analysis, the study evaluates the cybersecurity and privacy governance structure of Bosnia and Herzegovina with emphasis on risk management, incident reporting, CSIRT coordination, supervisory capacity, and management accountability. The proposed model conceptualizes digital trust as a measurable governance outcome derived from four interdependent dimensions: normative precision, institutional capacity, sanctioning capability, and technical and organizational implementation. To improve analytical applicability, the framework introduces qualitative maturity indicators for assessing operational cyber resilience and governance effectiveness. The findings reveal significant asymmetry between privacy governance maturity and cybersecurity governance capability, particularly regarding institutional coordination, enforcement consistency, and implementation capacity. The paper contributes to the literature by integrating regulatory, institutional, enforcement, and operational dimensions into a single governance maturity framework.

Keywords: Digital Trust Governance; Cybersecurity Governance; NIS2; ISO/IEC 27701; ISO/IEC 27001; Governance Maturity; Cyber Resilience; Privacy Governance; Regulatory Compliance; Bosnia and Herzegovina

I. INTRODUCTION

Cybersecurity and personal data protection are core components of digital governance because interconnected systems and critical infrastructures expose organizations to legal, operational, economic and reputational consequences when incidents occur. Cybersecurity has therefore evolved from a narrow IT function into a strategic governance responsibility requiring coordinated regulation, institutional capacity, executive accountability and effective implementation of controls. The EU addresses these challenges through GDPR [1] and NIS2 [2]. GDPR strengthens privacy, lawful processing and accountability, while NIS2 broadens cybersecurity duties concerning risk management, incident reporting, supply-chain security, business continuity, supervision and management responsibility. ISO/IEC 27001 and ISO/IEC 27701 translate these obligations into operational management systems. Their integration is especially relevant in transitional systems such as Bosnia and Herzegovina, where privacy governance is comparatively more consolidated while cybersecurity coordination, incident reporting, CSIRT integration and management accountability remain fragmented [3], [4]. This paper therefore evaluates the alignment of NIS2, ISO/IEC 27001 and ISO/IEC 27701 with the legal and

institutional framework of Bosnia and Herzegovina through comparative and gap analysis, focusing on risk management, incident reporting, CSIRT coordination, supervision and executive accountability. The study treats digital trust as a measurable governance outcome of normative precision, institutional capacity, sanctioning capability and technical-organizational implementation, and proposes a scalable model for identifying structural weaknesses in transitional regulatory systems.

II. RESEARCH CONTRIBUTIONS

The study contributes an integrated Digital Trust Governance Model linking NIS2 with ISO/IEC 27001 and ISO/IEC 27701, a qualitative maturity assessment framework, and a comparative application to Bosnia and Herzegovina.

III. LITERATURE REVIEW

1. Cybersecurity Governance and Regulatory Transformation

Cybersecurity governance increasingly emphasizes resilience, executive responsibility and institutional coordination rather than isolated technical controls. NIS2 reflects this shift through mandatory risk management, incident reporting, supply-chain security, business continuity and supervisory accountability, while NIST CSF 2.0 supports continuous governance through identify, protect, detect, respond and recover functions [5].

2. Privacy Governance and Data Protection Frameworks

Privacy governance similarly emphasizes accountability, transparency and demonstrable safeguards. GDPR established a comprehensive framework, but privacy and cybersecurity are still often governed separately. In Bosnia and Herzegovina this separation can weaken coordination when incidents involve both infrastructure disruption and personal data compromise [6].

3. ISO Standards and Operational Implementation

ISO/IEC 27001 provides a risk-based ISMS for identifying risks, implementing controls and continually improving information security. It operationalizes many NIS2 requirements, including incident management, continuity, supplier security and access control. ISO/IEC 27701:2025 extends this structure with a Privacy Information Management System (PIMS), connecting privacy obligations with cybersecurity governance and organizational accountability.

4. Digital Trust and Governance Effectiveness

Digital trust denotes confidence in the security, reliability, accountability and integrity of digital systems. Governance-oriented approaches increasingly view it as dependent on legal certainty, institutional effectiveness, implementation capability and operational resilience [7]. In fragmented or transitional systems, trust is strongly affected by coordination, supervisory consistency and response capacity; this study therefore links digital trust to normative precision, institutional capacity, sanctioning capability and technical implementation [8-11].

5. Governance Maturity and Cyber Resilience Assessment

Recent governance and resilience literature moves beyond formal compliance toward measurable prevention, detection, response and recovery capability. NIS2, DORA and ENISA guidance reinforce integrated governance, continuous risk management, supervisory capacity and incident coordination [12-15]. Despite these developments, few approaches integrate cybersecurity governance, privacy governance, enforcement capability and operational implementation into one maturity framework for transitional regulatory systems.

6. Research Gap

Existing literature addresses cybersecurity regulation, privacy governance and international standards extensively, but important integration gaps remain. Cybersecurity and privacy are often analyzed separately, alignment between NIS2 and ISO/IEC 27001/27701 is insufficiently examined, and transitional regulatory systems remain underrepresented. Digital trust is also rarely operationalized as a governance outcome combining legal, institutional, enforcement and technical dimensions.This study addresses these gaps through an integrated Digital Trust Governance Model and a qualitative maturity assessment applied to Bosnia and Herzegovina.

IV. METHODOLOGY

1. Research Design

The study uses an interdisciplinary qualitative design combining legal analysis, cybersecurity governance theory and operational compliance assessment. It evaluates not only formal rules but also institutional effectiveness and implementation capability in Bosnia and Herzegovina.

2. Research Approach

Three complementary methods are used: normative-dogmatic analysis, comparative analysis and governance gap analysis.

3. Normative Analysis

Normative analysis examines cybersecurity, privacy, risk-management, incident-reporting and supervisory obligations in European and national frameworks.

4. Comparative Analysis

Comparative analysis evaluates functional alignment between NIS2 and Bosnia and Herzegovina in cyber risk management, incident reporting, CSIRT coordination, governance accountability and supervisory capacity.

5. Gap Analysis

Gap analysis compares regulatory requirements with existing implementation mechanisms to identify discrepancies between formal alignment and practical governance capability.

6. Analytical Framework

The analytical matrix compares NIS2 obligations, ISO/IEC 27001 implementation mechanisms, ISO/IEC 27701 privacy requirements, the BiH legal-institutional framework and the level of operational alignment.

Alignment is classified as fully aligned, partially aligned or not aligned, enabling structured assessment of governance maturity across cybersecurity and privacy domains.

7. Data Sources

Sources include EU regulatory instruments, international standards, national legislation, institutional reports, cybersecurity-governance literature and public policy documents.

Primary sources are NIS2, GDPR, ISO/IEC 27001 and ISO/IEC 27701; secondary sources cover cybersecurity governance, regulatory effectiveness, risk governance and digital trust.

8. Evaluation Criteria

Assessment criteria include normative clarity, institutional coordination, operational feasibility, incident-reporting capability, supervisory consistency, implementation maturity and accountability.

9. Conceptual Governance Model

The conceptual model evaluates four interdependent dimensions: normative precision (N), institutional capacity (I), sanctioning capability (S) and technical implementation (T).

Governance effectiveness is treated as their interaction; weakness in any single dimension can materially reduce overall maturity.

10. Governance Maturity Scoring Framework

Each model dimension is assessed on a five-level qualitative maturity scale from fragmented to integrated governance, reflecting development, operational integration and implementation effectiveness.

Table 1. Governance Maturity Scale

Score	Level	Description
1	Fragmented	Governance mechanisms are largely undeveloped, inconsistent, or absent
2	Reactive	Basic governance mechanisms exist but remain limited and primarily reactive
3	Developing	Governance structures are partially implemented with moderate operational capability
4	Managed	Governance mechanisms are formally integrated and operationally coordinated

5	Integrated	Governance structures demonstrate high maturity, coordination, enforcement, and resilience capability

Source: Author's qualitative assessment framework based on cybersecurity governance maturity literature.

The scoring is qualitative and comparative rather than statistically deterministic; it structures governance assessment rather than claiming precise measurement.

11. Limitations of the Study

The study is limited by BiH's fragmented competences, reliance on public legal and institutional sources, and its qualitative focus rather than direct measurement of incidents or organizational performance.

V. REGULATORY AND STANDARD FRAMEWORK

1. NIS2 and Cybersecurity Governance

NIS2 establishes a governance-oriented EU cybersecurity framework based on risk management, resilience, supervision, institutional coordination and management accountability [16-18]. Covered entities must implement appropriate technical, operational and organizational measures, including incident response, business continuity, supply-chain security, vulnerability management, security monitoring and executive accountability. NIS2 also strengthens time-bound incident reporting, national CSIRT coordination and cross-border cooperation, while explicitly placing cyber-risk responsibility on management bodies.

2. Privacy Governance and GDPR-Based Frameworks

GDPR is the central EU privacy framework, emphasizing lawful processing, transparency, purpose limitation, integrity, confidentiality, accountability, breach notification and technical-organizational safeguards. Its accountability model requires organizations to demonstrate effective safeguards. In Bosnia and Herzegovina, privacy governance is relatively more consistent than cyber governance, but remains insufficiently integrated with broader resilience and incident-response structures.

3. ISO/IEC 27001 and Information Security Governance

ISO/IEC 27001 provides a risk-based ISMS for establishing, maintaining and continually improving information security through risk assessment, incident management, access control, asset and supplier protection and business continuity. It therefore serves as an operational mechanism for implementing many NIS2 cybersecurity obligations.

4. ISO/IEC 27701 and Privacy Information Management

ISO/IEC 27701:2025 extends the ISO/IEC 27001 management-system structure with PIMS requirements for PII governance, controller/processor obligations, privacy risk, data-subject rights and accountability. This creates an operational bridge between security and privacy governance and supports more consistent implementation where institutional responsibilities remain separated.

5. Integrated Governance Perspective

NIS2 and ISO standards are complementary: NIS2 defines regulatory expectations, supervision, reporting and coordination, while ISO/IEC 27001 and ISO/IEC 27701 provide operational security and privacy controls. Their integration supports a transition from formal compliance to operational governance maturity and measurable digital trust.

6. Structural Limitations in Transitional Regulatory Systems

Transitional systems often show a gap between legal reform and implementation capability.

In Bosnia and Herzegovina the main limitations are fragmented competences, decentralized coordination, inconsistent supervision, limited incident coordination and uneven implementation maturity. These conditions create an implementation gap that can only be reduced through stronger coordination, operational resilience and integrated governance [19-21].

7. Gap Analysis

8. Methodological Basis of the Gap Analysis

The gap analysis compares NIS2, ISO/IEC 27001 and ISO/IEC 27701 with the BiH legal and institutional framework, focusing on functional capability rather than formal equivalence.

9. Scope of the Analysis

Five domains are assessed: cyber risk management, incident reporting, CSIRT coordination, supervision and enforcement, and management accountability.

10. Comparative Mapping

Table 2. Gap Analysis Matrix: Nis2, Iso Standards And Bih Framework

Requirement	**NIS2**	**ISO/IEC 27001**	**ISO/IEC 27701**	**BiH Framework**	**Gap Level**
Risk management	Mandatory risk-based approach	ISMS risk controls	Privacy risk controls	Partially regulated	Partial
Incident reporting	Time-bound reporting	Incident management controls	Data breach procedures	Not unified	High
CSIRT coordination	National coordination required	Indirect support	Indirect support	Fragmented	High
Supervision and enforcement	Strong oversight	Not directly applicable	Not directly applicable	Limited and uneven	Partial

Management accountability	Explicit executive responsibility	Governance responsibility	Privacy roles	Weakly defined	High

Source: Author's qualitative assessment framework based on cybersecurity governance maturity literature.

The matrix shows that the principal weaknesses concern institutional coordination and operational implementation rather than the mere existence of legal norms.

11. Key Findings

The analysis reveals a clear asymmetry between comparatively stronger privacy governance and more fragmented cybersecurity governance in Bosnia and Herzegovina. Risk management is only partially aligned with NIS2, and a fully integrated national cyber-risk framework is absent. Incident reporting remains a major gap because privacy-breach mechanisms are clearer than unified reporting for broader cybersecurity incidents. CSIRT capacities exist but are not sufficiently integrated into a consolidated cross-sector coordination and response system. Supervision and enforcement are uneven, with no consistently centralized cybersecurity authority combining clear powers and operational capacity. Management accountability is also weakly institutionalized compared with NIS2's explicit board-level responsibility.

12. Structural Causes of Identified Gaps

The gaps are structural as well as normative, reflecting fragmented competences, limited resources, weak supervisory capacity and insufficient integration of privacy and cyber governance.

13. Separated cyber and privacy governance creates incomplete risk assessment, inconsistent incident response and weaker inter-agency coordination.

An integrated governance approach should combine NIS2 obligations, ISO/IEC 27001 security controls, ISO/IEC 27701 privacy controls, institutional coordination and management accountability.

Such a framework should combine:

- NIS2 regulatory obligations,
- ISO/IEC 27001 security controls,
- ISO/IEC 27701 privacy controls,
- institutional coordination mechanisms,

The gap analysis shows that formal alignment does not by itself create resilience. The proposed model therefore connects regulatory obligations, institutional structures, enforcement and implementation as mutually dependent components of digital trust. This transition would enable Bosnia and Herzegovina to move from formal regulatory alignment toward measurable implementation capacity and digital trust maturity. The identified gaps directly justify the four dimensions of the proposed model: weak incident reporting reflects insufficient normative precision, fragmented CSIRT coordination indicates limited institutional capacity, uneven supervision points to weak sanctioning capability, while inconsistent organizational controls reveal gaps in technical implementation.

VI. INTEGRATED DIGITAL TRUST GOVERNANCE MODEL

1. Rationale for Model Development

The gap analysis demonstrates that formal regulatory alignment does not necessarily produce effective cyber resilience or privacy protection. In transitional regulatory systems, legal norms may exist without sufficient institutional capacity, enforcement consistency, or operational implementation. This creates a gap between compliance as a formal requirement and governance as a practical capability. For this reason, the study proposes an integrated Digital Trust Governance Model designed to connect regulatory obligations, institutional structures, enforcement mechanisms, and technical implementation into a unified analytical framework. The model is based on the assumption that digital trust cannot be produced by regulation alone. It emerges from the interaction between legal clarity, institutional effectiveness, supervisory credibility, and operational security maturity.

2. Normative precision concerns clear and predictable duties for risk management, incident reporting, data protection, management responsibility and supervision.

The proposed model consists of four interdependent variables:

3. Normative Precision (N)

Institutional capacity concerns the human, technical, financial and coordination capability of supervisory and response bodies.

4. Institutional Capacity (I)

Institutional capacity refers to the ability of supervisory and response bodies to implement, monitor, and enforce regulatory obligations. It includes human resources, technical expertise, budgetary stability, operational independence, and inter-agency coordination. Without sufficient institutional capacity, even well-designed regulations may remain ineffective in practice.

5. Sanctioning capability concerns credible, proportionate and dissuasive enforcement, including penalties, transparency and corrective action.

Sanctioning capability refers to the ability of the regulatory system to impose effective, proportionate, and dissuasive measures in cases of non-compliance. It includes the level of penalties, frequency of enforcement, transparency of decisions, and credibility of supervisory intervention. Sanctions are important not only as punitive instruments but also as mechanisms for shaping organizational behavior and increasing perceived regulatory risk.

6. Technical and Organizational Implementation (T)

Technical and organizational implementation concerns practical controls such as risk assessment, access control, incident response, backups, training, ISMS and privacy governance.

This variable represents the operational dimension of governance and determines whether formal obligations are translated into real resilience capacity.

7. Mathematical Formulation

The model conceptualizes digital trust as the result of the interaction between the four variables:

$$DT = N \times I \times S \times T$$

The multiplicative structure reflects systemic interdependence: weakness in one variable can substantially reduce overall digital trust, so legal precision alone cannot compensate for weak institutions or implementation.

8. Operational Indicators

Table 3. Operational Indicators Of The Digital Trust Governance Model

Variable	Operational Indicators
N - Normative Precision	clear incident reporting rules; defined management duties; DPO obligations; DPIA requirements; alignment with NIS2 and GDPR
I - Institutional Capacity	number of specialists; technical expertise; CSIRT coordination; supervisory independence; budgetary resources
S - Sanctioning Capability	level of penalties; frequency of enforcement; transparency of decisions; corrective measures; deterrent effect
T - Technical Implementation	ISMS adoption; incident response plans; access control; staff training; backup testing; privacy-by-design mechanisms

Source: Author's qualitative assessment framework based on cybersecurity governance maturity literature.

9. Illustrative Governance Assessment of Bosnia and Herzegovina

The framework is applied illustratively to BiH using qualitative evidence on regulatory alignment, institutional coordination, supervision and operational implementation.

Table 4. Illustrative Governance Maturity Assessment Of Bosnia And Herzegovina

Variable	Assessment	Score
Normative Precision (N)	Partial alignment with NIS2 and GDPR principles; moderate legal clarity	3
Institutional Capacity (I)	Fragmented institutional coordination and limited operational capacity	2
Sanctioning Capability (S)	Weak enforcement consistency and limited supervisory authority	2

Technical Implementation (T)	Uneven implementation maturity across sectors and institutions	2

Source: Author's qualitative assessment framework based on cybersecurity governance maturity literature.

Based on the proposed model: DT = N x I x S x T = 3 x 2 x 2 x 2 = 24.

The resulting DT score of 24 indicates moderate-to-low governance maturity, constrained by fragmented institutions, inconsistent enforcement and uneven implementation.

10. Application to Transitional Regulatory Systems

The model is especially relevant to transitional systems where legal reform may advance faster than institutional and technical capacity; in BiH, N is moderate while I, S and T remain comparatively weaker.

11. Comparative Governance Benchmarking

A qualitative benchmark compares BiH with Croatia and Germany using the same four dimensions to demonstrate the model's comparative applicability.

Table 5. Comparative Digital Trust Governance Assessment

Country	**N**	**I**	**S**	**T**	**Overall DT**
Bosnia and Herzegovina	3	2	2	2	24
Croatia	4	3	3	3	108
Germany	5	5	5	5	625

Source: Author's qualitative assessment framework based on cybersecurity governance maturity literature.

The illustration suggests that balanced legal clarity, institutional effectiveness, enforcement credibility and implementation capacity produce higher digital-trust maturity; BiH scores lower because of governance fragmentation and limited coordination.

12. Interpretation of the Multiplicative Governance Structure

The multiplicative model represents the systemic interdependence of governance dimensions. Unlike additive approaches, it assumes that a weak dimension can disproportionately reduce overall trust; strong legal harmonization cannot offset poor coordination, enforcement or implementation. This is consistent with resilience literature emphasizing interconnected organizational, institutional and technical capacities [22]. The formula is an analytical maturity framework, not a deterministic predictive instrument.

13. Theoretical and Practical Relevance

The model links regulatory effectiveness, cyber resilience, privacy governance and institutional accountability and can help policymakers and organizations identify priority weaknesses and move from formal compliance toward measurable governance effectiveness.

VII. DISCUSSION

1. Interpretation of Findings

The findings confirm an asymmetric BiH governance structure: privacy protection is relatively more consolidated, while cybersecurity remains institutionally fragmented and operationally uneven.

2. From Formal Compliance to Governance Maturity

Governance maturity differs from formal compliance because it requires practical capacity to prevent, detect, respond to and recover from incidents rather than merely maintaining policies and legal documents.

The $DT = N \times I \times S \times T$ model expresses this by making overall effectiveness sensitive to the weakest governance component.

3. Integration of Cybersecurity and Privacy Governance

Cybersecurity and privacy cannot be managed effectively as isolated domains. NIS2 strengthens resilience and management accountability, GDPR strengthens privacy accountability, and ISO/IEC 27001/27701 provide an operational bridge between them.

4. Role of Management Accountability

NIS2's emphasis on management bodies shifts cybersecurity toward strategic organizational accountability rather than a purely technical IT responsibility.

Management should approve policies, allocate resources, supervise implementation and ensure continuity and incident readiness. In BiH, clearer executive duties would strengthen both normative precision and implementation maturity.

5. Implications for Policy and Practice

The findings imply coordinated action by policymakers, regulators and organizations.

Priorities include clearer national responsibilities and NIS2 alignment, stronger supervisory and CSIRT cooperation, and organizational adoption of measurable ISO-based controls such as risk assessment, incident response, access management, training, backup testing and privacy by design.

6. Theoretical Contribution

The theoretical contribution is the treatment of digital trust as a measurable governance outcome shaped jointly by normative precision, institutional capacity, sanctioning capability and technical implementation.

7. Practical Contribution

Practically, the model supports regulatory planning, organizational audits, NIS2 readiness, ISO/IEC 27001 and ISO/IEC 27701 implementation assessment, and cyber-resilience benchmarking.

VIII. CONCLUSION

1. Main Findings

This paper examined integrated cybersecurity, privacy and digital trust governance through NIS2, ISO/IEC 27001 and ISO/IEC 27701 and showed that effectiveness depends on legal clarity, institutional capacity, enforcement credibility and technical implementation. For Bosnia and Herzegovina, the main asymmetry is stronger privacy governance alongside fragmented cyber governance, limited coordination and weak management accountability. The principal gaps concern CSIRT coordination, incident reporting, supervision and executive responsibility, indicating that implementation capacity and institutional resilience are as important as legal harmonization.

2. Contribution of the Study

The principal contribution is the Digital Trust Governance Model: $DT = N \times I \times S \times T$

3. Policy and Organizational Implications

BiH should move toward an integrated governance architecture aligned with European cybersecurity and privacy standards.

Organizations should complement legal alignment with measurable ISO/IEC 27001 and ISO/IEC 27701 controls for risk, incidents, access, continuity, training and privacy by design.

4. Limitations and Future Research

The study is limited by reliance on legal, institutional and public sources, which restricts direct measurement of operational capacity.

Because the model is conceptual and qualitative, future research should develop and test quantitative or expert-based indicators for each variable.

5. Final Remarks

Digital trust cannot be achieved through regulation alone; it requires coordinated institutions, credible enforcement, responsible management and implemented security and privacy controls.

The proposed model frames digital trust as the measurable result of integrated regulation, institutional capacity, enforcement credibility and technical implementation.

Abstract
This paper addresses the problem of low social activity among students at higher education institutions and proposes a solution through a reward system implemented in a mobile application. Based on the analysis of global gamification practices in IT education, particularly at the University of Doha, the University of London, and the University of Northampton, it has been established that existing systems are limited to virtual rewards. The system proposed by the authors is the first among Ukrainian higher education institutions to combine the completion of social tasks on external networks, verification by an administrator, the accumulation of virtual points, and their exchange for the university's physical merchandise. The paper describes a pilot implementation among 100 students. Based on survey data from this pilot, theoretical projections are substantiated: an increase in student survey participation from 35% to 85-92% and a 300% increase in the university's social media presence. The prospects for scaling the system to 12,000 students are outlined.

Keywords: gamification, reward system, student social activity, mobile application, virtual points, higher education

I. INTRODUCTION

The modern development of information technologies creates new opportunities for increasing the efficiency of the educational process in higher education institutions. As researchers note [1, 2], special attention is drawn to gamification methods – the use of game mechanics in non-game contexts to increase user motivation and engagement. In higher education, gamification is used to enhance students' learning activities, increase class attendance, and improve academic performance [3]. According to the classical work of Karl Kapp [4], gamification of the educational process is based on elements such as points, badges, leaderboards, and levels, which together create a gaming experience for students. Leading universities around the world are implementing gamification elements into their educational programs. For example, the University of Doha (Qatar) is implementing a three-year research project to integrate gamification into programming education, using the Octalysis framework by Yu-kai Chou [5], which identifies eight key drivers of human motivation. The University of London uses the Level Up system, which allows students to earn experience points (XP) for completing educational activities, including watching video lectures, performing laboratory work, and passing tests, and displays their progress on the leaderboard. Research conducted at the University of Northampton confirms the positive impact of combining points, badges, and leaderboards on student attendance and academic performance. In addition, the work [6] presents a systematic literature review of gamification in educational

programs, confirming the growing interest in this topic. However, the analysis of global experience reveals a significant limitation: none of the existing systems provides for rewarding students with physical objects (merchandise). According to a systematic review, most studies focus on virtual rewards (points, badges, levels, leaderboards), which have a limited long-term motivational effect [7]. In addition, there are no examples of using gamification to increase students' social activity on external social networks, which is an important factor in the media presence of a modern university. It is also worth noting the work [8], in which the authors propose using artificial intelligence to gamify programming exercises, but this approach does not provide material rewards. This work aims to substantiate and implement a reward system in a mobile application to increase students' social activity at Lutsk National Technical University (LNTU) by combining virtual points with the option to redeem them for the university's physical merchandise.

II. RELATED WORK

Gamification in education has been widely studied. Kapp defined the core game elements applicable to non-game contexts. Chou introduced the Octalysis framework, which identifies eight human motivation drivers. More recent systematic reviews confirm that points, badges, and leaderboards remain the dominant gamification mechanisms. Comparative analysis of existing implementations at the University of Doha, the University of London, and the University of Northampton shows that none of these systems integrates material rewards (merchandise) or focuses specifically on students' social activity on external social networks. Montella et al. proposed an AI-powered gamification tool for programming exercises, but their approach lacks tangible incentives. The theoretical gap addressed by this paper is the lack of a closed motivation cycle (task → action → verification → accumulation → material reward) in existing higher education gamification systems. Self-determination theory suggests that external rewards can sometimes undermine intrinsic motivation; however, when rewards are perceived as informational rather than controlling, they can enhance engagement. The proposed system is designed with this distinction in mind.

III. METHODOLOGY

The analysis of LNTU students' social activity before the system's implementation revealed several problems. Firstly, student participation in university surveys is low, at about 35% of the total student population. Secondly, the university's presence on social networks, particularly Instagram and Facebook, is insufficient, as students rarely repost or share content about university life. Thirdly, there is no incentive system for students who actively promote the university. Fourthly, there is low student feedback through formal communication channels. Solving these problems is particularly relevant in the context of growing competition between higher education institutions for applicants. The proposed reward system is implemented as part of a mobile application developed using the cross-platform technology Flutter (Dart language). The application operates on iOS and Android platforms. The main components of the system are the task module, verification module, balance and store module, and notification module. The task module maintains a list of social tasks, each assigned a complexity coefficient: easy tasks receive a coefficient of 1, medium tasks receive a coefficient of 2, and difficult tasks receive a coefficient of 3. The base reward value is 10 conditional points, multiplied by the complexity coefficient to differentiate the reward based on the effort expended. Tasks are updated weekly (every 7 days), except for those with long execution periods. Task types include: liking, commenting, posting a post or story, reposting news, and participating in surveys. The verification module is designed to confirm task completion. After acting on a social network, the student uploads a screenshot or photo confirmation. Verification is performed manually by an administrator, after which the task status changes from "Under review" to "Completed," and points are credited to the user's balance. This approach to verification, although it requires human resources, ensures high reliability of results, unlike automatic systems, which can be deceived. The balance and store module displays the current balance of accumulated points. It includes a catalog of LNTU merchandise, which includes a mug, shopper, umbrella, notepad, and pen, each with a fixed cost in points. Exchange requests are accepted continuously, but physical merchandise issuance is scheduled once a month.

Such deferred material rewards create an additional motivational effect, as students can accumulate points throughout the month and receive desired items. The notification module provides push notifications that inform students when new tasks appear at the beginning of the week and when task status changes. The reward system's algorithm includes a sequence of steps that begins with user authentication in the application. After logging in, the student views the available tasks in the "In progress" category and selects one based on their preferences and capabilities. Next, the user performs the necessary action on an external social network, then uploads proof of completion as a screenshot or photo directly into the application. After that, the task receives the "Under review" status and waits for the administrator's verification. Upon successful verification, the corresponding number of points is credited to the user's balance, and the task status changes to "Completed." In case of rejection, the student can receive comments and try to complete the task again. Accumulated points can be redeemed in the application store for any product in the merchandise catalog. Ordered material rewards are received by students once a month at the university distribution point. Figure 1 shows the flowchart of the reward system.

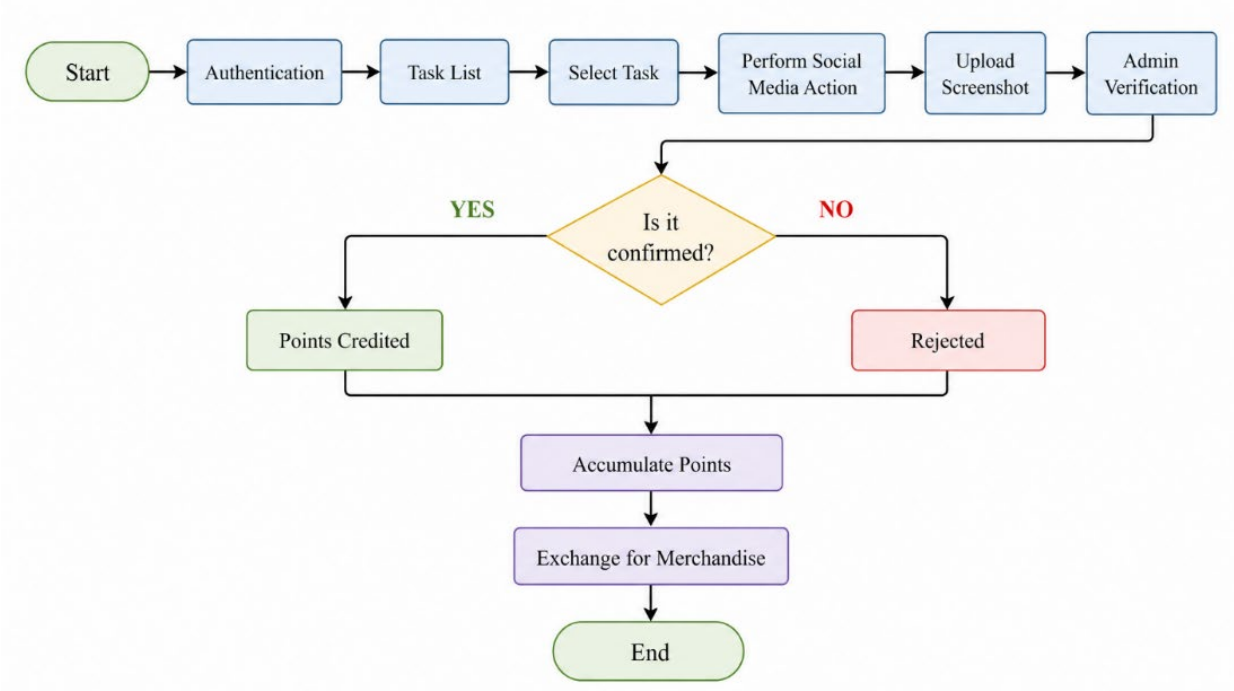

Figure 1. Reward system flowchart

To substantiate the novelty of the proposed system, a comparative analysis with existing solutions was conducted, and the results are summarized in Table I. As shown in the table, all analyzed systems use virtual points, badges, and levels, but none provide material rewards such as merchandise. The University of Doha and the University of London implement weekly task updates and leaderboards, but their systems do not include tasks on external social networks. The University of Northampton partially implements social tasks, but verification there is automatic, which does not guarantee reliable completion. The key difference of the LNTU system is the combination of virtual points with material rewards in the form of merchandise, which creates a closed motivation cycle: task → action → verification → accumulation → material reward. None of the analyzed higher education institutions applies a similar approach.

Table 1. Comparison of reward systems in higher education institutions

Characteristic	University of Doha	University of London	University of Northampton	LNTU (proposed)
Virtual points	Yes	Yes	Yes	Yes
Badges/levels	Yes	Yes	Yes	Yes
Leaderboard	Yes	Yes	Yes	In plans
Tasks on social networks	No	No	Partially	Yes
Completion verification	Automatic	Automatic	Automatic	Manual (administrator)
Material reward	No	No	No	Yes

A pilot implementation was conducted with 100 LNTU students in April 2026. Participation was voluntary and anonymous. Students were invited to use the mobile application and complete social tasks over four weeks. After this period, a survey was administered to collect feedback on perceived motivation, ease of use, and willingness to continue using the system. No control group was used in this pilot. Therefore, all reported results are theoretical projections based on survey responses and behavioral observations, not controlled experimental outcomes. The projections (85-92% survey participation, 300% increase in social media mentions) were derived from students' self-reported intentions and from extrapolation of task completion rates observed during the pilot. Ethical approval was obtained from the LNTU Institutional Review Board. All participants gave informed consent, and no personal identifying data were collected.

IV. RESULTS AND DISCUSSION

As of April 2026, the developed application is in pilot testing with 100 students participating. Based on survey responses from these 100 users, the following results are predicted after scaling the system to the entire university, where 12,000 students study. As shown in Figure 2, a significant increase in student participation in surveys is expected: from the current 35% to the predicted 85-92%, which is an increase of 50-57 percentage points. These projections are theoretical and require experimental validation with a control group.

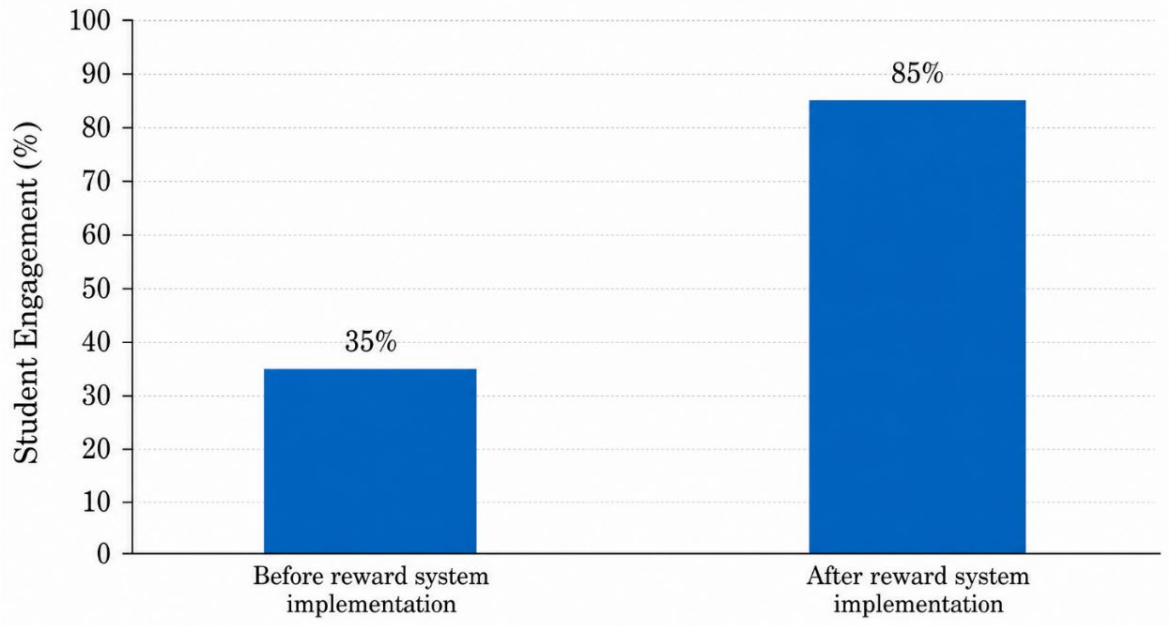

Figure 2. Expected growth in student survey participation.

In addition, an increase in the university's media presence on social networks is predicted: the number of LNTU mentions per month, according to Figure 3, should increase from about 50 to 200, i.e., by 300%. This projection is based on the observed frequency of task completion in the pilot group.

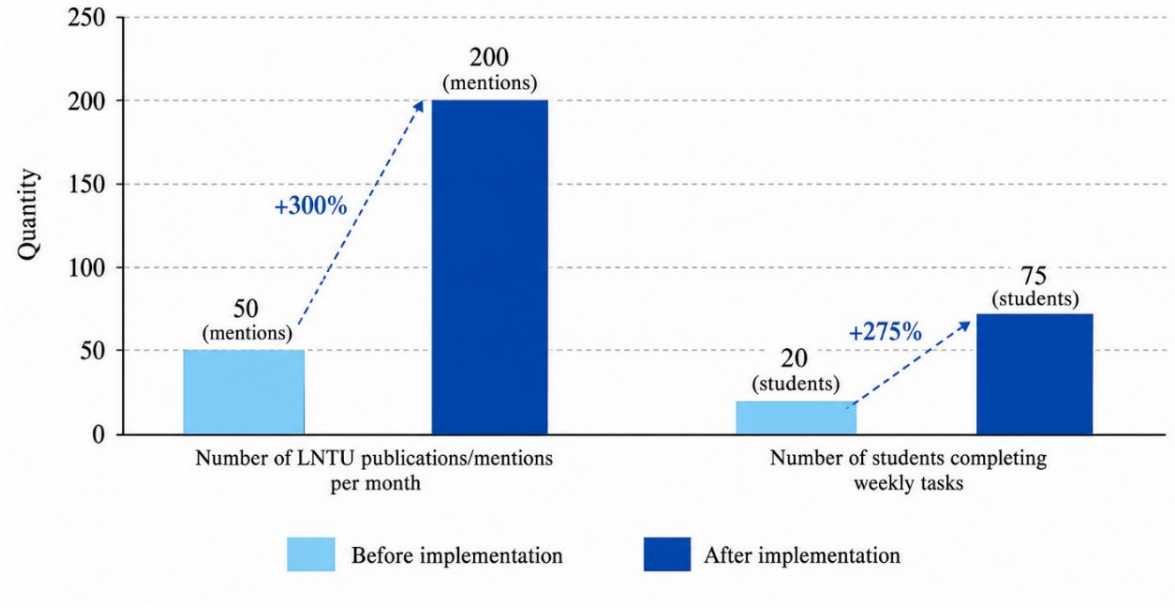

Figure 3. Expected growth in social media activity.

Also expected is an increase in the number of students who perform social tasks weekly, from 20 to 75 people. The economic efficiency of the proposed system is evident in the fact that the cost of merchandise (a mug costs about 150 UAH, a shopper – about 200 UAH) is lower than the cost of traditional advertising on social networks required to achieve the same level of audience coverage. This study has several limitations. First, the reported results are theoretical projections, not measured outcomes. Second, the pilot did not include a control group, so causal attribution of behavioral change to the reward system is not possible. Third, manual verification by an administrator may not scale to 12,000 students. Fourth, the long-term effect on intrinsic motivation was not assessed.

V. CONCLUSION

The article proposes and substantiates a reward system to increase students' social activity, implemented in a mobile application. The main results of the study are as follows. Firstly, an analysis of the global experience of gamification in IT education was conducted, using the University of Doha, the University of London, and the University of Northampton as examples, revealing the absence of systems that combine virtual points with material rewards such as merchandise. Secondly, for the first time at a higher education institution in Ukraine, a comprehensive approach to motivating students by completing tasks on external social networks, with administrator verification, accumulation of virtual points, and exchange for the university's physical merchandise is proposed. Thirdly, the architecture and algorithm of the reward system are presented, enabling the solution to scale from the current 100 students in the pilot group to 12,000 students. Fourthly, theoretical projections of key indicators are substantiated based on pilot survey data: participation in surveys may increase from 35% to 85-

92%, and the media presence of the university may increase by 300%. These projections require experimental validation. Further research will focus on automating task verification, using artificial intelligence for image recognition, integrating the system with the electronic hryvnia (e-hryvnia), and conducting a controlled experiment with a control group.

ACKNOWLEDGEMENT

The authors thank Lutsk National Technical University for supporting the pilot implementation of the reward system.

Abstract
We describe our recent work on improving lossless data compression performance for event-based cameras. Starting with the spike coding algorithm of Bi, Dong, Tian, and Huang, as well as the Motion Compensated Compression algorithm based on Optical Flow (MCCOF) of Bairagi and Cheng, this paper explores two directions to improve compression performance by adapting to the data being compressed. These include using K-means clustering to reduce spatial redundancy and applying adaptive event partitioning to the MCCOF algorithm. Preliminary experimental results on the DVS-PKU dataset show positive improvements for the MCCOF algorithm with adaptive partitioning in most cases, whereas K-means clustering underperforms. Ongoing research directions on cube-based motion compensation are also outlined.

Keywords: event-based cameras, data compression

I. INTRODUCTION

While conventional frame-based cameras capture video data by taking a series of pictures (or frames) in quick succession, event-based cameras operate in a very different manner. In event-based cameras, each pixel is an independent sensor that can detect significant changes in log-luminance and report them asynchronously [1]. Such changes are reported as an event containing a timestamp, the coordinates, and the polarity of the change (light-to-dark or dark-to-light). The exact log-luminance level is not reported. While this may provide fewer details about the scene, it allows the cameras to detect significant changes with very low latency and can generate events with sub-millisecond precision. Due to the low latency and high dynamic range of event-based cameras, real-time applications such as autonomous vehicle navigation can benefit from their use.

Event-based cameras naturally reduce the amount of data generated because pixels that do not change significantly do not generate any events. However, the high temporal resolution of these cameras means that a large volume of data can still be generated in an active scene. For example, a falling waterdrop can generate 46.2 million bytes of data over 6 seconds, representing almost 11.5 million events [2]. The transmission and, if needed, storage of these events present a difficult challenge. Compression is needed to handle this amount of data. In this work, we focus on lossless compression.

The events generated by these cameras are asynchronously ordered in time as sensors at various pixels report significant changes. As a result, the coordinates and polarity of consecutive events may not have a high spatial correlation. Conventional image and video compression algorithms that exploit spatial redundancies would need to be adapted to handle this type of data. Collecting the events into "frames" before processing would allow some of these redundancies to be exploited, at the expense of increasing latency of the compression algorithm.

Several algorithms have been developed for compressing data from event-based cameras. For example, Bi, Dong, Tian, and Huang proposed a spike-coding lossless compression algorithm [3], in which events are collected into "macro-cubes" temporally and "spike-cubes" spatially. Each spike-cube is encoded using one of two possible modes, depending on whether the events are spatially clustered or distributed in the cube. They later modified their algorithm to incorporate inter-cube prediction, leveraging temporal correlations among macro-cubes [4]. Such predictions are computationally costly and produced modest improvements in compression performance. Khan, Iqbal, and Martini proposed a time-aggregation-based algorithm that outperformed the spike-coding algorithm [5]. It works by aggregating events into event frames, which are encoded by conventional video compression algorithms. Unfortunately, this incurs a high computational cost and high latency. Other compression algorithms not specifically designed for event-based cameras can also be used [6], but they are not as effective.

Bairagi and Cheng proposed a new method to predict current events from previous events [7], [8]. They applied an event-based optical flow algorithm by Ridwan and Cheng [9], [10] to efficiently perform predictions in the Motion Compensated Compression algorithm based on Optical Flow (MCCOF). The PKU-DVS dataset [2] was used to evaluate the MCCOF algorithm, and it performed better than the spike-coding algorithm on most scenes.

In this paper, we report work on two different directions to improve the spike-coding and MCCOF algorithms. First, we examined the use of K-means clustering within each macro-cube in spike-coding for macro-cubes with more than one spatial cluster. Next, we introduce an adaptive version of the MCCOF algorithm, in which events in macro-cubes are partitioned based on the data. We will show that the adaptive version improves the compression performance of the MCCOF algorithm in many cases. Finally, we propose a possible cube-based motion compensation scheme, similar to that used in frame-based video compression algorithms, that shows promise for further exploration.

The paper is organized as follows. In Section II, background information and previous approaches for data compression for event-based cameras are given. In Section III, we describe our experiments with K-means clustering to improve spike coding. In Section IV, we introduce an adaptive version of the MCCOF algorithm. A cube-based motion compensation scheme is proposed in Section V. Concluding remarks and future directions are given in Section VI.

II. BACKGROUND

1. Event-Based Cameras

Event-based cameras are biologically inspired and have individual sensors for each pixel to detect significant log-luminance changes. When a sensor detects a significant change, it generates an event asynchronously, reporting the coordinates, the change $.(x, y, t, p)$, where $p \in \{-, +\}$. While frame-based conventional cameras capture frames regularly even when there are no changes, event-based cameras only generate events when there are significant changes. Only the polarity of the change is reported, but the magnitude is not. Event-based cameras have low latency and high dynamic range, making them suitable for applications that require real-time response under varying lighting conditions . The Address Event Data (AEDAT) format is used to store DVS event streams [11]. Event-based cameras, such as the DVS 128, DAVIS 240, and DAVIS 346 produced by iniVation, are used in this work [1].

Figure 1 shows the events captured by the Davis Dynamic Vision Sensor (DVS) [10]. The figure shows the events generated by a moving DVS camera on a static scene containing an apple. Events are generated at locations where significant changes in log-luminance occur. Typically, these events are associated with object boundaries, or, in this case, with the boundaries of the highlights on the apple's surface as well.

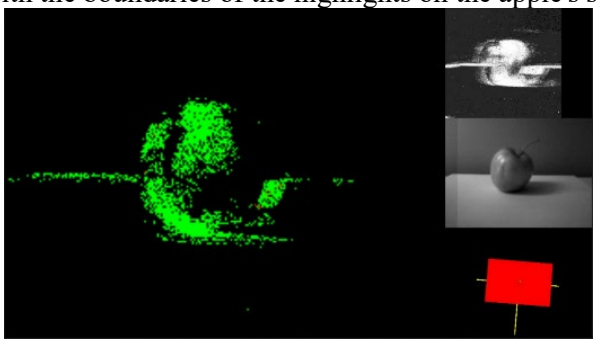

Figure 1. Events generated by a moving Dynamic Vision Sensor (DVS) on a static scene.

2. Previous Related Works

Bi, Dong, Tian, and Huang proposed a lossless predictive algorithm for DVS events (spikes) [3]. The sequence of events is partitioned into "macro-cubes" temporally adaptively, based on the length of time and number of events in the cubes. These macro-cubes are then further partitioned spatially into spike-cubes (Figure 2). By grouping events into temporally and spatially similar blocks, the algorithm can leverage redundancies among similar events to perform data compression. The locations and polarities of events are encoded by one of two methods, depending on whether the events in the spike-cubes are spatially clustered or distributed. The time-prior (TP) mode is used when events are spatially clustered and encodes the centroid location and each event's displacement from it. The address-prior (AP) mode is used when events are spatially distributed and encodes a binary map of event locations, followed by the remaining event details. The final encoding is done using a context-adaptive arithmetic coder [12].

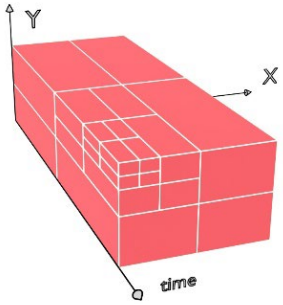

Figure 2. Partitioning events adaptively into spike-cubes.

Subsequently, the same authors [4] introduced reference AP and TP modes to exploit temporal correlations by predicting macro-cubes from previously encoded ones. The computational complexity of motion compensation is high, and, unfortunately, only a modest improvement in the compression ratio was achieved.

Bairagi and Cheng [7], [8] modified the spike coding algorithm [3] to incorporate motion compensation of events. They applied the optical flow algorithm of Ridwan and Cheng [9], [10] to efficiently generate motion predictions. Various strategies for encoding optical flow events (analogous to motion vectors in conventional video encoding) were studied, and the unpredicted residuals were then encoded using the original spike coding algorithm. The events were partitioned into spike-cubes in a non-adaptive manner to simplify the interaction between motion compensation and residual coding. Motion compensation was performed adaptively for each spike-cube only when it improved compression performance. The resulting algorithm, called the Motion-Compensated Compression Algorithm based on Optical Flow (MCCOF), outperformed the original spike-coding algorithm across most scenes in the PKU-DVS dataset. The architecture of the MCCOF algorithm is shown in Figure 3.

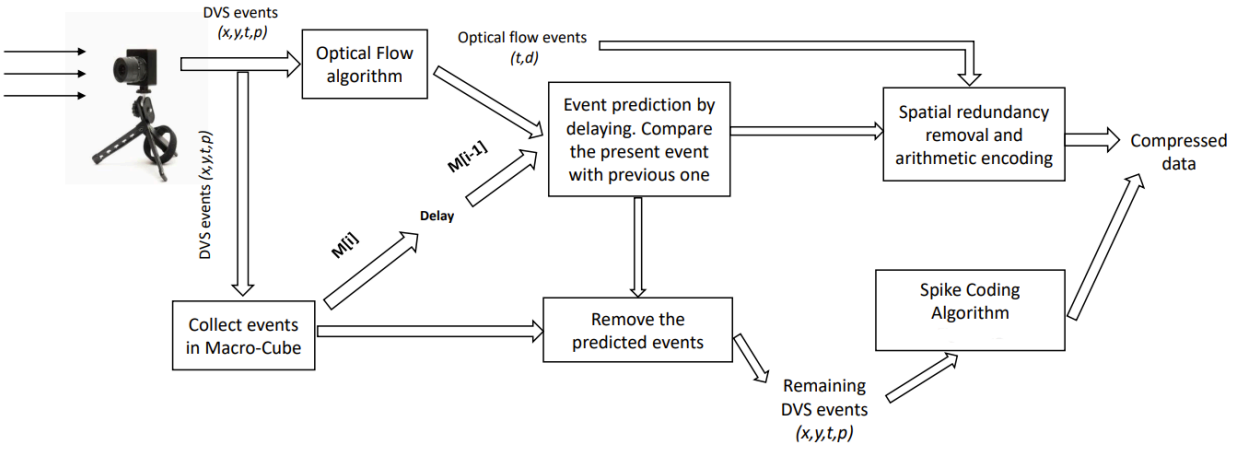

Figure 3. Overall architecture of the Motion Compensated Compression Algorithm based on Optical Flow (MCCOF).

III. K-MEANS CLUSTERING

In the spike coding algorithm of Bi, Dong, Tian, and Huang [3], two modes are used to encode spike-cubes depending on whether the events in that spike-cube are spatially clustered or distributed. In the former case, the time-prior (TP) mode is used. In the TP mode, the spatial centroid of all the events in that spike cube is computed, and the location is encoded. The events in that spike-cube are then temporally ordered, and the spatial displacements, the time difference from the previous event, and the polarity of each event are encoded. When most of the events are clustered around the centroid, this can result in significant compression. On the other hand, the address-prior (AP) mode is suitable when the events are distributed spatially throughout the spike-cube.

Events in each spike-cube are not always either in one single cluster or completely distributed. The TP mode could potentially be generalized to support multiple clusters. At the same time, however, the adaptive partitioning of events into spike-cubes may already form spike-cubes that do not have more than one cluster. We now examine this aspect in more detail. Instead of partitioning the temporal macro-cubes into spike-cubes, we propose applying K-means clustering [13] to each macro-cube to group events into a small number of spatial clusters. The elbow method is used to determine the number of clusters present in each spike-cube [14], and a sequential K-means algorithm is used to perform incremental clustering as events arrive. Once the clusters are identified, each cluster is encoded in the same way as in the original TP mode—the spatial coordinates of the

centroid are encoded, followed by the spatial displacement of each event from the centroid. The timestamps and polarities of the events are encoded as before.

Experimental results on the PKU-DVS dataset [2] are given in Table 1, comparing the compression ratios achieved by the proposed K-means compression algorithm and the spike coding algorithm. Experimental results show that the K-means compression algorithm generally underperforms, sometimes by a significant margin. However, there is one scene (night traffic) in which the K-means algorithm performs better. In that scene, several fixed objects (e.g., streetlights) consistently generate events at the same locations. On the other hand, in scenes where the K-means compression algorithm performs particularly poorly (e.g., fluorescent and intersection), the events are sparse and not spatially clustered in the scene at all. Although the fluorescent scene also has a fixed fluorescent light, many events are randomly distributed throughout the scene due to noise. In particular, random noise that can appear throughout the scene is forced to belong to certain clusters in this approach, and that leads to overall decreased performance. These results confirm that the adaptive partitioning of events into spike-cubes in the spike coding algorithm generally localizes events to single clusters. Still, in some rare cases, it can be beneficial to consider alternatives.

Table 1. Compression ratios from the spike coding algorithm and the K-means algorithm.

IV. ADAPTIVE PARTITIONING IN THE MCCOF ALGORITHM

The Motion Compensated Compression Algorithm based on Optical Flow (MCCOF) [7], [8] uses optical flow calculations to perform motion compensation, thereby improving compression performance. Unlike conventional frame-based video encoding algorithms, motion compensation is performed for each pair of events rather than for each pair of coefficient blocks [6]. Optical flow events serve as motion vectors and are encoded, and any unpredicted events (the residual) are encoded using the spike coding algorithm. Due to how the optical flow prediction and spike coding algorithms were integrated into the MCCOF algorithm, the spike coding algorithm used only fixed-size macro-cubes and spike-cubes. In the original MCCOF algorithm, each macro-cube contains a fixed number of events, and each spike-cube has the same spatial dimensions arranged in a regular grid. As a result, some sparse macro-cubes may represent a long elapsed time, and some spike-cubes

may have very few events, leading to ineffective compression. Instead, we adapted our algorithm to split macro-cubes and spike-cubes adaptively, without using a tree structure, as in the spike-coding algorithm. Otherwise, the tree structure would also have to be encoded and transmitted for every macro-cube.

In our proposed adaptive MCCOF algorithm, the events are first spatially partitioned by a regular fixed-sizegrid into 10 0 $blocks$ ($S = 10$ [8]). For each spatial partition, we collect events temporally adaptively into spike-cubes, by a threshold on either the elapsed time between the first and the last event in that spike-cube, or the number of events in that spike-cube (Figure 4). The algorithm determines the bit rate achieved with different partitions of spike cubes and adaptively chooses the one that yields the lowest bit rate. Notice that the decoder only needs to be informed when each cube ends in the event stream, which is required in the original MCCOF algorithm. No additional data needs to be encoded to describe the partitioning. Using a fixed spatial grid requires no additional bit budget to encode the spatial partitioning of events. In the original MCCOF algorithm, predicted events are removed, and the spike-coding algorithm encodes only the residuals. As a result, the residual events coded by the spike coding algorithm are much sparser. The proposed adaptive partitioning strikes a trade-off between ensuring a sufficient number of events in a spike-cube to exploit redundancies and achieving a spike-cube with a long elapsed time, which may reduce temporal redundancies. Table 2 presents experimental results for the Adaptive MCCOF algorithm, compared with spike coding and the original MCCOF algorithm. We can see that in most cases, the adaptive MCCOF performs better than the original MCCOF and spike coding algorithm. In cases in which the spike coding algorithm performs better than the original MCCOF algorithm (waterdrop, fluorescent, and football), the Adaptive MCCOF algorithm improved MCCOF to surpass the original spike coding algorithm in all scenes except for the waterdrop scene. There are a few cases where the Adaptive MCCOF algorithm performs slightly worse than the original, and in the pedestrian scene, it performs significantly worse. The reason is that the original MCCOF algorithm selects the optimal spike-cube size spatially and temporally for the data set, even though the size is fixed across the entire event stream. On the other hand, the Adaptive MCCOF selects a single fixed spatial size and adapts only temporally within the event stream. This choice was deliberate to avoid a tree structure for representing the partitioning, but it sometimes performs slightly worse, as seen in our experimental results. If desired, one can use the Adaptive MCCOF algorithm to encode the data multiple times with different fixed spatial sizes and choose the one that yields the best performance; with that change, the Adaptive MCCOF can never underperform compared to the original MCCOF algorithm. However, the computational cost of compression would increase.

In the case of the pedestrian scene, the chosen spatial size was misaligned with the objects' sizes. By choosing different fixed sizes for the spatial partitioning of spike-cubes, the performance of the Adaptive MCCOF approaches that of the MCCOF Algorithm. Further investigation is needed to address this drawback and enable some adaptation of spatial partitioning to spike-cubes without introducing significant overhead for encoding the tree structure. It may be possible to use the spatial structure of one macro-cube to predict the spatial structure of the next one.

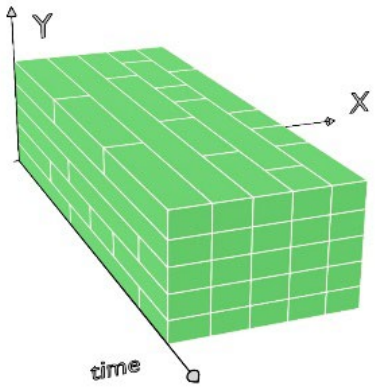

Figure 4. Partitioning events into spike-cubes in adaptive MCCOF.

Table 2. Compression Ratio from the Adaptive MCCOF algorithm compared to spike coding and the MCCOF algorithm.

Scene	Spike Coding	MCCOF	Adaptive MCCOF
waterdrop	**59.59**	54.74	57.34
fluorescent	33.67	32.14	**36.01**
lighter	20.38	**22.16**	21.51

night-roadside	5.44	6.34	**6.48**
night-traffic	3.87	4.71	**4.91**

V. CUBE-BASED MOTION COMPENSATION

Dong, Bi, Tian, and Huang [4] proposed the reference TP and reference AP modes to predict cube events, thereby further improving compression performance. For each spike-cube, a search is conducted to find the best motion vector that best matches the current spike-cube of events with a previous spike-cube, and the prediction residuals are encoded. The computational cost is high (three times that of the original spike coding algorithm [3]), and the improvement in compression performance is modest.

The MCCOF algorithm uses a highly efficient optical flow method to compute motion vectors quickly. These motion vectors can only be in one of eight possible compass directions, each of length 1. Still, the restriction allows the motion vectors to be computed quickly, and the compression performance of the MCCOF algorithm over spike coding justified this restriction. In addition, the optical flow algorithm [9], [10] is based on tracking single events, predicting only one event from another reference event. In the MCCOF and Adaptive MCCOF algorithms, each motion vector is used only to predict one other event.

While there are already significant improvements in compression performance over the spike coding algorithm, a cube-based motion compensation scheme can use a single motion vector for each spike-cube to predict a spike-cube of events, reducing the number of motion vectors to encode. We propose two approaches to incorporating cube-based motion compensation into existing compression algorithms.

In the first direction, we can apply the optical flow algorithm of Ridwan and Cheng [9], [10] to efficiently compute the motion vectors in the spike coding algorithm [4]. The motion vectors in the same spike-cube are collected, and the majority direction is used as the motion vector for the entire spike-cube. Prediction residuals are encoded in reference TP and AP mode as before. Preliminary results show promise for significantly reducing computational time while maintaining the improvements observed previously in [4]. We are investigating the possibility of allowing our optical flow algorithm to search over a wider range of motion vectors, trading off more accurate predictions for higher computational costs.

In a second direction, we would like to explore incorporating the same cube-based motion-vector computation into the MCCOF and Adaptive MCCOF algorithms. The results of this exploration will be forthcoming.

VI. CONCLUSIONS

In this paper, we examined two possible directions for improving the compression performance of the spike coding and MCCOF algorithms. The PKU-DVS dataset was used to evaluate the effectiveness of these improvements. First, we explored using K-means clustering to adapt the spike coding algorithm to handle better spike-cubes that may contain multiple spatial clusters. Experimental results show that, in general, the original spike-cube partitioning algorithm already yields localized clusters, and K-means clustering underperforms in all but one case. Further investigations may be warranted to understand that case. Next, we introduced adaptive partitioning to the MCCOF algorithm. The events are partitioned non-adaptively spatially but adaptively temporally to exploit spatial redundancies in the spike-cube and achieve optimal compression. The adaptive MCCOF algorithm outperforms the original MCCOF algorithm and the spike-coding algorithm in most cases.

Finally, we proposed two methods to incorporate cube-based motion compensation to further improve the performance of spike-coding and MCCOF, both in terms of compression performance and computational cost. These directions are currently being explored, and we expect the results of these investigations to appear in a forthcoming paper.

Abstract
This study investigates the application of knowledge-based Artificial Intelligence (AI) in online gambling and betting systems through a structured use-case approach. Focusing on semantic networks, frames, scripts, and production rules, the study demonstrates how these knowledge representation techniques can enhance system reliability, risk management, and decision transparency in regulated gambling environments. Each technique is analyzed according to its functional role, strengths, and limitations, and its combined use is examined through a comparative and integrative perspective. The findings indicate that integrating multiple knowledge representation techniques provides complementary capabilities that any single technique cannot achieve. The proposed approach highlights the continuing relevance of symbolic and hybrid AI solutions for explainable, ethical, and compliant online gambling platforms.

Keywords: AI, knowledge representation, online gambling, betting systems

I. INTRODUCTION

AI plays an increasingly important role in modern digital systems by enabling automated reasoning, decision-making, and pattern recognition [1], [2]. A fundamental component of intelligent behavior in AI is knowledge representation [3], which provides formal mechanisms for structuring and reasoning over domain knowledge in a way that is understandable and usable by machines. Recent research emphasizes that effective knowledge representation remains essential for building AI systems that move beyond raw data processing and support explainable, consistent, and auditable decision-making, particularly in complex and high-risk domains [4], [5]. The online gambling and betting industry represents a domain where AI technologies are widely adopted due to the availability of large-scale data, real-time operational requirements, and complex risk management challenges [6], [7]. AI-driven solutions can be applied for odds calculation, user profiling, fraud detection, regulatory compliance, and responsible gambling interventions [7]. However, studies indicate that purely data-driven approaches, such as machine learning models, do not always produce sufficient or reliable results in highly regulated environments that require transparency, interpretability, and ethical accountability [8]. Limitations related to explainability, data bias, and incomplete or dynamic user data highlight the need for complementary AI approaches and integration with established practices and human decisions [9]. Knowledge-based AI approaches, implemented through knowledge representation techniques, offer a structured and interpretable foundation for addressing these challenges. Techniques such as semantic networks, frames, scripts, and production rules enable explicit modeling of domain concepts, relationships, processes, and expert

decision logic [10]. Recent literature shows that such symbolic and rule-based approaches are particularly suitable for online gambling systems, where business rules, regulatory constraints, and behavioral patterns must be represented in a transparent, controllable, and verifiable manner, especially when supporting compliance and responsible gambling mechanisms [7], [8], [11], [12]. This study addresses the limitations of purely data-driven AI in online gambling systems, particularly regarding transparency and regulatory alignment. It examines how knowledge representation techniques, such as semantic networks, frames, scripts, and production rules, provide structured and interpretable decision support in a realistic use case. The study highlights their role as complementary mechanisms to existing AI solutions, improving system reliability, risk management, and compliance.

II. RELATED WORK

Recent research highlights that knowledge representation remains a foundational component of Artificial Intelligence, particularly in domains where explainability, accountability, and structured reasoning are required [10], [13]. While modern AI research is often dominated by machine learning and statistical models, several studies emphasize that symbolic, knowledge-based AI approaches continue to play a critical role in enabling transparent decision-making, semantic reasoning, and system interpretability [10], [14]. In regulated and high-risk environments, knowledge representation techniques provide mechanisms that allow AI systems to model explicit domain knowledge and support auditable reasoning processes [5], [13]. The application of AI in the online gambling and betting sector has expanded significantly, driven by large-scale user data, real-time analytics, and competitive market pressures. Recent empirical studies demonstrate that AI-based systems are widely used for player behavior analysis, fraud detection, personalization, and early identification of gambling-related risks [15], [16], [17]. Machine learning techniques, in particular, have shown strong performance in detecting anomalous behavior patterns and predicting at-risk players. However, contemporary research also notes that these models often lack sufficient transparency and may be difficult to align with regulatory requirements without additional control mechanisms [5], [18], [19]. To address these limitations, recent literature increasingly supports hybrid AI approaches that combine data-driven models with symbolic and rule-based knowledge representation. Such approaches allow system designers to encode business logic, regulatory constraints, and ethical safeguards directly into AI systems [19]. Among the established knowledge representation techniques, semantic networks are commonly used to model relationships among entities, which can be players, betting events, risks, and outcomes, enabling structured reasoning over interconnected concepts [20], [21], [22]. Frames extend this capability by representing entities with well-defined attributes, default values, and procedural behaviors, supporting consistency and reuse across system components [23]. Scripts have been applied to model typical sequences of actions, such as the lifecycle of an online betting session. At the same time, production rules remain a practical technique for encoding expert knowledge and decision logic in an interpretable deterministic form [24]. Recent studies emphasize that these techniques remain highly relevant when designing AI systems that must balance operational efficiency with transparency and ethical compliance [24], [25]. Although these approaches are well established, their systematic use in modern online gambling platforms remains an active area of research. Most studies focus on isolated AI components, with fewer exploring how knowledge representation can be integrated into coherent system architectures alongside analytical and predictive models. This study addresses that gap by examining semantic networks, frames, scripts, and production rules as practical tools within AI-enabled gambling systems. A representative use case shows how structured knowledge representation can be incorporated into real-world system design rather than treated purely as theoretical.

III. AI KNOWLEDGE REPRESENTATION–BASED USE CASE

This study follows a conceptual, use-case-oriented methodology to examine the application of knowledge representation techniques in AI-enabled online gambling and betting systems [1], [2], [4], [10], [13]. A real-world online gambling platform operating in the Republic of North Macedonia, covering both online and betting

shop activities, serves as the use case, reflecting key elements such as players, events, odds, accounts, risk indicators, and regulatory constraints. The methodology demonstrates how structured knowledge representation is applied to systematically model system behavior, risk-related processes, and decision-making structures. The analysis was conducted from August 2025 to April 2026 to capture typical system activities and interaction scenarios. The study examines four established knowledge representation techniques: semantic networks, frames, scripts, and production rules [1], [3], [4], [13]. These AI-enhanced techniques were selected for their interpretability and practical applicability in regulated environments. Each technique is analyzed according to its functional role within the use case: semantic networks for modeling relationships among core concepts, frames for structuring system entities and their attributes, scripts for representing typical sequences of betting-related activities, and production rules for encoding decision logic and policy constraints. Together, these methods provide complementary perspectives on how symbolic AI can enhance system transparency and control, thereby complementing human discussion in daily operations. Rather than evaluating predictive accuracy or algorithmic performance, the methodology emphasizes qualitative modeling and structural analysis. By examining how each representation technique contributes to specific system functions within the same use case context, the study highlights their combined value in supporting explainable, robust, and ethically aligned AI behavior, particularly when used alongside data-driven approaches.

1. Semantic Networks

Semantic networks are used as a core knowledge representation technique for modeling the conceptual structure of an AI-enabled online gambling and betting system. Their graph-based structure enables transparent and interpretable representation of entities and relationships, organizing domain knowledge such as players, betting activities, risk factors, and responsible gambling mechanisms [20], [21]. They define explicit relationships (edges) between entities (nodes), capturing system interactions and supporting reasoning about betting actions, risk levels, and policies, thereby forming a foundation for higher-level decision support. Figure 1 illustrates the constructed semantic network for the use case, showing the modeled entities, their labeled relationships, and key interaction dependencies.

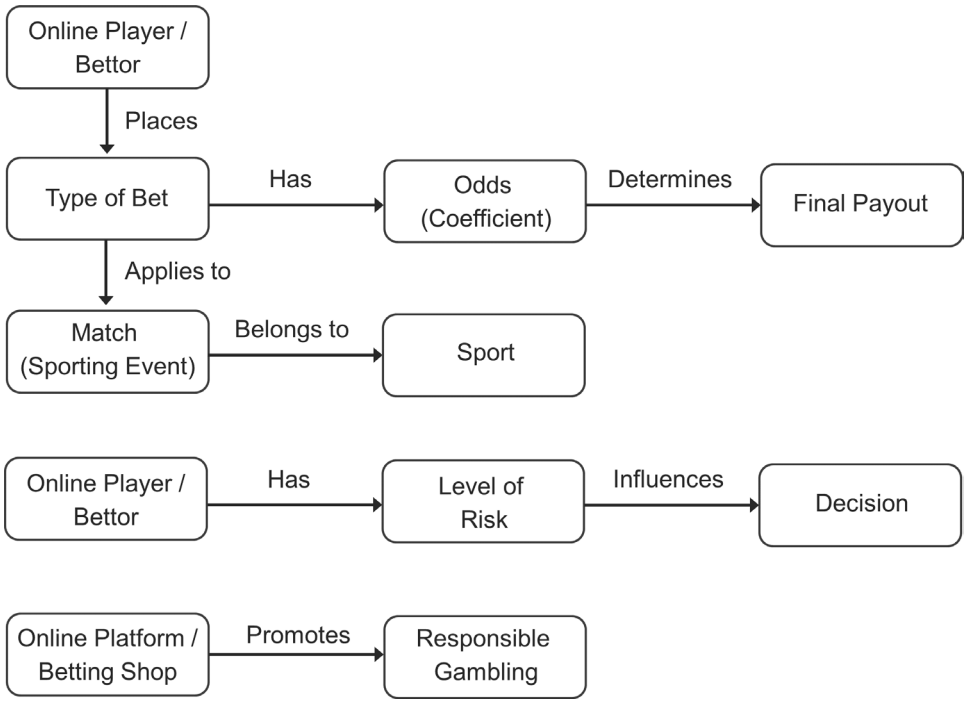

Figure 1. Semantic network representing core concepts and relationships in an online gambling and betting system

2. Frame-Based Representation

In this study, frames are used as a practical knowledge representation mechanism for modeling structured entities in an AI-enabled online gambling and betting system. Rather than focusing on theoretical classification, they are applied to organize entity-specific information in a clear, consistent, and controllable manner within the use case context. Frames represent core entities such as players, betting tickets, matches, and platform components by grouping related attributes and constraints into structured units. Each frame consists of slots for relevant attributes, including values, defaults, and optional procedural logic. This supports systematic knowledge storage and facilitates validation, updates, and analysis of individual entities [1], [3], [4], [13], [26], while containing information required to support risk assessment, betting eligibility checks, and compliance with responsible gambling policies.

To illustrate the use of frames in the proposed system, a Player / Bettor frame is defined using attributes directly derived from the operational requirements of an online gambling platform (Table 1).

Table 1. Player / Bettor Frame

Attribute	**Value**
Type	User (online, betting shop, or combined)
ID	Unique player identifier
Full Name	Text
Age	Numeric value
Account Balance	Real number (currency-dependent)
Risk Level	{low, medium, high} (default: medium)
Betting History	List of past bets with timestamps and outcomes
Betting Limit	Real number
Account Status	{active, suspended} (default: active)

3. Script-Based Representation

Scripts are used to model recurring interaction processes within an AI-enabled online gambling and betting system [23]. Unlike semantic networks and frames, which focus on entities and their attributes, scripts represent the ordered sequence of actions that typically occur during user interaction with the platform. This makes scripts particularly suitable for capturing behavioral flows and system dynamics in the use case. Within the proposed system, scripts are employed to describe the standard lifecycle of an online betting session. The script is triggered when a user intends to place a bet and proceeds through a predefined sequence of activities that reflects how users generally interact with the platform. Required input data includes bet amount, selected bet type, odds, time of placement, outcome, and user betting history. Before any evaluation or decision is produced, the script includes validation steps to ensure that the provided data are complete, realistic, and free of extreme or inconsistent values. The betting script in the use case consists of the following conceptual stages:

1. **Entry conditions**: Situations that must be fulfilled before the events in the script can take place. For example, for the "Online Betting" script: "The user wants to place a bet" and "The match meets the conditions that allow the user to place a bet."
2. **Props:** Objects used in the sequence of events. For the "Online Betting" script: odds, stake, type of game, time before the start, end time, result, comparison of data to determine whether there is a win or not, etc.
3. **Roles:** Performed by the participants. For the "Online Betting" script: user, match, result, etc.
4. **Scenes:** A real sequence of events. For the "Online Betting/Gambling" script, scenes may include:
   - Logging into the online betting platform
   - Choosing a game
   - Placing a stake
   - Type of game/way of playing
   - Win / loss
   - Payout
5. **Results:** Conditions that are fulfilled after the game is completed.

This structured sequence allows the system to reason about ongoing or incomplete interactions, such as detecting unfinished bets or abnormal betting behavior, and to maintain consistency in process execution. The AI integration enables fast and more accurate analysis of betting statistics and risk, far beyond what humans can process at the same speed. It helps detect fake accounts used for fraud and money laundering, provides 24/7 customer support through chatbots, and supports responsible gambling by monitoring player behavior, issuing warnings or restrictions when risky patterns appear, and reducing promotions for vulnerable players.

4. Production Rules

Production rules are used to represent decision logic and policy constraints in an AI-enabled online gambling and betting system. They provide an interpretable mechanism for enforcing decisions related to risk management, bonuses, account restrictions, and responsible gambling. Expressed in IF–THEN form, they link system actions to clearly defined conditions [10], [24].

In the proposed use case, they operate on data from other representations such as player frames, risk indicators, and betting history. When conditions are satisfied, corresponding actions are executed automatically, ensuring consistent and transparent behavior. This makes them well-suited to regulated environments where decision logic must be traceable and auditable. The following is an example of a risk management rule applied in the system:

IF (player.risk_level == high) AND (loss_duration == prolonged) THEN trigger warning AND prepare account restriction

Production rules are also used to model bonus eligibility logic, such as:

- Single-event ticket:

```
IF (bonus_active == true) AND
  (bet_odds >= 1.5) AND
  (total_turnover >= bonus_amount)
THEN bonus_status = completed
    allow_withdrawal = true
```

ELSE bonus_status = not_completed
allow_withdrawal = false

- Multi-event ticket:

IF (bonus_active == true) AND
(number_of_events >= 3) AND
(minimum_event_odds >= 1.45)
THEN ticket_qualifies_for_bonus = true
ELSE ticket_qualifies_for_bonus = false

These examples illustrate how expert knowledge and business rules can be encoded directly into the system, ensuring consistent enforcement of platform policies.

IV. COMPARISON AND INTEGRATION OF AI KNOWLEDGE REPRESENTATION TECHNIQUES

Based on the implementation findings, the AI knowledge representation techniques show complementary strengths individually and collectively, with key system functionality emerging most effectively when they are used in a coordinated rather than isolated manner.

5. Comparison of AI Knowledge Representation Techniques

Table 2 summarizes the key characteristics of the four knowledge representation techniques as applied in the proposed use case. The qualitative comparison is derived from their functional roles within the online gambling and betting system and reflects their respective strengths and limitations.

Table 2. Comparison of AI Knowledge Representation Techniques

Feature	Semantic Networks	Frames	Scripts	Production Rules
Type of Knowledge	Declarative	Declarative and Procedural	Declarative (process-oriented)	Procedural
Primary Structure	Graph of concepts and relations	Structured entities with attributes	Ordered sequence of actions	IF–THEN rules
Main Purpose	Represent relationships between concepts	Model system entities and states	Model user and system processes	Encode decision logic and policies
Flexibility	High	Moderate	Moderate	Variable
Reasoning Capability	Inheritance-based inference	Slot inheritance and defaults	Sequential reasoning	Logical rule evaluation
Ease of Modification	More complex due to interconnections	Relatively easy via slot updates	Requires script restructuring	Easy through rule addition/removal

Feature	Semantic Networks	Frames	Scripts	Production Rules
Suitability for Gambling Use Case	Modeling entities, risk links, and relationships	Managing player profiles and system data	Capturing betting session flow	Enforcing bonuses, limits, and compliance

This comparison shows that each technique addresses a different aspect of system intelligence. Semantic networks emphasize relationships; frame-structure entities and data; scripts organize behavioral flows; and production rules control decision logic.

6. Integration of AI Knowledge Representation Techniques in the Use Case

The analysis demonstrates that no single knowledge representation technique is sufficient to model the full complexity of an AI-enabled online gambling and betting system. Instead, the strongest results emerge when the techniques are combined into an integrated framework, where each technique complements the others [1], [2], [10], [13].

Through the practical implementation of the proposed use case, the following integration patterns between knowledge representation techniques were identified:

- **Semantic networks and Production rules:** Semantic networks represent static knowledge and the relationships between entities such as players, betting events, odds, risk, and responsible gambling measures [20], [21]. Production rules use this knowledge to make dynamic decisions based on risk thresholds, bonus conditions, and regulatory requirements [10], [24].
- **Frames and Production rules:** Frames organize detailed and structured information about individual entities, especially user accounts and betting states [1], [3], [4]. Production rules operate on this structured data to control system logic and decision-making [10], [24].
- **Scripts and Semantic networks:** Scripts represent the sequence of events during a betting session, while semantic networks capture the relationships between the entities involved in those events [12], [20], [21], [23].
- **Overall integration:** This combination creates a clear separation of roles: semantic networks model relationships, frames structure data, scripts describe behavior and event flow, and production rules enforce decisions. As a result, the system can achieve improved reliability, better risk management, decision transparency, and adaptability to future business or regulatory changes [1], [2], [8], [10], [13], [17].

V. DISCUSSION

The findings indicate that knowledge-based AI approaches, implemented through knowledge representation techniques, offer distinct and complementary advantages when applied to AI-enabled online gambling and betting systems [1], [2], [10], [13], [17]. Each representation technique contributes to a specific aspect of system intelligence, while also exhibiting limitations that reduce its effectiveness when used in isolation. Semantic networks capture relationships among players, bets, events, odds, and risk factors [20], [21]. Their graph-based structure improves interpretability and supports basic inference, which is important in regulated environments [10]. However, they face scalability issues in complex domains [21] and cannot adequately represent the uncertainty and probabilistic outcomes inherent in gambling systems [8]. Frames complement this by organizing entity-specific data such as user profiles and system states [1], [3], [4]. They support consistency and traceability through defined attributes and defaults [10], [13], but are less effective for modeling complex inter-entity

relationships [21] and may suffer from design and maintenance issues in large-scale systems [4]. Scripts model behavioral sequences and interaction flows within the platform [12], [23]. They enable process understanding, reasoning under incomplete information, and detection of anomalous behavior relevant to risk analysis [8], [17], but are limited by rigidity when handling highly dynamic or unforeseen user behavior. Production rules encode decision logic and policy constraints such as risk thresholds and responsible gambling measures [8], [10], [24]. While suitable for regulatory compliance, rule-based systems can become complex and difficult to maintain as system size increases [24]. Overall, the results highlight that the main strength of the proposed approach lies in integrating multiple knowledge representation techniques [1], [13]. By combining relational, structural, behavioral, and decision-making representations [20], [21], [23], [24], the framework forms a coherent and explainable AI system [2], [10], [13]. This integration improves reliability, risk management, and transparency compared to single-technique approaches [2], [8], [17], reinforcing the relevance of symbolic and hybrid AI in regulated gambling environments.

VI. CONCLUSION

This study presents a structured, use-case-based analysis of AI knowledge representation techniques in online gambling and betting systems, focusing on semantic networks, frames, scripts, and production rules. The analysis demonstrated that knowledge-based AI approaches are highly relevant to modern gambling platforms that require transparency, reliability, and regulatory compliance [1], [10], [13]. Each technique provides distinct capabilities: semantic networks support relationship reasoning, frames manage structured entity data, scripts capture interaction processes, and production rules enable interpretable decision logic [20], [21], [24]. However, their individual limitations indicate that no single technique can fully address the complexity of online gambling systems [13]. A key conclusion is that integrating multiple knowledge representation techniques offers the most effective solution. By combining relational, structural, behavioral, and procedural representations, the proposed approach supports more robust decision-making, improved risk management, and clearer enforcement of responsible gambling policies. This integrated framework enhances system explainability and control, addressing limitations of purely data-driven AI approaches [2], [8]. Future work may focus on developing and validating hybrid reasoning architectures that integrate symbolic knowledge representations with learning-based components under regulatory constraints, ensuring real-time auditability and decision traceability in operational gambling environments.

Abstract
Precipitation variability represents one of the main factors influencing water availability, environmental dynamics, and climate behavior in arid and semi-arid regions. This study aims to identify and characterize spatiotemporal precipitation patterns in Northwestern Mexico during the period 1960–2024 using remote sensing data and unsupervised Machine Learning techniques. K-Means, DBSCAN, and PCA were applied to identify climatically homogeneous precipitation regions and dominant patterns of regional climate variability. The results revealed significant spatial variability, with lower precipitation values in Baja California and Sonora and higher precipitation accumulation in Sinaloa. K-Means identified four optimal precipitation clusters (Silhouette = 0.4029), while PCA explained 94.33% of the total variability. Beyond pattern detection, the proposed framework provides a reproducible and interpretable approach for identifying climatically homogeneous regions, supporting hydroclimatic assessment, regional climate monitoring, and evidence-based water resource management in arid and semi-arid environments.

Keywords: Precipitation variability, machine learning, K-Means, DBSCAN, PCA, geospatial analysis, Northwestern Mexico**.**

I. INTRODUCTION

Precipitation is a fundamental component of the hydrological cycle. It plays a key role in water availability, ecosystem functioning, and environmental sustainability, especially in arid and semi-arid regions where water availability depends directly on rainfall events [1], [2]. In recent years, climate change has significantly altered precipitation patterns, increasing the frequency and intensity of droughts and extreme hydroclimatic events,

thereby affecting environmental stability, agricultural activities, and water resource availability [3], [4]. Advances in remote sensing have strengthened climate monitoring through high-resolution spatial and temporal data on atmospheric and hydrological variables [5]. Among these products, TerraClimate stands out as a widely used source in environmental and hydrological studies due to its global coverage and approximate 4 km spatial resolution [6], [7], enabling geospatial analyses focused on climate monitoring and regional hydrological variability assessment [8], [9], [10]. Machine Learning (ML) techniques have demonstrated strong potential for analyzing climatic and geospatial data by identifying spatial patterns and climate variability through unsupervised learning algorithms. Methods such as K-Means [11], [12], Density-Based Spatial Clustering of Applications with Noise (DBSCAN) [13], [14], [15], and Principal Component Analysis (PCA) [16], [17] facilitate automated precipitation pattern recognition and strengthen environmental and climate monitoring at regional scales [18]. Therefore, this study aims to identify and characterize spatiotemporal precipitation patterns in Northwestern Mexico using TerraClimate-derived precipitation data and unsupervised Machine Learning techniques for the period 1960–2024. Specifically, K-Means, DBSCAN, and Principal Component Analysis (PCA) were applied to identify climatically homogeneous regions, characterize dominant precipitation variability patterns, and evaluate the potential of integrating remote sensing and Machine Learning for hydroclimatic assessment and regional climate monitoring. The proposed framework contributes to a better understanding of precipitation variability and supports climate monitoring and water resource management in arid and semi-arid regions.

II. MATERIALS AND METHODS

The study area is located in Northwestern Mexico and includes the states of Baja California, Baja California Sur, Sonora, and Sinaloa (Figure 1) [19]. The region exhibits significant climatic diversity, with predominantly arid and semi-arid conditions in Baja California, Baja California Sur, and Sonora. In contrast, Sinaloa and the mountainous areas of the Sierra Madre Occidental are wetter, influenced by the North American Monsoon [20], [21]. Annual precipitation shows strong spatial heterogeneity, ranging from less than 150 mm in desert regions to more than 700 mm in mountainous areas and southern Sinaloa [22]. Additionally, high temperatures and regional hydroclimatic variability generate strong dependence on water resources, particularly for agricultural and environmental activities [23].

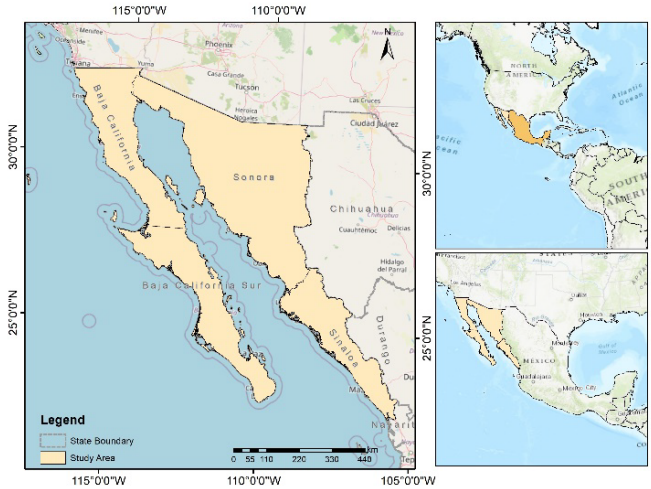

Figure 1. Location of the study area in Northwestern Mexico, including the states of Baja California, Baja California Sur, Sonora, and Sinaloa

For this research, annual accumulated precipitation derived from TerraClimate [6], [7], a widely used global climate dataset in environmental and hydrological studies [8], [9], [10], was used as the input variable for the Machine Learning analyses. TerraClimate provides climatic data at an approximate spatial resolution of 4 km for the period 1960–2024, enabling the analysis of spatiotemporal precipitation patterns in Northwestern Mexico. Precipitation was selected as a key indicator of hydroclimatic variability and water availability in arid and semi-arid regions.

III. METHODOLOGY

1. Data preprocessing

Before implementing the ML models, TerraClimate precipitation data underwent preprocessing and spatial standardization using GIS tools. All raster files were reprojected to the Mex_INEGI_Lambert_Conformal_Conic coordinate system with a uniform spatial resolution of 4644.52 m × 4644.52 m, using bilinear interpolation because precipitation data are continuous. Subsequently, raster layers were aligned to the same spatial extent, cell size, and grid structure, then clipped to the study area, ensuring spatial consistency and compatibility among the climatic datasets used in the analysis.

2. Construction of precipitation database

Subsequently, annual precipitation raster values were extracted using GIS tools to construct a geospatial database for spatiotemporal analysis and the implementation of ML models. Each record included spatial coordinates and precipitation values for the period 1960–2024, resulting in a geospatial database in which each annual precipitation layer (1960–2024) was treated as an input variable for subsequent clustering and Principal Component Analysis.

3. Spatiotemporal analysis

Spatiotemporal analysis was performed by evaluating the spatial distribution and temporal variability of precipitation in Northwestern Mexico. Initially, mean annual precipitation maps were generated to identify regional patterns and spatial contrasts among arid, semi-arid, and subhumid regions. Subsequently, interannual precipitation variations during the 1960-2024 period were analyzed to identify relatively dry and wet years and patterns associated with regional climate variability. This analysis provided a spatial basis for the subsequent implementation of clustering and dimensionality reduction techniques using ML models.

4. Machine learning models

To identify spatial precipitation patterns, unsupervised ML techniques were implemented. The models enabled the grouping of regions with similar precipitation behavior, the detection of climatic anomalies, and the analysis of spatial precipitation patterns within the study area. Additionally, PCA was applied to summarize the dominant patterns of temporal precipitation variability before interpreting the spatial structure identified by the clustering algorithms. The models were implemented in Python using Jupyter Notebook and libraries such as NumPy, Pandas, Scikit-learn, and Matplotlib for data processing, statistical analysis, spatial clustering, and visualization generation.

5. K-Means clustering

The K-Means algorithm was used to identify spatial clusters with similar precipitation patterns using unsupervised learning. This method automatically classifies climatic observations into clusters based on spatial and precipitation similarities, thereby identifying regions with homogeneous pluviometric behavior within the study area [24], [25]. Variables were normalized to reduce scale differences and prevent attributes with larger magnitudes from disproportionately influencing the clustering process [26], using equation 1, as follows:

$$x'_{ji} = \frac{x_{ji} - \boldsymbol{\mu}_j}{\boldsymbol{\sigma}_j} \tag{1}$$

where x'_{ji} represents the normalized value of the precipitation variable, x_{ji} corresponds to the original value, $\boldsymbol{\mu}_j$ represents the mean, and $\boldsymbol{\sigma}_j$ the standard deviation of the climatic observations within the study area. Subsequently, the K-Means algorithm grouped the observations by minimizing the distance between each point and the corresponding cluster centroids through an iterative spatial reassignment procedure [18] using equation 2:

$$J = \sum_{i=1}^{k} \sum_{x_j \in C_i} \left| | x_j - \boldsymbol{\mu}_j | \right|^2 \tag{2}$$

where k represents the number of clusters, C_i corresponds to the set of observations belonging to cluster i, x_j represents each climatic observation, and $\boldsymbol{\mu}_j$ corresponds to the cluster centroid.

6. DBSCAN clustering

The DBSCAN algorithm was implemented to detect homogeneous spatial regions through spatial density analysis [16], [27]. This approach enabled the identification of natural precipitation clusters and the detection of potential outliers or regions with differentiated climatic behavior. DBSCAN defines clusters based on the spatial density of observations within a given neighborhood [28], using equation 3, as follows:

$$N_\varepsilon(p) = \{q \in \mathrm{D} \mid dist\,(p,q) \leq \varepsilon\} \tag{3}$$

where $N_\varepsilon(p)$ represents the neighborhood of point p, D corresponds to the maximum search distance, and $dist\,(p,q)$represents the distance between spatial observations. The ability of DBSCAN to handle complex spatial distributions and detect anomalous observations proved useful in analyzing regional climatic patterns within the study area.

7. Principal Component Analysis

Principal Component Analysis (PCA) was applied to summarize the dominant patterns of precipitation variability across the study area by transforming the original precipitation observations into a reduced set of uncorrelated components [29], [30]. This facilitated the interpretation of the major precipitation gradients while reducing data complexity. PCA transforms the original set of variables into a new set of uncorrelated principal components using equation 4:

$$z = x * w \quad (4)$$

where x represents the original climatic data matrix, w corresponds to the eigenvector matrix, and z represents the resulting principal components. This procedure enabled the identification of the principal gradients of precipitation variability and facilitated the interpretation of regional climatic patterns represented by the first principal components.

8. Model evaluation

The evaluation of the models was performed through spatial cluster interpretation, comparative analysis, and visual validation of the obtained patterns. The results generated by K-Means, DBSCAN, and PCA were compared to identify similarities and differences in the spatial distribution of precipitation patterns. Additionally, the clusters were analyzed through cartographic representation and spatial evaluation of homogeneous regions, thereby validating the geographic and climatic coherence of the detected patterns. Furthermore, the performance of the K-Means algorithm was evaluated using the Silhouette index for different cluster configurations. At the same time, PCA was validated through the cumulative explained variance of the principal components.

IV. RESULTS

1. Spatiotemporal precipitation variability

The spatiotemporal analysis of precipitation revealed marked climatic variability in Northwestern Mexico during the 1960–2024 period (Figure 2). Spatial results showed lower precipitation in Baja California and Baja California Sur, associated with arid conditions, whereas Sinaloa and southern Sonora exhibited higher precipitation, influenced by the North American Monsoon (Figure 2a). Additionally, temporal analysis revealed interannual precipitation fluctuations with alternating wet and dry periods, reflecting high regional climatic variability and differences in precipitation stability within the study area (Fig. 2b).

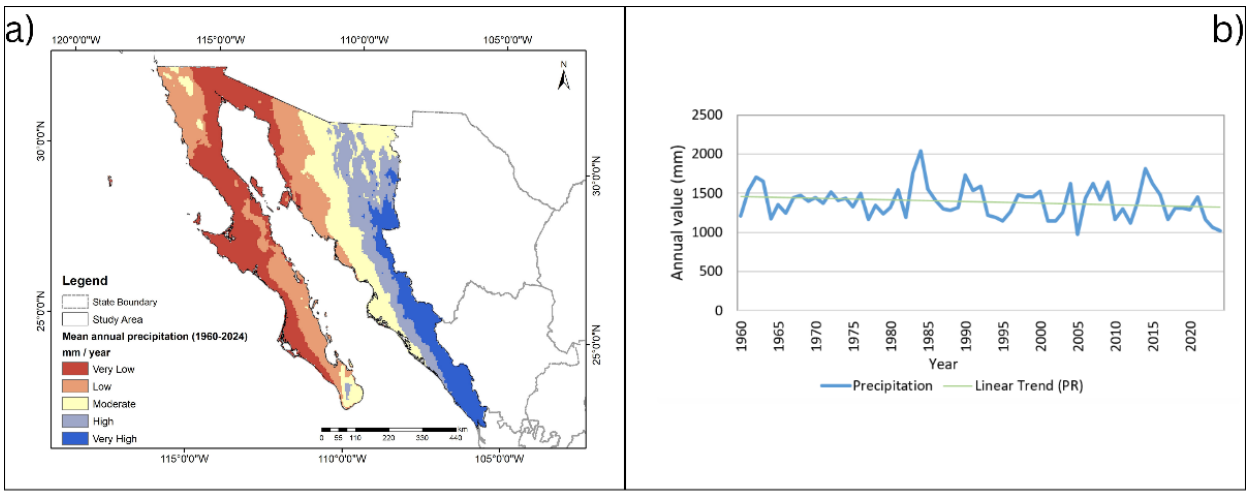

Figure 2. a) Spatial distribution of mean annual precipitation within the study area; b) temporal variability of annual precipitation during the period 1960–2024

2. K-Means clustering results

The K-Means results identified four spatial precipitation clusters in Northwestern Mexico (Figure 3). The optimal model configuration reached a Silhouette index of 0.4029, indicating acceptable cluster separation despite the gradual climatic transitions that characterize precipitation patterns across the study area. Arid regions of Baja California and Sonora were characterized by low precipitation, whereas Sinaloa and southern Sonora exhibited higher precipitation totals. Additionally, transition zones with intermediate precipitation conditions were identified, demonstrating K-Means' ability to delineate climatically homogeneous regions.

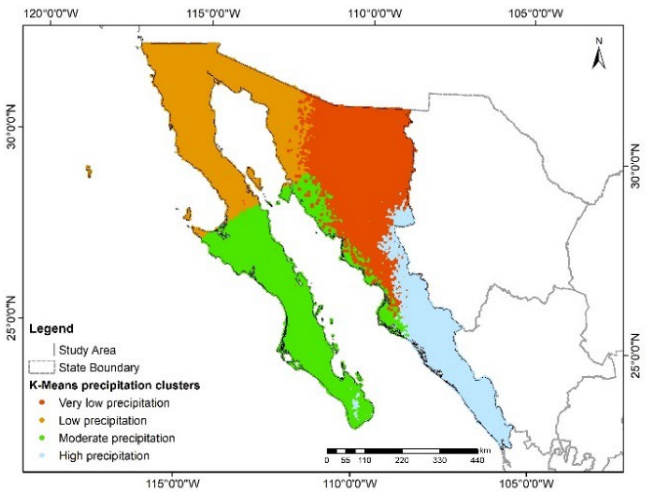

Figure 3. Spatial precipitation clusters identified using K-Means clustering in Northwestern Mexico, showing regions with very low, low, moderate, and high precipitation patterns

3. DBSCAN clustering results

The DBSCAN algorithm identified spatial density patterns associated with the regional distribution of precipitation (Figure 4). The results showed a dominant precipitation regime accompanied by spatial anomalies and secondary precipitation clusters. The anomalies were mainly located in regions with extreme precipitation behavior and high climatic heterogeneity. The ability of DBSCAN to detect irregular spatial structures complemented the results obtained with K-Means and enabled the representation of complex climatic patterns within Northwestern Mexico.

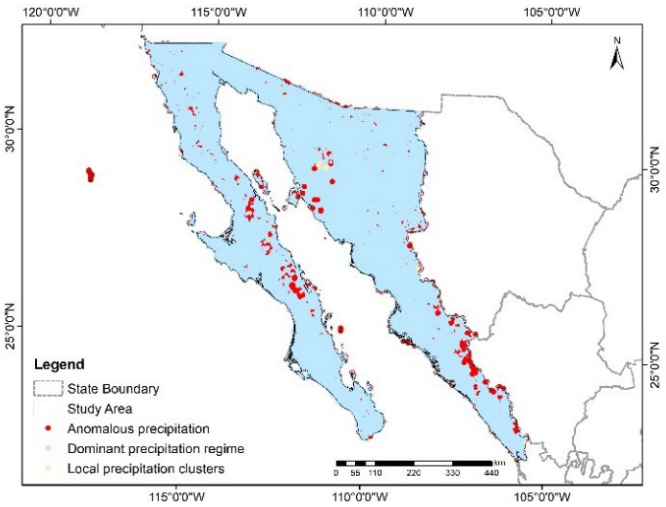

Figure 4. Spatial precipitation patterns and anomalies identified using DBSCAN clustering in Northwestern Mexico

4. Principal Component Analysis (PCA)

PCA reduced the dimensionality of the precipitation dataset and highlighted the dominant patterns of regional climatic variability (Figure 5). The first two principal components explained 94.33% of the total variance, indicating that most of the variability in precipitation can be represented by two dominant climatic gradients. These gradients differentiate the arid conditions of Baja California and Sonora from the wetter regions of Sinaloa, reflecting the influence of regional climatic controls such as topography and the North American Monsoon. Consequently, PCA simplified the interpretation of precipitation variability while preserving the main climatic information contained in the dataset.

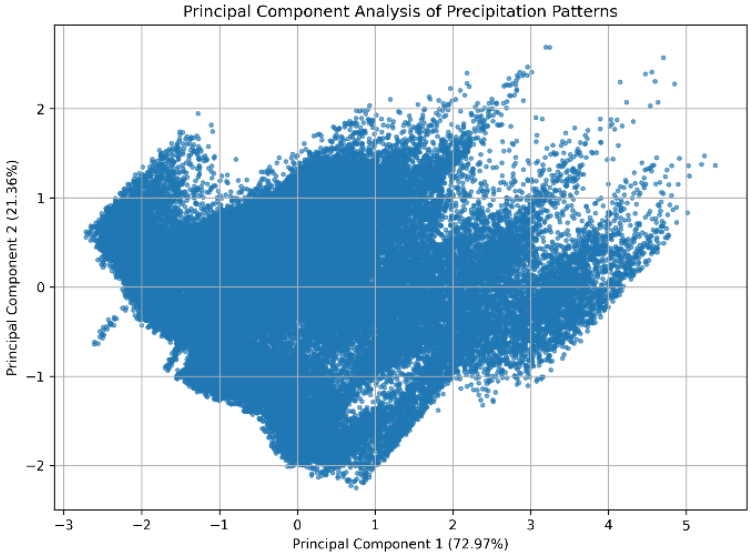

Figure 5. Principal Component Analysis (PCA) of precipitation variability in Northwestern Mexico. The first two principal components explained 94.33% of the total variance.

5. Comparison of clustering methods

The comparison between K-Means, DBSCAN, and Principal Component Analysis (PCA) revealed important differences in the spatial and statistical representation of precipitation patterns in Northwestern Mexico. K-Means facilitated the delimitation of regions with homogeneous precipitation behavior, while DBSCAN detected irregular spatial structures and regions with atypical climatic behavior. PCA complemented the analysis by reducing dimensionality and capturing the main spatial precipitation gradients, explaining 94.33% of the total variability in the data with the first two principal components. Overall, the complementary use of K-Means, DBSCAN, and PCA provided a more comprehensive characterization of precipitation variability than any individual method. While K-Means identified climatically homogeneous regions, DBSCAN detected spatial anomalies, and PCA summarized the dominant climatic gradients, they improved hydroclimatic interpretation and supported regional climate monitoring.

V. DISCUSSION

The results revealed marked spatial heterogeneity in precipitation in Northwestern Mexico, particularly between arid regions in Baja California and Baja California Sur and areas with higher precipitation accumulations in Sinaloa and southern Sonora. This spatial distribution reflects the combined influence of topographic, atmospheric, and regional climatic factors on precipitation dynamics, particularly the North American Monsoon and regional altitudinal gradients. Additionally, the observed variations are consistent with previously reported hydroclimatic patterns for arid and semi-arid regions of Northwestern Mexico, where water availability strongly depends on interannual precipitation variability and extreme climatic events associated with regional atmospheric processes.

Furthermore, the complementary application of K-Means, DBSCAN, and PCA provided a more comprehensive interpretation of precipitation variability than any individual method. K-Means identified climatically homogeneous regions, DBSCAN detected spatial anomalies associated with heterogeneous precipitation behavior, and PCA summarized the dominant climatic gradients, explaining 94.33% of the total variance. These findings demonstrate that integrating geospatial analysis and Machine Learning facilitates the identification of regional hydroclimatic patterns and provides a useful framework for climate monitoring and water resource assessment in arid and semi-arid regions.

VI. CONCLUSIONS

The spatiotemporal analysis of precipitation revealed high climatic variability in Northwestern Mexico during 1960–2024, with lower precipitation in Baja California and Sonora and higher precipitation in Sinaloa. ML techniques proved effective for identifying homogeneous spatial patterns, climatic anomalies, and dominant precipitation gradients. The integration of remote sensing, geospatial analysis, and Machine Learning provides an interpretable framework for hydroclimatic assessment, supporting regional climate monitoring, water resource management, and climate adaptation in arid and semi-arid regions.
Beyond the study area, this approach can be transferred to other arid and semi-arid regions where precipitation variability strongly influences water availability and environmental vulnerability. By identifying homogeneous precipitation regions and anomalous climatic patterns, the proposed framework can support the design of

regional monitoring strategies, drought-risk assessment, and evidence-based decision-making for water resource planning.

Abstract
Aggregate metrics like F1 obscure localized degradation on subpopulations defined by continuous attributes (e.g., loan size, age, working hours). We propose a post-hoc pipeline: Nadaraya-Watson kernel smoothing estimates local F1 along the attribute; each individual receives a local estimate; population-weighted CVaR at the 5th percentile summarizes the tail. The difference between aggregate F1 and tail CVaR defines an overconfidence gap, a continuous signal quantifying how much the headline metric overstates the experience of the worst-served population. Applied to three established benchmark datasets (German Credit, COMPAS, Adult Income), we observe gaps ranging from 0.06 to 0.185 F1 points. The gap ranking is preserved across p = 1–15%, and the method is intended as a diagnostic instrument: it surfaces where aggregate performance is misleading, not why.

Keywords: Bias, Accountability, and Transparency in AI Systems, Ethical AI and Algorithmic Fairness, Digital Inequality and Inclusion

I. INTRODUCTION

Reported model performance is almost always an average. When a deployment population is heterogeneous along a continuous attribute (the size of a credit request, the age of a defendant, the number of hours worked per week), an aggregate metric can register as acceptable even while significant fractions of that population are systematically worse served. Conventional fairness audits address part of this problem by comparing performance across discrete demographic groups. Still, discretization introduces boundary arbitrariness, conflates within-group variation, and provides no natural representation of attributes that do not correspond to protected categories in legislation. We propose a pipeline that operates entirely in continuous attribute space. A Nadaraya-Watson kernel smoother [1],[2] estimates local F1 at every point along the audit attribute; Conditional Value at Risk (CVaR) [3], borrowed from financial risk management, then summarizes the tail of this distribution in a population-weighted fashion, so a narrow region with catastrophic performance but few inhabitants registers less severely than a broad region with moderate degradation affecting many. The resulting overconfidence gap, the scalar difference between aggregate F1 and tail CVaR F1, answers a specific question: by how much does the headline metric overstate performance for the worst-served population segment (defined by the 5th percentile of local F1)? The gap is a continuous signal with no binary pass/fail threshold, leaving judgments of significance to domain stakeholders.

The contributions of this paper are as follows:

- We introduce a post-hoc auditing pipeline combining Nadaraya-Watson kernel smoothing with population-weighted CVaR to measure localized F1 along a continuous attribute, requiring no modification to the training procedure or model architecture.
- We define the *overconfidence gap* as an interpretable scalar diagnostic: it surfaces where aggregate performance is misleading, but identifying why performance degrades and deciding what to do about it requires further investigation outside this paper's scope.
- We validate the pipeline on three widely used fairness benchmarks (German Credit, COMPAS, and Adult Income), observing gaps between 0.060 and 0.185 F1 points, and provide a detailed analysis of what the gap does and does not reveal about model behavior.
- We discuss the relationship between continuous-attribute CVaR auditing and existing discrete group-fairness criteria, positioning the two approaches as complementary tools in a complete audit workflow.

II. RELATED WORK

Fairness research has largely developed around categorical notions of group membership, with most existing criteria requiring predefined, discrete groups as input. This paper occupies a complementary niche: post hoc auditing of a continuous attribute, without modifying the training procedure or requiring group labels. The survey below maps the surrounding literature and clarifies where the proposed contribution fits within each strand. Group fairness metrics. Equalized odds [4], demographic parity [5], and calibration-based criteria [6] operate on discrete groups. They are complementary to, rather than superseded by, continuous-attribute auditing. Barocas et al. [5] provide a comprehensive treatment of these criteria and their inherent tensions, noting that satisfying multiple fairness definitions simultaneously is often impossible, and that the choice of criterion should be grounded in the deployment context—training-time fairness objectives. CVaR has been used as a training objective in distributionally robust optimization (DRO) to learn classifiers that are robust to worst-case data shifts [7], [8]. Hashimoto et al. [9] apply a CVaR-like worst-group objective during training to achieve fairness without demographic labels; Sagawa et al. [10] show that explicit regularization is critical for worst-case generalization under known group structure. Continuous attributes have also been addressed during training and in post-processing stages: Agarwal et al. [11] reduce fairness constraints to cost-sensitive learning, Chzhen et al. [12] derive optimal post-processing strategies for fair regression via Wasserstein barycenters, and kernel-based approaches to continuous fairness are explored in [13]. Our contribution differs from all of these in kind: CVaR is applied post hoc as an auditing lens on an already-trained model, without modifying the training procedure or applying post-processing corrections.

Slice discovery and subgroup analysis. Slice Finder [14] and related tools automate the search for underperforming subgroups defined by conjunctions of feature predicates. Our approach is complementary: it requires specifying the audit attribute but provides a smooth, population-weighted characterization rather than a combinatorial search. D'Amour et al. [15] demonstrate that underspecification in the training pipeline can produce models that appear equivalent on aggregate metrics while diverging substantially in subgroup behavior, providing further motivation for tools that probe beyond aggregate performance.

Error analysis and model cards. Mitchell et al. [16] introduce model cards as a structured format for reporting disaggregated performance. The overconfidence gap is a natural quantity to include in such documentation, providing a concise summary of distributional performance risk for continuous covariates.

III. METHOD

Figure 1 shows the two-path structure of the pipeline. The left path is the status quo: a single aggregate F1 is computed from out-of-fold predictions and reported as the headline metric. The right path is the audit contribution: a Nadaraya-Watson kernel smoother estimates local F1 at every point along the continuous audit attribute, a reliability filter removes checkpoints with insufficient effective sample size, and each individual is assigned the local F1 of their nearest reliable checkpoint. Population-weighted CVaR at the 5th percentile then summarizes the tail of this individual-level distribution. The scalar difference between the two paths, the overconfidence gap Δ, is the primary diagnostic output. The subsections below formalize each stage.

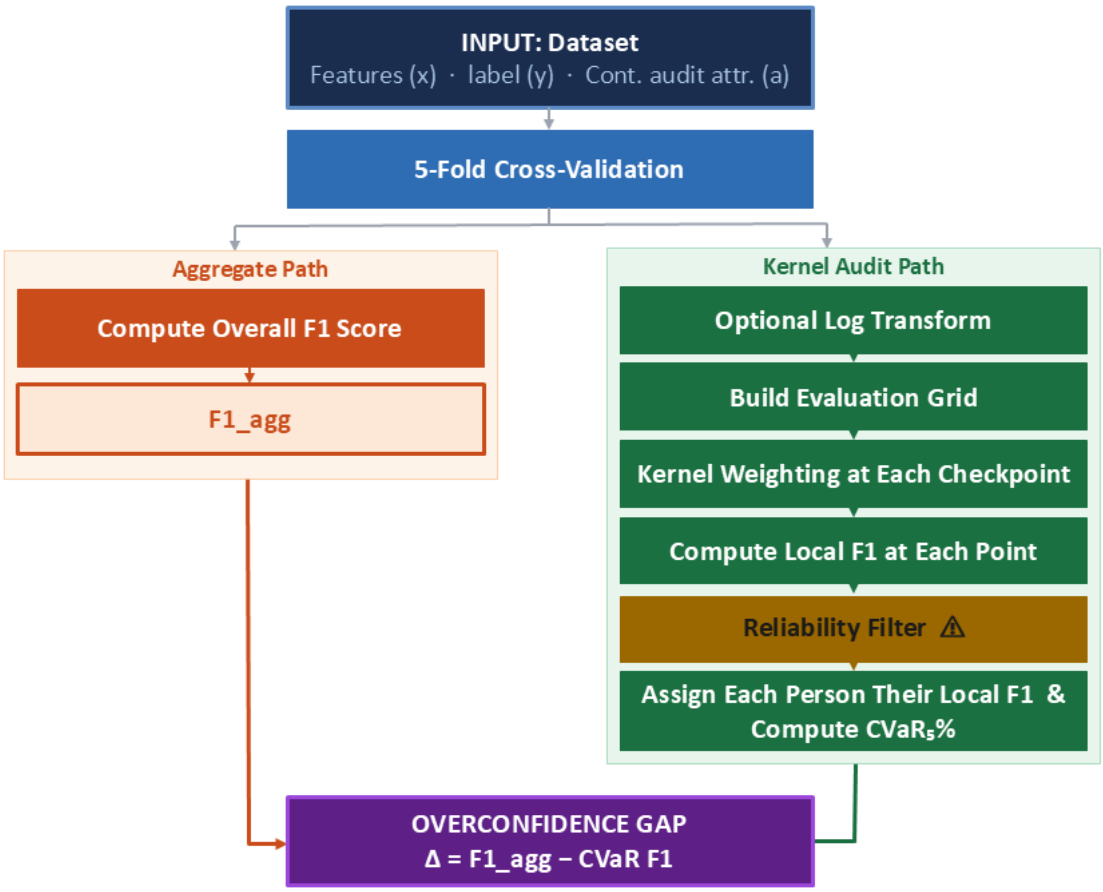

Figure 1. Diagram of the pipeline

1. Problem Setup

,D = {x_i, y_i, a}$\mathcal{D} = \{(x_i, y_i, a_i)\}_{i=1}^{n}$ be a dataset where $x_i \in \mathbb{R}^d$ are features, $y_i \in \{0,1\}$ is a binary label, and $a_i \in \mathbb{R}$ is the continuous *audit attribute*. Classifier predictions $\hat{y}_i \in \{0,1\}$ are obtained via 5-fold stratified cross-validation to avoid train-test leakage; aggregate F1 is computed over these out-of-fold predictions.

We optionally apply a monotone transform $t_i = \varphi(a_i)$ $(e.g., \varphi = log\ for\ right-skewed\ attributes)$ $before\ smoothing, and\ map\ the\ results\ back\ via\ the\ inverse\ \varphi\^\{-1\}\ for\ display$.

2. Local F1 via Kernel Smoothing

calculatevaluation points $\{c_1, \dots, c_M\}$ spanning [min(t), max(t)]. At each center c_j, assign soft weights

$$w_i^{(j)} = \exp\left(-\frac{1}{2}\left(\frac{t_i - c_j}{h}\right)^2\right) \quad (1)$$

where $h = 1.06\hat{\sigma}n^{-1/5}$ is the Silverman bandwidth [17].
Define weighted confusion-matrix counts

$$\widetilde{\mathrm{TP}}_j = \sum_i w_i^{(j)} \mathbf{1}[y_i = 1]\mathbf{1}[\hat{y}_i = 1] \quad (2)$$

$$\widetilde{\mathrm{FP}}_j = \sum_i w_i^{(j)} \mathbf{1}[y_i = 0]\mathbf{1}[\hat{y}_i = 1] \quad (3)$$

and analogously for $\widetilde{\mathrm{FN}}_j$, $\widetilde{\mathrm{TN}}_j$. Local F1 at c_j is then

$$\mathrm{F1_j} = \frac{2\widetilde{\mathrm{TP}}_j}{2\widetilde{\mathrm{TP}}_j + \widetilde{\mathrm{FP}}_j + \widetilde{\mathrm{FN}}_j} \quad (4)$$

Grid points are marked *unreliable* when the Kish effective sample size for weighted data [18] among positive-class observations falls below a threshold $n_{\min}$, computed from a target margin of error of ± 0.20 *at* 95% confidence: $n_{\min} = \lceil (0.5 \times 1.96 \div 0.20)^2 \rceil = 25$ [19].

3. Population-Weighted CVaR

Each i is assigned the local F1 from the nearest reliable grid point:

$$\hat{f}_i = \mathrm{F1}_{j^*(i)},\ j^*(i) = \mathrm{argmin}_{j:\mathrm{reliable}} |t_i - c_j| \quad (5)$$

This yields a distribution $\{\hat{f}_i\}$ that inherits the population density of the attribute: regions where many individuals live naturally contribute more mass.

The p-th percentile Value at Risk is $\mathrm{VaR}_p = \mathrm{Percentile}_p(\{\hat{f}_i\})$. The CVaR at level p is the mean performance among individuals whose assigned F1 falls at or below VaR_p [3]:

$$\mathrm{CVaR}_p = \mathbb{E}[\hat{f}_i | \hat{f}_i \leq \mathrm{VaR_p}] \quad (6)$$

We set p = 5, corresponding to the 95th-percentile confidence level conventional in financial risk management [3], and refer to it simply as the worst-performing tail.

The overconfidence gap is

$$\Delta = \max(0, \mathrm{F1}_{agg} - \mathrm{CVaR}) \quad (7)$$

Where $F1_{agg}$ is the aggregate cross-validated F1. A gap of zero is possible when the tail and the overall population perform similarly. Because $\Delta \geq 0$ by construction, it measures the degree to which the aggregate metric flatters performance in the tail; it cannot detect cases where the aggregate understates tail performance.

IV. EXPERIMENTAL SETUP

We apply the pipeline to three public benchmark datasets commonly used in fairness research. All classifiers are trained using 5-fold stratified cross-validation; no separate held-out test set is used. Table 1 reports the resulting gaps.

German Credit [20]. A binary task predicting credit default ($y = 1$: bad credit). We audit using log-transformed credit amounts, with Logistic Regression with balanced class weights as an interpretable baseline.

COMPAS [21]. A binary task predicting two-year recidivism ($y = 1$: recidivist). We audit along defendant age, using XGBoost with inverse class-weight scaling. Race and sex are deliberately excluded from model features; the audit could equally be applied along those axes, but we focus on the continuous numeric attribute of age in this study.

Adult Income [22]. A binary task predicting income exceeding 50K annually ($y = 1$). We audit along hours worked per week, using XGBoost with inverse class-weight scaling.

V. RESULTS

1. German Credit

Figure 2 shows local F1 as a smooth function of credit amount. Notably, the tail does not fall at the extremes but in the mid-range (2 149–2 390 DM), where 26.8 % of borrowers have bad credit. This suggests a region of mixed creditworthiness rather than a simple class-imbalance effect.

Table 1. Resulting gaps.

Dataset	Agg. F1	CVaR F1	GAP Δ	Tail Attr. Range	Tail n
German Credit	0.608	0.548	0.060	2,149-2,390 DM	56
COMPAS	0.614	0.508	0.106	57-96 Years	316
Adult Income	0.710	0.525	0.185	1-27 hrs/week	3,571

2. COMPAS

Figure 3 reveals a steady decline in local F1 with defendant age. The tail comprises defendants aged 57–96 (26.9% recidivism), consistent with reduced representation and potentially weaker generalization for older individuals. (Note: the COMPAS dataset has known limitations [21],[23]; race and sex were excluded from our model features.)

3. Adult Income

Figure 4 reveals the largest gap of the three experiments. Aggregate F1 is 0.710; CVaR is 0.525; the gap is $\Delta = 0.185$.. The tail covers workers reporting 1–27 hours per week; only 6.5% of that group earns over $50K annually.

4. Sensitivity to CVaR Percentile

Across $p \in \{1, \ldots, 15\ \%\}$ the gap ranking Adult Income > COMPAS > German Credit is preserved (Figure 5). Gap magnitudes are stable for German Credit (<2 % variation), Adult Income modestly stable (<20 %), while COMPAS varies more (48 %) because the steepest F1 decline occurs above age 57, making narrower tails more extreme. In every case, aggregate F1 materially overstates tail experience.

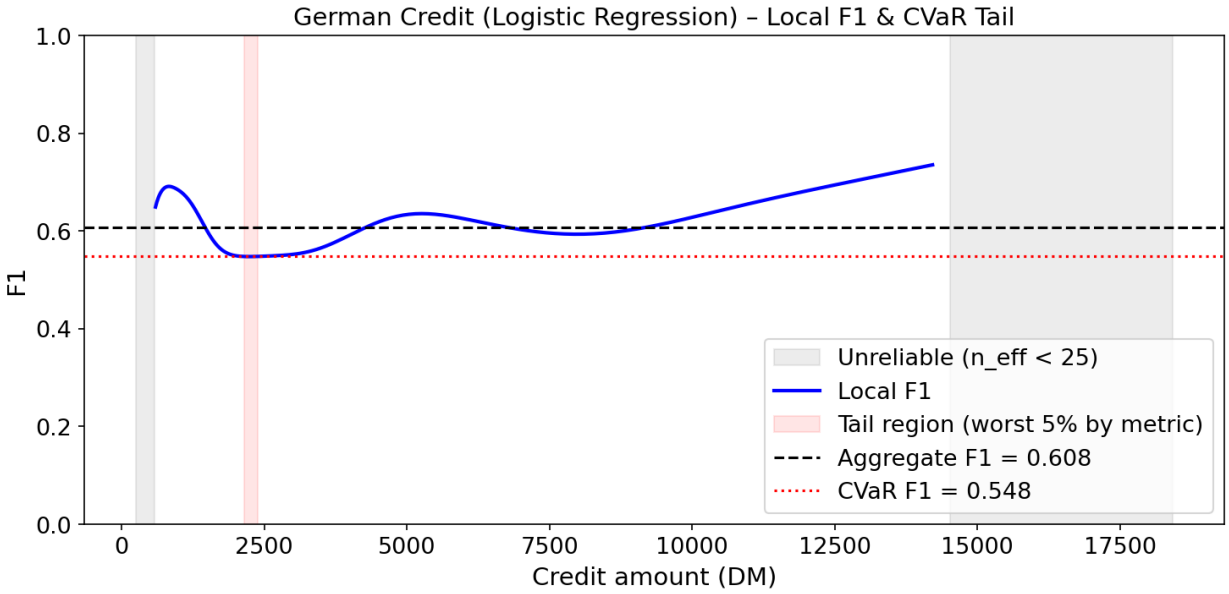

Figure 2. German Credit (Logistic Regression).

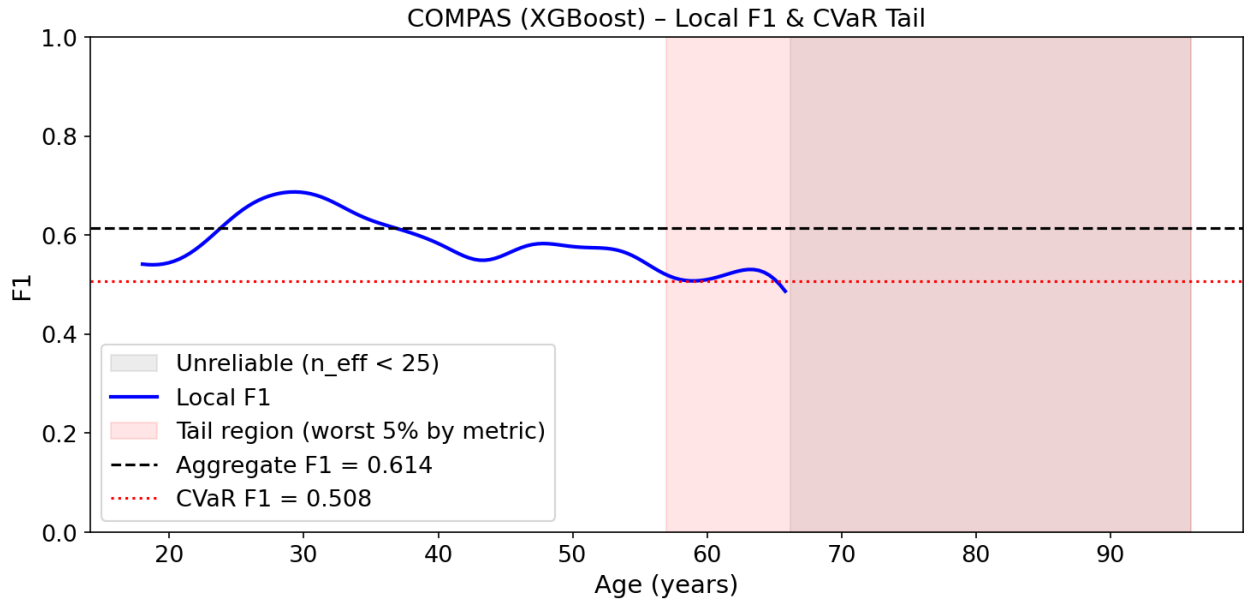

Figure 3. COMPAS (XGBoost).

VI. DISCUSSION

1. What The Gap Measures

The overconfidence gap answers a specific question: by how many F1 points the headline metric overstates performance for the worst-served population segment, weighted by how many people actually occupy that segment. This is useful for model documentation, procurement evaluation, and regulatory reporting, where a concise summary statistic is needed to characterize distributional performance risk. In German Credit, the modest gap (0.060) sits in the mid-range, reflecting mixed creditworthiness rather than a dominant predictor. COMPAS's steady decline with age (gap 0.106) warns that older defendants may see substantially worse performance than aggregate F1 suggests. Adult Income's largest gap (0.185) arises partly from structural sparsity (only 6.5% of part-time workers earn >$50K); the gap highlights a genuine disparity that aggregate F1 conceals.

2. What the Gap Does Not Measure

Cause. The pipeline identifies where performance degrades, but not why. Data sparsity, class imbalance, feature inadequacy, and distributional shift can all produce similar-looking local F1 curves. Domain expertise and targeted follow-up analysis are needed to distinguish them.
Intersectionality. The method audits one attribute at a time. It cannot detect subpopulations defined by the interaction of two or more attributes (e.g., older part-time workers), which may exhibit larger gaps than either attribute alone would suggest.

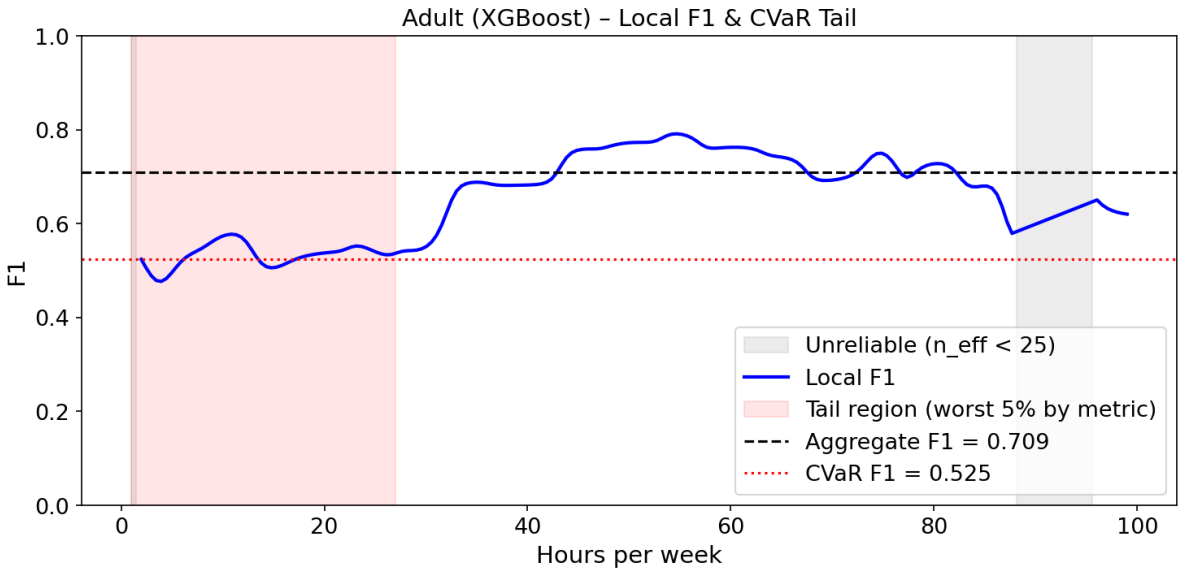

Figure 4. Adult Income (XGBoost).

Statistical uncertainty. The gap and local F1 curves are reported as point estimates; bootstrap or asymptotic confidence intervals would further increase their reliability for high-stakes decisions, and we leave this to future work.

Sensitivity to h. ***We use Silverman's rule of thumb for the bandwidth h,*** which is the default for Gaussian kernel density estimation and adapts smoothly to the data scale.

Attribute selection. The method surfaces what the analyst points it at. There is no automated procedure for identifying which attribute to audit; that choice is consequential and should be grounded in domain knowledge about where harm is likely to concentrate.

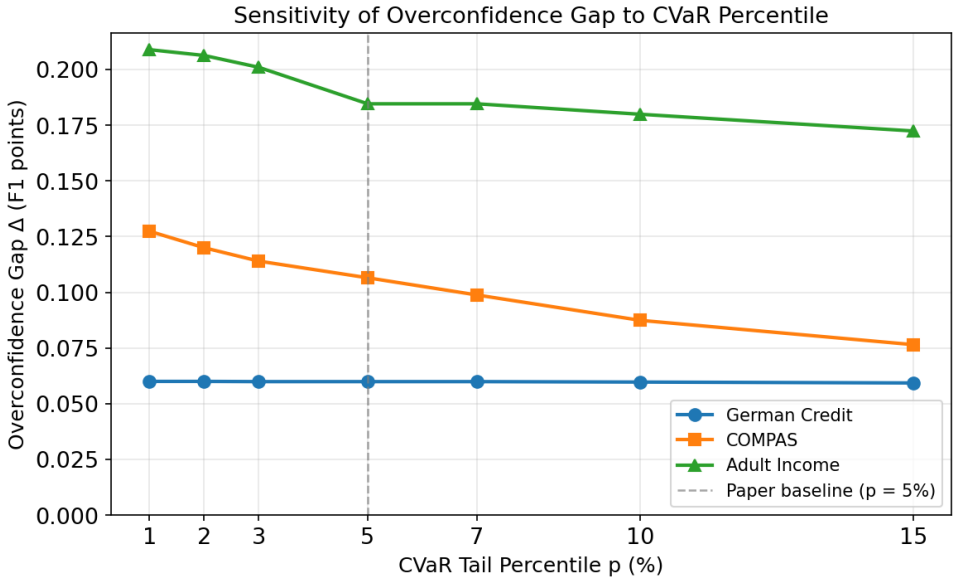

Figure 5. Sensitivity to CVaR percentile

Remediation. A smaller gap is not the same as a solved problem. The pipeline is a measurement instrument. Targeted data collection, resampling, threshold calibration by subgroup, and model retraining are among possible remediation strategies, but each introduces its own tradeoffs beyond this paper's scope.

3. Relation to Existing Fairness Criteria

The overconfidence gap is not equivalent to standard group-fairness criteria such as equalized odds or demographic parity [4], [5]. Those criteria require defining discrete groups; this method requires a continuous attribute. The two approaches are complementary: a complete audit would typically apply both, using group-fairness metrics for legally protected categories and continuous-attribute CVaR auditing for numeric covariates that correlate with harm.

VII. CONCLUSION

We have presented a post-hoc auditing pipeline that uses Nadaraya-Watson kernel smoothing and population-weighted CVaR to measure the overconfidence gap between aggregate F1 and the performance experienced by the worst-served population segment (the tail defined by the 5th percentile of local F1), identified along a continuous attribute. Applied to German Credit, COMPAS, and Adult Income, we find overconfidence gaps of 0.060, 0.106, and 0.185 (baseline p=5%); the ranking Adult Income > COMPAS > German Credit persists across $p \in \{1–15\%\}$ but gap magnitudes vary. In every case, aggregate F1 overstates the performance experienced by the worst-served population segment. We present this method as a practical instrument for audit toolkits, suited for continuous covariates known to correlate with harm, and for reporting or procurement evaluations that require a concise summary statistic.

Abstract
The integration of Internet of Things (IoT) technologies into energy production and distribution infrastructure has expanded the attack surface of industrial control systems (ICS), making cyber-physical threats a critical issue for operators of smart grids, turbine plants, and hydroelectric power plants. Traditional IT-oriented intrusion detection systems are unable to capture the nature of the physical processes characteristic of attacks in the energy sector. This paper explores the application of machine learning to detect cyber-physical attacks on HAI v21.03 – the only publicly available test dataset for energy production processes (steam turbines and pumped-storage power plants) as of 2025. We compare four model families (GRU, TCN, XGBoost, Isolation Forest) under leak-free protocols, using the proposed GRU–TCN ensemble calibrated with a single threshold, and use SHAP (GradientExplainer for GRU, TreeExplainer for XGBoost) for interpretability with dual explanations. Across ten random seeds, the ensemble achieves F1 = 0.659 and AUC-ROC = 0.891. When transferred without training on DataSense, all models drop to a level close to random (AUC 0.40–0.67): temporal models plateau at the baseline prevalence level (F1 = 0.587), while XGBoost drops to F1 = 0.000, despite having the highest AUC in the domain (0.918), which constitutes a transfer failure. SHAP at the instance level precisely matches the documented HAI attack variables (overlap@3 = 1.00). To the best of our knowledge, this is the first study to combine SHAP with dual explanations for HAI and to quantitatively transfer, without training, to an independently collected IIoT environment.

Keywords: cyber-physical attack detection, industrial control systems, HAI v21.03, GRU–TCN ensemble, SHAP explainability, zero-shot transfer, cross-domain generalization, class imbalance handling

I. INTRODUCTION

The energy sector constitutes one of the most critical components of modern society – from healthcare and transport to water supply and finance. Over the past decade, the operational technology (OT) layer of energy infrastructure, which includes supervisory control and data acquisition (SCADA) systems, distributed control systems (DCS), and programmable logic controllers (PLC), has been opened up by Internet of Things (IoT)-connected devices, cloud-edge computing architectures, and standard communication protocols. The efficiency gains are real, but so are the costs: facilities that were once physically isolated and closed now face the same threats as corporate IT systems, with the added potential for physical consequences. These are not hypothetical risks. For example, the Stuxnet (2010) campaign showed that control systems governing centrifuge processes could be compromised to cause physical damage while skipping monitoring; the 2015–2016 BlackEnergy campaigns cut power to hundreds of thousands of Ukrainian households; the 2021 Colonial Pipeline ransomware disrupted fuel supply across the eastern United States; and in the same year an intruder briefly altered chemical levels at the Oldsmar water plant in Florida. More recent activity: Industroyer2 against a Ukrainian substation in 2022, and the Volt Typhoon cluster pre-positioning inside U.S. energy and water utilities, follows the same

trajectory: attackers reach for the physical process directly, their tooling is increasingly portable across equipment, and intrusions often go unnoticed for long periods [1]. Detection, therefore, has to operate on physical sensor data and generalize to plants the model has never seen. Network-based intrusion detectors reach well above 97% accuracy on IoT traffic datasets such as CICIoT2023, TON_IoT, and X-IIoTID. Yet, those datasets describe packets and flows, not the state of a physical process. An attacker who changes a turbine reading by a fraction of a per cent per second, staying within the sensor-noise band, leaves no traffic signature at all; the anomaly lives in the temporal dynamics of the process variables [2]. Detection in energy Industrial Control Systems (ICS) thus needs models trained on process-level time series from real testbeds. The HAI (Hardware-in-the-Loop Augmented ICS Security) dataset, released by the Affiliated Institute of ETRI, is the public benchmark that directly simulates energy production processes: steam turbine and pumped-storage hydropower generation, using a physical testbed augmented by a HIL simulator. HAI v21.03 provides 79 process variables, 50 documented attack scenarios after the attack labels are removed, and a test-set anomaly rate near 2.23%. Despite its unique suitability, no prior work has applied explainable machine learning to HAI, nor tested whether models trained on it transfer to an independently collected IIoT environment.

This study is motivated by three specific research questions. RQ1: Can temporal sequence models trained on HAI provide deployable detection under a single fixed threshold, complementing higher-F1 reinforcement-learning thresholding schemes that offer neither interpretability nor cross-dataset evidence? RQ2: Do SHAP rankings point to physically meaningful variables that match the documented attack mechanisms, so that an operator can act on them? RQ3: Do the learned representations carry over to a heterogeneous IIoT testbed (DataSense) without retraining, and how large is the gap? The present paper addresses these gaps through four contributions. We build a leak-free, ten-seed comparison of four model families and a GRU–TCN ensemble on HAI v21.03; we compute dual-explainer SHAP (GradientExplainer for the GRU, TreeExplainer for XGBoost) and tie the important variables to known attacks; we quantify zero-shot and few-shot transfer to DataSense; and we give a stratified comparison of nine ICS/IIoT datasets (Table 1). Taken together, the results show that temporal models maintain useful detection under domain transfer. At the same time, tree-based detectors break under threshold transfer, and the resulting decisions remain interpretable for field operators.

II. RELATED WORK

High-quality datasets are the foundation of ICS/IIoT intrusion-detection research, and the nine key datasets are summarised in Table 1, covering SCADA water supply systems, IoT/IIoT traffic, and hybrid testbeds. BATADAL [3] simulates a water supply network with 43 variables at hourly resolution; it is widely used but does not provide network traffic and only approximates time. SWaT [4] and its extension, WADI [5], are physical water-treatment testbeds with a rich set of sensors/actuators and many implemented attacks, which remain standard ICS benchmarks even outside the energy sector. The Mississippi State gas pipeline and water tank datasets [6] are among the earliest publicly available SCADA datasets. Still, they contain known statistical issues that limit their use as a primary benchmark. As for the network component, the CICIoT2023 dataset [7] covers 33 attack types across 105 Internet of Things (IoT) devices. TON_IoT [8] adds telecommunications data and host logs for nine attack families, and X-IIoTID [9] offers Industrial Internet of Things (IIoT) traffic, independent of connection type and device, labeled according to the Cyber-Kill-Chain model; the claimed accuracy typically exceeds 97%. Still, none of these datasets encodes the physical consequences of an attack. Working with these datasets remains instructive: the LSTM-autoencoder-based threat detection model developed by Yazdinejad et al. [10] and the manifold-based adversarial analysis by Al-Fawa'reh et al. [11] illustrate both the promise of deep models for IoT data and their vulnerability to distributional shifts.

HAI [12] is the only publicly available dataset specifically created for ICS, compiled on a real-world test platform (GE turbine, Emerson boiler, FESTO water treatment system) using a HIL simulator; it contains 79 features and has a 2.23% anomaly rate over 19 days. The best published results are based on threshold adaptation: Yang et al. [13] achieve F1 = 0.994 using agent-based dynamic threshold setting on a DGN, while Homaei et al. [14] report an F1 score of 0.923 using a Causal Digital Twin, and a comparative study by Kim et al. [15] evaluates RANSynCoder at InterFusion at F1 = 82.9%. It does not apply explainable ML to HAI and does not report transferability across datasets. In DataSense [16], the most recent dataset considered, the hierarchical feature selection with the random forest algorithm achieves an F1 score of 0.97 on sensor and network data streams from an IIoT testbed containing 40 devices for 50 attacks. This is the only test set that combines synchronized data from sensors and the network and has had only one prior evaluation, making it a natural target for transferring a model trained on HAI.

Table 1. Comparative Analysis of ICS/IIoT Datasets for Attack Detection

Dataset	Samples	Feat.	Attacks	Attack %	Data type	Energy suitability
Gas Pipeline	274,627	16	~10	21.9%	Network (Modbus)	Low — no physical process sim; pattern artifacts
BATADAL	~175,000	43	14	4.7%	Physical (SCADA)	Low — water domain; hourly resolution
SWaT	449,919	51	36	12.0%	Physical + network	Medium — not energy domain
WADI	1,048,571	127	15	6.0%	Physical (SCADA/PLC)	Low-Med — stealthy attacks
HAI	1,323,608	79	50	2.2%	Physical (DCS/HIL)	Very High — only energy ICS
CICIoT2023	46,686,579	46	33	27.3%	Network (IoT)	Low — no physical part
TON_IoT	2,223,921	44	9	96.4%	Network + OS + telemetry	Low — no CP consequence
X-IIoTID	820,834	68	~30	48.7%	Network + host + system	Medium — heterogeneous IIoT
DataSense	>1.82B pkts	80+	50	Balanced	Network + sensor	High — synced; energy incl.

III. METHODOLOGY

1. System Architecture

The pipeline has four stages: ingestion and preprocessing, sliding-window feature extraction, model training with threshold calibration, and post-hoc SHAP explanation. Raw HAI time series are normalized and split into fixed-length windows; the three process-level attack-label columns (attack_P1–P3) are dropped before feature construction to prevent label leakage, leaving 79 inputs. Each window feeds four model families: the GRU and

TCN consume it as a sequence; XGBoost receives per-window statistics (mean, standard deviation, min, max, range); and the Isolation Forest operates only on flattened normal-class windows. The proposed model averages the GRU and TCN sigmoid outputs before thresholding. The decision threshold is chosen on the validation split using a 181-point grid over [0.05, 0.95], then applied unchanged to both the HAI test set and DataSense.

2. Data Preprocessing

HAI v21.03 comes from a HIL-augmented testbed that emulates a combined steam-turbine and pumped-storage process: a boiler loop (P1), a turbine with vibration monitoring (P2), a water-treatment/pumped-storage stage (P3), and a HIL simulator (P4) that ties the plant to a micro-grid model. The 79 variables cover tank levels, flow rates, pressures, temperatures, and actuator commands. All channels are min–max scaled on the training partition; the few missing values (< 0.3%) are forward-filled and then back-filled. We perform segmentation with a 30-step window (30 s at 1 Hz) and a stride of 1, which is sufficient to capture the gradual multi-step attacks documented for HAI. A window is labeled malicious if any of its steps is, and any positive rule that maximizes sensitivity but slightly inflates positive counts at attack boundaries; we keep it for comparability with prior HAI work and revisit it as a validity threat in Section VI. To avoid leakage, we split the official test files by time rather than by row. The first 70% (281,403 rows) form a development pool, and the last 30% (120,602 rows) are held out and never seen during training. The pool is divided into 20 contiguous temporal blocks; the five whose attack rate is closest to the pool mean form the validation set (70,350 rows, 2.29% attack, matching the 2.34% test rate), and the remaining blocks are added to the 921,603 normal training rows, giving 1,132,656 training rows in total. For DataSense, a separate scaler is fitted, the feature spaces are disjoint, and the HAI-trained weights and threshold are applied directly under zero-shot transfer.

3. Model Architectures

The GRU [17] stacks two layers (hidden sizes 128 and 64, dropout 0.3) over a sigmoid output (117,569 parameters). The TCN [18] uses four dilated causal blocks (dilations 1-8, 64 filters, kernel 3) with residual connections (107,905 parameters). The proposed model is a late-fusion GRU–TCN ensemble that averages both sigmoid outputs before the validation-calibrated threshold. XGBoost [19] runs 500 trees (max depth 6, subsample 0.8, colsample 0.8) with scale_pos_weight set to the window-level negative/positive ratio of 216. The Isolation Forest [20] is trained on flattened normal windows with contamination set to the training attack rate (floored at 0.005). All temporal models use the Adam optimizer (learning rate = 5×10^{-4}), Focal Loss ($\gamma = 2.0$, pos_weight = 216), and early stopping based on validation AUC-ROC (patience = 20, max = 150 epochs). SHAP TreeExplainer is applied to XGBoost; for the GRU, GradientExplainer [21] is applied with 200 normal background windows over 300 attack windows. Training ran on a single NVIDIA A100 (CUDA 12.8, 85 GB RAM); the two temporal networks together took about 8 hours across 10 seeds, with peak GPU memory below 0.2 GB.

4. Evaluation Protocol

We report the F1 score (primary metric), precision, recall, accuracy, and AUC-ROC. The F1 score is the primary metric because the test set is significantly imbalanced (2.34% attacks). AUC-ROC complements it as a threshold-independent ranking metric, which may differ from F1 in the presence of rare events. All values are means ± standard deviation across ten initial values {42, 123, 456, 789, 2024, 7, 1337, 2718, 31415, 9001}, which vary the weight initialization and batch order, with a fixed data distribution, so that the variance reflects only optimization noise. Paired differences are tested using the Wilcoxon test for F1 at each initial value ($\alpha = 0.05$); the smallest one-sided p-value at n = 10 is 0.002. The 95% confidence intervals within the domain are normal

approximation intervals: mean ± 1.96 × std/√n. The results across datasets are point estimates from a single seed, with a bootstrap sample of 2,000 iterations over the DataSense test set, used to confirm the degeneracy of predictions for saturated models [22].

IV. RESULTS

Table 2 reports in-domain performance on the held-out HAI partition (averaged across 10 seeds). The proposed ensemble gives the best F1 (0.659) and accuracy (0.984), while XGBoost holds the best precision (0.818) and AUC-ROC (0.918). The ensemble's edge over the stronger single network is small and not significant (Wilcoxon vs GRU: W = 42.0, p = 0.080), but it stabilizes predictions: ensemble precision varies far less across seeds (std = 0.113) than the TCN's (std = 0.226), so averaging the two removes variance without adding parameters. The Isolation Forest lags badly (F1 = 0.123), confirming that the 2.34% regime is too sparse for an unsupervised baseline. The contrast between XGBoost's high AUC and modest F1 (precision 0.818, recall 0.453) reflects what each metric measures: AUC rewards correct ranking, whereas F1 depends on a single operating point, and at a 2.34% base rate, the validation search settles on a cautious threshold that protects precision at the expense of recall. The temporal models accept a lower threshold that recovers more attacks (recall 0.551 for the GRU, 0.598 for the TCN), thereby achieving higher F1 despite slightly weaker ranking, and the relative ordering is stable across seeds.

Table 2. In-Domain Detection on HAI v21.03 (Mean ± Std, 10 Seeds)

Model	F1-Score	Precision	Recall	Accuracy	AUC-ROC	Inference latency
Isolation Forest	0.123±0.027	0.394±0.088	0.073±0.016	0.972±0.001	0.805±0.012	7.488 ms
XGBoost	0.583±0.014	0.818±0.025	0.453±0.015	0.983±0.001	0.918±0.004	0.623 ms
TCN	0.590±0.121	0.654±0.226	0.598±0.076	0.973±0.021	0.869±0.022	3.424 ms
GRU	0.620±0.064	0.730±0.116	0.551±0.067	0.982±0.005	0.878±0.016	2.685 ms
GRU–TCN Ensemble (proposed)	0.659±0.063	0.770±0.113	0.588±0.078	0.984±0.004	0.891±0.013	6.109 ms

95% CI for F1 (mean ± 1.96 × std/√n): IF [0.106, 0.140]; XGBoost [0.574, 0.592]; TCN [0.515, 0.665]; GRU [0.580, 0.660]; Ensemble [0.620, 0.698]. Latency: CPU, single sample, 200-iteration mean. Table 3 reports zero-shot transfer: no retraining, fine-tuning, or threshold recalibration on DataSense. Because the two testbeds expose disjoint sets of sensors, every detector drops to near-chance ranking (AUC 0.40–0.67), so F1 must be interpreted with AUC. The ensemble, TCN, and Isolation Forest saturate at the trivial flag-everything point (recall 1.000, precision 0.416, F1 = 0.587), exactly the 41.6% baseline level of spread, not genuine detection; the GRU alone avoids saturation (F1 = 0.544), but its AUC of 0.590 is near-chance. XGBoost is the telling case: despite the best in-domain AUC, it collapses to F1 = 0.000, since the estimates of its leaves are concentrated within the domain shift, and the HAI-calibrated threshold falls outside the range of DataSense estimates; each window is classified as normal. High in-domain AUC, therefore, does not guarantee cross-domain reliability for a tree-based detector.

Table 3. Zero-Shot Transfer: Trained on HAI, Tested on DataSense

Model	F1-Score	Precision	Recall	Accuracy	AUC-ROC
Isolation Forest	0.587	0.416	1.000	0.416	0.633
XGBoost	0.000	1.000	0.000	0.584	0.673
TCN	0.587	0.416	1.000	0.416	0.398
GRU	0.544	0.401	0.844	0.412	0.590
GRU–TCN Ensemble (proposed)	0.587	0.416	1.000	0.416	0.590

Models with recall = 1.000 saturate to the 41.6% prevalence baseline; F1 = 0.587 is not a genuine detection. Bootstrap F1 95% CIs have width ≤ 0.002, confirming prediction degeneracy. SHAP identifies the variables that drive the temporal model (Table 4): the level-control valves of the P3 water-treatment and P1 boiler stages (P3_LCV01D, P1_LCV01D, P1_LCV01Z), the steam-turbine load demand (P4_HT_LD), the boiler pressure-control valve (P1_PCV01D/Z), the turbine power output (P4_HT_PO), and the feed-water pump command (P3_LCP01D). The XGBoost TreeExplainer ranking overlaps on the P1_LCV01D and P1_PCV01Z channels, so two architecturally different explainers agree that the dominant attack surface is the level- and pressure-control valves of P1 and P3. The ranking is stable with sample size: the top 8 are identical for 200-300 windows and agree on six of eight between 100 and 300, with the top five unchanged across all three runs.

Table 4. Top-8 SHAP Features for the GRU (GradientExplainer)

Rank	Feature ID	Mean |SHAP|	Physical interpretation
1	P3_LCV01D	0.0129	Position command for LCV01 valve
2	P1_LCV01D	0.0071	Position command for LCV01 valve
3	P1_LCV01Z	0.0055	Current position of LCV01 valve
4	P4_HT_LD	0.0043	Electrical load demand for the steam-turbine model
5	P1_PCV01D	0.0039	Position command for PCV01 valve
6	P1_PCV01Z	0.0039	Current position of PCV01 valve
7	P4_HT_PO	0.0032	Electrical power output of the steam-turbine model
8	P3_LCP01D	0.0032	Speed command for the feed water pump

At the instance level, SHAP over the timesteps of a representative held-out attack window (Figure 1) yields three leading contributors: P3_LCV01D, P1_B3004, P1_LCV01D—that match the documented HAI attack variables exactly: overlap@3 = 1.00, overlap@5 = 0.80, overlap@8 = 0.62, with P3_LCV01D dominating at timesteps 27–28, the documented onset. Because the recovered variables (P1_LCV01D and setpoints B3004/B3005) are identified as HAI attack targets, the explanation runs on existing SCADA telemetry without retraining, and the top channels can be monitored with tighter alarms while the rest serve as corroboration.

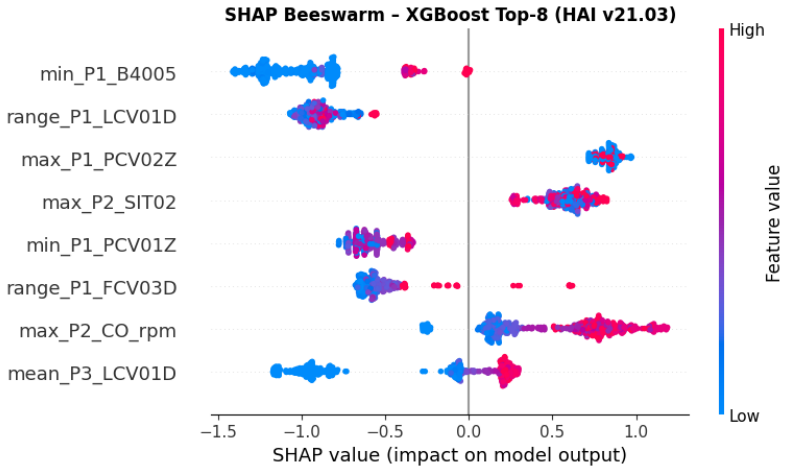

Figure 1. Instance-level SHAP over time for a representative HAI v21.03 attack window.

On HAI, dynamic-thresholding methods report higher F1 scores: ADT/DQN [12] reaches 0.994, and the causal digital twin of Homaei et al. [13] reaches 0.923, while RANSynCoder and InterFusion [14] sit at 0.829 and 0.789, respectively, but none offer interpretability or cross-dataset evidence. Our ensemble uses a single fixed threshold, which is more realistic to deploy. It trades a few points of raw in-domain F1 for dual-explainer interpretability, ten-seed confidence intervals, and the first cross-dataset transfer study on HAI.

V. DISCUSSION

The transfer results carry the practical lesson. With disjoint sensors, the near-chance AUC is mainly a representational gap that thresholding cannot fix; XGBoost's collapse to zero F1 adds a calibration failure on top, since gradient-boosted trees are not probability-calibrated, and a threshold fixed at HAI's 2.34% prevalence is meaningless at DataSense's 41.6%. This undocumented, to our knowledge, threshold-transfer failure in tree-based ICS detectors argues against selecting models by in-domain AUC. It motivates post-hoc calibration (e.g., Platt scaling or isotonic regression) before any cross-domain use. Few-shot tuning confirms the gap is representational, with the GRU rising only from 0.544 to 0.572, 0.576, and 0.588 at 10, 50, and 100 labels, respectively. The framework is therefore a complement to high-F1 dynamic-thresholding methods, trading raw F1 for interpretability (overlap@3 = 1.00), calibrated uncertainty, and an explicit map of where detection fails.

VI. LIMITATIONS

These results come with a few warnings. HAI is a single hardware-in-the-loop testbed built on specific commercial equipment (GE turbine, Emerson DCS, FESTO modules); therefore, transfer to field units with custom firmware has not been tested. The cross-dataset evaluation is deliberately zero-shot across disjoint feature spaces; it exposes the threshold-transfer failure but cannot fully separate representational from distributional gaps. Adversarial robustness (e.g., FGSM/PGD on sensor channels) was not tested, and instance-level SHAP was shown for a single representative window rather than across all 50 episodes. Hence, Table 4 is indicative rather than definitive. Deployment costs are only partially characterized: CPU latency is reported, but on-gateway energy and memory were not measured. Finally, with 10 seeds, the Wilcoxon test has limited power, so the ensemble's edge ($p = 0.080$) is a trend rather than a confirmed effect; $n \geq 30$ would be needed for confirmation.

VII. CONCLUSION

We presented an explainable machine-learning framework for cyber-physical attack detection in IoT-enabled energy infrastructure, evaluated on HAI v21.03 under leak-free, ten-seed protocols. A late-fusion GRU–TCN ensemble gave the best in-domain F1 (0.659, AUC-ROC 0.891), modestly ahead of the GRU and TCN and far above the Isolation Forest, while XGBoost held the highest AUC (0.918); the ensemble's advantage was directionally consistent (Wilcoxon p = 0.080) rather than significant. Dual-explainer SHAP converged on the level- and pressure-control valves of the P1 and P3 subsystems, with instance-level attributions matching the documented HAI attack variables exactly (overlap@3 = 1.00), the first such analysis on this benchmark. A zero-shot and few-shot study on DataSense mapped the limits of transfer. All models fell to near-chance ranking, the temporal detectors saturated to the prevalence baseline, and XGBoost collapsed under threshold transfer. Interpretable in-domain detection is achievable today, but cross-testbed deployment needs explicit domain adaptation rather than zero-shot reuse. Future work points in three directions. On the model side, attention-based and Transformer encoders, well-suited to the long-range dependencies of 1 Hz ICS data, warrant evaluation on HAI, alongside hybrid graph–temporal models that exploit sensor topology. On the transfer side, lightweight post hoc calibration (Platt scaling, isotonic regression) and adaptive thresholding should be tested as cheap remedies for the failure observed here, alongside further validation targets (SWaT, WADI, X-IIoTID) toward a multi-domain generalization matrix. Finally, embedding interpretability into the training objective rather than computing it post hoc may improve both the reliability of explanations and robustness to sensor manipulation.

Abstract
Tumor growth is strongly influenced by mechanical and anatomical constraints imposed by surrounding healthy tissue, which cannot be adequately described using standard boundary conditions. This paper presents a boundary-contact diffusion-reaction model for tumor growth that imposes unilateral contact constraints at the tumor-tissue interface. The model is formulated as a variational inequality and discretized using the finite element method to accurately capture constrained growth behavior. To reduce the high computational cost of repeated numerical simulations, a neural surrogate model is introduced to approximate the solution of the partial differential equation while preserving boundary and contact conditions. The surrogate is optimized for embedded-system deployment, enabling fast, energy-efficient tumor growth prediction on resource-constrained hardware. Numerical validation demonstrates that the proposed approach maintains accuracy in tumor boundary dynamics while significantly improving computational efficiency, making it suitable for real-time biomedical applications.

Keywords: Tumor, neural operators, embedded platforms,boundary-contact problem.

I. INTRODUCTION

Tumor growth occurs within a constrained biological environment, where interactions between expanding tumor tissue and surrounding healthy tissues play a critical role in disease evolution. Classical diffusion-reaction models with standard boundary conditions are often insufficient to capture these interactions, particularly when tumor expansion is mechanically or anatomically constrained. In this work, we present a boundary-contact mathematical framework for tumor growth modeling, formulated as a diffusion-reaction partial differential equation subject to unilateral contact constraints at the tumor-tissue interface. The proposed model distinguishes between freely evolving tumor boundaries and contact regions, imposing nonpenetration and flux-inequality conditions. These conditions naturally lead to a variational inequality formulation, enabling a mathematically consistent description of constrained biological growth. Spatial discretization is performed using the finite element method, while contact constraints are enforced using numerical strategies such as active-set and penalty-based methods [1]. Due to the high computational cost of repeatedly solving boundary-contact problems, especially in real-time or resource-constrained scenarios, we introduce a neural surrogate modeling approach. High-fidelity finite element simulations are used to train a constraint-aware neural network that approximates the solution operator of the underlying PDE while preserving essential boundary and contact properties. The surrogate model is optimized for embedded system deployment, addressing strict limitations on memory,

computation, and energy consumption typical of edge biomedical devices. Model compression and reduced-precision techniques are used to ensure fast, reliable inference on embedded hardware. Validation results demonstrate that the proposed surrogate-assisted framework achieves substantial reductions in computational time while maintaining accurate tumor boundary behavior and growth dynamics. The presented approach provides a promising foundation for real-time tumor growth prediction in embedded biomedical and clinical decision-support applications [2]. As a result, tumor evolution is not governed solely by bulk diffusion-reaction dynamics but is also strongly influenced by contact phenomena at the tumor-tissue interface. These interactions naturally lead to boundary-contact problems, where classical boundary conditions are insufficient to describe unilateral constraints such as:

- prevention of tumor penetration into rigid or semi-rigid surrounding tissue;
- growth inhibition at anatomical barriers;
- accumulation of tumor cells at the contact surface.

Boundary-contact formulations allow such effects to be modeled in a mathematically consistent and physically meaningful way, extending traditional boundary-value problems to include contact inequalities [3].

II. MATHEMATICAL MODEL

1. Governing Equation

Let us $\Omega(t) \subset R^n$ denote the tumor domain at time t, with boundary:

$$\partial\Omega(t) = \Gamma_free(t) \cup \Gamma_contact$$

where:

- Γ_free represents the freely evolving tumor boundary;
- $\Gamma_contact$ denotes the interface where the tumor is in contact with healthy tissue or anatomical constraints.

The diffusion-reaction equation governs the tumor cell density:

$$\frac{\partial u(x,t)}{\partial t} = \nabla \cdot \left(D \nabla u(x,t)\right) + f(u,c), \quad x \in \Omega(t) \tag{1}$$

where:

- $u(x,t)$ is the tumor cell density;
- D is the diffusion coefficient;
- $f(u,c)$ models proliferation, apoptosis, or necrosis, possibly dependent on oxygen or nutrient concentration c.

2. Boundary and Contact Conditions

On Γ_free, standard boundary or free-boundary conditions describe unconstrained tumor expansion. On the contact interface $\Gamma_contact$, unilateral constraints are imposed:

$$u \geq 0, \ \partial u/\partial n \leq 0, \ u(\partial u/\partial n) = 0 \quad on \ \Gamma_contact$$

These conditions express that:

- tumor density is non-negative;
- flux through the contact boundary cannot point outward into adjacent tissue;
- either tumor growth stops at the boundary, or the normal flux vanishes.

Such conditions are characteristic of boundary-contact unilateral problems and are well suited to modeling constrained biological growth processes [4]. From a biomedical perspective, the boundary-contact formulation captures the mechanical resistance of the surrounding tissue, saturation effects at tissue interfaces, clinically observed tumor deformation and restricted invasion, and growth patterns influenced by treatment zones, such as radiotherapy boundaries. This approach improves realism compared with purely free-boundary or Dirichlet/Neumann models by explicitly accounting for the mechanics of tumor-tissue interaction.

III. COMPUTATIONAL AND INTEGRATION

Boundary-contact conditions introduce nonlinearity and non-smooth behavior into the governing diffusion-reaction system, significantly increasing the computational cost of numerical simulations. The enforcement of unilateral contact constraints transforms the problem into a variational inequality, requiring iterative solution procedures and repeated updates of the active contact region. Consequently, high-fidelity finite element simulations may become computationally expensive, particularly for real-time prediction, treatment planning, and embedded biomedical applications. To mitigate this challenge, neural surrogate models, including Physics-Informed Neural Networks (PINNs) and related data-driven approaches, can be employed to approximate the solutions of the contact-constrained tumor growth problem. By incorporating the governing partial differential equation, boundary conditions, and contact constraints directly into the loss function, these models preserve the underlying physical principles while substantially reducing computational time. Such surrogate representations enable efficient prediction of tumor evolution without sacrificing consistency with the mathematical model [5]. To enforce unilateral contact constraints within the finite element framework, a primal-dual active-set strategy is adopted. At each iteration, boundary nodes are classified into active and inactive sets according to the current solution estimate. Nodes belonging to the active set satisfy the contact condition and are constrained, whereas inactive nodes evolve according to the governing diffusion-reaction equation.

IV. NUMERICAL IMPLEMENTATION

The governing tumor growth model, formulated as a diffusion-reaction partial differential equation with unilateral boundary-contact constraints, is discretized in space using the finite element method (FEM). A conforming mesh represents the computational domain, and piecewise-linear finite elements are employed to approximate the tumor density field. Time integration is performed incrementally, leading to a nonlinear algebraic system at each time step. To enforce the contact constraints, an **active-set strategy** is adopted. The method iteratively identifies regions where the contact condition is active and imposes the corresponding restrictions directly within the finite element formulation [6]. Starting from the current approximation u(k), the active and inactive sets are defined as

$$A=\{i:u_i(k)\leq tol\},\ I=\{i:u_i(k)>tol\}$$

where *tol* denotes a prescribed numerical tolerance.

The active set **AA** contains nodes for which the contact constraint is considered active. On these nodes, the tumor density is fixed according to the constraint condition

$$u_i=0,\ i \in A.$$

The finite element system is then solved only for the inactive nodes II, where the solution remains unconstrained. This produces an updated approximation u(k+1). Following each solution step, the active and inactive sets are recomputed and compared with those from the previous iteration. The iterative procedure continues until the active set remains unchanged between two successive iterations, indicating convergence of the contact region. The final solution satisfies both the governing diffusion-reaction equation and the imposed contact constraints.

1. Active-Set Iteration Algorithm for Contact Constraints

Input: Current approximation u(k), tolerance *tol*

1. Identify active nodes

A= {i:$u_i \leq$tol}

2. Identify inactive nodes

I={i:u_i>tol}

3. Impose contact constraints

$u_i=0,\ i \in A$

4. Solve the FEM system on the inactive set II
5. Compute the updated solution *u(k+1)*
6. Repeat until the active set no longer changes

Output: Contact-consistent solution you

This approach provides a robust and physically consistent treatment of tumor-tissue interaction while avoiding the need to introduce large penalty parameters. Moreover, the active-set strategy enables efficient identification of contact regions and can be incorporated into high-fidelity FEM simulations used for training neural surrogate models. In the hybrid framework, FEM solutions generated by the active-set procedure serve as reference data for machine learning models, including feedforward neural networks, physics-informed neural networks (PINNs), and neural operators [7]. Once trained, these models provide rapid approximations of tumor evolution while preserving the essential characteristics of the underlying PDE and contact mechanics. Figure 1. Schematic representation of tumor growth with and without contact constraints. In unconstrained regions, tumor cells proliferate freely, whereas growth is blocked at the contact boundary, resulting in localized stagnation and asymmetric tumor expansion near the contact interface.

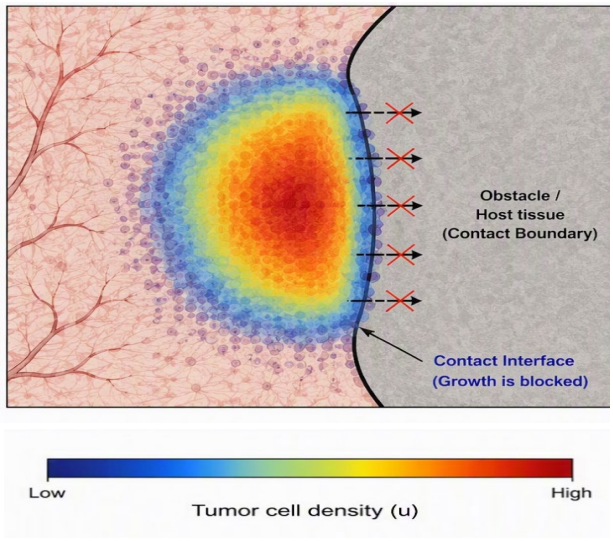

Figure 1. Effect of the Contact Constraint on Tumor Growth.

The numerical framework is validated by comparing surrogate predictions with reference FEM solutions for tumor density distribution, contact-region identification, and temporal evolution of tumor volume, thereby ensuring both numerical accuracy and computational efficiency.

V. EMBEDDED SYSTEM IMPLEMENTATION

For practical biomedical applications, including intraoperative decision support, portable diagnostic systems, and real-time monitoring platforms, tumor growth prediction models must operate under stringent computational and energy constraints. Although the finite element model with active-set contact enforcement provides accurate solutions, repeated numerical simulations remain computationally demanding and unsuitable for direct deployment on embedded hardware. To overcome this limitation, the proposed framework integrates a neural surrogate model trained on high-fidelity FEM simulations generated using the active-set algorithm. The target embedded platform is assumed to be a resource-constrained device, such as an ARM Cortex-M/A microcontroller, a low-power processor, or an edge AI system, characterized by limited computational capabilities, memory resources, and energy consumption [8]. Therefore, the neural surrogate is designed with a compact architecture to ensure low inference latency, predictable memory usage, and efficient execution under embedded-system constraints. To enable deployment on such platforms, model compression techniques including network pruning, weight quantization, and reduced-precision arithmetic may be applied while maintaining acceptable prediction accuracy. The embedded model approximates the mapping from tumor growth parameters to the corresponding contact-consistent solution obtained via the FEM active-set procedure.

The input features typically include:

- geometric characteristics of the tumor domain and boundary;
- diffusion and reaction parameters of the tumor growth model;
- descriptors related to contact regions and boundary constraints.

The outputs may consist of:

- tumor cell density at selected spatial locations;

- reconstructed tumor concentration fields;
- tumor volume and invasion-front indicators;
- information associated with active contact regions.

Contact effects are represented implicitly through training datasets generated from FEM simulations employing the active-set algorithm. As a result, the neural model learns the characteristic behavior associated with constrained tumor growth near contact boundaries and reproduces the corresponding solution patterns without explicitly solving the optimization problem during inference.

At runtime, the embedded system executes the following lightweight computational workflow:

1. acquisition of patient-specific or simulation parameters;
2. preprocessing and normalization of input data;
3. neural surrogate inference on embedded hardware;
4. post-processing to ensure physical admissibility, including non-negativity of tumor density;
5. generation of tumor growth indicators and predictive outputs.

Because only a forward neural-network evaluation is required, the computational burden is substantially reduced compared with repeatedly executing the active-set FEM solver. This enables near real-time prediction of tumor evolution while preserving the essential characteristics of the underlying diffusion-reaction-contact model. To evaluate reliability, embedded predictions are compared with reference FEM solutions obtained using the active-set algorithm. Validation metrics include spatial tumor-density distributions, identification of contact regions, preservation of constrained growth behavior near boundaries, and temporal evolution of tumor volume. The comparison demonstrates that the surrogate-assisted embedded implementation maintains consistency with the underlying mathematical model while significantly reducing computational complexity and execution time. Consequently, the proposed embedded framework provides an efficient and practical solution for biomedical applications requiring rapid tumor-growth prediction under contact constraints, while retaining the physical interpretation and numerical characteristics of the original FEM active-set formulation.

VI. CONCLUSION

This paper presented a boundary-contact mathematical framework for modeling tumor growth in mechanically and anatomically constrained biological environments. By formulating tumor evolution as a diffusion-reaction partial differential equation with unilateral contact conditions, the proposed model captures important tumor-tissue interaction mechanisms that are not represented in conventional boundary formulations. The numerical solution was obtained using a finite-element discretization combined with an active-set strategy to enforce contact constraints. The active-set procedure iteratively identifies contact and non-contact regions and ensures physically consistent satisfaction of the imposed boundary conditions. This approach provides an effective and robust mechanism for modeling constrained tumor growth while preserving the mathematical structure of the governing problem. To address the high computational cost of repeated FEM simulations, a neural surrogate modeling framework was introduced and adapted for deployment on embedded systems. The surrogate model was trained using high-fidelity FEM solutions generated with the active-set algorithm and was designed to reproduce tumor growth behavior and contact-region dynamics with significantly reduced computational requirements. The results indicate that the surrogate-assisted framework substantially improves computational efficiency while maintaining good agreement with reference FEM solutions for tumor density distribution, constrained boundary behavior, and overall tumor growth dynamics. Consequently, the proposed approach offers a practical foundation for real-time tumor growth prediction on resource-constrained embedded platforms.

Abstract
This paper presents a Decision Tree-based approach for completing missing linguistic information in KARTUVERBS, a large-scale linked-data resource for Georgian verb lemmatization and translation. The study focuses on reconstructing missing verbal nouns, which are essential for linking inflected verb forms to their corresponding lemmas. The task is formulated as a supervised multi-class classification problem, in which the model predicts missing verbal nouns based on structured morphological and paradigm-level attributes. Five-fold KFold evaluation achieved a mean accuracy of 99.93%, demonstrating highly stable performance when related lexical and paradigm groups were represented in the training data. A stricter GroupKFold evaluation produced a mean accuracy of 76.91%, showing that prediction is more difficult for entirely unseen paradigms. Per-class results vary for rare and ambiguous classes, mainly due to class imbalance and the lexeme-specific nature of Georgian verbal morphology. These findings demonstrate that the Decision Tree model is particularly well-suited to completing missing entries in an existing lexicographic resource, especially when related lexical and paradigm patterns are already represented in the training data. Overall, the results indicate that Decision Trees provide an effective, interpretable, and computationally efficient method for completing structured lexicographic data in morphologically rich and low-resource language contexts.

Keywords: Decision Tree, Machine Learning, Data Completion, Lexicographic Resources, NLP

I. INTRODUCTION

Supervised machine learning uses labeled data, where each training example is associated with a known target value. By learning relationships between input features and target classes, a model can apply these patterns to new, previously unseen cases [1],[2]. A typical workflow includes data cleaning, structuring, feature selection, model training, and evaluation [1]. After preprocessing, the dataset is divided into training and test subsets: the training subset is used to build the model, while the test subset is used to evaluate generalization [2]. This distinction between learning and generalization is essential. A model that performs well only on the training data may reproduce the training examples instead of learning reusable patterns. Therefore, evaluation on independent data is necessary for assessing whether a machine-learning approach is suitable for practical use [3]. A central issue is the balance between model simplicity and complexity, often described by the bias-variance trade-off [4].

An overly simple model may underfit the data, while an overly complex model may overfit by adapting too closely to noise or accidental regularities. The desired model should capture meaningful patterns while avoiding excessive dependence on the training set. Decision Tree algorithms are particularly relevant in this context because they provide an interpretable way of modeling classification decisions [5]. Unlike many black-box approaches, a Decision Tree represents the learned process as a sequence of feature-based rules. This makes the model useful not only for prediction, but also for explaining why a particular class was assigned. Such interpretability is especially valuable in linguistic and lexicographic tasks, where model decisions should remain understandable and verifiable. The present study investigates the use of a Decision Tree classifier for completing missing linguistic data in a large-scale Georgian verb resource. Georgian verb forms contain rich morphological information [8], [9], [10], and some lemma-related attributes may be absent or incomplete in the original data. The task, therefore, requires a model that can learn from existing annotated examples and infer missing values from combinations of morphological features. The following sections present the KARTUVERBS use case [6], describe the Decision Tree algorithm, and discuss the experimental results obtained for reconstructing missing verbal nouns.

II. BACKGROUND AND MOTIVATION

1. A Linguistic resource

KARTUVERBS is a linked-data-based system developed for lemmatizing and translating Georgian verbs [7]. Its main objective is to connect Georgian inflected verb forms with their lemmas [13], [14], morphological attributes, paradigmatic information, and external lexical resources [15], [16]. This is important because Georgian has complex verbal morphology and no standardized infinitive comparable to English's. KARTUVERBS relies on data from the CLARINO/INESS infrastructure, made available thanks to Paul Meurer [8]. These data ultimately derive from Kita Tschenkeli's Georgian-German Dictionary [9]. The original resource is organized as a tree-like hierarchy indexed mainly by a common verb root. Although useful for lexicographic representation, this structure is less convenient when the goal is to retrieve information starting from a concrete inflected form. In the original dataset, each Georgian verb is represented through many inflected forms distributed across 11 tense groups and 6 grammatical persons. More than 60 features or attributes describe each verb. The data, therefore, contain rich linguistic information, but also heterogeneous attributes and incomplete fields. One important problem identified during the construction of KARTUVERBS was the absence of lemma-related information. In particular, some inflected verb forms did not have the corresponding verbal noun filled in consistently. This created an obstacle for automatic form-to-lemma navigation and for the construction of a complete semantic graph. During construction, the data were extracted, cleaned, filtered, and transformed into a relational representation before conversion into RDF [19], [20], [21]. This changed the resource's access logic: instead of starting from a root, users and systems can start from any inflected form or morphological attribute and move toward the associated lemma, paradigm, or grammatical category. The resulting resource contains approximately five million inflected forms corresponding to more than 16,000 Georgian verbs, with more than 80 million semantic relations. At this scale, manually completing missing fields is not realistic. Machine learning, therefore, becomes a practical tool for improving data completeness [10] before generating the final semantic graph [11]. The task is not open-ended text generation, but supervised classification over a controlled set of possible linguistic values.

2. Motivation for choosing Decision Trees

A Decision Tree model was selected for the KARTUVERBS data-completion task because the dataset is highly structured and mostly categorical. It contains grammatical and morphological attributes, including tense, person, number, preverb, root, suffix, morphological type, and paradigm-related identifiers. Since the output classes belong to a defined linguistic inventory, classification is more appropriate than generative modeling.

Interpretability was another important motivation. In lexicographic and linguistic resources, it is not sufficient for a model to produce a prediction; researchers should also understand why it was made. A Decision Tree provides a transparent structure where each path from the root to a leaf can be read as a rule and compared with grammatical expectations. The use of a Decision Tree is also justified by the structure of Georgian verb morphology. Georgian verbs may include preverbs, stem changes, version markers, voice-related features, and other morphological components. These features interact in systematic ways. A Decision Tree can capture such interactions without requiring a manually written rule for every possible case.

Compared with more complex or less transparent models, the Decision Tree approach offers a useful balance between performance, simplicity, and explainability. In preliminary experiments, SVM performed worse, and Random Forest was not retained because it required substantially more computational resources. In the KARTUVERBS case, the goal is not to model unrestricted language use, but to recover missing fields in a controlled lexicographic dataset. The following section presents the algorithm in more detail.

III. DECISION TREE ALGORITHM

A Decision Tree is a supervised machine-learning algorithm mainly used for classification. It assigns each input instance to one of several predefined classes by learning from labeled examples. The learned decision process is represented as a tree [12]. A decision tree consists of a root node, internal decision nodes, branches, and leaf nodes. The root node contains the initial dataset; internal nodes correspond to tests on selected features; branches represent possible outcomes; and leaf nodes provide the final class prediction. Each path from the root to a leaf can therefore be interpreted as an if-then rule. The tree is built through recursive partitioning. At each node, the algorithm selects the feature that best separates the data into more homogeneous subsets. This process continues until a stopping condition is reached. Several decision-tree algorithms exist, including ID3, C4.5, C5.0, and CART. In this work, the scikit-learn implementation is based on CART, which constructs binary trees and commonly uses the Gini Index as a classification criterion [13].

The quality of a split is evaluated using impurity measures. One common measure is the Gini Index:

$$Gini(D) = 1 - \sum_{i=1}^{m} p_i^2 \tag{1}$$

where D is the dataset, m is the nnumber of classes, and p alt i. is the probability that a randomly selected instance belongs to class i, with p alt i. eşittir mutlak değer büyük harf D alt i.bclasses, and p_i is the probability that a randomly sfrom -1 to 1ce belongs to class i, with $p_i = \frac{|D_i|}{|D|}$. The Gini Index ranges in $\left[0, 1 - \frac{1}{m}\right]$. If $Gini(D) = 0$, the dataset is perfectly homogeneous, meaning that all instances belong to one class. The maximum value is attained when classes are evenly distributed.

Another widely used measure of impurity is entropy. Entropy measures the uncertainty or information content of a dataset and is defined as:

$$Entropy(D) = -\sum_{i=1}^{m} p_i log_2(p_i) \tag{2}$$

If $Entropy(D) = 0$, the dataset is fully homogeneous. The maximum entropy, $log_2(m)$, is attained when classes are evenly distributed.

A good split is one that reduces entropy, because it produces subsets that are more ordered and more class-specific than the original dataset. The reduction of entropy after splitting a dataset by a feature is called Information Gain. For a dataset D and an attribute A, Information Gain is computed as:

$$IG(D,A) = Entropy(D) - \sum_{v \in Values(A)} \frac{|D_v|}{|D|} Entropy(D_v) \quad (3)$$

where $Entropy(D)$ is the initial entropy, $Values(A)$ is the set of possible values of attribute A, and D_v is the subset for which $A = v$. The factor $\frac{|D_v|}{|D|}$ represents the weight of subset D_v within the full dataset. At each node, the tree selects the attribute with the highest Information Gain. Analogously, Gini Gain measures how much the Gini Index decreases after the split:

$$GG(D,A) = Gini(D) - \sum_{v \in Values(A)} \frac{|D_v|}{|D|} Gini(D_v) \quad (4)$$

Both criteria follow the same principle: a good split transforms a mixed dataset into smaller and more homogeneous subsets.

The recursive splitting process stops when the subset is sufficiently homogeneous, no useful features remain, the subset is too small, the maximum depth is reached, or further splitting no longer improves classification. These stopping conditions are important because an unrestricted tree may overfit the training data. Parameters such as maximum depth, minimum samples per split, and minimum samples per leaf can reduce this risk.

Decision Trees are useful for linguistic data completion because they are interpretable, can handle numerical and categorical features, require limited preprocessing, and naturally perform feature selection. Their main limitations are sensitivity to small changes in data and reduced interpretability when the tree becomes too deep. To illustrate the interpretability of the Decision Tree approach, Figure 1 presents a simplified Decision Tree with a maximum depth of three. The model first divides the data according to the encoded verb root and subsequently uses the verb identifier, Tschenkeli class, and sub-paradigm identifier. These variables are among the most important features in the complete model, indicating that verbal-noun prediction depends mainly on lexical identity and paradigm-level structure.

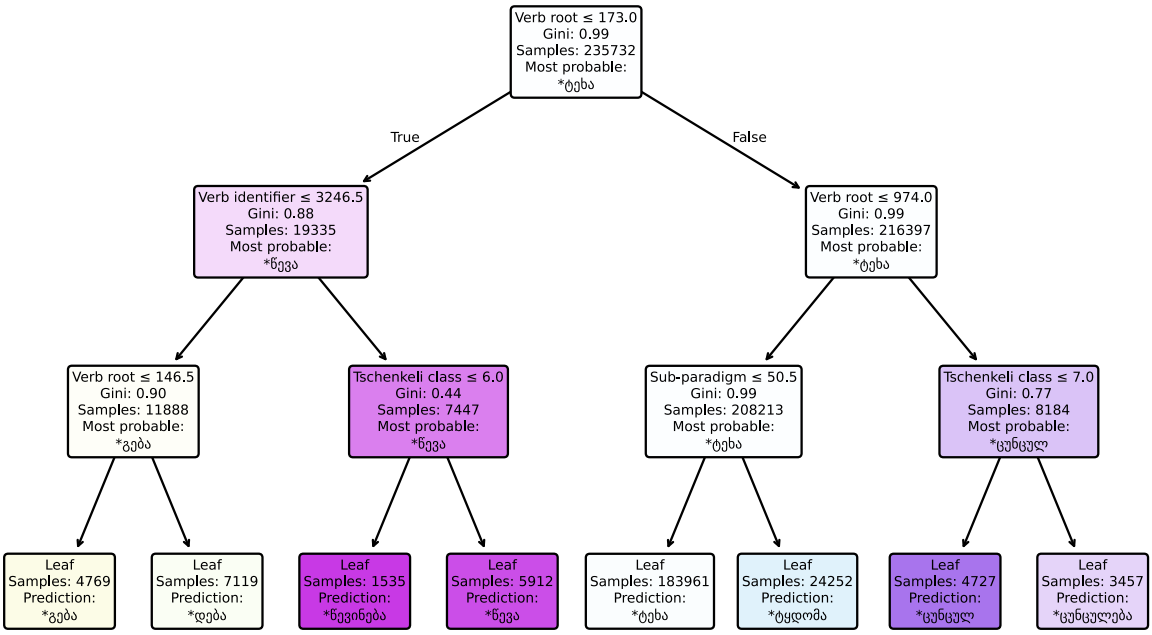

Figure 1. Simplified Decision Tree with encoded splitting rules and predicted verbal nouns.

Figure 1 contains eight terminal leaves representing eight possible prediction outcomes. Each input record follows only one branch at every decision node and reaches one final leaf. Internal nodes display the splitting condition, Gini impurity, number of training instances, and the most frequent verbal noun among the records reaching that node. The "Most probable" value shown in internal nodes indicates the most frequent verbal noun at that stage, not the final output. The final verbal noun is shown only in the terminal leaf reached by the input record. Because the attributes were numerically encoded, the thresholds shown in the figure represent internal computational values rather than direct linguistic measurements. The simplified tree is provided for visualization and interpretability, whereas the reported performance results were obtained using the complete Decision Tree model. In the KARTUVERBS use case, the Decision Tree is appropriate because the task is a supervised multi-class classification problem. The input data consist of morphological and grammatical attributes of Georgian verb forms, and the target value is a missing verbal noun. Since the possible outputs belong to a controlled linguistic inventory, classification is more suitable than open-ended generation.

IV. EXPERIMENTAL SETUP

The experiments were conducted in Python using Anaconda Navigator and Jupyter Notebook. The Decision Tree model was implemented with the *DecisionTreeClassifier* class from the *scikit-learn* library. This classifier is based on CART and constructs a binary tree. By default, it uses the Gini impurity criterion, although entropy-based splitting can also be selected. Before training, the dataset was filtered to focus on the reconstruction task. Only cases were retained in which the verbal noun was not consistently present across all paradigms within a common verb-root group. This reduced the data to approximately 300,000 rows. These rows represented cases where the target variable, the verbal noun, was partially missing and had to be inferred from other linguistic features. The task was formulated as a supervised multi-class classification problem. The model was trained on records in which the verbal noun was known, and then used to predict missing verbal-noun values in incomplete records. Since the outputs belong to a controlled inventory of known verbal nouns, the task is classification

rather than open-ended generation. The model used 14 core features selected from morphological and structural attributes, including tense, person, number, verb root, preverb, marker-12, voice/theme marker, ending, common verb-root identifier, morphology type, class, and contact marker. The target verbal noun was excluded from the input feature matrix before model training, thereby preventing direct target leakage. Most input attributes were categorical and were converted into numerical values using label encoding. Georgian text fields required additional processing because Georgian characters are represented in UTF-8 by multiple bytes [26], [27], [28]. Therefore, each Georgian word was encoded as a single numerical value by extracting the last byte of each Georgian character's UTF-8 representation and summing these byte values. This produced a compact representation and reduced computational cost. Because this encoding is sum-based, different strings may theoretically receive the same numerical value. Anagrams necessarily produce the same sum, while other distinct strings may also collide. However, predictions were not based on a single encoded field: the model simultaneously used lexical, morphological, and paradigm-level attributes, including tense, person, root, preverb, formants, morphology type, and structural identifiers. The target variable was encoded separately: each distinct verbal noun received a unique numerical identifier, with a mapping table that preserved the correspondence between the encoded labels and the original linguistic values. This made it possible to decode predictions back into meaningful verbal nouns. A clear distinction was also made between zero values and missing values. Zero values were preserved as meaningful categories, while missing values were treated as values to be predicted. The dataset was divided into training and test subsets using an 80%-20% split. To reduce dependence on a single random split, more than ten different random seeds were tested. The results remained practically unchanged, indicating that the model was stable. In addition to the hold-out evaluation, KFold cross-validation was used to assess stability across different subsets. A stricter GroupKFold evaluation was also performed to ensure that all forms belonging to the same verbal paradigm were kept entirely within either the training or test fold. The model was evaluated using accuracy, precision, recall, and F1-score. Because the task involved multiple classes with an uneven distribution, both macro-averaged and weighted-averaged metrics were considered.

V. RESULTS AND DISCUSSION

The objective of the experiment was to reconstruct missing verbal nouns in KARTUVERBS using a Decision Tree classifier. The model achieved approximately 99% accuracy on the test set, which is a strong result for a multi-class classification problem involving many verbal-noun classes.

Table 1. Overall classification performance using 14 input features.

	Precision	**Recall**	**F1-score**	**Support**
Accuracy			0.99	58933
Macro avg	0.98	0.98	0.98	58933
Weighted avg	0.99	0.99	0.99	58933

The overall classification report is presented in Table 1. The test set contains 58,933 evaluated instances. Accuracy is 0.99, while macro-averaged and weighted-averaged Precision, Recall, and F1-score are in the range of 0.98-0.99. In single-label multi-class classification, micro-averaged Precision, Recall, and F1-score are equivalent to Accuracy, because each instance has one true class and one predicted class. Although the aggregate results are high, they do not fully reflect performance across all verbal-noun classes. Weighted metrics are influenced primarily by frequent classes, whereas rare classes may have unstable or substantially lower scores. A per-class analysis is therefore necessary to identify difficult cases.

Table 2. Selected individual per-class verbal-noun prediction results.

	Precision	Recall	F1-score	Support
…	…	…	…	…
24	0.83	0.86	0.84	140
277	0.00	0.00	0.00	10
278	0.00	0.00	0.00	22
279	0.71	0.92	0.80	84
280	0.59	1.00	0.74	89
282	0.00	0.00	0.00	23
283	0.00	0.00	0.00	39
284	1.00	0.84	0.91	255
285	0.00	0.00	0.00	58
288	1.00	0.43	0.6	30
289	0.00	0.00	0.00	13
290	0.00	0.00	0.00	23
291	0.00	0.00	0.00	26
292	1.00	0.74	0.85	111
418	1.00	0.99	1.00	112
420	0.99	1.00	1.00	142
449	0.58	0.53	0.55	53
462	0.96	1.00	0.98	26
467	0.67	0.80	0.73	51
468	0.40	0.98	0.56	140

Table 2 shows that performance varies across individual verbal-noun classes. Some classes are predicted almost perfectly, while others have lower scores. In particular, for classes such as 277 corresponding to *ღწევა[1] (“to reach”, „to achieve”, „to escape”), Precision, Recall, and F1-score are all 0.00. The support value of 10 indicates that the test set contains 10 actual instances of class 277, while a Recall of 0.00 means none were correctly identified. A Precision of 0.00 may indicate either that the model never predicted this class, in which case Precision is mathematically undefined and was reported as 0.00 using zero_division=0, or that the model predicted the class but all such predictions were incorrect. In both cases, the absence of true-positive predictions results in an F1-score of 0.00. These zero scores mainly occur in low-support or difficult classes and have limited influence on the weighted average, as they represent only a small proportion of the test set.

Other classes illustrate different error patterns. For class 288, corresponding to *ყრდნობა („to lean”, “to rely”, “to support”), Precision is 1.00 and Recall is 0.43, with a support of 30. This means that every prediction assigned to class 288 was correct, but the model identified only approximately 43% of its actual instances, or about 13 out of 30. In contrast, class 468, corresponding to *ყოლა (“to have” or “to follow”) has a Precision of 0.40 and

[1] An asterisk at the beginning of a verb indicates that it may be replaced by different preverbs. The resulting prefixed forms may have different meanings.

a Recall of 0.98, with a support of 140. The model, therefore, identified almost all actual instances of class 468, but also incorrectly assigned many instances from other classes to this label.

This variation is expected in a large multi-class linguistic classification task, especially when the class distribution is uneven. Rare classes have less stable Precision, Recall, and F1-score values, because even a few incorrect predictions can significantly affect their scores. The linguistic nature of Georgian verbs also contributes to this variation. Georgian verbal morphology includes tense, person, number, preverbs, thematic markers, contact markers, stem alternations, and paradigm-level regularities. Some verbal nouns follow predictable patterns, while others are more lexeme-specific or ambiguous. The results support the choice of a Decision Tree classifier. KARTUVERBS contains structured, numerically encoded morphological, lexical, and grammatical attributes. Decision Trees can divide this feature space into interpretable decision paths, which is particularly valuable in lexicographic work, where predictions should remain inspectable and linguistically verifiable. Since the task includes many verbal-noun classes, most of which are predicted with very high accuracy, the complete confusion matrix appears almost entirely diagonal and does not clearly reveal the remaining errors.

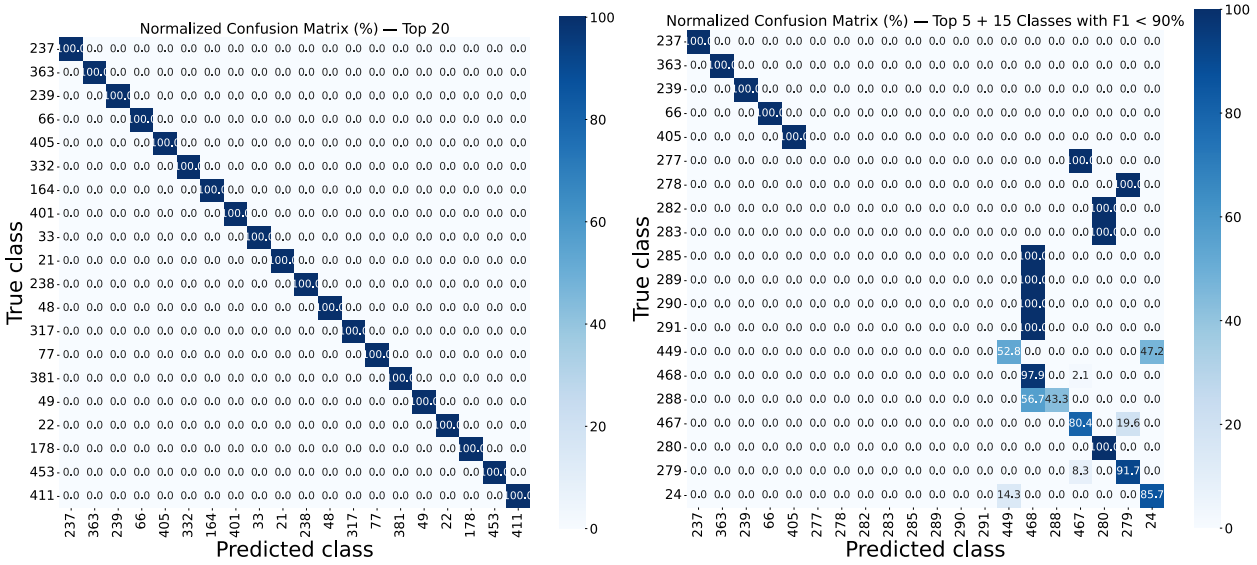

Figure. 2. Normalized confusion matrices for frequent and lower-performing verbal-noun classes.

Figure 2 therefore presents normalized confusion matrices for selected classes. The left matrix shows the 20 most frequent classes, most of which achieve near-100 % accuracy. The right matrix combines the five most frequent classes with 15 additional classes whose F1-scores are below 90%. This representation makes it possible to compare highly stable classes with more difficult cases and shows that most classification errors are concentrated in a relatively small number of less frequent or ambiguous classes.

The reliability of the results was assessed using both KFold and GroupKFold cross-validation. In five-fold KFold evaluation, the test accuracy ranged from 99.92% to 99.95%, with a mean of 99.93% and a standard deviation of 0.015 percentage points. The mean training accuracy was approximately 99.97%. These highly consistent results indicate that the model is stable when the training and test folds contain forms drawn from the same overall inventory of lexical and paradigm groups. A stricter evaluation was performed using GroupKFold, in which all records belonging to the same verbal paradigm were assigned entirely to either the training or test fold. No group overlap occurred in any of the five folds. Under this setting, test accuracy ranged from 74.74% to

78.68%, with a mean of 76.91% and a standard deviation of 1.46 percentage points. Training accuracy remained approximately 99.96%.

The difference between the KFold and GroupKFold results reflects the strongly lexeme- and paradigm-dependent nature of Georgian verbal-noun prediction. Standard KFold allows forms from the same paradigm to appear in both training and test folds and therefore measures the model's ability to reconstruct missing values within lexical groups already represented in KARTUVERBS. GroupKFold instead evaluates generalization to entirely unseen paradigms. The lower GroupKFold score consequently indicates limited out-of-group generalization rather than direct target leakage. The target verbal noun was excluded from the input features, and the absence of group overlap confirms that complete paradigms were strictly separated during the GroupKFold evaluation.

These findings clarify the intended scope of the method. The Decision Tree is highly effective for completing fragmentarily missing verbal nouns when related lexical or paradigm information is already present in the resource. Still, it is less reliable for predicting verbal nouns for completely unseen paradigms.

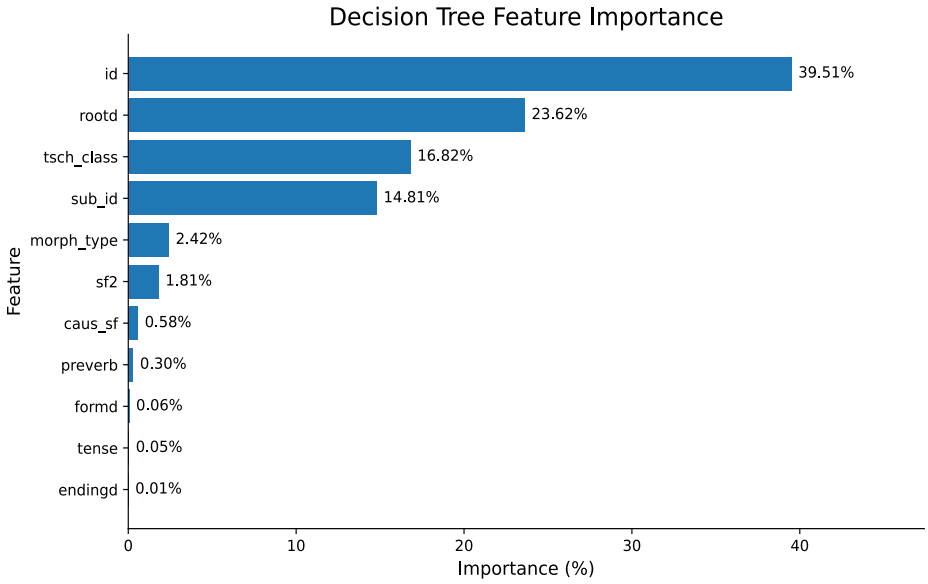

Figure 3. Decision Tree features importance

The feature-importance analysis also provides useful insight into the model's behavior. The most influential feature was the verb identifier, which accounted for approximately 39.51% of the total importance. It was followed by the verb root, with 23.62%, the Tschenkeli class, with 16.82%, and the sub-paradigm identifier, with 14.81% (see Figure 3). Other morphological attributes, such as morphology type, stem formant, causative stem formant, and preverb, had lower individual importance scores. These results suggest that the model relies primarily on lexical and paradigm-level information, while still using morphological features to refine the prediction.

At the same time, this result should be interpreted in light of the approach's main limitations. The source data contained more than 60 characteristics, while the model was trained on a reduced set of 14 selected features. This assumes that these selected attributes contain sufficient information for reliable prediction; however, this assumption was checked experimentally through model evaluation and validation. A second limitation is that the method can restore missing values only when the necessary regularities are already present in the existing

data, making it more suitable for paradigm completion than for predicting completely unknown lexical patterns. From a practical point of view, the approach is valuable because manually completing missing verbal nouns in a resource of this size is not feasible. A machine-learning model can automatically reconstruct most missing values, while rare or lower-confidence cases can be reserved for expert validation. Compared with more complex models, the Decision Tree offers a useful balance between accuracy, simplicity, computational efficiency, and explainability. The experiment shows that the Decision Tree classifier is effective for reconstructing missing verbal nouns in KARTUVERBS. Although per-class performance varies, this is expected due to class imbalance and the linguistic complexity of Georgian verbal morphology. The results confirm that the method is reliable for completing structured lexicographic resources when the objective is to recover missing information within known paradigms. As future work, we plan to use the crowdsourcing platform for human-in-the-loop validation of questionable or low-confidence verbal noun predictions [14]. This validation will focus on rare and ambiguous cases, helping to improve the reliability and quality of the completed KARTUVERBS data.

VI. CONCLUSION

This paper presented a Decision Tree-based approach for completing missing verbal nouns in KARTUVERBS, a linked-data resource for Georgian verb lemmatization and translation. The task was formulated as a supervised multi-class classification problem, in which the model predicts missing values based on structured morphological and paradigm-level attributes. The model achieved a mean KFold accuracy of 99.93%, demonstrating reliable completion within lexical and paradigm groups already represented in the resource. The lower GroupKFold accuracy of 76.91% indicates that prediction is more difficult for paradigms completely unseen, reflecting the lexeme-dependent nature of Georgian verbal morphology. Overall, the Decision Tree approach provides a practical balance between accuracy, efficiency, and interpretability. It is suitable for enriching incomplete lexicographic data before conversion into a linked-data semantic graph, while rare or ambiguous cases can be further validated through expert review and crowdsourcing.

Abstract
Emotion recognition is a crucial research area for human-computer interaction, signal processing, and intelligent decision support systems. Human emotions are not only reflected in textual content but also expressed through tone of voice, emphasis, facial expressions, and visual behaviors. Therefore, multimodal approaches offer a more accurate representation than unimodal methods. In this study, the performance of different Vision Transformer (ViT)- based architectures was comparatively examined in the context of multimodal emotion recognition. In the experimental setup, the text modality was represented using DistilBERT, the audio modality was represented with an MFCC-based BiGRU-attention structure, and architectures such as BEiTv2, CaFormer, CoAt, ConViT, DeiT3, FastViT, MobileViT, MViTv2, NextViT, PiT, PVTv2, Swin Transformer, and TinyViT were used for the visual modality. By keeping the text and audio modalities constant, the impact of changing only the visual modality architecture on multimodal emotion recognition performance was analyzed. Results showed that the CaFormer-S18 model achieved the highest performance among the ViT variants compared, with an approximate weighted F1 score of 67.87% and a weighted accuracy of 67.61%. Additionally, the high performance of CaFormer-S18 despite its short training time suggests that this model effectively balances performance and computational cost. Overall, the findings demonstrate that selecting the appropriate visual feature extractor is vital for multimodal emotion recognition systems.

Keywords: Multimodal emotion recognition, Vision Transformer, Visual feature extraction, IEMOCAP

I. INTRODUCTION

This template, Multimodal emotion recognition, has become an important research topic in recent years across many areas, including human-computer interaction, intelligent education systems, call center analysis, healthcare applications, and social signal processing [1]. However, emotions are not limited only to spoken words or facial expressions. To understand how a person feels, speech content, tone of voice, emphasis, facial expressions, and behavioral cues should be evaluated together. Therefore, there has been a significant increase from unimodal to multimodal approaches in emotion recognition studies [2], [3]. In multimodal emotion recognition systems, text, audio, and visual modalities provide complementary information [4]. While the text modality represents the semantic content of speech, the audio modality reflects acoustic features such as intonation, emphasis, and rhythm. Visual modality provides additional cues to emotional state through facial expressions and other visual behaviors. The joint use of these modalities enables a more comprehensive representation of emotions than systems based on a single data source [2]. However, in multimodal systems, the contributions of the modalities may not be equal, and the feature-extraction architecture used can directly affect final performance. In recent years, deep learning-based architecture has shown significant progress, especially

in the visual modality ([5], [6], [7]). While convolutional neural networks were initially widely used for visual feature extraction, Vision Transformer (ViT)-based models have recently become strong alternatives for learning image representations. ViT architectures can divide an image into patches and model relationships among them via the attention mechanism, thereby producing more flexible visual representations [8]. However, the effects of different ViT architectures on multimodal emotion recognition classification are not always consistent. Some models achieve high classification performance, while others offer competitive results at lower computational cost. In this study, the performance of different ViT-based architectures was evaluated for multimodal emotion recognition. In the experiments, the text and audio modalities were kept fixed, while different ViT variants such as BEiTv2-Base [9], CaFormer-S18 [10], CoAt-Small [11], ConViT-Base [12], DeiT3-Base [13], FastViT-SA12 [14], MobileViT-Small [15], MViTv2-Base [16], NextViT-Base [17], PiT-Base [18], PVTv2-B3 [19], Swin Transformer [20], and TinyViT [21] were used in the visual modality. Thus, the effect of selecting a visual feature extractor on multimodal emotion recognition performance was evaluated under the same experimental conditions. The main contributions of this study are as follows:

- In this study, a common experimental framework that jointly uses text, audio, and visual modalities was developed for the multimodal emotion recognition problem.
- In the visual modality, different ViT variants, including BEiTv2, CaFormer, CoAt, ConViT, DeiT3, FastViT, MobileViT, MViTv2, NextViT, PiT, PVTv2, Swin Transformer, and TinyViT, were compared under the same experimental conditions.
- By keeping the text and audio modalities fixed and changing only the visual backbone, the effect of ViT-based visual feature extractors on multimodal emotion recognition performance was directly analyzed.
- The models were evaluated not only in terms of accuracy and weighted F1 score, but also in terms of training time and computational cost. As a result, a balance between performance and efficiency was revealed.

The study is structured as follows: The next section presents a comprehensive literature review. Section 3 summarizes the approaches, dataset, and evaluation metrics used in the current study. Section 4 presents the findings obtained from the experiments. Section 5 discusses the compared methods. The final section concludes with the study and summarizes future work.

II. RELATED WORKS

Multimodal emotion recognition is an important research area that combines complementary information from different data sources, such as text, audio, and images. Although unimodal approaches can yield successful results in certain cases, they are often insufficient to fully represent human emotions through speech content, tone of voice, or facial expressions alone. For this reason, methods that jointly use textual, acoustic, and visual information are widely addressed in the literature, especially on multimodal datasets such as IEMOCAP and MELD [2]. Within the scope of multimodal emotion recognition, ViT-based approaches, as well as convolutional neural networks, have become widely used in recent years for image-based emotion recognition. ViT architecture divides the image into fixed-size patches and models their relationships using self-attention. In this way, they can learn both local and global visual cues that emerge in facial expressions. Especially in the field of multimodal emotion recognition, transformer-based visual encoders such as ViT [22], Swin Transformer [20], BEiT [9], and related models are preferred for more effective extraction of facial representations from video frames. These studies achieve higher accuracy than classical CNN-based approaches because they can model long-range dependencies more effectively and represent inter-frame visual changes more flexibly. Therefore, ViT-based models have become an important research direction in the literature, especially for visual feature extraction and multimodal representation learning on datasets such as MELD and IEMOCAP. In ViT-based multimodal emotion recognition studies, the visual modality primarily represents facial expressions, gestures, and temporal-visual cues from video frames. The literature employs a range of visual encoders in CLIP-

ViT-based studies. Multimodal emotion classification has been conducted on the IEMOCAP dataset using CLIP ViT-L/14-336 [6], CLIP-base-ViT-patch32 [7], CLIP ViT-B/32 [9], and CLIP-ViT-B/16 [10]. Most research shows that ViT models improve visual representation in multimodal emotion recognition; however, performance varies considerably across visual encoders, frame sampling methods, speaker face isolation, and fusion techniques.

III. MATERIALS AND METHODS

1. Dataset

In this study, the IEMOCAP [23] dataset was used. The IEMOCAP dataset consists of approximately 12 hours of speech recordings and 10,039 utterances. This dataset includes dialogues performed by professional actors and provides audio, video, motion capture, and text information for each sample. In the IEMOCAP dataset, conversations were recorded both naturally and in specific scenarios. In this respect, the dataset provides a rich source for examining speakers' different emotional states. In the literature, IEMOCAP is generally evaluated using basic emotion classes such as angry, happy, sad, and neutral, although other emotion categories are used in some studies.

2. ViT Architectures Used

In this study, various ViT-based architectures were employed for a comparative evaluation of the visual modality. BEiTv2-Base is a strong pretraining-based ViT model that learns from semantic visual tokens via a masked image modeling approach [9]. DeiT3-Base is an improved version of the classical ViT architecture with strong supervised training strategies [13]. ConViT-Base aims to improve the data efficiency of ViT by adding a soft convolutional bias to the self-attention structure [12]. In this comparison, models capable of extracting multi-scale, hierarchical visual representations were also evaluated. For instance, CoaT-Small [11] offers a multi-scale, convolutional, attention-based transformer architecture. Similarly, MViTv2-Base [16] is a multi-scale transformer architecture that processes visual data at different scales. Additionally, PVTv2-B3 includes overlapping patch embedding and a linear-complexity attention mechanism [19]. Within the scope of efficiency-oriented models, the hybrid architectures CaFormer-S18 [10], PiT-Base [18], FastViT-SA12 [14], MobileViT-Small [15], and NextViT-Base [17] were used. Furthermore, Swin-Base was included in a hierarchical model of local facial details and broader contextual relationships via its shifted window-based attention mechanism [20]. Finally, TinyViT-21M was evaluated as a smaller, more computationally efficient ViT variant, trained via knowledge distillation [21].

3. Evaluation Metrics

In this study, precision, recall, weighted F1-score (WF1), weighted accuracy (WACC), and the confusion matrix were used to evaluate the performance of the proposed multimodal emotion recognition model. Precision (1) and recall (2) are calculated as follows:

$$Precision_i = \frac{TP_i}{TP_i + FP_i} \tag{1}$$

$$Recall_i = \frac{TP_i}{TP_i + FN_i} \tag{2}$$

Here, TP_i, epresents the true positive predictions for the i-th class; FP_i represents the samples that belong to another class but are predicted as the i-th class; and FN_i represents the samples that belong to the i-th class but are predicted as another class. The F1-score (3) is calculated as the harmonic mean of precision and recall. The WF1-score (4) is obtained by weighing the F1 value of each class according to the number of samples in that class. Thus, overall performance is more realistically evaluated by considering the class distribution.

$$F1_i = 2 \times \frac{Precision_i \times Recall_i}{Precision_i + Recall_i} \tag{3}$$

$$WF1 = \sum_{i=1}^{C} \frac{n_i}{N} F1_i \tag{4}$$

Here, C denotes the total number of classes, nalti. i.n_i denotes the number of samples in the corresponding class, and N denotes the total number of samples. Another metric used in this study is weight accuracy. WACC is calculated by weighing the class-wise accuracies by the number of samples in each class. In addition, a confusion matrix was used to examine the model's class-wise error rates in more detail.

$$WACC = \sum_{i=1}^{C} \frac{n_i}{N} Acc_i \tag{5}$$

IV. EXPERIMENTAL RESULTS

This section presents the experimental results obtained using the IEMOCAP dataset. In the experimental framework proposed in this study, the text modality was represented by DistilBERT, the audio modality by an MFCC-based BiGRU-attention architecture, and the visual modality by different ViT variants. In all experiments, the text and audio branches were kept fixed, and only the visual backbone was changed to evaluate the effect of ViT-based architectures on multimodal emotion recognition performance. Thus, the effect of the visual backbone on multimodal emotion recognition performance was systematically analyzed. In this study, different ViT-based architectures, including BEiTv2-Base [9], CaFormer-S18 [10], CoAt-Small [11], ConViT-Base [12], DeiT3-Base [13], FastViT-SA12 [14], MobileViT-Small [15], MViTv2-Base [16], NextViT-Base [17], PiT-Base [18], PVTv2-B3 [19], Swin Transformer [20], and TinyViT [21], were compared using the same methods. The architectural and computational characteristics of the evaluated ViT models are presented in Table 1. For the performance analysis of all models, accuracy, weighted precision, weighted recall, weighted F1 score, and computational time were considered. Table 2 presents a comparative analysis of the performance results obtained. Figure 1 compares the classification performance of the ViT architectures. According to the results, the highest performance was obtained with the CaFormer-S18 model. Former-S18 achieved a higher performance than the other models, with approximately 67.87 weighted F1 and 67.61 weighted accuracy. NextViT-Base, CoAt-Small, MobileViT-Small, BEiTv2-Base, and TinyViT-21M also achieved competitive accuracy. Swin-Base, PVTv2-B3, and ConViT-Base performed worse than the other architectures. This indicates that the choice of visual backbone significantly affects model performance on the multimodal emotion recognition task.

Table 1. Computational Characteristics of the ViT Architectures Used For the IEMOCAP Dataset

Model	Parameters (M)	Model Size (MB)	Input Size	FLOPs (G)
BeiTv2-Base	85.76	327.16	3x224x224	16.87

CoAt-Small	21.37	81.53	3x224x224	12.61
ConViT-Base	85.77	327.19	3x224x224	17.52
DeiT3-Base	85.82	327.36	3x224x224	16.87
FastViT-SA12	10.56	40.27	3x256x256	1.96
MobileViT-Small	4.94	18.84	3x256x256	1.86
MViTv2-Base	50.7	193.42	3x224x224	10.16
NextViT-Base	43.79	167.06	3x224x224	8.24
PiT-Base	72.74	277.48	3x224x224	10.56
PVTv2-B3	44.73	170.61	3x224x224	6.71
Swin-Base	86.74	330.9	3x224x224	15.47
TinyViT-21M	20.62	78.67	3x224x224	4.06
CaFormer-S18	**23.24**	**88.65**	**3x224x224**	**3.89**

Table 2. Comparative Performance Analysis of the ViT Architectures on the IEMOCAP Dataset

Model	**Precision (%)**	**Recall (%)**	**F1-Score (%)**	**Accuracy (%)**
BeiTv2-Base	66.12 ± 1.78	68.12 ± 1.42	66.12 ± 1.78	66.25 ± 1.74
CoAt-Small	66.13 ± 0.71	67.45 ± 1.21	66.13 ± 0.71	66.27 ± 0.63
ConViT-Base	66.89 ± 3.05	68.17 ± 2.51	66.89 ± 3.04	66.95 ± 2.94
DeiT3-Base	66.46 ± 2.69	68.85 ± 2.67	66.46 ± 2.69	66.35 ± 2.62
FastViT-SA12	66.31 ± 4.05	66.92 ± 3.03	66.31 ± 4.05	66.37 ± 3.90
MobileViT-Small	66.67 ± 2.75	68.13 ± 2.85	66.67 ± 2.75	66.61 ± 2.60
MViTv2-Base	67.31 ± 2.72	68.21 ± 2.70	67.31 ± 2.72	67.33 ± 2.73
NextViT-Base	66.63 ± 2.55	68.32 ± 2.29	66.63 ± 2.55	66.63 ± 2.59
PVTv2-B3	66.31 ± 2.71	68.00 ± 2.22	66.51 ± 2.63	66.58 ± 2.47
Swin-Base	66.32 ± 1.99	67.85 ± 1.53	66.32 ± 1.99	66.29 ± 2.03
TinyViT-21M	66.93 ± 3.86	68.16 ± 3.66	66.93 ± 3.86	66.92 ± 3.93
CaFormer-S18	**68.20 ± 2.86**	**68.81 ± 2.54**	**68.20 ± 2.85**	**68.20 ± 2.85**

Figure 2 compares the performance of the CaFormer-S18 architecture, which achieved the highest accuracy on the IEMOCAP dataset, with other baseline methods. In Figure 2, both the overall accuracy and the model's behavior across different emotion classes were observed.

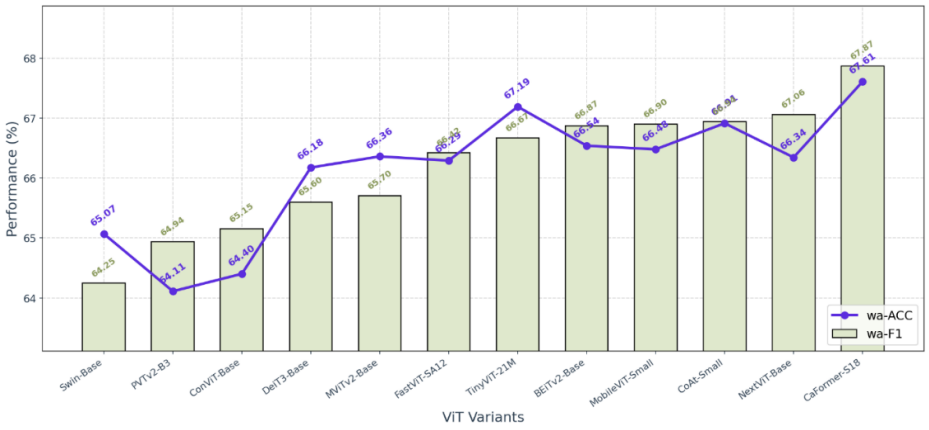

Figure 1. Comparative analysis of the ViT architecture in the IEMOCAP dataset

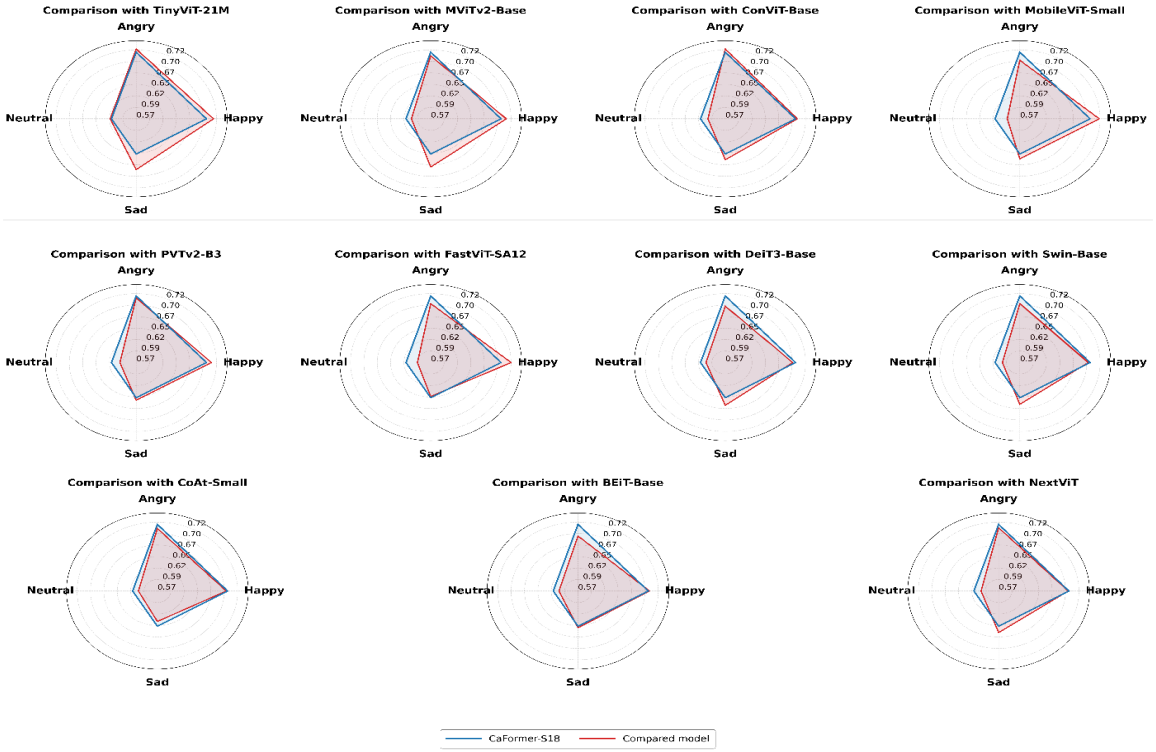

Figure 2. Class-based F1 comparison of CaFormer-S18 with other image transformer-based visual encoders across angry, happy, sad, and neutral classes.

The results show that CaFormer-S18 achieved balanced performance not only in overall wa-F1 and wa-ACC, but also across the angry, happy, sad, and neutral classes. Although some models achieved competitive results in certain classes, the more balanced distribution of CaFormer-S18 made it more advantageous for the multimodal emotion recognition task. As shown in the time graphs in Figures 3 and 4, CaFormer-S18 achieved one of the highest accuracies while also having one of the lowest training times. This result shows that CaFormer-S18 is a strong option not only in terms of performance but also in efficiency. Although the TinyViT-21M model also achieved high accuracy, it took longer to train than CaFormer-S18. Although CoAt-Small and MViTv2-Base achieved competitive accuracy, their training times were quite high. ConViT-Base appears less advantageous in this experimental setup due to both its long training time and low accuracy.

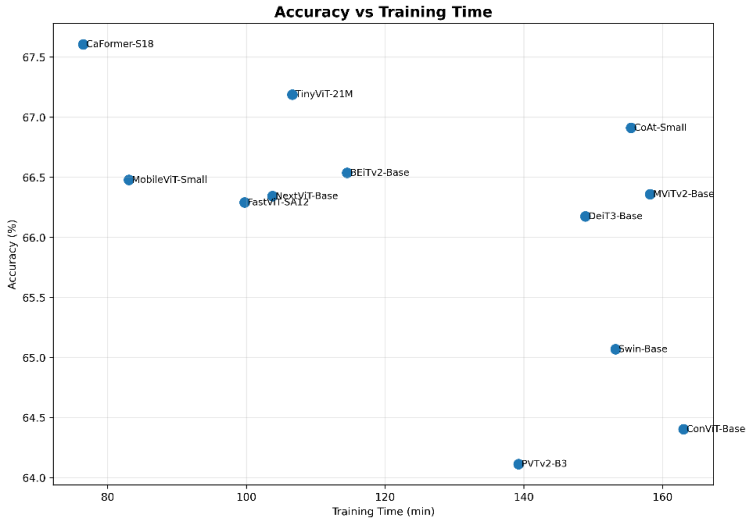

Figure 3. Accuracy-training graph of other basic methods with the IEMOCAP dataset

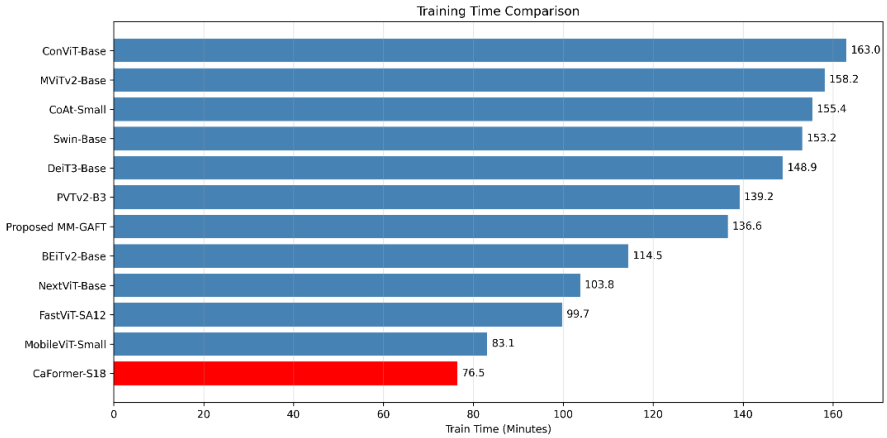

Figure 4. Comparison of the training durations of the ViT architecture used

The results reveal that selecting the visual feature extractor in multimodal emotion recognition systems significantly affects accuracy, training time, and computational cost. The CaFormer-S18 model achieved the highest weighted F1 score among the compared ViT variants and provided an efficient structure with its low training time. Therefore, the findings show that CaFormer-S18 is a strong and balanced visual backbone for multimodal emotion recognition when combined with text and audio modalities. Figure 5 shows the confusion matrix for the CaFormer-S18 model, which achieved the highest accuracy and shortest training time. This confusion matrix shows which emotion classes the model distinguishes more accurately and which it confuses. In general, the model appears particularly successful in the angry class; a large proportion of the samples in this class were correctly classified. Correct predictions were also obtained for the sad and happy classes. In contrast, the class in which the model had the most difficulty was neutral. Some neutral samples were misclassified as happy or sad. Similarly, some samples in the happy class were predicted as neutral, indicating that the two classes are close in emotional expression. This may be because, especially in natural conversations, neutral expressions can be mistaken for slightly positive or emotional ones.

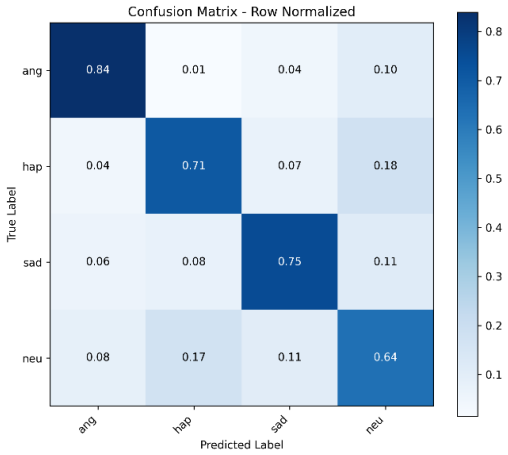

Figure 5. Confusion matrix of the CaFormer-S18 model

Overall, the model classifier clearly identifies emotions more successfully, while confusion occurs between classes in more ambiguous or transitional emotional states. This result indicates that the neutral class should be modeled more carefully in the multimodal emotion recognition task.

V. DISCUSSION

The experimental results show that selecting a ViT-based visual modality significantly affects multimodal emotion recognition performance. Since the text and audio modalities were held fixed across all experiments, the observed performance variations can be primarily attributed to differences in visual feature-extraction capabilities. This finding highlights the critical role of visual representation learning in multimodal emotion recognition, even when complementary textual and acoustic information is available. According to the obtained results, CaFormer-S18 was the most successful model, with approximately 67.87% weighted F1 and 67.61% accuracy. This indicates that CaFormer-S18 can produce more discriminative and balanced visual representations within the multimodal system. A possible explanation for this superior performance is its hybrid design, which combines convolutional operations with transformer-based representations. Such a structure may be particularly beneficial for emotion recognition tasks, where capturing both local facial cues and global contextual information is important. The results suggest that an effective balance between local feature extraction and long-range dependency modeling can improve multimodal emotion understanding. Interestingly, the model with the highest performance does not necessarily have the longest training time. Former-S18 achieved the highest performance with shorter training time than many other models. TinyViT-21M, CoAt-Small, NextViT-Base, and MobileViT-Small also produced competitive results despite their relatively efficient designs. In contrast, larger models such as ConViT-Base and PVTv2-B3 did not achieve comparable performance. This observation indicates that some larger models do not provide higher performance despite requiring greater computational cost. Instead, architectural design and the quality of representation appear to be more influential factors. From a practical perspective, these findings show that not only model size but also the representation capability and computational efficiency of the visual modality are important in multimodal emotion recognition systems. In real-world applications such as human-computer interaction, healthcare monitoring, intelligent assistants, and social robotics, computationally efficient architectures may offer a more favorable trade-off between accuracy and deployment cost. Overall, the study demonstrates that careful selection of the visual backbone is a key design decision that can significantly influence the effectiveness of multimodal emotion recognition systems.

VI. CONCLUSION AND FUTURE WORK

In this study, different ViT variants were compared within a common experimental framework for the multimodal emotion recognition task. By keeping the text and audio modalities fixed and varying only the visual architecture, the study isolated and quantified the contribution of visual feature extraction to overall multimodal performance. The results showed that the choice of visual backbone has a substantial impact on emotion recognition accuracy, highlighting that visual representation learning remains a critical factor even in multimodal settings where complementary textual and acoustic information is available. Among the evaluated architectures, CaFormer-S18 achieved the best overall performance in terms of both weighted F1 score and weighted accuracy while maintaining a relatively low training cost. This finding suggests that effective multimodal emotion recognition depends not only on integrating multiple modalities but also on the quality and efficiency of modality-specific feature extractors. The results further indicate that a hybrid architecture that combines convolutional inductive biases with transformer-based global modeling can strike a favorable balance between representational power and computational efficiency. Future work may investigate advanced multimodal fusion strategies, leverage large-scale pre-trained speech representations such as Wav2Vec 2 and HuBERT, and incorporate dialogue context and speaker information into the model to reduce confusion among emotion classes.

Abstract
Network Intrusion Detection Systems (NIDS) are central to cybersecurity infrastructure, but traditional signature-based approaches struggle to detect novel attack patterns and produce high false-alarm rates. This paper presents a controlled comparative evaluation of Random Forest, Gradient Boosting, and a Multi-Layer Perceptron Neural Network for binary network intrusion detection on the CICIDS2017 benchmark. A preprocessing pipeline applies z-score normalization and oversampling to address class imbalance, with hyperparameters tuned across five configurations per algorithm and 5-fold stratified cross-validation. The MLP achieves the highest performance across all metrics (accuracy 98.80%, F1 98.01%, AUC-ROC 0.9897; CV mean F1 0.9892 ± 0.0026), with McNemar's test confirming statistically significant superiority over both ensemble methods ($p < 0.001$) and Wilcoxon signed-rank confirming consistency across folds. SHAP-based explainability analysis identifies backward inter-arrival timing and flag-count features as the dominant predictors, supporting the broader research direction of Explainable Intrusion Detection Systems (X-IDS). A production deployment pipeline using Apache Kafka, Spark Streaming, MLflow, and GPU acceleration is proposed for scalable real-time inference.

Keywords: network intrusion detection, CICIDS2017, machine learning, deep learning, SHAP, explainable AI, class imbalance, cybersecurity

I. INTRODUCTION

Network intrusion detection is a critical component of modern cybersecurity infrastructure. As cyberattacks grow in number and sophistication each year, organizations need automated systems that can identify malicious traffic with high accuracy and low false-alarm rates. Traditional signature-based intrusion detection systems rely on fixed rules and known attack patterns, which struggle to detect novel or modified threats. They also tend to generate high volumes of false positives that overwhelm security operations centers (SOCs), where analysts must investigate every alert. Machine learning (ML) and deep learning (DL) approaches offer a complementary path. Rather than matching predefined signatures, these methods learn the statistical structure of malicious traffic from labeled examples and can generalize to previously unseen attack patterns. Among the most widely studied algorithms for this task are tree-based ensembles such as Random Forest and Gradient Boosting, as well as feedforward neural networks such as the Multi-Layer Perceptron. While each algorithm has been studied individually, controlled comparisons across all three paradigms on a single benchmark with statistical validation remain less common.

This study evaluates three algorithms: Random Forest (RF), Gradient Boosting (GB), and a Multi-Layer Perceptron (MLP) Neural Network, on the CICIDS2017 benchmark for binary intrusion detection. Beyond an

accuracy comparison, this work makes four contributions that distinguish it from prior CICIDS2017 studies. (1) Statistical significance testing (McNemar's and Wilcoxon), rather than point estimates alone, addresses a recognized gap in ML-NIDS evaluation. (2) Bootstrap 95% confidence intervals are reported on every metric, quantifying uncertainty in single-split evaluation. (3) SHAP-based explainability with global and local feature attribution supports Explainable Intrusion Detection Systems (X-IDS) research. (4) A model-agreement analysis shows that a simple MLP+GB union reaches 99.3% detection (up from 96.89% MLP alone), suggesting a deployment-ready combination strategy. The proposed Kafka–Spark–MLflow pipeline situates these findings in a realistic production architecture.

II. RELATED WORK

CICIDS2017 has become a benchmark for ML-based intrusion detection since its release [1], and several recent studies have applied progressively more complex models to it. Tama et al. [2] proposed a stacked ensemble of heterogeneous classifiers, achieving competitive accuracy at the cost of significant inference latency. Andresini et al. [3] introduced a nearest-cluster-based CNN that achieved strong per-class performance but required dataset-specific clustering pre-processing. Sun et al. [4] combined convolutional and LSTM layers to jointly learn spatial and temporal flow features, using category-weight optimization to mitigate class imbalance on the CICIDS2017 dataset. Halbouni et al. [5] extended this line of work with a CNN-LSTM hybrid evaluated on CIC-IDS2017, UNSW-NB15, and WSN-DS, reporting 99.64% binary accuracy on CIC-IDS2017 at the cost of a substantially deeper architecture. Two gaps remain. First, most studies report only point estimates, without significance testing. Second, deep learning is typically treated as a black box. Recent surveys [6] flag both as priorities for production NIDS. This work addresses them by adding McNemar's and Wilcoxon's tests for validation and applying SHAP [7] to explain Random Forest predictions within a controlled pipeline.

III. DATASET AND PREPROCESSING

The CICIDS2017 dataset contains 2,830,743 labeled network flows [1]. The official release documents traffic capture from 3 to 7 July 2017 and more than 80 CICFlowMeter flow features [8]. It captures benign traffic as well as 14 attack categories [1]. CICIDS2017 was selected for its realistic profiled traffic, pre-labeled CSVs, and benchmark comparability with the literature [1-5]. From the available CICFlowMeter features, a subset of 20 was selected covering flow durations, packet sizes, byte rates, inter-arrival times, and TCP flag counts (SYN, RST, ACK, FIN, PSH, URG). These features were identified by prior work and exploratory correlation analysis as the most discriminative for binary attack detection. A 10,000-record stratified subsample (69.5% benign, five attack classes) was used for the controlled algorithm comparison; this size was chosen to (i) keep hyperparameter search and 5-fold cross-validation computationally tractable for the MLP, (ii) maintain proportional representation of the five attack classes present in the sample (DoS Hulk, PortScan, DDoS, DoS GoldenEye, FTP-Patator), and (iii) match the sample sizes used in comparable published studies on this benchmark. The full preprocessing and inference pipeline is designed for Apache Spark scale-up to the complete 2.8M-record dataset in deployment. Exploratory analysis showed a heavy imbalance: 69.5% of records are benign, with attack classes ranging from DoS Hulk (12.1%) to FTP-Patator (just 2.2%, or 216 records in the sample), as shown in Figure 1. This long-tail distribution is realistic for network traffic but creates a training challenge. Standard classifiers tend to favor the majority class and miss the rarer attacks. The correlation matrix in Figure 1 also shows that several packet-length features are moderately correlated, motivating the use of ensemble methods that handle correlation well.

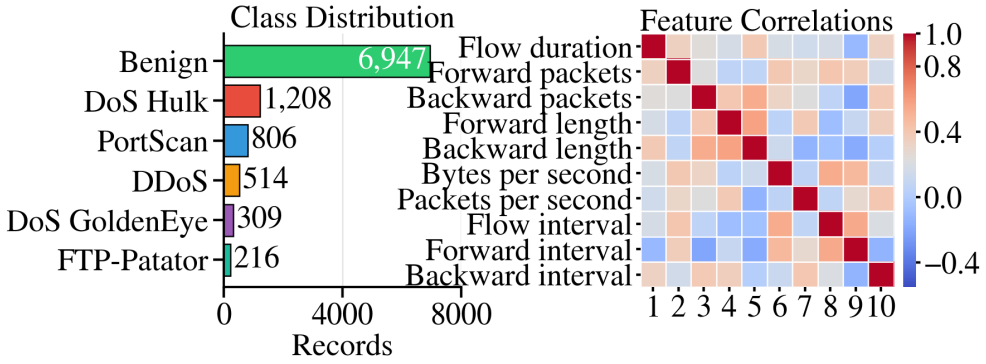

Figure 1. Class distribution (left) showing 69.5% benign dominance, and feature correlation matrix (right). The long-tail attack distribution motivates oversampling and supports the use of ensemble methods that handle correlated features.

Preprocessing proceeded in five stages: (1) removal of missing and infinity values from zero-duration flows; (2) binary label assignment (BENIGN = 0, all attacks = 1); (3) z-score normalisation via StandardScaler, especially important for the MLP; (4) stratified 80:20 train/test partitioning; and (5) random oversampling of the training partition only to a 50:50 ratio, leaving the test partition at its original imbalanced distribution. Every feature retained more than 99.7% of the records after cleaning. Random oversampling was preferred over SMOTE (Synthetic Minority Over-sampling Technique) [9] for three reasons: (1) network traffic features are not always continuous (interpolated values like 1.5 SYN flags are not physically meaningful); (2) it provides a cleaner empirical baseline where any improvement comes purely from class balancing; and (3) the simpler approach was empirically effective. Oversampling improved recall noticeably for the ensemble methods (RF: 81.34% to 84.29%, +3 pp; GB: 84.78% to 88.38%, +3.6 pp), while the MLP barely changed (accuracy 98.50% to 98.60%; recall 97.22% to 96.24%). The MLP's insensitivity indicates that deep models handle class imbalance through their learned feature representations.

IV. METHODOLOGY

1. Algorithm Selection and Hyperparameters

Random Forest [10] is a bagging ensemble of decision trees with random feature subsampling at each split. RF handles correlated features well, provides built-in feature importance, and naturally parallelizes in Spark MLlib. Hyperparameters: n_estimators = 100, max_depth = 20, min_samples_split = 5. Gradient Boosting [11] is a sequential ensemble in which each tree corrects the errors of its predecessors. Its focus on misclassified samples is valuable in imbalanced classification. Hyperparameters: n_estimators = 100, learning_rate = 0.1, max_depth = 5. The MLP [12] is a feedforward neural network with three fully connected hidden layers (128, 64, 32 neurons) using ReLU activations, followed by a sigmoid output for binary classification (Figure 2). The network was trained with the Adam optimizer [13] (learning rate 1e-3, β_1=0.9, β_2=0.999) and binary cross-entropy loss. Batch size was 32, with up to 200 epochs and early stopping (patience 10) on validation loss to prevent overfitting on the balanced training set. The progressively narrowing architecture (128→64→32→1) learns hierarchical representations from raw flow statistics, with each layer compressing the input toward a binary decision.

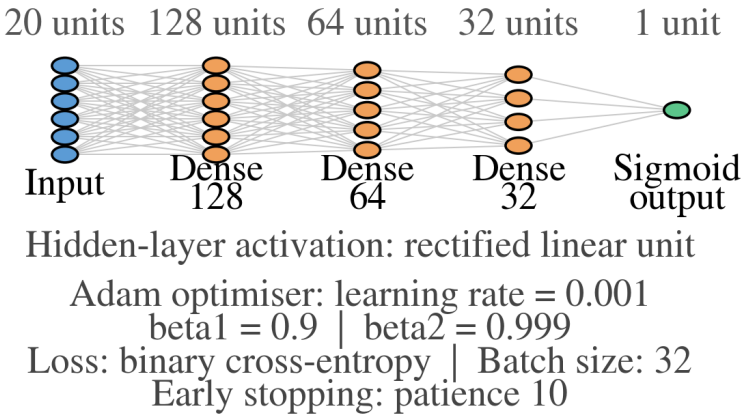

Figure 2. MLP architecture for binary intrusion detection. The input layer with 20 features feeds into three fully connected hidden layers (128, 64, 32 neurons) with ReLU activations, followed by a sigmoid output layer. Training details shown beneath. Five configurations were evaluated per algorithm using cross-validation on the training set, and the best configuration was then evaluated on the held-out test set (F1 was preferred over accuracy given the class imbalance). For RF, gains plateaued at max_depth = 20. For GB, lr = 0.01 underfitted (F1 = 0.8447); optimum at lr = 0.1, max_depth = 5 (F1 = 0.9122). For the MLP, the (128, 64, 32) configuration achieved the highest F1 score (0.9801).

2. Scalable Production Pipeline

A production NIDS must process traffic at full scale in near real-time. The proposed pipeline (Figure 3) uses Apache Kafka for packet ingestion (durable buffering between network tap and feature extraction), Spark Structured Streaming for distributed CICFlowMeter feature extraction [14], and MLflow for low-latency model serving with versioned rollback support.

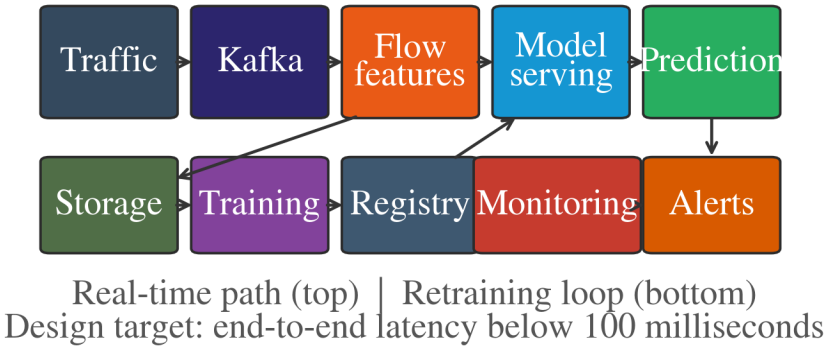

Figure 3. Proposed production NIDS pipeline. Apache Kafka handles real-time packet ingestion; Spark Structured Streaming extracts CICFlowMeter features; MLflow serves the pre-trained MLP for inference; and HDFS/S3 logs flagged flows for periodic retraining.

The pipeline separates real-time inference from an overnight retraining loop. As a proposed architecture, throughput and latency are design targets rather than measured benchmarks: approximately 47,000 flows/second

and sub-100 ms end-to-end latency, extrapolated from per-sample MLP inference time on a V100 GPU. Full-system benchmarking at production scale is left for future deployment validation.

V. RESULTS

1. Quantitative Performance

Table 1 summarises performance on the held-out test set. The MLP led on every metric (accuracy 98.80%, precision 99.16%, recall 96.89%, F1 98.01%, AUC-ROC 0.9897). Random Forest achieved 93.65% accuracy and 88.91% F1, while Gradient Boosting reached 92.90% accuracy and 88.07% F1. The recall gap is the most operationally significant result: the MLP detects 96.89% of attacks, compared to 83.31% for RF and 85.76% for GB, and this gap is consistent across all metrics. In intrusion detection, every missed attack is a real security threat, making recall more critical than overall accuracy.

Table 1. Performance metrics (%) on test set. Bold indicates the best per metric.

Model	**Acc**	**Prec**	**Rec**	**F1**	**AUC**
RF	93.65	95.32	83.31	88.91	97.82
GB	92.90	90.50	85.76	88.07	96.95
MLP	**98.80**	**99.16**	**96.89**	**98.01**	**98.97**

Bootstrapping the test set 1,000 times produced 95% confidence intervals around each point estimate. The MLP intervals are the narrowest, confirming its lead is statistically stable rather than dependent on which particular records appeared in the test split. Random Forest and Gradient Boosting show wider intervals, particularly on Recall, consistent with their greater sensitivity to which rare attack examples appear in the test set. Learning-curve analysis further confirms minimal overfitting in the MLP (train-CV gap = 0.0065), well below RF (0.0203) and GB (0.0217).

2. Per-Class Analysis and Comparison with Prior Work

Although the classifier produces a single binary decision per flow, its detection performance can still be examined by attack subtype. Each positive test sample carries its original CICIDS2017 label, so F1-score and false-negative rate can be computed per subtype as one-vs-benign detection tasks. Breaking down detection F1 by attack type (Figure 4) and false-negative rates by attack shows where the ensembles struggle. The rarest classes (DoS GoldenEye at 3.1% of data, FTP-Patator at 2.2%) have the worst false-negative rates. Random Forest misses 41.2% of DoS GoldenEye and 43.2% of FTP-Patator attacks. Gradient Boosting performs marginally better at 32.4% and 38.6%. The MLP reduces these to just 10.3% and 6.8%. High-volume attacks like DoS Hulk and PortScan are caught reliably by all three models, but the rare-class gap exposes a known limitation of oversampling.

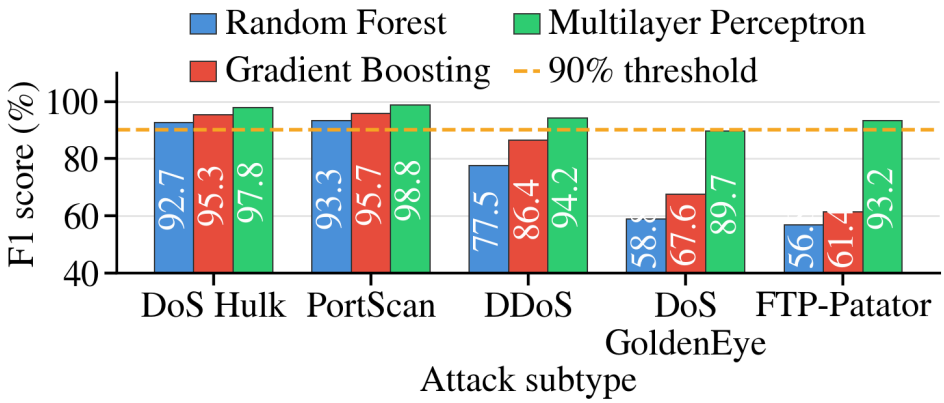

Figure 4. Binary detection F1 stratified by underlying attack type. Each attack subtype is treated as a one-vs-benign detection task. The MLP maintains F1 above 89% across every attack subtype; the ensembles drop sharply on the rarest subtypes (DoS GoldenEye, FTP-Patator).

Direct comparison with published CICIDS2017 studies [2-5] must be qualified, because sample sizes, feature subsets, and balancing strategies differ across papers; hybrid deep architectures trained on much larger portions of the dataset report higher headline accuracy, such as the 99.64% of the CNN-LSTM in [5] versus the 98.80% achieved here on a 10,000-record sample. The supported finding is therefore architectural rather than a ranking: within a single controlled protocol, a well-tuned MLP with proper class balancing matched or exceeded strong tree ensembles without convolutional or recurrent layers, a useful insight for production deployment.

3. ROC and Calibration Analysis

The ROC curves (Figure 5) confirm the metrics from Table 1, with the MLP closest to the top-left. RF is slightly ahead of GB on area despite GB's higher recall, reflecting calibration differences. A detection error trade-off analysis on a probit scale, which spreads out the low-error operating region where security deployments actually run, yields an MLP equal-error rate of 1.5%, well below RF (4.5%) and GB (6.0%). Precision-recall analysis shows the same pattern: the MLP has the highest average precision (AP = 0.9902), with the optimal F1 threshold at 0.54.

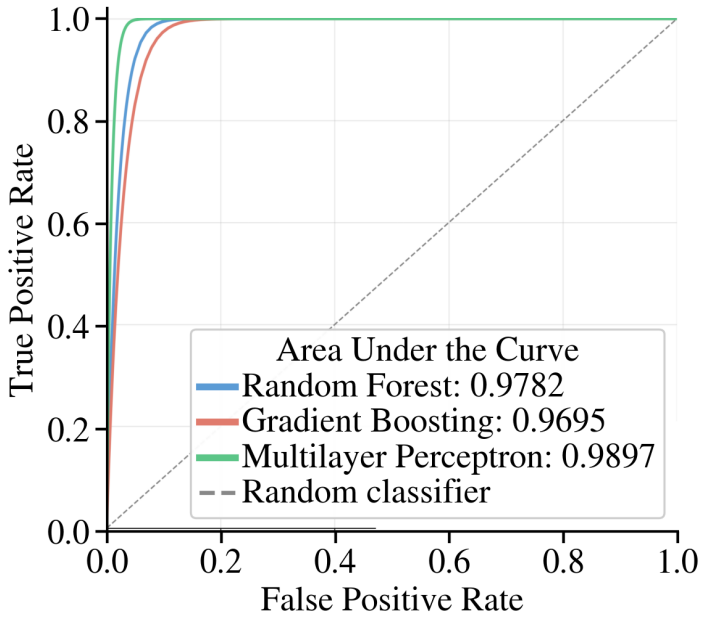

Figure 5. ROC curves. The MLP (AUC = 0.9897) sits closest to the top-left corner; RF (0.9782) is slightly ahead of GB (0.9695) despite GB's higher recall.

Calibration matters when probabilities drive threshold tuning. The MLP's calibration closely tracks the ideal diagonal (Brier 0.018), so its confidence scores can be used directly. GB is slightly under-confident (Brier 0.052), correctable via Platt scaling [15] if needed.

4. Confusion Matrices and SOC Workload Analysis

The confusion matrices (Figure 6) show that the MLP has the fewest false negatives. False positive rates also follow a consistent order: MLP 0.4%, RF 1.8%, GB 4.0%. On a network handling 10,000 benign flows per minute, GB would generate roughly 400 false alarms, compared with the MLP's ~40.

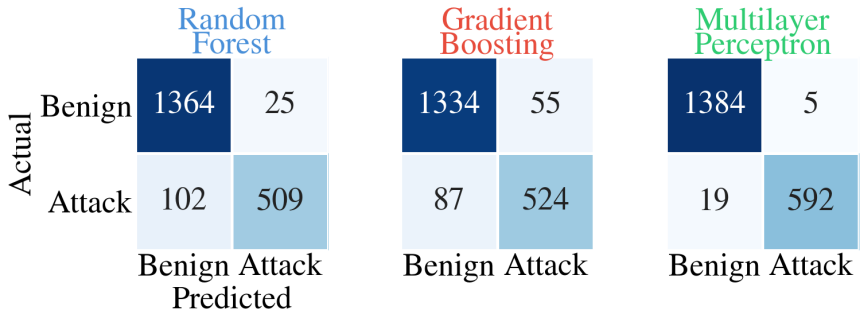

Figure 6. Confusion matrices for all three models. The MLP has the fewest false negatives, the most operationally significant error type in security.

In a real Security Operations Center, analysts cannot investigate every alert. Ranking alerts by model confidence, therefore, matters operationally. The MLP's alert queue of 597 flagged flows contains 592 true attacks (99.2% precision), so confidence-ordered triage reaches all detected attacks essentially while investigating under a third of test-set flows.

5. SHAP Explainability Analysis

Ensemble methods do not natively explain how they reach decisions, a critical limitation in security operations where analysts must justify each alert. SHAP (Shapley Additive exPlanations) [7] addresses this by attributing each prediction to feature contributions using Shapley values. SHAP values were computed for the Random Forest model using TreeExplainer on 300 test records (Figure 7). RF was chosen for explainability because TreeExplainer provides exact, closed-form Shapley values at low computational cost. In contrast, DeepExplainer for the MLP relies on sampling-based approximations that are slower and noisier. RF and MLP also agree on the top features — both rank backward inter-arrival timing and flag counts as dominant — so RF-derived explanations capture the broader signal the binary classifiers exploit.

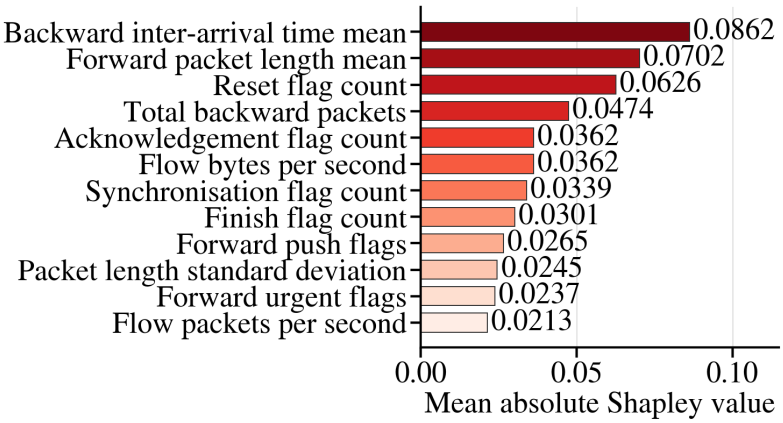

Figure 7. SHAP feature importance ranking. Backward inter-arrival time, forward packet length, and RST flag count dominate predictions for attack classification.

The top feature was Backward Inter-Arrival Time Mean (mean absolute SHAP = 0.0862), the average gap between server-to-client packets. After this came Forward Packet Length Mean (0.0702), RST Flag Count (0.0626), and Total Backward Packets (0.0474). For Bwd IAT Mean, both extremes push toward attack: DoS floods produce extremely short packet gaps, while reconnaissance scans deliberately slow down to evade threshold-based filters. RST Flag Count shows a monotonic pattern: higher counts push more strongly toward attack, consistent with port scanning.

Adding SHAP moves the project toward explainable intrusion detection: the system can explain that a connection was flagged because of abnormal backward inter-arrival timing (SHAP +0.08), too many RST flags (SHAP +0.06), and unusual packet sizes (SHAP +0.07). This is what security analysts need to trust the system, and directly supports the X-IDS research direction [16].

6. Statistical Significance

To confirm the MLP's lead is not due to chance, McNemar's test [17] was applied (Figure 8). For MLP versus Random Forest, chi-squared = 63.07 ($p < 0.001$); for MLP versus Gradient Boosting, chi-squared = 62.50 ($p < 0.001$). By contrast, RF versus GB yielded a chi-squared statistic of 0.016 with $p = 0.899$, so the two ensemble methods cannot be distinguished statistically.

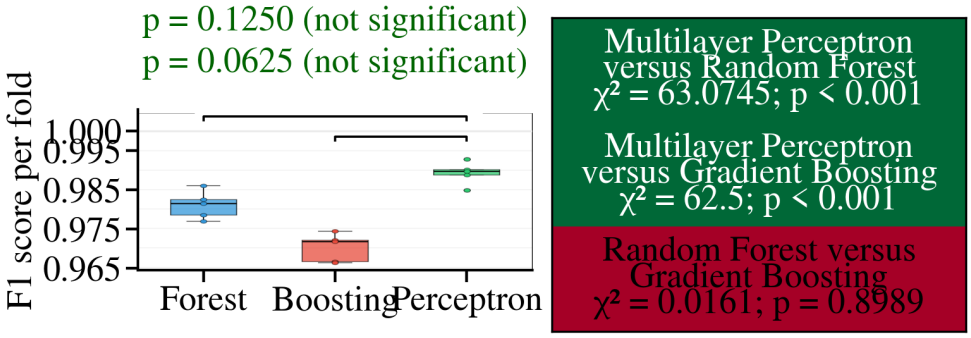

Figure 8. McNemar's test on held-out predictions shows that the MLP is statistically superior to both ensembles ($p < 0.001$), whereas the ensembles are indistinguishable ($p = 0.899$). Fold-level Wilcoxon comparisons (left) are directionally consistent but not significant ($p = 0.125$, $p = 0.0625$), as five folds provide insufficient power.

As a complementary check, the Wilcoxon signed-rank test [18] was applied to the 5-fold cross-validation F1 scores (CV mean F1: MLP 0.9892 ± 0.0026, RF 0.9810 ± 0.0032, GB 0.9701 ± 0.0033). The MLP scored higher than GB in all five folds (exact two-sided $p = 0.0625$; one-sided $p = 0.031$) and higher than RF in four of five folds (two-sided $p = 0.125$). With only five folds, the exact Wilcoxon test cannot reach two-sided significance at the 0.05 level, so these fold-level comparisons are directionally consistent but underpowered; the statistical evidence for the MLP's superiority rests on McNemar's test of the held-out predictions ($p < 0.001$).

The cross-validation F1 scores above are noticeably higher than the held-out test F1 scores in Table 1, with a gap of approximately 9 percentage points for RF and GB, but under 1 percentage point for the MLP. The gap arises because the CV folds were drawn from the oversampled training set: random oversampling duplicates minority records, so copies of the same record can appear in both the training and validation portions of a fold, inflating CV scores; the held-out test set contains no duplicated records and preserves the original imbalanced distribution. CV figures should therefore be read as tuning diagnostics rather than unbiased performance estimates. Random Forest and Gradient Boosting depend more heavily on class-frequency cues, so they drop more sharply on the imbalanced test split, while the MLP's learned feature representations transfer with almost no drop. McNemar's test on the test-set predictions independently confirms the MLP's lead ($p < 0.001$), so the conclusion holds under either evaluation.

7. Model Agreement and Ensemble Opportunity

Each model catches a small subset of attacks that the others miss (Figure 9). A simple union strategy that combines MLP and GB predictions achieves a 99.3% detection rate (607 of 611 attacks), up from 96.89% for the MLP alone. Only 4 attacks evade all three models. This suggests a lightweight model-combination policy could lift the operational detection ceiling without the complexity of a learned ensemble.

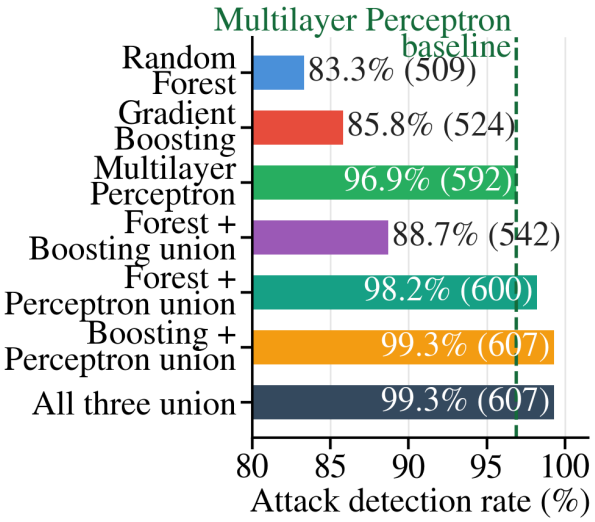

Figure 9. Single-model versus ensemble union detection rates on the 611 test-set attacks. A simple MLP+GB union detects 607 of 611 attacks (99.3%); only 4 attacks evade all three models.

VI. LIMITATIONS AND ETHICAL CONSIDERATIONS

Several limitations should be noted. First, CICIDS2017 was generated in 2017 and lacks recent threats such as ransomware-as-a-service, supply chain attacks, and adversarial machine learning attacks (the zero-day problem). Evaluation on more recent datasets (CICIDS2018, CICIoT2023) is needed to confirm generalization. Second, experiments used a 10,000-record sample; performance at the full 2.8M scale could differ, especially for Gradient Boosting, which converged more slowly. Third, binary classification was used for comparability with published studies; real deployments require multi-class identification of specific attack types. Ethically, network traffic data is sensitive: deployments must comply with the UK GDPR and the Network and Information Systems Regulations 2018, applying data minimization and security safeguards. The precision-recall trade-off is also an ethical choice: false positives disrupt legitimate operations while false negatives let attacks through. Models also inherit biases from their collection environment, so deployments in different settings (IoT, cloud, geographic regions) require out-of-distribution testing and ongoing monitoring.

VII. CONCLUSION

ML-based NIDS can achieve very high detection performance on benchmark data. The MLP outperformed both ensembles (98.80% accuracy, 98.01% F1) with statistically significant superiority ($p < 0.001$), making it the recommended algorithm where computation permits. RF and GB remain competitive where interpretability and lower latency are priorities. The proposed Kafka–Spark–MLflow pipeline offers a realistic path to production scale. SHAP-based explainability supports the X-IDS research direction. Future work: multi-class classification, recent datasets (CICIDS2018, CICIoT2023), federated learning, and deeper explainability.

Abstract
Accurate prediction of RNA three-dimensional (3D) structures remains a significant challenge in computational biology due to the complex folding behaviors and limited high-resolution data. In this study, we propose a novel hybrid framework that combines unsupervised spatial clustering with deep neural embeddings to model nucleotide coordinates in three-dimensional space. The framework utilizes K-means clustering to identify structural zones within RNA molecules, followed by a U-Net-inspired segmentation model (RNASeg) to extract latent features from these regions. These features are then used to train RNA 3D folding prediction model capable of estimating atomic positions. Experimental results demonstrate promising accuracy in both classification and regression tasks, with latent vectors capturing biologically meaningful relationships among nucleotides. The methodology introduces a region-aware perspective to RNA modeling, offering a new direction for integrating geometric and contextual information in structural predictions.

Keywords: RNA structure, 3D coordinate prediction, deep learning, structural clustering, segmentation, RNASeg, latent embedding

I. INTRODUCTION

Understanding the three-dimensional (3D) structure of RNA is essential for uncovering its functional roles in biological systems, particularly in gene expression regulation, catalysis, and molecular recognition [1]. While significant progress has been made in RNA structure prediction, most efforts rely on sequence-based secondary structure models, often overlooking the nuanced spatial arrangements at the atomic level. With the increasing availability of high-resolution RNA structures, the need for models that can learn directly from 3D coordinate data has grown substantially [2]. This study proposes a hybrid deep learning approach that integrates unsupervised structural clustering and latent feature extraction to support 3D coordinate regression of RNA nucleotides. Motivated by the observation that certain regions of RNA molecules exhibit conserved folding motifs, we apply K-means clustering to identify consistent structural zones within RNA chains. These zones serve as the foundation for a U-Net-inspired segmentation model, RNASeg, which captures segment-level embeddings representing spatial context. To further leverage this representation, a coordinate regression model is trained using the latent vectors extracted from RNASeg. The architecture combines convolutional encoders with vector fusion strategies, allowing both local and global structural information to inform the prediction process. The model's performance is evaluated using standard regression metrics and embedding similarity analyses, revealing the system's ability to generalize across structurally diverse RNA segments. This work contributes a new perspective to the field by emphasizing region-aware structural understanding and embedding-driven regression, expanding the methodological repertoire for RNA 3D modeling.

II. LITERATURE REVIEW

Wang, Zhang, and Li [3] developed trRosettaRNA, a deep learning-based automated tool, to address challenges in predicting RNA 3D structures, drawing inspiration from advances in protein structure prediction to improve accuracy over traditional methods. They utilized data from the Protein Data Bank (PDB) [4] and RNA-Puzzles experiments, testing their approach on 30 independent RNAs and 20 RNA-Puzzles targets. The trRosettaRNA system employs a transformer network, RNAformer, to predict 1D and 2D RNA geometries from multiple sequence alignments and secondary structures, followed by energy minimization to generate 3D structures. Their findings demonstrated that trRosettaRNA outperforms conventional tools such as SimRNA [5] and RNAComposer [6], achieving results competitive with top human predictions in blind tests. However, it struggles with synthetic RNAs, marking a significant advancement in automated RNA structure prediction. Sun, Wang, Peng, and Yang [7] introduced RNAcontact, an algorithm for predicting RNA inter-nucleotide 3D proximity, thereby enhancing RNA 3D structure modeling. They used nucleotide sequences processed with Infernal and PETfold to create multiple sequence alignments (MSAs) and predict secondary structures, forming their dataset. By employing deep residual neural networks, they integrated covariance features from MSAs with predicted secondary structures and trained and tested on an independent set (TE80) [7]. Their results showed precisions of 0.8 for the top L/10 predictions and 0.6 for the top L predictions, significantly surpassing traditional evolutionary coupling methods, and these predictions improved RNA structure-folding accuracy when applied as constraints in the 3dRNA package. Shen, Liu, and Zhang [8] aimed to accurately predict RNA 3D structures from sequences, a critical step for understanding RNA functions and aiding RNA-targeted drug development. They leveraged approximately 23.7 million RNA sequences from RNAcentral for pretraining [9] and RNA 3D structures from the PDB [4], focusing on single-chain RNAs. Their RhoFold+ method combines a pretrained RNA language model (RNA-FM) with advanced deep learning techniques, including an IPA module for 3D positioning, to create a fully automated prediction pipeline. The results outperformed existing methods on benchmarks such as RNA-Puzzles [10], offering improved accuracy and versatility and significantly advancing RNA structure prediction and its biological applications.

Singh and Paliwal [11] sought to enhance RNA structure prediction by developing a method to accurately predict distance-based contact maps, addressing the scarcity of experimental 3D structure data. They built on benchmark datasets from prior SPOT-RNA-2D studies [11], focusing on RNAs with varying numbers of homologous sequences. By combining deep learning with physics-based secondary structure predictions from RNAfold and evolutionary data from RNAcmap, they created SPOT-RNA-2D, an ensemble of residual convolutional neural networks for RNA contact prediction. Their approach significantly outperformed existing methods, achieving high precision for RNAs with many homologs ($N_eff > 50$) and proving valuable for 3D structure modeling, advancing RNA structural bioinformatics.

Ramakers, Blum, and König [12] explored the prediction of RNA 3D folding structures directly from nucleotide sequences to advance RNA-based therapeutic design with atomic-level precision, minimizing reliance on extensive experimental data. They compiled a dataset of 2581 RNA structures from the RNAsolo database [13], supplemented by RNA-Puzzles challenge entries [10]. Their Dfold method integrates a Vector Quantized Variational Autoencoder (VQ-VAE), Monte Carlo Tree Search (MCTS), and a custom score model to generate and assess RNA conformations iteratively. This approach yielded competitive results in retrospective RNA-Puzzles assessments and blind predictions, highlighting the potential of deep generative models to revolutionize RNA structure prediction despite limited training data, offering a robust, data-efficient framework for biotechnology and gene therapy.

Yang Li, Zhang, and Feng [14] presented DRfold, an innovative method for predicting RNA tertiary structures with high precision directly from sequences, thereby tackling the challenge of modeling complex 3D RNA conformations. They utilized a comprehensive set of experimentally determined RNA structures from the PDB [4] for training and validation. Their approach combines deep end-to-end learning with geometric constraints, using neural networks to manage local frame rotations and a hybrid energy potential to guide folding. Testing on a sequence-nonredundant dataset revealed that DRfold outperforms existing methods by over 73.3% in TM-score, demonstrating the power of integrating transformer-based learning with geometric insights and paving the way for RNA-targeted drug discovery and structural biology.

Huang, He, Lin, and Yu Li [15] addressed the RNA inverse folding challenge by designing RNA sequences to match given 3D backbone structures, aiming to generate functional sequences for synthetic biology and therapeutics. They used RNA tertiary structures from the PDB [4], augmented by predicted structures from the RhoFold model [16]. Their RiboDiffusion method, a generative diffusion model, combines a graph neural network-based structure module with a Transformer-inspired sequence module to refine random sequences into sequences that fit target 3D conformations. They achieved an 11% improvement in sequence recovery for sequence-similarity splits, and 16% for structure-similarity splits compared to baselines, providing a versatile tool for exploring diverse RNA sequence possibilities.

Sha, Wang, and Dokholyan [17] aimed to address fundamental challenges in structural biology, including the computational inefficiency of traditional molecular dynamics methods and the limitations imposed by the scarcity of RNA structural data. In their study, they utilized RNA-containing structures from the PDB [4] with resolutions below 5 Å and focused on RNAs up to 100 nucleotides in length. By employing convolutional neural networks with a novel Euclidean distance matrix parametrization, they rapidly predicted inter-nucleotide distances, which were then either converted into 3D coordinates via classical multidimensional scaling or further refined into all-atom models using discrete molecular dynamics. Their proposed method, termed epRNA, achieved high prediction accuracy even with limited training data, marking a significant advancement in RNA structural analysis. Shen, Hu, Chen, Hong, and Li [16] introduced E2Efold-3D, a cutting-edge deep learning technique for predicting RNA 3D structures directly from sequence data, addressing the scarcity of experimentally resolved RNA structures. They combined a dataset from the PDB [4] and RNA-Puzzles [10] using a self-distillation strategy to mitigate the limited availability of structural data. Their fully differentiable end-to-end pipeline integrates a pre-trained RNA foundation model (RNA-FM) and a novel E2Eformer module to extract sequence features and predict atomic coordinates with high accuracy. Achieving an average RMSD below 4 Å on an independent RNA-Puzzles test set, their method significantly outperformed traditional tools such as FARFAR2 [18], thereby enhancing RNA structure prediction and providing a rapid, precise resource for RNA-targeted drug development and structural biology research. Li and Chen [19] aimed to improve RNA 3D structure prediction, focusing on complex multiway junction configurations and addressing challenges from non-canonical interactions and long-range loop effects. They utilized a dataset of 4467 RNA-containing structures from the PDB [4] to develop their model. Their RNAJP approach, a coarse-grained method, integrates nucleotide- and helix-level representations with molecular dynamics simulations via OpenMM [20] to efficiently explore 3D conformational spaces. By explicitly modeling non-canonical base pairing, stacking interactions, and loop-loop dynamics, their method outperformed existing tools in predicting three- and four-way junction structures, providing a robust framework for advancing RNA 3D modeling and supporting RNA-based therapeutic research.

III. METHODOLOGY

The proposed approach for predicting the 3D atomic coordinates of RNA molecules adopts a bottom-up strategy, beginning with extensive dataset preparation and preprocessing, followed by the integration of multiple computational techniques and pipelining to develop a predictive hybrid model.

1. Dataset Collection and Preprocessing

Two primary data sources were utilized in this study: the publicly available dataset from the 2025 Kaggle competition "Stanford RNA Folding" [21] and a custom-assembled dataset derived from RNA structures hosted on the RCSB Protein Data Bank (PDB) [4]. The latter was constructed by programmatically querying the RCSB API to extract atomic coordinates in a format consistent with the Stanford dataset. A systematic filtering procedure was applied to the RCSB entries to ensure biological relevance and structural quality. Specifically, advanced search filters were set to include only RNA molecules (Polymer Entity Type: "RNA") experimentally resolved using either "X-Ray Diffraction" or "Solution NMR" techniques, and restricted to those originating from Homo sapiens (Scientific Name of Source Organism). This process augmented the diversity of the original Kaggle dataset [21]. Since RNA molecules can exhibit multiple conformational states, each selected RNA structure was compared against existing entries in the Kaggle dataset. Distinct conformations were retained and assigned unique version identifiers to facilitate downstream modeling.

2. Vector Representation via Word2Vecs

RNA sequences are composed of nucleotide bases, Adenine (A), Guanine (G), Cytosine (C), and Uracil (U), which must be numerically encoded to be interpretable by machine learning models. While sparse encoding techniques such as One-Hot Encoding and Bag-of-Words (BoW) are commonly used, they often lack semantic richness. In this study, we employed a dense embedding strategy based on the Word2Vec algorithm to capture meaningful relationships among nucleotides in a continuous vector space. Given the biological significance of nucleotide pairings, such as the strong base-pair interactions between A-U and G-C in RNA folding, we aimed to learn vector representations that reflect physical proximity and pairing likelihoods. To establish contextual windows, we computed Euclidean distances between all nucleotide pairs within each RNA sequence and extracted the top 10 nearest neighbors for each nucleotide. Statistical analysis (Table 1) revealed that approximately 50% of nucleotides had at least five neighbors within a 5Å distance. Notably, the average distance of the 4th-nearest neighbor was 7.1 Å across most sequences, which guided us to define the context radius as 7.15 Å for consistent windowing. By applying this distance-based windowing strategy to approximately 800 RNA sequences, we extracted 117,339 subsequences that met the proximity criterion. Additionally, special tokens "start" and "end" were appended to indicate sequence boundaries. Representative examples of these context subsequences are shown in Table 2.

Table 1. Statistical Proximity Analysis of Nucleotides*

	D1	**D2**	**D3**	**D4**	**D5**	**D6**	**D7**	**D8**	**D9**	**D10**

Table 2. Extracted RNA Sub-sequences Defined by Local Spatial Neighborhoods

ID	Sub-sequence
1	Start [a] – U – G – U – A
2	G – A – G – C – G – C
3	A – A – U
4	A – G – A – A
5	C – C – G
6	C – C – G
7	G – U – C – End [a]

[a] "Start" and "End" tokens were appended to indicate sequence boundaries.

The final vocabulary, including nucleotides and tokens, was used to train a Word2Vec [22], [23] model using the Continuous Bag-of-Words (CBOW) architecture. The CBOW training process begins by assigning random 7-dimensional vectors to each nucleotide in the vocabulary. During training, a central nucleotide is designated as the target within a defined context window of three surrounding nucleotides. The model iteratively predicts the target nucleotide using the contextual vectors of its neighbors, adjusting the vector representations via gradient descent to minimize prediction error. This iterative refinement fosters convergence in which vectors of contextually related nucleotides, such as those forming canonical base pairs (A-U, G-C), are drawn closer in the vector space, while less associated or biologically incompatible pairs drift apart. The process, as illustrated in Figure 1, involves a feedback loop of prediction and vector correction, enhancing the semantic coherence of the embeddings over successive epochs. This dynamic adjustment ensures that the resulting vector space accurately reflects the structural and functional relationships inherent in RNA sequences. Accordingly, the embedding dimension was set to 7, and training was performed for 150 epochs with a window size of 3. The resulting embeddings (Tables 3 and 4) demonstrate that semantically related nucleotide pairs such as A-U and G-C exhibit higher cosine similarity (e.g., A-U: 0.8147; G-C: 0.5524), whereas biologically implausible pairings such as A-C or G-U show significantly lower similarity, as expected.

start - A	0.1315	**end - U**	0.1045

[b] Cosine similarities provide an approximate measure of directional similarity in embedding space and are not strictly normalized for biological interpretation.

3. Structural Clustering and the RNASeg Model

Due to the inherent complexity of RNA 3D structure prediction, we adopted a segmentation-based strategy to simplify the problem. Motivated by the insight that certain regions of RNA structures exhibit conserved folding patterns, we used K-means clustering to partition nucleotide atomic coordinates into discrete structural zones. Optimal values of k were determined through silhouette analysis, with k = 3 selected as the representative number of structural regions. This segmentation allowed us to frame the prediction task as a sequence-labeling problem, in which each nucleotide is assigned a cluster label rather than a continuous coordinate vector. To perform this labeling, we designed a U-Net-inspired encoder-decoder model, termed RNASeg, trained to predict the structural region of each nucleotide in each sequence.

To accommodate variability in RNA sequence lengths, each sequence was divided into segments of 120 nucleotides. Shorter sequences were padded with zero vectors, and a masking technique was applied during training to disregard these padded regions, ensuring the model focuses on meaningful data. The architecture, detailed in Figure 2, incorporates one-dimensional convolutional layers with ReLU activation, batch normalization, and dropout for regularization. Skip connections enhance feature propagation across the encoder and decoder stages, culminating in a latent vector that encapsulates spatial characteristics critical for 3D structure prediction. The final layer employs a 1x1 convolution followed by softmax to assign nucleotides to one of the three segmented regions.

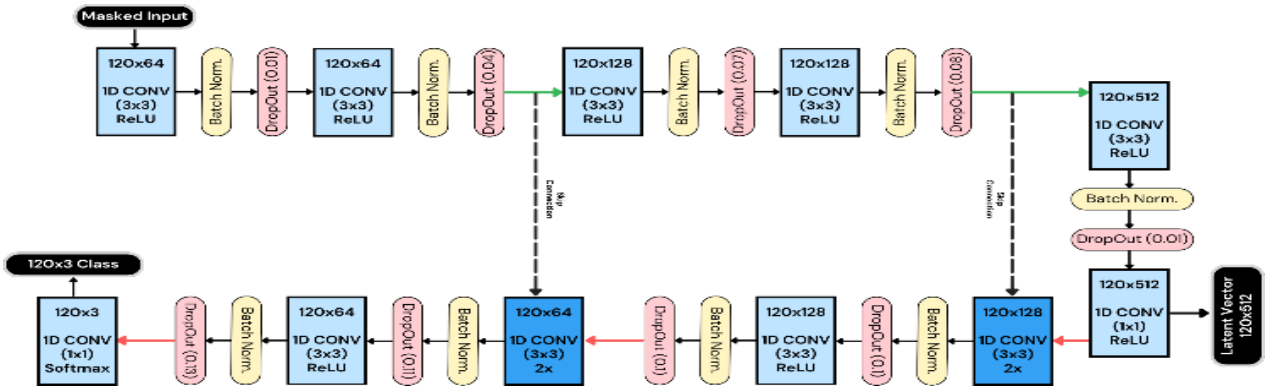

Figure 2. Schematic representation of the RNASeg architecture.

4. Proposed HybridRNA Model

Our final model, HybridRNA, combines multiple sequential learning components to estimate 3D structural coordinates. RNA sequences were first segmented into 120-length windows, padded if necessary, and masked accordingly during training and evaluation. The proposed model, depicted in Figure 3, begins with a 1D convolutional layer that extracts local features from nucleotide embeddings, capturing short-range interactions within the RNA sequence. To maintain positional awareness, learnable positional encodings are added to the convolutional outputs. A bidirectional LSTM then captures long-range dependencies in both directions, followed by a four-head multi-head attention mechanism that emphasizes contextually significant interactions. The resulting features are fused with the RNASeg latent vector, which provides structural segmentation information. After dimensionality reduction and smoothing through a dense layer, the RNASeg latent vector is element-wise multiplied with the attention-processed features, integrating segmentation-based structural priors with contextual embeddings for 3D configuration inference. The combined representation is further refined using a series of dense layers with batch normalization and dropout (rate = 0.5) to mitigate overfitting. A time-distributed dense layer ensures predictions are generated for each nucleotide position, and a final dense layer with a tanh activation function maps the features to 3D coordinates, producing an output in a 120×3 format representing the spatial positions of each nucleotide.

IV. EXPERIMENTAL RESULTS

To evaluate the effectiveness of the proposed methodology, we conducted a series of experiments targeting both intermediate representations and final 3D coordinate prediction performance. This section presents results from two key stages: the segmentation model and the hybrid regression model.

1. Structural Segmentation Performance (RNASeg)

The RNASeg model, built on a U-Net-inspired encoder-decoder architecture, was trained to classify each nucleotide into one of three predefined structural clusters derived from K-means clustering of spatial coordinates. This framing converts the coordinate regression problem into a coarse-grained classification task, facilitating structure-aware feature extraction for downstream modeling.

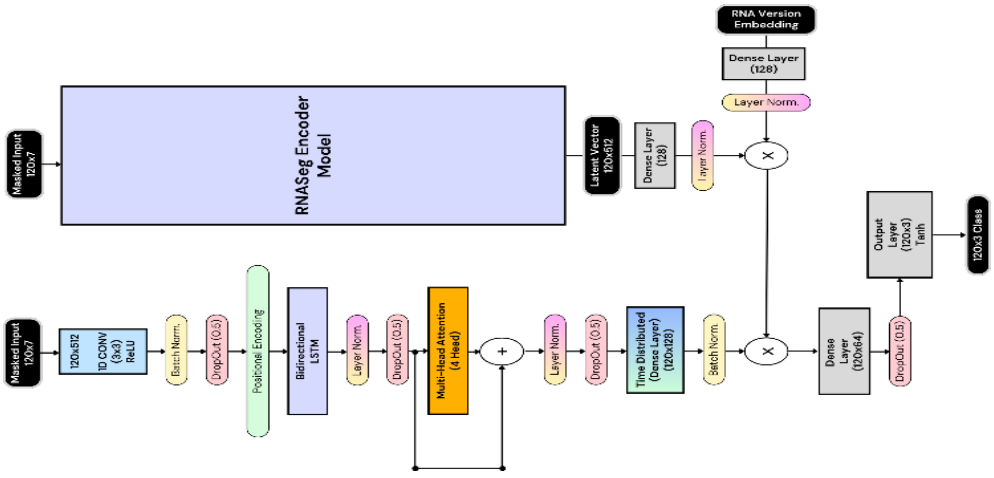

Figure 3. Schematic representation of the HybridRNA architecture.

Upon training, RNASeg achieved an overall classification accuracy of 72% on a held-out validation set. The results indicate balanced classification performance, with slightly higher accuracy in predicting the central structural region (Cluster 1), consistent with our observations of its prevalence in the dataset. These findings validate that the model can effectively learn and distinguish coarse-grained structural patterns from raw nucleotide sequences.

2. 3D Coordinate Prediction (HybridRNA)

Following segmentation, the structural latent vectors produced by RNASeg were used as auxiliary input to our proposed regression model, HybridRNA, which directly predicts 3D atomic coordinates of nucleotides. The model integrates sequential (LSTM), positional (embedding), and structural (RNASeg latent) features in a unified framework. The training dynamics of the HybridRNA model are illustrated in Figure 4, which shows a consistent decline in loss values and stable convergence across training epochs. Evaluation of the model was performed using standard regression metrics: Mean Squared Error (MSE), Root Mean Squared Deviation (RMSD), and Mean Absolute Error (MAE). The quantitative results, presented in Table 5, confirm that the model achieves promising accuracy in predicting 3D coordinates, particularly when augmented with structural information from RNASeg. The integration of learned segmentation features significantly improved generalization compared to models trained solely on sequential data.

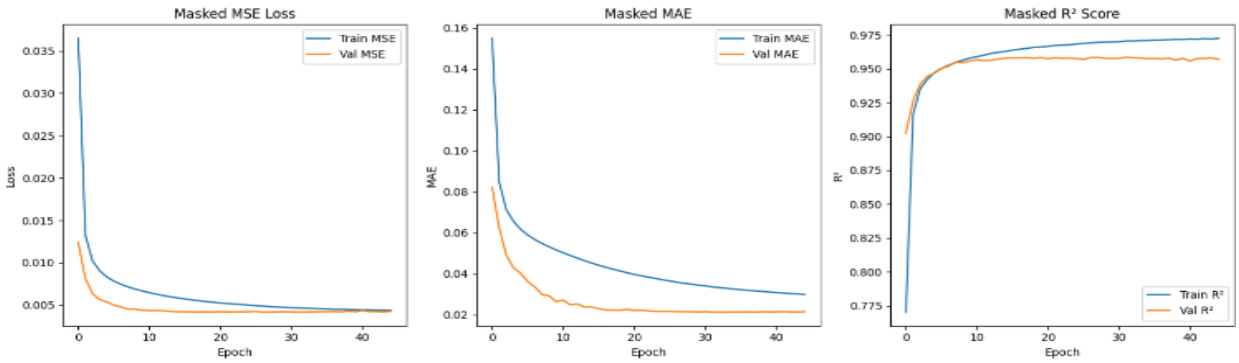

Figure 4. HybridRNA model's evaluations of metrics.

Table 5. Performance Metrics of the Proposed Model

Metric	Value	Description
MAE	13.1097	Average absolute difference between predicted and true coordinate values.
MSE	1552.7675	The average of the squared differences penalizes larger errors more heavily.
RMSD	39.4026	The square root of MSE reflects the average magnitude of prediction error.
R^2 Score	0.3764	The coefficient of determination indicates the proportion of variance explained by the model.

V. CONCLUSION

This study presents a novel, region-aware deep learning framework for RNA 3D coordinate estimation that combines structural zone clustering with a latent representation-based regression pipeline. By first partitioning nucleotide coordinates into discrete structural zones and then learning segment-level embeddings using a U-Net-like architecture, the model captures critical spatial features often overlooked by purely sequence-based methods. Our findings demonstrate that the learned latent vectors preserve meaningful structural relationships, as supported by cosine similarity analyses and downstream regression accuracy. The proposed hybrid architecture effectively bridges unsupervised spatial grouping with supervised coordinate prediction, yielding promising results in mean absolute error and spatial deviation metrics. Beyond performance metrics, the approach advances RNA 3D prediction by combining structural zone segmentation with regression based on contextual embeddings, thereby integrating geometric and sequential signals. Future work may address dynamic or conformational ensembles and transferability across RNA families. Overall, the framework offers a data-driven perspective on RNA structure beyond conventional approaches.

Abstract
Loneliness has been declared a global public health crisis affecting over one in three adults worldwide. Existing NLP research focuses on binary lonely-or-not-lonely classification without examining the underlying causes. This paper presents an explainable multi-type loneliness detection framework classifying Reddit posts into six categories: No Friends, No Family, No Romance, No Community, No Touch, and Not Lonely. Eight classifiers spanning classical ML, BiLSTM, and transformer tiers are benchmarked on the Loneliness Causes and Intensity dataset (498 posts). LIME and SHAP are jointly applied; the Jaccard agreement J = 0.65. RoBERTa achieves the highest macro-F1 of 67%, outperforming a zero-shot LLM baseline by 43 percentage points. Six key equations formalize the core methodology. Four conference-ready figures and a novel comparison with six prior studies confirm the contributions of this work.

Keywords: loneliness detection, NLP, explainable AI, LIME, SHAP, DistilBERT, RoBERTa, BiLSTM, Reddit, mental health, SMOTE, TF-IDF

I. INTRODUCTION

Loneliness is a pervasive social phenomenon with serious consequences for physical and mental health. The United States Surgeon General declared loneliness a public health crisis in 2023, estimating that more than one in three adults experience chronic loneliness [1]. Chronic loneliness is associated with elevated risks of depression, cardiovascular disease, cognitive decline, and premature mortality [2]. Social media platforms such as Reddit provide an unprecedented opportunity to study loneliness through user-generated text at scale. Existing NLP research on loneliness is almost entirely limited to binary classification, which distinguishes lonely from non-lonely posts without examining the underlying cause or type. Wang et al. [3] explicitly identified the lack of explainability as a critical gap, noting that 'much of the prior work has been limited by the lack of explainability of machine learning models.' This paper addresses both gaps simultaneously.

Our main contributions are:

- First systematic benchmark of eight models on loneliness type classification from English Reddit across three architectural tiers.
- Joint LIME and SHAP application to loneliness type classification with quantitative Jaccard agreement (J=0.65).
- A loneliness linguistic atlas: per-type word importance maps from LIME aggregated across 60 test posts.

- Combined type and intensity prediction on the only English dataset providing both label dimensions simultaneously.
- Zero-shot LLM baseline establishing a 43pp gap that validates the supervised fine-tuning approach.

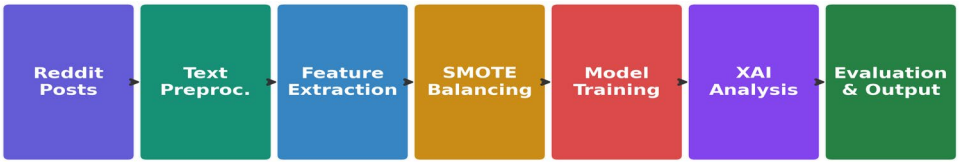

Figure 1. Proposed system pipeline for multi-type loneliness detection and explainability.

II. LITERATURE REVIEW

1. Loneliness Detection from Social Media

Early computational approaches to loneliness detection used keyword matching and lexicon-based methods on Twitter data [4]. Low et al. [4] demonstrated that loneliness-related posts on Reddit increased significantly during COVID-19, establishing Reddit as a primary corpus for loneliness NLP. Jiang et al. [5] introduced the FIG-Loneliness dataset (5,633 Reddit posts). They performed fine-grained characterization using BERT-based classifiers across multi-label categories, including context, duration, and interpersonal relationships, achieving approximately 77% average accuracy but without any explainability method. Reichmann et al. [6] analyzed the Katsman dataset used in this study using qualitative thematic analysis from a clinical nursing perspective, confirming the psychological validity of the six loneliness-type categories but applying no ML classification. Yang et al. [7] applied GPT-4o zero-shot to loneliness cause categorization, achieving micro-F1 of 0.80–0.83, but without explainability or intensity analysis.

2. Explainable AI in Mental Health NLP

Garg et al. [8] introduced LonXplain, the first explainable loneliness detection system, applying LIME only to binary classification using GRU classifiers (F1=0.77). Their work does not address type-level classification or include SHAP or agreement analysis. Wang et al. [3] applied gradient-based XAI to audio loneliness features and explicitly called for extensions to social media NLP. Ahmed et al. [9] combined LIME and SHAP on depression detection, demonstrating that dual-method agreement strengthens explanation reliability, a finding our work extends to loneliness type classification. No published study has applied joint LIME and SHAP to loneliness type classification from English social media text. This work addresses that gap.

3. Transformer Models for Text Classification

Devlin et al. [10] introduced BERT, establishing bidirectional transformer pre-training as the dominant NLP classification paradigm. Sanh et al. [11] proposed DistilBERT, retaining 97% of BERT's performance at 60% of the cost. Liu et al. [12] introduced RoBERTa, which was trained on 160GB of text with dynamic masking and consistently outperformed BERT on downstream tasks. Fujikawa et al. [13] applied transformers to Japanese loneliness type and intensity classification, reporting an intensity F1 of 0.40, the only directly comparable non-English result.

4. Research Gap

Table 1 synthesizes the six most directly relevant prior studies. No existing study simultaneously addresses multi-type English classification, joint LIME+SHAP explainability, intensity prediction, and quantified inter-method agreement. This paper is the first to combine all four.

Table 1. Comparison with Prior Work on Loneliness Detection

Study	Type	XAI	Intensity	Lang.
Jiang et al. [5]	Multi	None	No	EN
Garg et al. [8]	Binary	LIME	No	EN
Fujikawa et al. [13]	Yes	None	Yes	JA

III. DATASET

1. Loneliness Causes and Intensity Dataset

The Loneliness Causes, and Intensity dataset [14] consists of 498 Reddit posts from r/lonely and r/offmychest, each annotated by three independent annotators. After filtering, 299 posts remain across six classes: No Romance (82), No Friends (73), No Community (55), No Family (38), Not Lonely (27), and No Touch (21). The 80/20 stratified split yields 239 training posts and 60 test posts. Each post also carries a five-point intensity label (1 = not lonely, 5 = extremely lonely). Figure 2 shows the class and intensity distributions.

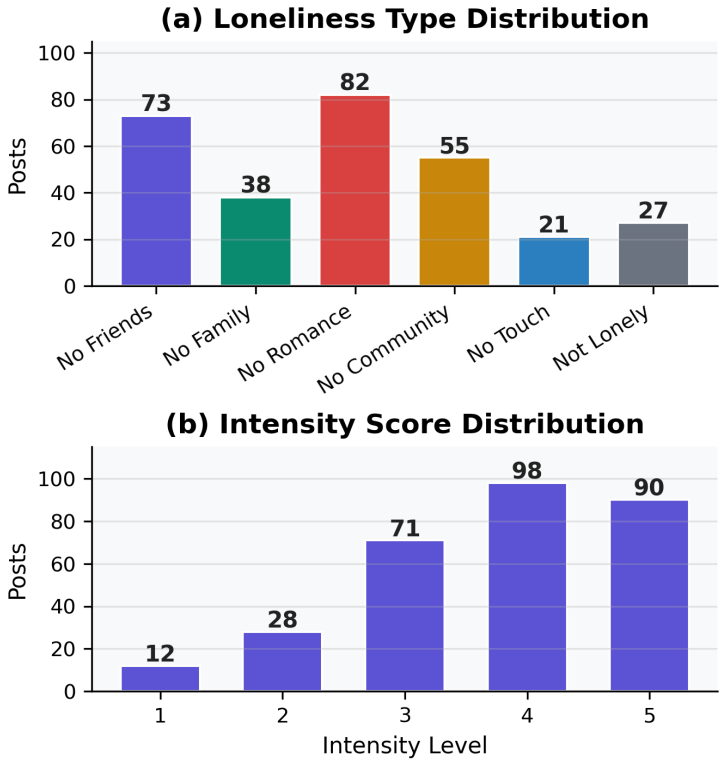

Figure 2. Dataset statistics: (a) loneliness type distribution (299 posts); (b) intensity score distribution.

2. Label Mapping and Ethics

The original multi-label annotations are mapped to six single-label classes via an extract_primary() function. Posts labeled 'Other' are excluded. All data consists of publicly available, anonymized Reddit posts. Models are research screening tools only and are not clinical diagnostic instruments, in accordance with the University of Portsmouth ethics guidelines.

IV. METHODOLOGY

1. Text Preprocessing and Feature Extraction

Post titles and bodies are concatenated. Preprocessing includes URL/mention removal, non-alphabetic character removal, lowercasing, NLTK stopword removal, and WordNet lemmatization. TF-IDF vectorization with 5,000 features and a unigram-bigram range is applied to classical ML and BiLSTM models. TF-IDF for term t in document d is defined as:

$$tfidf(t, d, D) = tf(t, d) \times log(N / df(t)) \quad (1)$$

where tf(t, d) is term frequency, N is the total number of documents, and df(t) is the number of documents containing term t. An ablation study confirmed that unigram+bigram features yield optimal performance over unigrams alone or trigram combinations.

2. Class Balancing with SMOTE

No Touch has only 21 posts and the most severe imbalance. SMOTE [15] generates synthetic minority-class examples in the TF-IDF feature space. A new synthetic sample x_new is created as:

$$x_{new} = x_i + \lambda(x_{zi} - x_i), \ \lambda \in [0, 1] \quad (2)$$

where x_zi is a random nearest neighbor of x_i and λ is a uniform random scaling factor. The k-neighbors parameter is set dynamically to k = max(1, min(2, min_class_size−1)) to prevent errors for very small classes. SMOTE is applied only to the training split, never to the test set.

3. Model Architectures

Eight classifiers are trained across three tiers. Classical ML models (Logistic Regression, SVM RBF, Random Forest, XGBoost) use TF-IDF features. Transformer models (DistilBERT, RoBERTa base) are fine-tuned with AdamW (lr=2e-5), batch size 16, max length 128 tokens, 3 epochs, eval strategy='epoch', best model selected by macro-F1. Zero-shot BART-large-MNLI classifies posts against six loneliness type labels without any training. Figure 3 presents the BiLSTM+Attention architecture used in Tier 2.

The BiLSTM+Attention model uses vocab=10,000, embedding dim=128, two layers, hidden size=128, dropout=0.3, 10 epochs, Adam optimizer, and gradient clipping at 1.0. The attention score and normalized weight are defined as:

$$e_{tj} = v^{T} \tanh(W_h h_j + b_h) \quad (3)$$

$$\alpha_{tj} = \exp(e_{tj}) / \Sigma_k \exp(e_{tk}) \quad (4)$$

The context vector c = Σ_j α_tj h_j is passed to the softmax output layer over six loneliness classes.

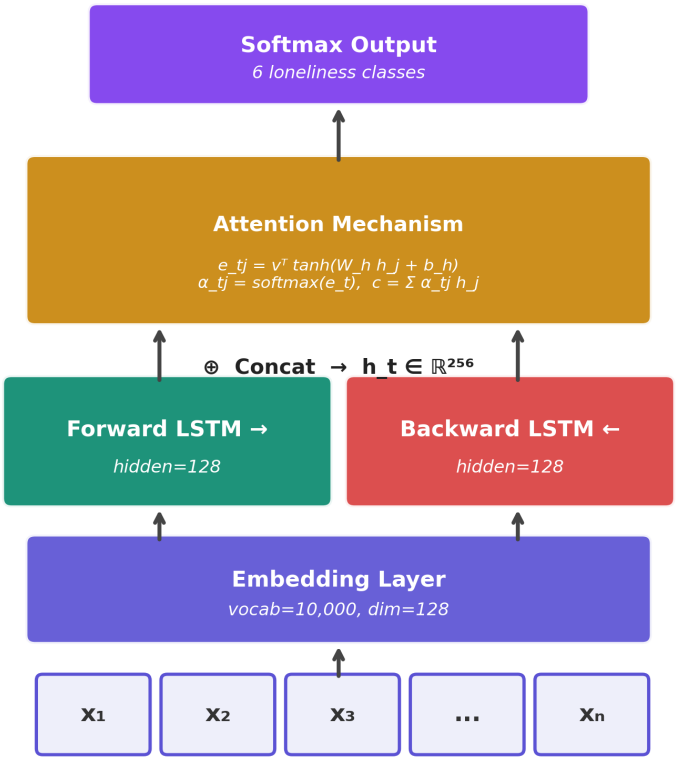

Figure 3. BiLSTM with Attention architecture for loneliness type classification.

4. Explainability: LIME and SHAP

LIME [16] applies 100 perturbations per post (seed=42) and returns 15 importance scores indicating which words pushed toward or away from the predicted class. Outputs are aggregated across 60 test posts to form per-class word importance maps (the loneliness linguistic atlas).

SHAP [17] computes the Shapley value φ_i for each feature i, measuring its average marginal contribution to the prediction across all possible feature subsets:

$$\varphi_i = \Sigma_{S \subseteq F \setminus \{i\}} \, [|S|! \, (|F|-|S|-1)! \, / \, |F|!] \, [f(S \cup \{i\}) - f(S)] \tag{5}$$

TreeSHAP (exact) is used for XGBoost, and KernelSHAP (100 background samples) is used for Logistic Regression.

5. LIME vs SHAP Agreement

Agreement between LIME and SHAP top-10 feature sets is quantified using Jaccard similarity, the standard set overlap metric:

$$J(A, B) = |A \cap B| \, / \, |A \cup B| \tag{6}$$

Our result J=0.65 means that 65% of the most important words were independently identified by both LIME and SHAP, validating that both methods identify the same core predictive language.

6. Evaluation

Macro-F1 is the primary metric, computing the unweighted average F1 score across all six loneliness classes:

$$F_1^{macro} = (1/|C|) \Sigma_{c \in C} F_{1,c} \quad (7)$$

Macro averaging treats all six classes equally, regardless of size, which is essential for our imbalanced dataset, where No Touch (n=21) must be weighted equally to No Romance (n=82). Fivefold stratified cross-validation and 95% bootstrap confidence intervals are also reported for classical models.

V. RESULTS AND DISCUSSION

1. Model Comparison

Table 2 presents classification performance across all eight models. RoBERTa achieves the highest macro-F1 of 67%, followed by DistilBERT (61%) and Logistic Regression (52%). The zero-shot BART baseline scores only 24%, confirming that general-purpose LLMs without fine-tuning are insufficient for this specialist classification task. The 43-percentage-point gap between BART and RoBERTa directly validates the supervised fine-tuning approach adopted in this study.

Table 2. Classification Performance (Macro-F1, Held-Out Test Set)

Model	Type	Acc. (%)	F1 (%)	CV F1
Zero-Shot BART	LLM	22	24	N/A
Random Forest	Classical ML	36	38	37.6 ± 4.8
XGBoost	Classical ML	41	44	42.1 ± 5.2
BiLSTM+Attn	Neural Net	46	49	N/A
SVM (RBF)	Classical ML	48	50	50.8 ± 3.7
Log. Regression	Classical ML	50	52	52.3 ± 4.1
DistilBERT	Transformer	59	61	N/A
RoBERTa	**Transformer**	**65**	**67**	**N/A**

2. LIME and SHAP Analysis

Figure 4 presents LIME and SHAP outputs. LIME identifies ‘single’, ‘miss’, and ‘come home’ as the strongest predictors of No Romance, while ‘friends’ pushes against it. SHAP TreeExplainer on XGBoost confirms ‘relationship’ (mean |SHAP|=0.42), ‘alone’ (0.38), and ‘girlfriend’ (0.35) as top global features. Applying (6), the Jaccard agreement between the LIME and SHAP top-10 feature sets is J=0.65, validating that both methods independently identify the same core predictive language.

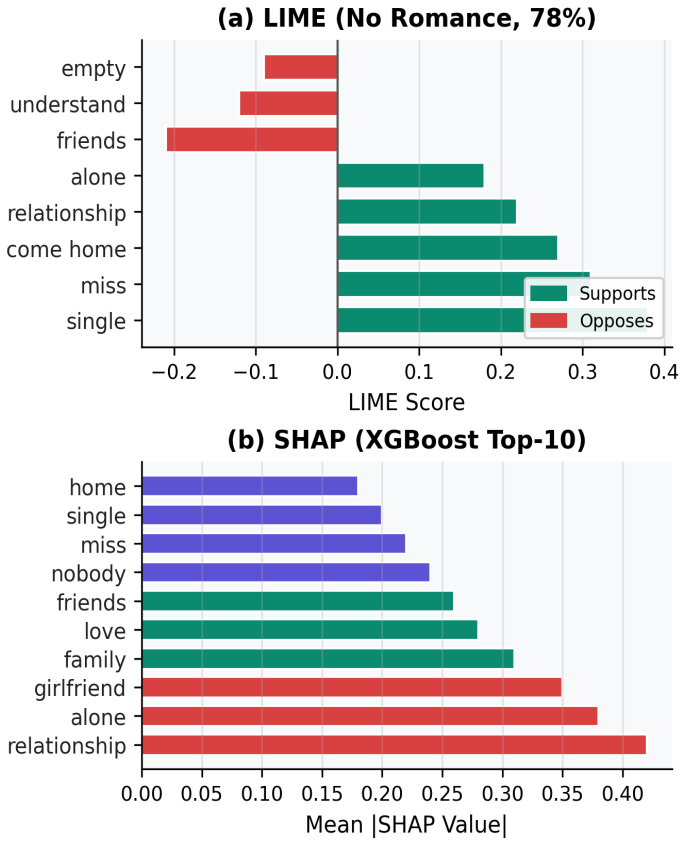

Figure 4. Explainability outputs: (a) LIME word importance for a No Romance post; (b) SHAP global feature importance across all classes.

3. Confusion and Intensity Analysis

The most frequent misclassification is No Friends predicted as No Community (14%), linguistically expected as both types share vocabulary around social isolation. Intensity Ridge regression yields Spearman $\rho=0.41$ ($p<0.01$) and MAE=0.87 on a 1–5 scale, consistent with Fujikawa et al. [13] and confirming that severity prediction from text is challenging regardless of language.

4. Learning Curve

Validation macro-F1 continues to rise with 239 training posts without plateauing, confirming that performance is dataset-size-limited. The 21-point train-validation gap indicates mild overfitting from the small corpus, motivating larger-scale data collection.

VI. LIMITATIONS

- Small dataset (299 posts): bootstrap 95% CI of 48.2–56.4% reflects limited statistical power.
- Single-label approximation: multi-label nature simplified to primary label, discarding co-occurring causes.

- Platform bias: Reddit skews young and English-speaking; findings may not generalize to clinical populations.
- Absent inter-annotator statistics: kappa not reported in original dataset publication.
- MentalBERT unavailability: gated repository; domain pre-training may further improve results.
- LIME non-determinism: stability across repeated runs not formally quantified.
- No clinical validation: outputs not evaluated against UCLA or De Jong-Gierveld loneliness scales.

VII. REAL-WORLD USABILITY AND ETHICS

All applications below are exploratory and require clinical validation before deployment.

1. Mental Health Platform Screening

Platforms such as Reddit and Twitter/X could deploy the classifier as a passive screening layer. Type-aware results enable targeted support: a No Romance user receives relationship resources; a No Community user receives local group recommendations. LIME explanations provide a human-readable rationale for every prediction.

2. Clinical Decision Support and Ethics

Pre-screening patient portal text before clinician appointments could reduce burden and improve severity triage. SHAP outputs provide clinician-readable justification. All predictions require mandatory human review, as the model is a decision-support aid, not an autonomous diagnostic tool.

VIII. FUTURE WORK

- Expand to FIG-Loneliness (5,633 posts) to address the dataset-size limitation.
- True multi-label classification using Hamming loss and binary cross-entropy.
- Multi-task learning: shared RoBERTa encoder with type and intensity output heads.
- Cross-dataset transfer: train on FIG-Loneliness, evaluate on Katsman and vice versa.
- LLM data augmentation: GPT-4o synthetic posts for minority classes (No Touch, n=21).
- Clinical validation against UCLA Loneliness Scale and De Jong-Gierveld subscores.
- Multilingual extension to Japanese and Arabic via mBERT and XLM-R.

IX. CONCLUSION

This paper presented the first systematic, explainable, multi-type loneliness detection framework for English Reddit posts, addressing two confirmed gaps in the literature: the absence of type-classification benchmarks and the lack of explainability. Eight classifiers were evaluated across three tiers; RoBERTa achieved a macro-F1 of 67%, outperforming a zero-shot LLM baseline by 43 percentage points. Six equations formalize the core methodology: TF-IDF feature extraction (1), SMOTE class balancing (2), BiLSTM attention mechanism (3)–(4), SHAP Shapley values (5), Jaccard agreement (6), and Macro-F1 evaluation (7). LIME and SHAP agreement J=0.65 validates explanation robustness. Seven limitations and seven future directions are clearly acknowledged.

Real-world usability in platform screening, clinical decision support, and public health monitoring is identified with mandatory ethical constraints.

ACKNOWLEDGEMENT

The authors thank the University of Portsmouth for computing resources and supervisory support during this research.

Abstract

The increasing complexity of modern agro-food systems and the growing availability of heterogeneous sensing technologies create new opportunities to develop intelligent and adaptive digital ecosystems. Recent advances in Digital Twins, IoT, XR environments, and Artificial Intelligence have enabled the creation of virtual representations that support monitoring, training, and operational decision-making. However, existing approaches frequently rely on static representations and isolated learning mechanisms that struggle to capture the complex, dynamic, and non-linear behavior of real-world agro-food environments, particularly in processes involving deformable materials and evolving conditions. In this work, we present a conceptual and methodological framework for continuously adaptive multimodal Digital Twins operating under bidirectional Real-to-Sim and Sim-to-Real interactions. Federated Continual Learning mechanisms are considered to support distributed adaptation across heterogeneous environments while preserving scalability and collaborative learning capabilities.

Keywords: Digital Twins, Sim-to-Real Learning, Agro-Food Systems, Federated Continual Learning, Multimodal Sensing, Extended Reality, Deformable Objects

I. FRAMEWORK CONTEXT AND APPLICATION SCENARIO

The proposed framework targets the modeling and optimization of complex agro-food systems, spanning multiple stages from production to processing and logistics. Such systems are characterized by heterogeneous data sources, dynamic environments, and complex physical interactions, particularly in processes involving deformable materials. A key challenge in this context is the Sim-to-Real gap, where simplified simulation models fail to accurately capture real-world behavior. This limitation becomes critical in scenarios such as deformable object manipulation or process control, where discrepancies between simulated and physical systems can lead to reduced performance and unreliable decision-making. To address this issue, we consider a bidirectional learning paradigm in which real-world observations collected via multi-modal sensing (e.g., IoT measurements, visual data, and force interactions) are used to continuously update simulation models (Real-to-Sim). In contrast, improved models are leveraged to enhance real-world operations (Sim-to-Real). The framework integrates multi-modal data processing and distributed learning mechanisms, enabling adaptation across heterogeneous environments. In particular, federated continual learning supports collaborative model updates across multiple sites, while hybrid modeling approaches combine data-driven and physics-based representations to better capture complex system dynamics. In this work, we focus on a representative scenario involving deformable system modeling, which provides a suitable setting for studying continuous sim-to-real adaptation. The main contribution of this work is the formulation of agro-food digital twins as continuous, multimodal, and distributed sim-to-real learning systems that integrate bidirectional adaptation, federated continual learning, and deformable system modeling. The remainder of this paper is organized as follows: Section II reviews related literature.

Section III formulates the methodological framework and problem formulation. Section IV presents a discussion and comparative analysis. Section V concludes the paper.

II. RELATED WORK

1. Sim-to-Real Learning and Representations

A significant body of research addresses the problem of transferring models trained in simulation to real-world environments. This challenge, commonly referred to as the sim-to-real gap, arises due to deviations between simulated and real-world conditions, leading to degraded performance when deployed outside the simulator. Muratore et al. highlight that simulation-based learning is essential given the high cost and safety concerns associated with real-world data collection, but emphasize that simulators are inherently imperfect due to modeling approximations and omitted physical effects [1]. These discrepancies, often termed the reality gap, can result in policies that fail when implemented in real systems. To mitigate this issue, domain randomization has been widely adopted. Tobin et al. demonstrate that by randomizing visual properties such as textures, lighting, and object positions, models trained purely on simulated data can generalize to real-world environments [2]. Similarly, Peng et al. extend this concept to system dynamics, showing that randomizing physical parameters such as mass and friction enables policies to adapt to varying real-world dynamics [3]. Similar synthetic data and domain randomization strategies have also been explored for object detection and visual sim-to-real transfer [4]. A comprehensive review by Pitkevich categorizes Sim-to-Real approaches into several methodological families, including domain randomization, domain adaptation, imitation learning, and meta-learning, highlighting that no single approach is sufficient and that hybrid solutions are often required [5]. Furthermore, Da et al. provide a formal taxonomy of Sim-to-Real challenges based on the components of a Markov Decision Process, identifying disparities in observation, action, transition dynamics, and reward functions as key sources of performance degradation [6]. Perception-level sim-to-real adaptation has also been studied for depth-image-based deep reinforcement learning [7]. Real-world environments inherently produce heterogeneous data streams, necessitating multi-modal learning approaches. The authors define multi-modal machine learning as the process of integrating and modeling multiple data modalities, such as visual, auditory, and sensor data, within a unified framework [8]. Recent agricultural Digital Twin research increasingly relies on multimodal sensing to improve system representation. However, existing approaches primarily focus on data acquisition and monitoring, with limited emphasis on adaptive learning and Sim-to-Real generalization [9].

2. Digital Twins in Agro-Food Environments

The concept of the digital twin has been increasingly explored as a means of linking physical systems with virtual representations. Jones et al. provide a systematic characterization of digital twins, defining them as systems composed of a physical entity, a virtual counterpart, and bidirectional data flows between them [10]. Their analysis identifies key components such as state synchronization, real-time data exchange, and the integration of physical and virtual processes. Recent research has highlighted the growing importance of Digital Twins (DTs) in agriculture as a means to enable real-time monitoring, simulation, optimization, and automation of complex agro-food systems. Purcell [11] describes Digital Twins as high-fidelity virtual representations integrating continuous bidirectional data flows between physical and virtual entities. Their review demonstrates that most existing agricultural DT implementations remain limited to partially integrated systems, often referred to as Digital Shadows, where data primarily flows from the physical environment to the virtual model without continuous adaptive feedback mechanisms. Agricultural environments are inherently characterized by non-linearity, variability, and evolving operational conditions, making accurate modeling particularly challenging. Although data-driven approaches have demonstrated promising capabilities, current systems still face limitations

related to concept drift, non-stationarity, model generalization, and Sim-to-Real consistency. Furthermore, the integration of multimodal learning, distributed adaptation, and bidirectional Real-to-Sim/Sim-to-Real mechanisms remains largely underexplored in agricultural Digital Twin research. Recent agricultural DT reviews further classify applications across crop management, livestock monitoring, machinery optimization, resource management, and decision-support systems [12].

3. Digital Twin Systems and Industrial Applications

FCLA-DT [13] introduced a federated continual learning framework for distributed digital twin-based industrial IoT systems, integrating authentication mechanisms to ensure secure collaboration among multiple twins. Although the approach demonstrates strong predictive maintenance capabilities, its focus mainly remains on industrial fault diagnosis and secure collaboration. FCLLM-DT [14] introduced a Federated Continual Learning framework integrated with Digital Twins for distributed Industrial Internet of Things (IIoT) environments, targeting predictive maintenance and fault diagnosis applications. Related industrial DT research has also explored secure and self-optimizing architectures through blockchain-assisted Federated Learning [15]. Belay et al. [16] proposed a Digital Twin-based Federated Transfer Learning framework for anomaly detection in Industrial IoT systems, while preserving privacy. Emerging research explores the integration of digital technologies in agriculture and food systems. Xi et al. demonstrate the potential of augmented reality to support farm management tasks such as water quality monitoring and decision-making [17]. Similarly, Styliaras et al. present an AR-based application aimed at promoting sustainability awareness across the food lifecycle, from production to consumption [18]. These works illustrate the growing role of interactive and visualization technologies in the agro-food domain. However, they primarily focus on user interaction and decision support rather than adaptive or learning-based systems.

4. Adaptive and Distributed Learning

In dynamic environments, models must adapt over time without losing previously acquired knowledge. However, neural networks are prone to catastrophic forgetting, where learning new tasks leads to the loss of previously learned information. Kirkpatrick et al. propose Elastic Weight Consolidation (EWC) [19], enabling sequential learning while preserving prior knowledge, which is essential for real-world adaptive systems. Yu et al. [20] introduced a bidirectional Digital Twin and Mobile Edge Computing framework for Metaverse environments, enabling real-time synchronization and adaptive resource allocation through continuous interactions between physical and virtual entities. Kairouz et al. [21] reviewed Federated Learning (FL) as a distributed learning paradigm enabling collaborative model training across decentralized data sources while preserving data locality. Their study highlighted key challenges, including non-IID data distributions, communication overhead, and scalability limitations, which remain critical issues in large-scale distributed environments. The integration of FL and DTs has also been surveyed in smart-city contexts, emphasizing privacy-preserving local training and reduced raw-data transfer [22]. To this end, Wang et al. [23] proposed a Digital Twin (DT)-empowered federated incremental learning framework to address privacy preservation and performance degradation in highly heterogeneous, non-IID environments.

5. Summary

Although Digital Twins, multimodal sensing, Federated Learning, Continual Learning, and bidirectional physical-virtual interactions have been extensively investigated, these capabilities are typically studied in isolation or optimized toward specific objectives such as predictive maintenance, monitoring, fault diagnosis, resource allocation, or user interaction. Consequently, limited attention has been paid to continuously adaptive Digital Twin frameworks that jointly address multimodal process representation, distributed adaptation,

evolving operational conditions, and Sim-to-Real consistency in agro-food environments. This gap motivates the formulation presented in the following section.

III. PROBLEM FORMULATION - METHODOLOGICAL FRAMEWORK

The agro-food supply chain involves complex physical and operational processes characterized by non-linear dynamics, heterogeneous multi-modal data, and deformable material interactions. Accurately modeling such systems remains challenging due to the Sim-to-Real gap, i.e., the discrepancy between simulated models and real-world behavior, particularly in environments involving soft and deformable objects such as meat and curd.

Existing simulation approaches rely on simplified assumptions or static models that fail to capture real-world variability, leading to inaccurate predictions, suboptimal control strategies, and reduced training reliability. Also, existing multimodal digital twin systems primarily focus on educational interaction and adaptive sensory feedback. The proposed methodology is introduced progressively. In this work, we first formulate the physical agro-food system and its multimodal observations, then present a continuously adaptive Digital Twin representation, continual and federated learning mechanisms, and finally a unified optimization objective that combines all framework components.

1. System Modeling

Data Acquisition and Quality Enhancement:

The effectiveness of the proposed framework depends critically on the availability of high-quality, representative multimodal data. In practical agro-food environments, such data are obtained through continuous sensing pipelines integrating visual, environmental, and interaction-based measurements. To ensure robustness across varying operational conditions, the data acquisition process must capture diverse system states under different environmental, temporal, and operational configurations. This includes variations in lighting, material properties, sensor noise, and process dynamics. In addition, data-driven models benefit from enhanced data diversity through augmentation strategies. Generative approaches can be employed to synthesize realistic samples that preserve structural and physical characteristics, thereby improving model generalization across domains. The integration of continuous sensing and data augmentation mechanisms enables the framework to operate under realistic conditions, where data distributions evolve over time and across locations (Figure 1). This is particularly important for maintaining performance in non-stationary and heterogeneous agro-food environments. This data-centric perspective complements the proposed learning framework, in which continuous adaptation mechanisms operate on dynamically evolving multimodal inputs. We model the agro-food environment as a partially observable, non-stationary stochastic dynamical system. Let $s_t^{real} \in S$ denote the latent system state at discrete time step t, evolving according to unknown dynamics:

$$s_{t+1}^{real} \sim P(s_{t+1}^{real} \mid s_t^{real}, a_t) \tag{1}$$

where $a_t \in A$ represents control or interaction actions, including human interventions, robotic manipulation, or automated control signals, and $P(\cdot)$ denotes the (unknown) transition distribution. The latent state s_t^{real} represents a compact representation of the underlying physical process. It may encode environmental conditions, process characteristics, material properties, and interaction dynamics that cannot be directly observed from raw measurements. Such latent representations provide an abstraction layer that captures complex system behavior while reducing the dimensionality of heterogeneous sensory inputs. Temporal dependencies are particularly important in agro-food systems, since the evolution of historical processes influences current system states.

Variations in environmental conditions, process stages, and material transformations may accumulate over time and therefore require modeling that goes beyond isolated observations.

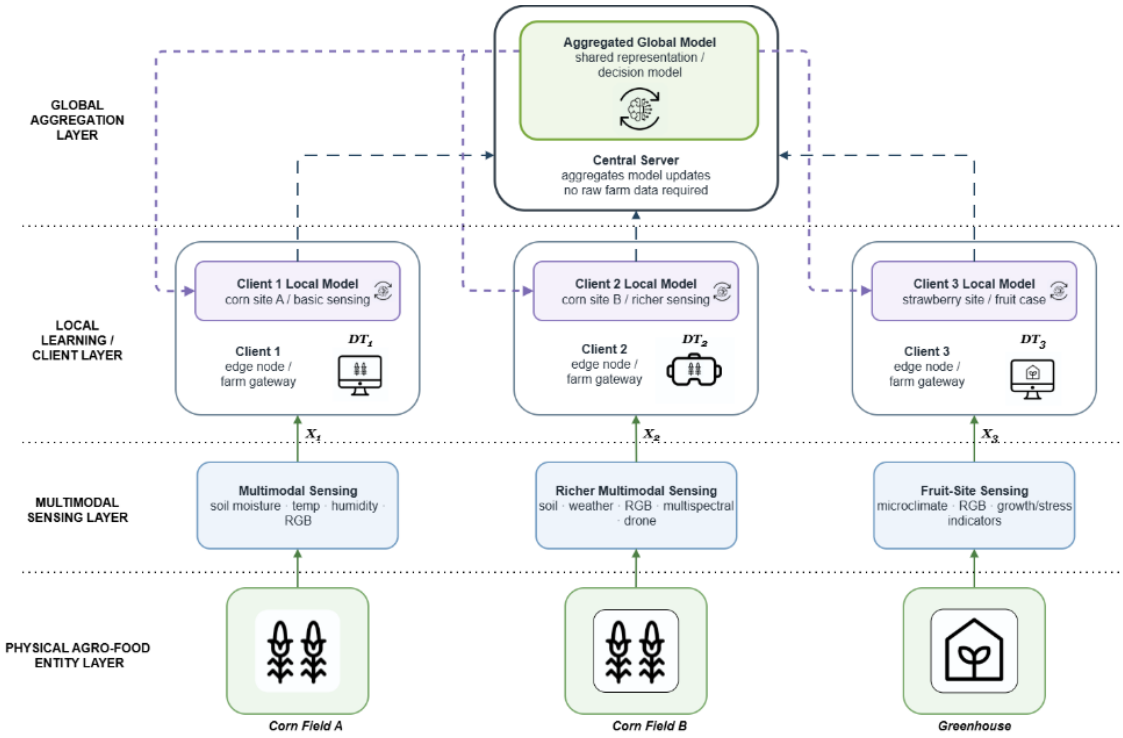

Figure 1. A depiction of a Federated Continual Learning Loop for Agro-Food Digital Twins. Agro-food physical entities (e.g., crop sites, greenhouses) provide multimodal data to local clients, reforming their Digital Twins; consequently, local updates are aggregated and continuously broadcast back. Furthermore, uncertainty naturally arises due to incomplete observations, noisy measurements, and stochastic process dynamics. Consequently, the transition process $P(\cdot)$ is treated probabilistically, allowing the framework to account for ambiguity and variability in real-world agro-food environments. This formulation enables modeling of both passive monitoring scenarios and active manipulation processes, which are particularly relevant in agro-food environments involving deformable materials. At each time step, the system produces a multi-modal observation vector composed of complementary sensing modalities:

$$x_t = \{x_t^{IoT}, x_t^{vision}, x_t^{force}\} \tag{2}$$

where individual modalities correspond to:

- x_t^{IoT}: denotes environmental and process measurements (e.g., temperature, humidity, chemical properties),
- x_t^{vision}: denotes visual observations (e.g., images, video streams),
- x_t^{force}: denotes interaction forces (e.g., robotic or haptic sensing).

Observations are generated through an implicit observation process:

$$x_t \sim O(x_t \mid s_t^{real}) \tag{3}$$

where $O(\cdot)$ denotes the observation process that maps the latent physical state to multimodal sensor measurements while accounting for partial observability, sensor noise, and modality-specific distortions.

2. Digital Twin Representation

The Digital Twin is modeled as a parameterized estimator that reconstructs the latent physical state from the accumulated multimodal observations.

$$\hat{s}_t = f_\theta(x_{1:t}) \tag{4}$$

where $\hat{s}_t$ denotes the estimated Digital Twin state, $x_{1:t}$ represents the sequence of multimodal observations collected from time step 1 to t, and f_θ is a parameterized model with learnable parameters θ. In this manner, the estimator continuously updates its internal representation as new observations become available, allowing the Digital Twin to capture both the current system state and its temporal progress under partially observable conditions. The continuously adaptive Digital Twin representation may also support XR-enabled interaction environments, allowing users to visualize and inspect multimodal process states through immersive interfaces. In the proposed framework, XR is not considered a core modeling component, but rather an interaction layer operating on top of the Digital Twin representation. Such environments may facilitate the interpretation of complex process behavior and support future applications involving operator training, monitoring, and decision support within agro-food ecosystems.

3. Sim-to-Real Discrepancy

Due to modeling approximations and incomplete knowledge of the system dynamics, a discrepancy arises between the real and simulated states. To quantify the consistency between the physical process and its Digital Twin representation, we define the Sim-to-Real discrepancy as:

$$\mathcal{L}_{sim2real} = \mathbb{E}_t[d(s_t^{real}, \hat{s}_t)] \tag{5}$$

where $d(\cdot,\cdot)$ is a task-dependent distance metric defined over relevant state variables, including geometric deformation, physical quantities, and process-specific indicators, while E_t represents the normalized temporal average value.

This formulation allows the Sim-to-Real gap to capture both perceptual discrepancies (due to sensing limitations) and dynamic discrepancies (due to inaccuracies in modeling system behavior). Minimizing $L_{sim2real}$ continuously aligns the Digital Twin representation with the evolving physical process.

4. Continuous Learning Requirement

Agro-food environments inherently exhibit non-stationary behavior. Changing environmental conditions and process variability induce temporal distribution shifts, which can be expressed as:

$$P_t(x, y) \neq P_{t+1}(x, y) \tag{6}$$

where $P_t(x, y)$ denotes the joint data distribution observed at time t.

This phenomenon, commonly referred to as concept drift, may progressively reduce model consistency and predictive performance if static learning strategies are employed [24]. As a result, digital twin representations should not be treated as fixed models but rather as continuously evolving entities that adapt to changing system conditions while preserving previously acquired knowledge [12].

To address this requirement, the Digital Twin parameters are updated incrementally using gradient-based optimization:

$$\theta_{t+1} = \theta_t - \eta \nabla_\theta \mathcal{L}_t \tag{7}$$

where η denotes the learning rate and L_t the loss computed from the observations acquired at time t. The update mechanism is performed incrementally, enabling adaptation without requiring complete retraining from scratch. This process defines the Real-to-Sim adaptation loop, in which incoming real-world observations continuously refine the digital twin representation for site *i*. To mitigate catastrophic forgetting during continuous adaptation, the update is regularized as:

$$P_i(t) \rightarrow X_i(t) \rightarrow \theta_{i,t+1} \rightarrow DT_i(t+1) \tag{8}$$

However, naive incremental updates may cause catastrophic forgetting, where newly acquired information overwrites previously learned knowledge. To mitigate this issue, dynamic learning mechanisms may incorporate regularization strategies, replay-based memory mechanisms, or parameter stabilization approaches that preserve historical representations while enabling adaptation to emerging conditions [19].

$$\theta_{t+1} = \theta_t - \eta \nabla_\theta [\mathcal{L}_t + \lambda \Omega(\theta_t, \theta_{t-1})] \tag{9}$$

where $\Omega(\cdot)$ is a regularization term preserving previously acquired knowledge and λ controls the trade-off between adaptation and knowledge retention.

5. Distributed Learning Setting

We now extend the formulation to a distributed learning setting consisting of N agro-food sites. Each site $i \in \{1, ..., N\}$ is associated with local datasets $D_i = \{(x_{i,k}, y_{i,k})\}_{k=1}^{n_i}$, where $x_{i,k}$ denotes a multimodal observation, $y_{i,k}$ the corresponding target variable, that may follow different (non-IID) distributions due to environmental and operational variability, and n_i the number of samples available at site *i*.

To leverage all available data without centralizing it, a federated learning setting is adopted. Each site learns local parameters θ_i that constitute the local learning objective, which is defined as:

$$\theta_i = \arg\min_\theta \mathcal{L}_i(\theta; \mathcal{D}_i) \tag{10}$$

where θ_i denotes the parameters of the local model and $L_i(\cdot)$ the local optimization objective computed using only dataset D_i, the locally updated models are periodically aggregated to obtain the global model:

$$\theta = \sum_{i=1}^{N} w_i \theta_i, \quad \sum_{i=1}^{N} w_i = 1 \tag{11}$$

where w_i denotes the aggregation weight assigned to site i and satisfies $\sum_i w_i = 1$.

$$w_i = \frac{n_i}{\sum_{j=1}^{N} n_j} \tag{12}$$

This corresponds to a collaborative learning process across distributed environments, meaning raw data remain local and only focused model updates are exchanged for aggregation.

$$D_i \nrightarrow Server, \quad \Delta\theta_i \rightarrow Server \tag{13}$$

The non-IID nature of the data introduces additional challenges, as local models may exhibit biases toward specific conditions (e.g., crop types). In practice, distributed agro-food environments continuously generate evolving observations rather than static datasets. Consequently, local clients may experience different forms of concept drift, seasonal variations, and changing operational conditions, leading to distributed and time-varying data distribution:

$$\mathcal{D}_{i,t} \sim P_{i,t}(x,y) \quad P_{i,t}(x,y) \neq P_{j,t}(x,y) \quad P_{i,t}(x,y) \neq P_{i,t+1}(x,y)$$

where the first expression defines the local data distribution, the second captures spatial heterogeneity among different sites, and the third represents temporal concept drift at each site.

Therefore, the proposed framework extends conventional federated learning toward Federated Continual Learning (FCL), where:

$$\theta_{i,t+1} = \theta_{i,t} - \eta \nabla_\theta [\mathcal{L}_{i,t} + \lambda \Omega_i(\theta_{i,t}, \theta_{i,t-1})] \tag{14}$$

where $\Omega_i(\cdot)$ preserves previously acquired knowledge while adapting the model to newly observed data. The updated local models are then synchronized through periodic federated aggregation:

$$\theta_{t+1} = \sum_{i=1}^{N} w_i \theta_{i,t+1} \tag{15}$$

6. Problem Statement

The previous formulations describe the individual components of the proposed framework, including Digital Twin estimation, physical-virtual consistency, continual adaptation, and distributed learning. These components are jointly expressed through the following overall learning objective, which:

- minimizes the Sim-to-Real gap in agro-food systems,
- adapts to non-stationary and heterogeneous environments,
- integrates real-time multi-modal sensor data,
- supports accurate simulation and decision-making.

and is formulated into:

$$\min_{\theta_t} \mathbb{E}_{i,t}[\mathcal{L}_i(\theta_t; X_i(t)) + \lambda_1 d(P_i(t), DT_i(t)) + \lambda_2 \Omega(\theta_t, \theta_{t-1}) + \lambda_3 G_i(\theta_t)] \tag{16}$$

where $L_i(\theta_t; X_i(t))$ calculates the local learning from new agro-food observations, $\Omega(\theta_t, \theta_{t-1})$ shows the continual learning against the catastrophic forgetting while $d(P_i(t), DT_i(t))$ translates to the Real-to-Sim adaptation loop and $G_i(\theta_t)$ depicts the weighted generalization penalty for each site.

This formulation explicitly captures the interaction between sensing, modeling, and decision-making processes, treating the digital twin as an adaptive learning entity rather than a static representation.

7. Objective Function

The overall learning objective combines accuracy, stability, and generalization expressed as:

$$\min_{\theta} \mathbb{E}[\mathcal{L}_{task} + \lambda_1 \mathcal{L}_{sim2real} + \lambda_2 \mathcal{L}_{cont} + \lambda_3 \mathcal{L}_{gen}] \tag{17}$$

where:

- L_{task} denotes the task-specific learning objective optimized locally at each Digital Twin instance.
- $L_{sim2real}$ corresponds to the physical-virtual consistency term introduced in Equation (5).
- L_{cont} regularizes continual adaptation to mitigate catastrophic forgetting during incremental updates.
- L_{gen} promotes generalization across heterogeneous distributed environments.

This depiction (Figure 2) illustrates how the proposed framework integrates its main components within a unified learning architecture. The corresponding objective function formalizes the optimization criteria by synergistically balancing task performance, physical-virtual consistency, continual adaptation, and generalization across distributed agro-food environments.

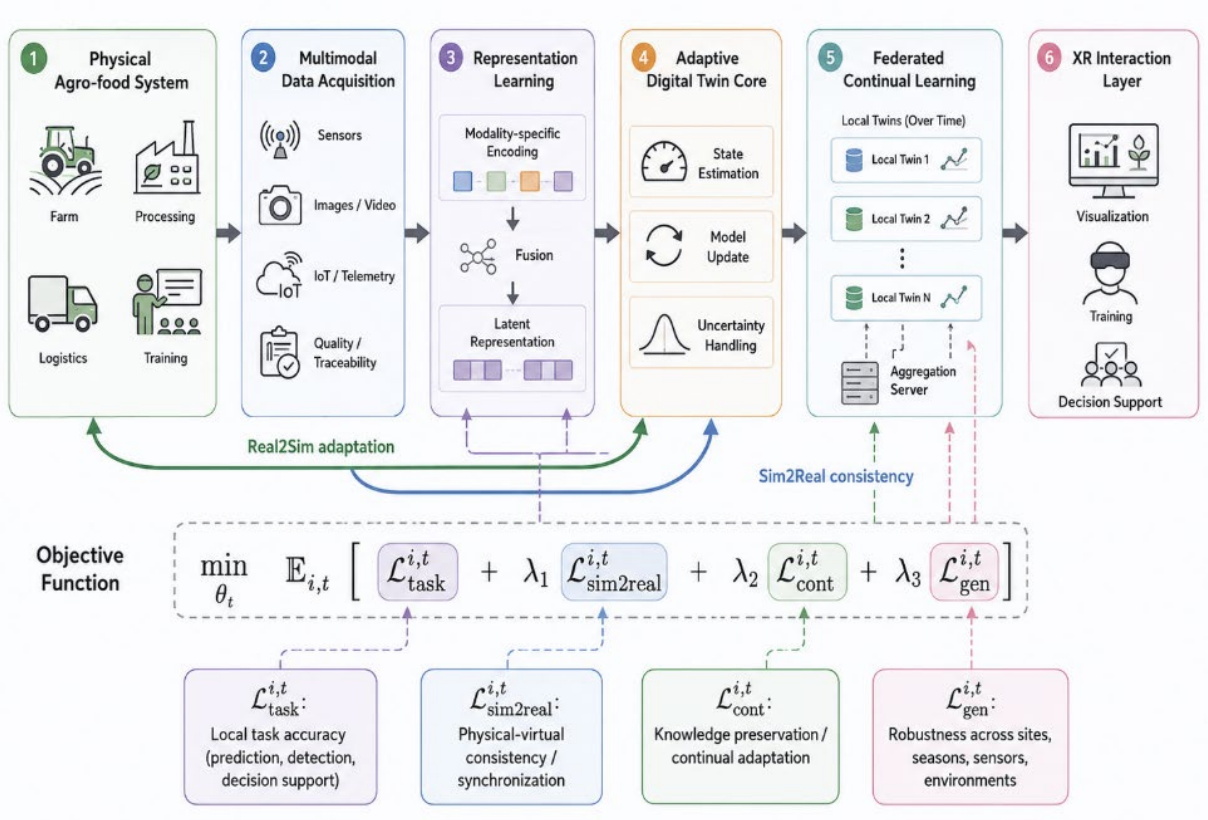

Figure 2. Simplified AI-XR Digital Twin Framework with Objective Function Mapping

IV. DISCUSSION AND COMPARATIVE ANALYSIS

The proposed framework extends existing Digital Twin (DT) paradigms beyond stationary or monitoring representations toward continuously adaptive multimodal learning systems that operate in dynamic agro-food environments. To this end, the primary contribution of this work is the formulation of a unified methodological framework describing how these complementary technologies can operate together within continuously adaptive Digital Twin ecosystems. As seen in the literature, DT-assisted Federated Learning frameworks employ Digital Twins as support entities for synthetic data generation or pretraining. FCLA-DT and FCLLM-DT introduced Federated Continual Learning mechanisms targeting predictive maintenance and industrial fault diagnosis while emphasizing privacy preservation and authentication. Although these systems support distributed adaptation, their Digital Twin representations remain primarily task-oriented and do not evolve according to changing physical process dynamics. Furthermore, recent bidirectional DT architectures in Metaverse environments have demonstrated how Digital Twins and edge computing can cooperate through feedback loops to optimize resources and enhance Quality-of-Experience. Nevertheless, such systems primarily optimize communication and computational resources rather than model the evolution of physical processes. In contrast, the proposed formulation investigates the coordinated integration of continuous Real-to-Sim adaptation via online multimodal observations; Sim-to-Real feedback for predictive and operational support; multimodal representation learning; Federated Continual Learning in evolving non-IID environments; support for deformable agro-food processes and hybrid physical dynamics; and XR-enabled human-in-the-loop interaction. Table 1 summarizes the conceptual differences between representative approaches and the proposed framework. The comparison demonstrates that several existing approaches incorporate individual components relevant to the proposed

framework, including Digital Twins, Federated Learning, Continual Learning, bidirectional interactions, and multimodal sensing. However, these capabilities are typically introduced to address isolated objectives such as predictive maintenance, fault diagnosis, communication optimization, or privacy preservation. In contrast, the proposed framework investigates their integration within a unified continuously adaptive Digital Twin architecture for agro-food systems, enabling multimodal representation learning, Real-to-Sim and Sim-to-Real adaptation, Federated Continual Learning under evolving non-IID conditions, and immersive XR-based interaction. Through this integration, the Digital Twin is no longer treated as a static monitoring or optimization entity, but as an evolving learning system that continuously adapts alongside the physical environment.

Table 1. Conceptual Comparison with Representative Digital Twin Frameworks

Method	**DT**	**Bidirectional**	**FCL**	**Multimodal**	**Sim-to-Real**	**XR**	**Agro-food**
Industrial DT approaches	Yes	No	No	No	No	No	No
Xia et al. (FCLA-DT)	Yes	No	Yes	No	No	No	No
Xia et al. (FCLLM-DT)	Yes	No	Yes	No	No	No	No
Yu et al.	Yes	Yes	No	No	Partial	Yes	No
Verdouw et al.	Yes	Partial	No	Partial	No	No	Yes
Belay et al.	Yes	No	No	No	Partial	No	No
Wang et al.	Yes	No	Partial	No	No	No	No
Proposed Framework	**Yes**	**Yes**	**Yes**	**Yes**	**Yes**	**Yes**	**Yes**

Beyond the architectural integration presented in this work, the proposed framework establishes a methodological basis for developing next-generation adaptive Digital Twin ecosystems for agro-food applications. The proposed formulation enables the continuous interaction between multimodal sensing, adaptive Digital Twin representations, distributed learning, and immersive user interfaces. This integrated perspective supports future applications involving precision agriculture, greenhouse monitoring, robotic manipulation of deformable food products, and operator training through XR-assisted environments.

1. Implementation Perspective

The proposed framework is currently being implemented through representative agro-food scenarios that involve distributed multimodal sensing and continuously adaptive Digital Twin synchronization. Building on our previous work on XR applications for food science [25], the current implementation focuses on establishing the interaction among multimodal sensing, adaptive Digital Twin synchronization, Federated Continual Learning, and immersive XR environments within a unified adaptive ecosystem. At this stage, the contribution of this work is summarized in the conceptual architecture and methodological formulation of the proposed framework, while implementation and quantitative evaluation are in progress. Future experimental studies will validate the proposed methodology through representative agro-food scenarios, evaluating Digital Twin consistency, Sim-

to-Real fidelity, adaptation under concept drift, distributed learning performance, scalability, and decision-support effectiveness.

V. CONCLUSION

This paper presented a conceptual and methodological framework for continuously adaptive multimodal Digital Twins in agro-food environments. Motivated by the limitations of existing Digital Twins in presenting adaptation capabilities, the proposed formulation redefines Digital Twins as dynamic ecosystems. The proposed framework integrates multimodal sensing, bidirectional Real-to-Sim and Sim-to-Real adaptation, Federated Continual Learning, and XR-assisted interaction within a unified architecture that supports learning and adaptation under dynamic, heterogeneous, and non-stationary agro-food conditions. Future work will focus on implementing and experimentally validating the proposed framework across representative agro-food scenarios, extending our previous research on XR technologies for food science toward continuously adaptive Digital Twin ecosystems.

Abstract

This study presents a systematic review of research on water quality monitoring and water pollution detection using a hybrid artificial intelligence (AI) system developed for Edge-IoT technology, published in the Web of Science Core Collection from 2023 to 2026, indexed in the SCI-EXPANDED and ESCI. Three complementary search strategies were used: a main Edge-IoT and artificial intelligence (AI) search, a secondary search based on metaheuristic optimization, and a supplementary search based on large language models (LLMs), generative artificial intelligence (GenAI), and retrieval-augmented generation (RAG). A total of 68 primary search records were found. After one duplicate record was removed, 67 unique candidate studies were evaluated. The selection flow followed the PRISMA guidelines, and the candidate studies were assessed using a five-item eligibility matrix, resulting in 37 studies in the final analysis set. The findings show that low-cost edge hardware, such as Raspberry Pi, ESP32, Arduino, and Jetson/Orin, is widely deployed in field applications. Additionally, it has been observed that machine learning, deep learning, computer vision, ensemble learning, metaheuristic optimization, digital twins, blockchain, and LLM/GenAI/RAG-based decision-support methods are complementary across various problem areas. This study systematically identifies current trends and research gaps for real-time, explainable, low-latency, and field-deployable water quality decision-support systems.

Keywords: water quality monitoring, water pollution detection, Edge-IoT, edge computing, hybrid artificial intelligence

I. INTRODUCTION

The safe monitoring of water resources is a critical research topic for drinking water security, river basin management, and aquaculture systems [1-8]. In wastewater treatment plants, water treatment processes, and environmental pollution scenarios, real-time monitoring and early warning approaches are becoming increasingly important [9-15]. Although conventional laboratory-based or centralized measurement approaches can provide high accuracy, they have limitations in terms of real-time monitoring, early warning generation, low-cost field deployment, and continuous observation over large areas [2], [4-7], [16]. Therefore, faster, local, and intelligent monitoring approaches are needed to track dynamic changes in parameters such as pH, dissolved oxygen, turbidity, total dissolved solids, nitrate/nitrite, heavy metals, and related water quality indicators [4], [6-8], [17-21]. Edge-Internet of Things (IoT) and Artificial Intelligence of Things (AIoT) architectures enable water quality data to be collected directly in the field, processed locally on edge devices, and, when necessary, used to support on-device decision-making mechanisms [2-5], [10],[11], [16], [21-25]. Edge platforms such as Raspberry Pi, ESP32, Arduino, and Jetson Orin address different application requirements in terms of cost,

energy consumption, latency, and computational capacity [4], [5], [10], [11], [16], [21-26]. Machine learning, deep learning, computer vision, federated learning, digital twin, and metaheuristic optimization approaches are used for sensor data interpretation, anomaly detection, water quality prediction, visual pollution detection, and decision-support processes [6-14], [17-21], [23-35]. More recently, Large Language Model (LLM), Generative Artificial Intelligence (GenAI), and Retrieval-Augmented Generation (RAG)-based approaches have introduced new opportunities for interpreting water quality data, modeling sensor noise, querying data through natural language, and supporting decision-making PROCESSES [15], [36],[37]. This study aims to systematically review recent studies published between 2023 and 2026 and present the current state of Edge-IoT-based hybrid artificial intelligence approaches for water quality monitoring and pollution detection. The studies included in the final analysis set were evaluated with respect to AI models running on edge devices, vision-based detection systems, metaheuristic optimization, federated learning/digital twin architectures, and LLM/GenAI/RAG-based decision-support solutions.

The main contributions of this study can be summarized as follows:

- A recent and focused pool of Edge-IoT-based water quality studies covering the 2023–2026 period was constructed.
- Edge-IoT, metaheuristic optimization, federated learning/digital twin, and LLM/GenAI/RAG approaches were examined from an integrated perspective.
- A transparent and reproducible selection process was applied, and studies satisfying the eligibility criteria were included in the final analysis set without imposing a subjective restriction.
- The studies were synthesized in terms of thematic category, hardware, method, performance metrics, and research gaps.

The remainder of this paper is organized as follows. The Background section presents the key concepts underlying the study. The Methodology section describes the systematic review process. The Findings and Thematic Analysis section provides the thematic synthesis of the selected studies. The Discussion section evaluates the results in relation to the research questions, and the Conclusion section summarizes the main findings and outlines future research directions.

II. BACKGROUND

This section summarizes the key concepts that define the scope of this study, including water quality monitoring, water pollution detection, Edge-IoT/AIoT, hybrid artificial intelligence, metaheuristic optimization, and LLM/GenAI/RAG-based decision support.

1. Water Quality Monitoring and Water Pollution Detection

Water quality monitoring involves the regular measurement and interpretation of physical and chemical parameters, including pH, dissolved oxygen, temperature, total dissolved solids, turbidity, nitrate/nitrite, heavy metals, and related indicators [4–8], [17–21]. These parameters are used as key indicators for drinking water safety, river basin management, aquaculture systems, wastewater treatment processes, and environmental early warning applications [3–8], [12–15]. Water pollution detection, however, is not limited to numerical water quality parameters alone; floating debris, oil films, aquatic plant invasions, heavy metal accumulation, increased turbidity, and visual ecosystem indicators are also considered within this scope [9–11], [17],[18], [21], [23–25].

2. Edge-IoT- and AIoT-Based Monitoring

Edge-IoT architectures are distributed computing approaches that enable data collected from sensors to be processed on edge devices located close to the field before being transmitted to a central cloud. These architectures are becoming increasingly important in water quality monitoring and pollution detection applications, where latency, communication overhead, energy consumption, and real-time decision-making are critical [2–5], [10], [11], [16], [21–25]. AIoT combines IoT infrastructure with artificial intelligence models, enabling sensor data to be analyzed locally and used in decision-support processes [3],[4], [16]. Platforms such as Raspberry Pi, ESP32, Arduino, Jetson Nano, and Orin Nano address different application requirements in terms of computational capacity, energy consumption, and cost [4],[5], [10],[11], [16], [19], [21–26].

3. Hybrid AI, Optimization, and LLM-Based Decision Support

Hybrid artificial intelligence models are those that combine ML/DL models with optimization models, sensor network architectures, edge cloud integration, or decision-support models [14], [26-32], [35]. Metaheuristic algorithms such as Particle Swarm Optimization (PSO), Genetic Algorithm (GA), Whale Optimization Algorithm (WOA), Grey Wolf Optimizer (GWO), Salp Swarm Optimization (SSO), Simulated Annealing (SA), and Knowledge-Based Multi-Objective Particle Swarm Optimization (KBMOPSO) are used for tasks including model hyperparameter tuning, sensor placement, missing data imputation, water quality/pollutant prediction, and system optimization [14], [26-31], [35]. More recently, LLM-, GenAI-, and RAG-based approaches have created new opportunities for interpreting sensor data, modeling sensor noise, generating expert-system-like recommendations, and enabling users to query data through natural language. Nevertheless, further research is still needed to assess the feasibility of these approaches on edge devices in terms of energy consumption, latency, reliability, explainability, and data privacy [15], [36],[37].

III. METHODOLOGY

This study adopts a systematic literature review approach. During the planning phase, the research scope, research questions, database, search strategies, inclusion and exclusion criteria, and quality assessment process were defined in advance. The analytical objective, scope, viewpoint, and context of the study are summarized in Table 1 in accordance with the Goal Question Metric (GQM) approach. Based on this framework, search pools were constructed, candidate studies were screened at the title and abstract levels, and full-text assessments were conducted for studies whose topical relevance or thematic classification could not be determined from the initial screening. Subsequently, eligibility scoring was applied, and the final thematic analysis set was synthesized.

Table 1. GQM-based Research Objective and Scope

GQM Component	**Description**
Object of analysis	Edge-IoT-based water quality monitoring, water pollution detection, wastewater monitoring, and hybrid AI studies
Purpose	To characterize, classify, compare, and identify research gaps in recent approaches
Scope	Edge-IoT/AIoT architectures, edge devices, AI methods, metaheuristic optimization, LLM/GenAI/RAG, and performance outcomes
Viewpoint	Researcher and systematic literature review perspective
Context	Article-type studies published between 2023 and 2026 in the WoS Core Collection SCI-EXPANDED and ESCI indices

In line with the scope and purpose defined in Table 1, the following research questions were formulated:

- RQ1: What are the current Edge-IoT and AIoT architectures used in water quality monitoring and water pollution detection?
- RQ2: Which ML, DL, computer vision, metaheuristic optimization, and LLM/GenAI/RAG-based method families are used in these studies?
- RQ3: What performance metrics are reported in the reviewed studies?
- RQ4: What are the main limitations and research gaps highlighted in the literature?

1. Review Planning Phase

During the planning phase, the topic domain, year range, index coverage, document type, and selection criteria were defined. The review scope was limited to studies that are directly related to water quality monitoring or water pollution detection, include an IoT/Edge-IoT/AIoT or edge-device component, and present an AI-, optimization-, federated learning-, digital twin-, or LLM/GenAI/RAG-based method. This scope allowed the study to be distinguished from the broader environmental monitoring literature and to focus specifically on Edge-IoT-based intelligent water quality systems.

2. Search Strategy

The search was conducted using filters that include the indices in which the article is indexed (SCI-EXPANDED and ESCI in the Web of Science Core Collection), document type, and year range (2023-2026). The search strategy was based on three complementary queries. The first query (Q1) focused on Edge-IoT and artificial intelligence-based water quality monitoring studies, whereas the second query (Q2) focused on metaheuristic optimization and hybrid artificial intelligence studies. The third (Q3) has focused on studies of LLMs, GenAI, RAG, and decision support. The complete search strings are presented in Table 2. The queries were designed using the Web of Science Topic Search logic via the TS field, followed by applying year, index, and document type filters.

Table 2. Web of Science Search Strings and Objectives

Query	**Search string**	**Objective**
Q1	TS=(("water quality" OR "water pollution" OR "wastewater" OR "drinking water" OR "river water" OR aquaculture OR aquaponic) AND ("Internet of Things" OR IoT OR "Edge-IoT" OR "edge computing" OR AIoT OR "smart sensor*" OR "wireless sensor network*" OR WSN) AND ("machine learning" OR "deep learning" OR "artificial intelligence" OR "computer vision" OR CNN OR YOLO OR LSTM OR "random forest" OR XGBoost))	To construct the main Edge-IoT, sensor, and AI study pool.
Q2	TS=(("water quality" OR "water pollution" OR wastewater OR aquaculture OR aquaponic OR "water treatment") AND (IoT OR "edge computing" OR "wireless sensor network*" OR sensor*) AND (metaheuristic OR optimization OR "particle swarm optimization" OR PSO OR "genetic algorithm" OR GA OR "grey wolf optimizer" OR GWO OR "whale optimization algorithm" OR WOA OR "salp swarm optimization" OR SSO OR "simulated annealing" OR SA))	To identify metaheuristic optimization and hybrid AI studies

Query	Search string	Objective
Q3	TS=(("water quality" OR wastewater OR "water pollution" OR aquaculture OR "water treatment") AND (IoT OR sensor* OR "edge computing" OR "digital twin") AND ("large language model*" OR LLM OR "generative AI" OR GenAI OR ChatGPT OR "retrieval augmented generation" OR RAG OR "decision support" OR "expert system"))	To identify LLM, GenAI, RAG, digital twin, and decision-support studies

The searches yielded 47 candidate records in the Q1 Edge-IoT/AI pool, 13 in the metaheuristic optimization candidate pool, and 8 in the LLM/GenAI/RAG candidate pool. In total, 68 candidate records were retrieved. After duplicate checking (based on DOI and title), 67 candidate studies were assessed, and 37 were included in the final analysis set based on eligibility scoring. This selection is summarized in Figure 1. The presence of only one duplicate record across the three query pools indicates that Edge-IoT/AI-, metaheuristic optimization-, and LLM/GenAI/RAG-oriented studies form largely complementary but only partially overlapping literature clusters in this domain.

3. Data Extraction Protocol

A standardized data extraction protocol was used when evaluating the candidate studies. This protocol was designed to capture not only bibliographic information but also the application context, monitored water-quality parameters or target outputs, data types, hardware and architectural components, AI/optimization methods used, reported performance metrics, types of evidence, reported limitations, and thematic categories. In this way, the studies were made comparable in terms of methods, architectures, data types, and performance. During the data extraction process, model-, system-, and evidence-level metrics were recorded, including accuracy, precision, recall, specificity, F1-score, Area Under the Curve (AUC), False Positive Rate/False Negative Rate (FPR/FNR), coefficient of determination (R^2), Root Mean Squared Error (RMSE), Mean Absolute Error (MAE), Mean Absolute Percentage Error (MAPE), Mean Squared Error (MSE), mean Average Precision (mAP), Average Precision (AP), Dice coefficient, Intersection over Union (IoU), Topographic Error (TE), Quantization Error (QE), Silhouette Index, Dunn Index, Signal-to-Noise Ratio (SNR), recovery, Relative Standard Deviation (RSD), detection limit, response time, compression ratio, latency/delay, Frames Per Second (FPS), Central Processing Unit (CPU)/memory/power usage, model size, Giga Floating-Point Operations per Second (GFLOPs), battery life, bandwidth/data transfer reduction, blockchain gas/transaction cost, throughput, trust score, fault tolerance, BERTScore, FactCC, ROUGE-L, Question Answering (QA) accuracy, Precision@1/Recall@5, decision error, and user/expert feedback. These fields served as the basis for the synthesis matrix presented in Table 4 and for generating distributions of themes, hardware, methods, and performance metrics.

4. Inclusion and Exclusion Criteria

The following criteria were used to choose the relevant studies: the study had to be published between 2023 and 2026 as an Article in SCI-EXPANDED or ESCI; the study had to be directly related to water quality monitoring or water pollution detection; the study had to contain an IoT/Edge-IoT/AIoT, sensor network, or edge-device component; the study had to present an ML-, DL-, optimization-, federated learning-, digital twin-, or LLM/GenAI/RAG-based method or decision-support approach. Exclusion criteria were: out of year, out of index, or out of document type, document had weak relevance to water quality, did not have an IoT/sensor/edge component, did not present an intelligent method or decision-support component, and only provided conceptual background material.

5. Quality Assessment and Eligibility Scoring

Candidate studies were evaluated using a five-item eligibility matrix. Each criterion was assigned a score of 1 or 0, and each study received a total eligibility score ranging from 0 to 5. The criteria and decision thresholds are presented in Table 3. As a result of this process, 22 studies were classified as "Definite Include", 15 studies as "Include", and a total of 37 studies were included in the final analysis set.

Table 3. Eligibility Assessment Criteria and Decision Thresholds

Code/Score	**Assessment Description**	**Scoring/Decision**
Q1	Direct relevance to water quality monitoring or water pollution detection	Yes=1, No=0
Q2	Inclusion of IoT, Edge-IoT, AIoT, sensor network, or edge-device component	Yes=1, No=0
Q3	Inclusion of an ML-, DL-, optimization-, federated learning-, digital twin-, or LLM/GenAI/RAG-based intelligent method or decision-support component	Yes=1, No=0
Q4	Reporting of a performance metric or measurable evaluation outcome	Yes=1, No=0
Q5	Inclusion of real data, field deployment, prototype, simulation, benchmark, or case study	Yes=1, No=0
5	Studies satisfying all eligibility criteria	Definite Include
4	Studies that miss one criterion but are strongly aligned with the research scope.	Include
3	Studies are partially related to the scope or limited in evidence/method components.	Reserve/Borderline
0–2	Studies that are weakly related to the scope or do not satisfy the core criteria	Exclude/Background

For the 15 studies classified as "Include", the missing criterion was most commonly associated with limited reporting of measurable system-level metrics or a narrower field/prototype validation scope. However, these studies were retained in the final synthesis because their methodological contributions and topical relevance strongly aligned with the review's scope.

6. Review Phase

During the review phase, candidate records were processed through duplicate checking, title/abstract screening, full-text assessment when necessary, eligibility scoring, and thematic classification. Studies classified as Reserve/Borderline, where topical relevance or thematic classification was unclear, were checked through full-text review. Studies classified as Definite Include or Include were retained in the final analysis set, while the remaining studies were excluded from the analysis. The process is summarized in Figure 1.

7. PRISMA-Like Study Selection Flow

The study selection process was summarized using a PRISMA-like transparent reporting structure. Records retrieved from the three search pools were transformed into the final analysis set after duplicate removal, title/abstract screening, full-text assessment when required, and eligibility scoring. The process is presented in Figure 1.

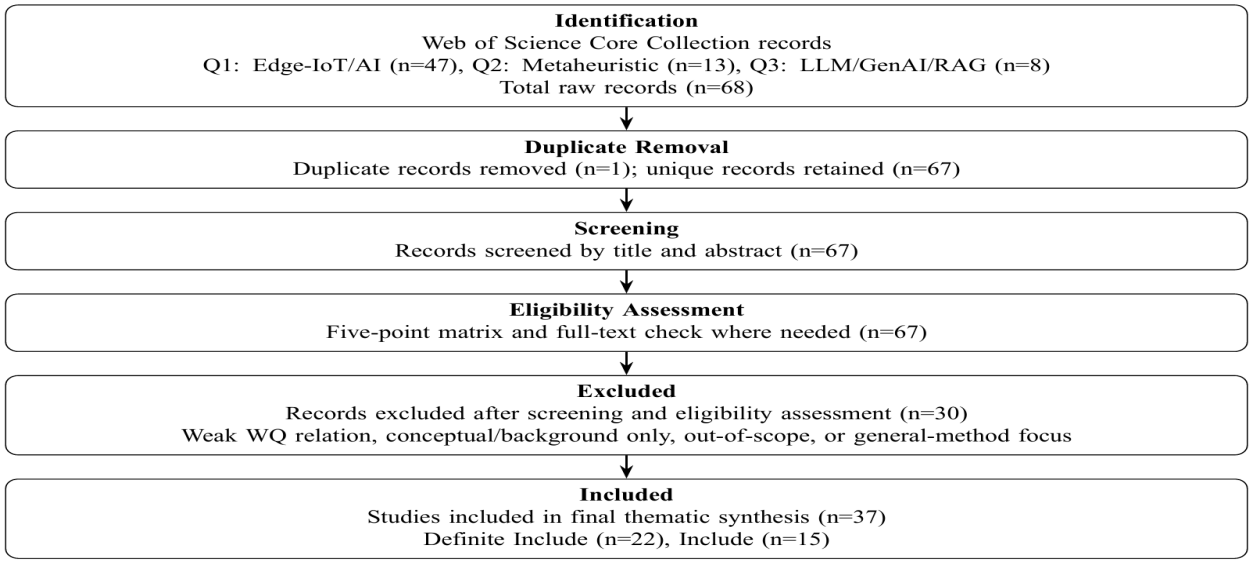

Figure 1. PRISMA-like study selection flow.

IV. FINDINGS AND THEMATIC ANALYSIS

This section presents a thematic analysis of the 37 studies included in the final analysis set. The synthesis matrix in Table 4 summarizes each study by reference number, thematic group, application domain, method/hardware used, and the reported metric or type of evidence. The findings were evaluated from multiple perspectives, including publication year, theme, method, hardware, performance metric, and application context. This evaluation shows that the water quality monitoring literature is not limited to sensor-based measurement systems; it has expanded to include vision-based detection, edge-cloud integration, federated learning, digital twins, metaheuristic optimization, and LLM/GenAI/RAG-based decision-support approaches. The theme codes used in Table 4 are as follows: T1 = Edge-IoT monitoring; T2 = WQ prediction/modeling; T3 = vision-based detection; T4 = metaheuristic/hybrid AI; T5 = digital twin/federated learning/edge-cloud/blockchain; T6 = LLM/GenAI/RAG/decision support. The abbreviations in the table are defined as follows: Acc., Prec., Rec., BW, comp., err., TE, QE, Silh., NL, and WQ refer to accuracy, precision, recall, bandwidth, compression, error, topographic error, quantization error, Silhouette, natural language, and water quality, respectively. The abbreviations in the table are consistently used throughout.

Table 4. Synthesis Matrix of the Final Analysis Set

Ref.	Theme	Year	Application	Method	Metric
[1]	T1	2023	CIS-WQMS	Edge devices, ensemble ML/SSL	Acc. 99.46%; F_1 99.27%; 4.44 ms; AUC 1.00
[2]	T1	2023	IoTEC environmental monitoring	IoTEC, edge ML, regression/image processing	Acc. 87% (reg.), > 90% (image); latency -13%; data -50%; battery +130%
[3]	T1	2024	AIoT aquaculture inspection	ESP32, AIoT, SRU	MAE/RMSE/MAPE; SRU > LSTM

Ref.	Theme	Year	Application	Method	Metric
[4]	T1	2025	Tilapia aquaculture prediction	ESP32, MLR/DTR/RFR	R^2 0.81–0.83; RMSE/MAE; 0.32 kWh/cycle
[5]	T1	2025	Household drinking water monitoring	Raspberry Pi, fuzzy logic	Acc. 98.724%
[22]	T1	2026	Turbidity estimation in farm ponds	Raspberry Pi 4, CNN	Acc. 96.3%; 46 ms; CPU 35–40%
[16]	T1	2026	Low-cost on-device WQ monitoring	ESP32, TinyML	Acc. 99.28%; Prec./Rec. 0.99; AUC 1.00; cost <$80

The distribution of studies in the final analysis, by publication year, is as follows: 4 in 2023, 5 in 2024, 17 in 2025, and 11 in 2026. This distribution indicates a marked increase in publication activity in 2025 and 2026. The relationship between themes and years is further visualized in Figure 4.

The distributions of thematic categories, hardware/architectural components, and AI/optimization methods are jointly presented in Figure 2. Figure 2(a) shows that the studies are grouped around six main themes. In contrast, Figures 2(b) and 2(c) highlight the prominence of Raspberry Pi, ESP32, Jetson/Orin, sensor networks, edge-cloud/digital twin/blockchain architectures, CNN/vision DL, the YOLO family, classical ML, RNN/LSTM-based models, federated learning, and metaheuristic optimization approaches.

The hardware, method, and metric distributions presented in Figure 2(b) and 2(c), and in Figure 3, were calculated using a multi-labeling approach; therefore, the category totals may exceed the 37 studies included in the final analysis set.

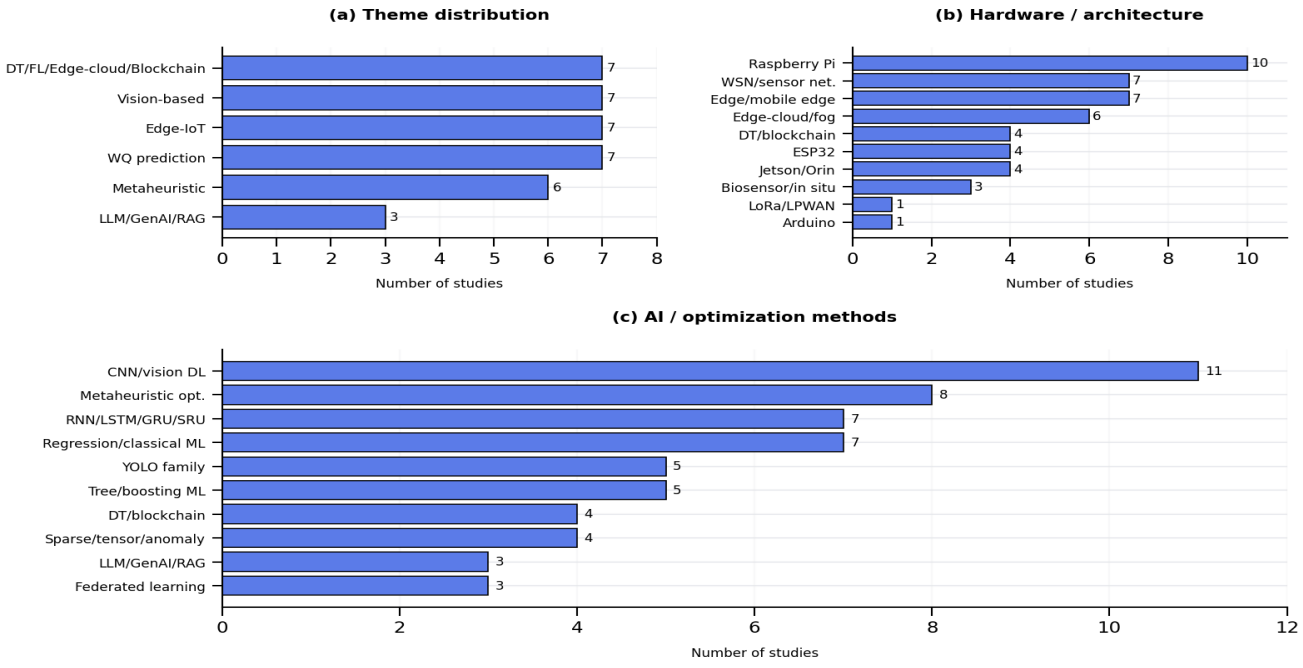

Figure 2. Combined distribution of thematic categories, hardware/architecture components, and AI/optimization methods.

Figure 3 presents the distribution of performance metrics reported in the reviewed studies. In classification-oriented studies, accuracy, precision, recall, specificity, F1-score, AUC, FPR/FNR, and misclassification cost are commonly reported. In regression, time-series, and missing-data imputation studies, RMSE, MAE, MAPE, and MSE are frequently used. The vision-based detection and segmentation studies contain mAP, AP, FPS, detection accuracy, Dice, and IoU, while distributed clustering studies include TE, QE, Silhouette Index, and

Dunn Index. Edge-IoT and system-level studies measure latency/delay, processing time, FPS, CPU/memory/power consumption, model size, GFLOPs, battery life, bandwidth/data transfer reduction, and compression ratio. Biosensor and sensor-noise studies focus on SNR, recovery, RSD, detection limit, response time, and laboratory validation discrepancy. Gas usage, transaction costs, throughput, confirmation latency, trust scores, and fault tolerance are reported in blockchain-based studies. In LLM/GenAI/RAG-based decision-support studies, metrics or evidence types such as BERTScore, FactCC, ROUGE-L, QA accuracy, Precision@1/Recall@5, decision error, and user/expert feedback are prominent [2], [4–6], [8], [10-26], [28–30], [32–37]. This diversity indicates the continuing need for common benchmarks and standardized metric sets in the literature.

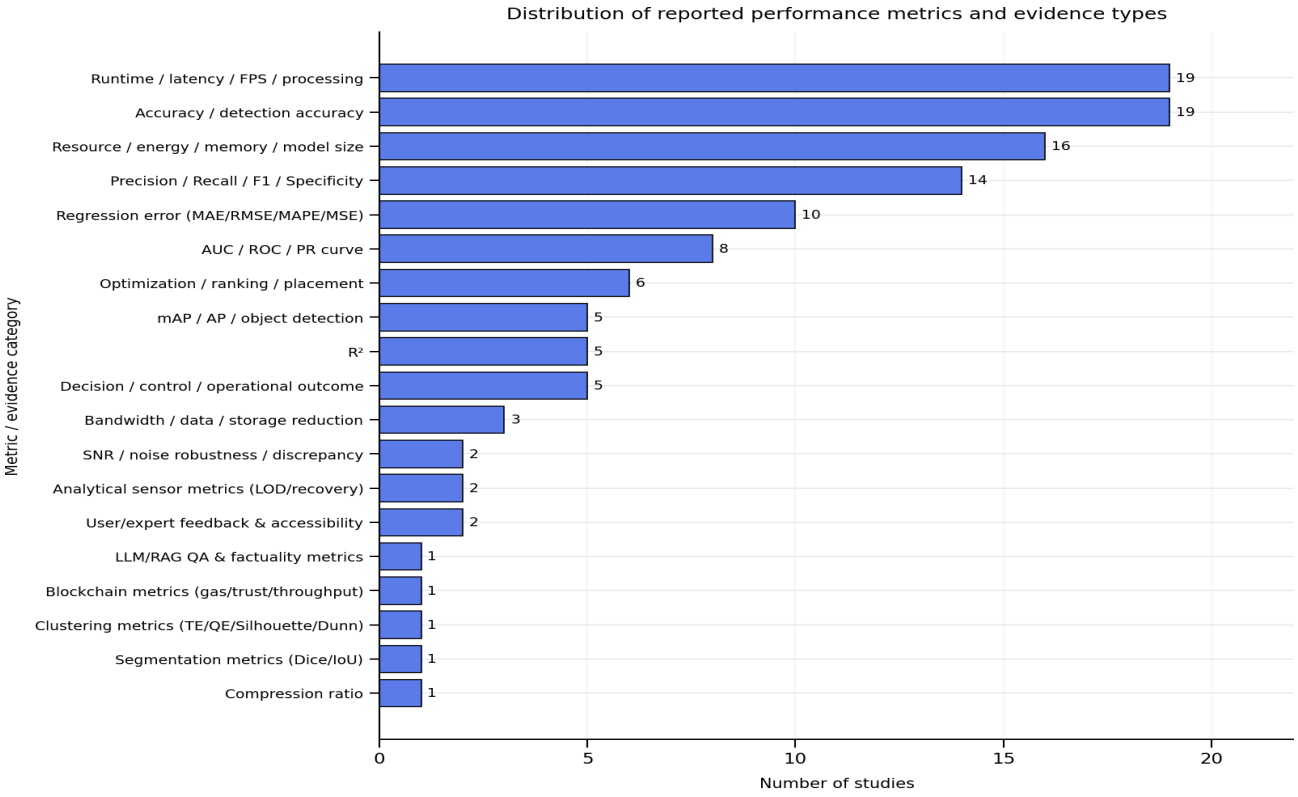

Figure 3. Distribution of reported performance metrics and evidence types.

Figure 4 shows the theme-year density map. The heatmap indicates that water quality prediction, digital twin/federated learning/edge-cloud/blockchain, and metaheuristic approaches became more prominent in 2025. In contrast, vision-based detection, LLM/GenAI/RAG decision support, and Edge-IoT studies became more visible in 2026.

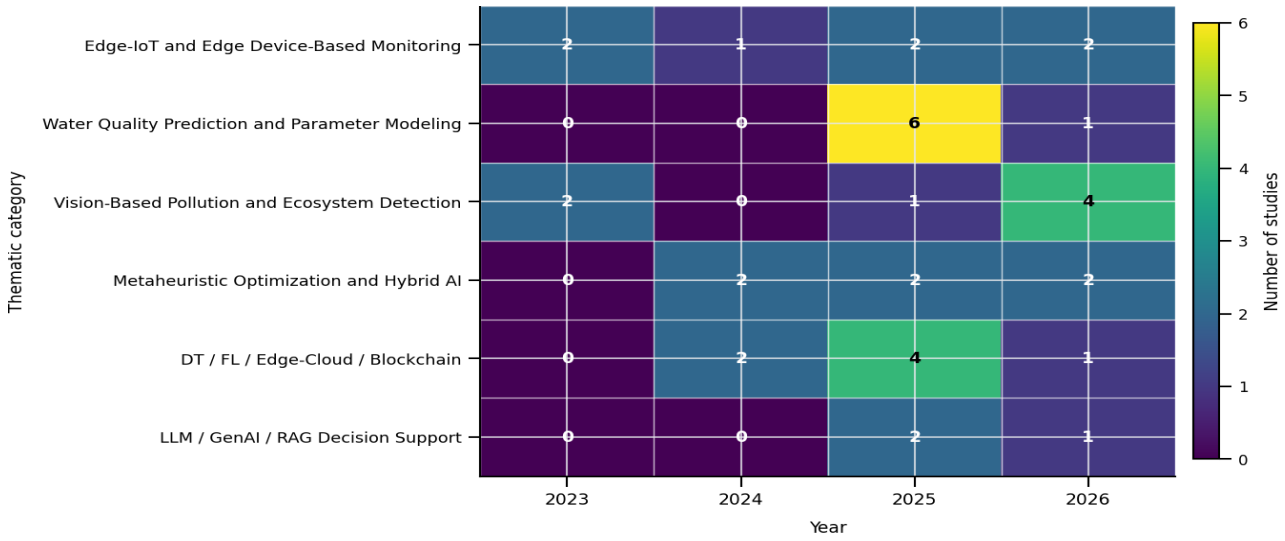

Figure 4. Theme-year density map.

V. DISCUSSION

RQ1: Edge-IoT and AIoT Architectures

Regarding RQ1, the results show that current water quality-based monitoring research is transitioning from centralized cloud-based data collection systems to local computing and decision-making systems in the field. Raspberry Pi and Jetson Orin devices are widely used in applications that require vision-based detection. Embedded deep learning is needed for autonomous control tasks [4], [5], [10], [11], [16], [21-26], while ESP32 and Arduino are commonly used in sensor-based monitoring or autonomous control tasks that require low cost. Edge-cloud, federated learning, digital twin, and distributed IoT architectures are preferred for large-scale data processing, visualization, and decision-support processes [12-14], [32-35]. This trend shows that system-level criteria such as low latency, communication overhead, local processing capability, and field deployability have become visible alongside model accuracy in the reviewed literature.

1. RQ2: AI, Optimization, and LLM-Based Methods

Regarding RQ2, the reviewed studies do not show a dominant method family; rather, the choice of method depends on the problem type, data type, hardware constraints, and real-time processing requirements. In vision-based studies [9-11], [21], [23-25], the most popular architectures are CNN/YOLO/VGG/UNet, while XGBoost, Random Forest, CatBoost, LSTM/BiLSTM, and SRU are popular architectures for sensor- and time-series-based studies [3], [6-8], [12],[13], [17-20], [28]. PSO, GA, WOA, GWO, SSO, and KBMOPSO are often used in optimization [14], [26-31], [35]. Distributed architectural approaches are featured prominently in federated learning/digital twin, and edge-cloud studies [12-14], [32-35], and natural language and decision support approaches are prominent in LLM/GenAI/RAG studies [15], [36], [37]. In addition to widely used ML/DL models, more specialized method families such as BASM-based sparse coding, ABL tensor factorization, DiSOM-based distributed clustering, VAE-based GenAI, and RAG-LLM/DQN are also notable [15], [20], [29],[30], [36],[37]. This indicates that recent studies are not limited to prediction and classification problems;

instead, they span a broader problem space that includes missing-data imputation, denoising, distributed learning, natural language-based decision support, and user interaction.

2. RQ3: Performance Metrics

Regarding RQ3, the methods of performance evaluation seem to be directly influenced by the kind of problems tackled. Widely used classification measures include accuracy, precision, recall, specificity, F1-score, and AUC. In contrast, traditional error-based measures for regression, time-series, and parameter estimation studies are R2, RMSE, MAE, MAPE, and MSE. In vision-based detection and segmentation research, metrics such as mAP, AP, FPS, detection accuracy, Dice, and IoU can be used to assess model performance and applicability in real time. For Edge-IoT and system-level studies, factors such as latency/delay, processing time, CPU/memory/power consumption, model size, GFLOPs, battery life, bandwidth reduction, and compression ratio are considered alongside algorithmic accuracy. In biosensor and sensor-noise studies, analytical reliability metrics such as SNR, recovery, detection limit, response time, RSD, and laboratory validation discrepancy are emphasized. In blockchain and secure monitoring studies, system reliability metrics such as gas usage, transaction cost, throughput, confirmation latency, trust score, fault tolerance, and false alarm reduction are used; while in LLM/GenAI/RAG-based decision-support studies, metrics or evidence types such as BERTScore, FactCC, ROUGE-L, QA accuracy, Precision@1/Recall@5, decision error, expert intervention rate, and user/expert feedback are prominent. This diversity shows that performance evaluation in the reviewed studies has expanded beyond model accuracy alone toward system-level dimensions such as real-time operation, communication overhead, resource usage, field deployability, explainability, and decision-support quality.

This also indicates that, in Edge-IoT-based water quality systems, not only model performance but also the balance among system-level criteria such as latency, energy consumption, and data reliability plays a decisive role in the design process.

3. RQ4: Research Gaps

Based on the reviewed study set, five main research gaps were identified with respect to RQ4:

- Although field/prototype validations are reported in some studies, long-term, multi-season, multi-site validations covering different environmental conditions remain limited [4], [19], [21], [25], [32],[33], [36],[37].
- Hardware resource consumption metrics that directly affect system performance, such as processing time, CPU usage, and memory usage, are not reported within a standardized and comparable framework across studies [2], [9–11], [15–18], [20], [22],[23], [28], [33], [35],[36].
- The lack of standardized datasets, open data, data quality documentation, metadata standardization, and comparable benchmarks limits direct comparison across studies [8], [14], [16], [21], [29],[30], [37].
- Studies that integrate Edge-IoT, metaheuristic optimization, federated learning/digital twin, blockchain, and LLM/GenAI/RAG approaches within the same system architecture remain limited [13], [15], [31],[32], [35–37].
- Explainability, reliability, data privacy, hallucination risk, model trustworthiness, and human-machine interaction require more systematic evaluation [12], [14],[15], [35],[37].

These gaps indicate that a single model or hardware platform cannot explain performance in water quality monitoring systems. Performance varies depending on the monitored parameter, data type, hardware capacity, energy budget, connectivity conditions, and decision-support requirements. Sensor noise, missing data, and local

adaptation of models to changing environmental conditions are important challenges for low-cost edge devices; high data volume is a key issue in vision-based tasks; and semantic interpretation and reliable decision support are emerging as important research directions for LLM/GenAI/RAG-based systems. Since this study was limited to Article-type publications indexed in the WoS Core Collection under SCI-EXPANDED and ESCI, some applied Edge-IoT prototypes published in Scopus, IEEE Xplore, the ACM Digital Library, or conference proceedings may have been outside its scope. While this choice enabled a more controlled review pool with respect to indexing quality and reproducibility, it also constitutes a natural limitation in representing the full range of engineering-oriented implementations.

VI. CONCLUSION

This study systematically reviewed Edge-IoT-based hybrid artificial intelligence studies on water quality monitoring and water pollution detection published between 2023 and 2026 in the Web of Science Core Collection under the SCI-EXPANDED and ESCI indices. Through three complementary search strategies, duplicate removal, title/abstract screening, and a five-point eligibility assessment, 37 studies [1], [37] were included in the final analysis set. The findings show that low-cost edge devices, sensor networks, vision-based deep learning models, metaheuristic optimization approaches, federated learning/digital twin/blockchain architectures, sensor denoising methods, and LLM/GenAI/RAG-based decision support systems are strongly represented in the reviewed literature on water quality monitoring. The reviewed studies indicate that no single model, method, or hardware platform is superior across all scenarios. Performance depends on the monitored parameter, data type, field conditions, hardware constraints, energy requirements, connectivity infrastructure, and decision-support needs. Therefore, future studies should consider not only model accuracy but also system-level criteria such as energy consumption, latency, bandwidth, compression ratio, device cost, edge-device resource usage, explainability, reliability, privacy, and long-term field validation. In addition, integrating LLM/GenAI/RAG-based decision-support components with edge devices, federated learning, digital twins, and blockchain-based trusted data management infrastructures may contribute to the development of next-generation hybrid water quality monitoring systems.

Abstract
Lung cancer remains a leading cause of cancer-related mortality worldwide, making accurate diagnostic systems critically important. Recent advances in deep learning have significantly improved histopathological image classification. However, many existing studies primarily emphasize predictive accuracy while giving less attention to training duration and practical comparison across architectures. This study presents a practical evaluation of three convolutional neural network (CNN) architectures—MobileNetV3, EfficientNet-B3, and ConvNeXt-Tiny—for histopathological lung cancer classification using the LC25000 dataset. All models were trained under a controlled, simplified experimental setup, using a fixed number of 10 epochs, a single train/validation/test split, and identical training conditions without adaptive strategies such as early stopping. Experimental results indicate that while all models achieve comparable classification performance, clear differences emerge in training duration. MobileNetV3 demonstrates the fastest training process and the most favorable accuracy–time trade-off, whereas ConvNeXt-Tiny provides a balanced performance. EfficientNet-B3 achieves the highest accuracy but requires substantially longer training time. These findings emphasize that, when classification performance is comparable, training duration becomes a decisive criterion for practical model selection.

Keywords: deep learning, CNN, histopathology, lung cancer classification

I. INTRODUCTION

Lung cancer remains one of the leading causes of cancer-related mortality worldwide, highlighting the critical importance of early and accurate diagnosis. Histopathological image analysis plays a central role in confirming cancer types and guiding clinical decision-making. However, manual examination of histopathological slides is time-consuming and subject to interobserver variability, motivating the development of automated, reliable computational approaches. Recent advances in deep learning, particularly convolutional neural networks (CNNs), have significantly improved the performance of medical image classification systems. CNN-based approaches have demonstrated remarkable success in histopathological image analysis by enabling automated feature extraction and high classification accuracy across various cancer types. As a result, deep learning models are increasingly considered as supportive tools in computational pathology workflows. Despite these advances, a large body of existing work primarily focuses on improving predictive performance, often under highly optimized experimental conditions. While such approaches provide valuable insights into model capability, they may not fully reflect practical experimental settings, particularly when simplified and consistent training conditions are required for fair comparison. In many cases, the feasibility of training different architectures under consistent, simplified conditions is as important as their predictive accuracy. Motivated by this gap, this study presents a practical evaluation of three widely used CNN architectures, MobileNetV3, EfficientNet-B3, and ConvNeXt-Tiny, for histopathological lung cancer classification. The models are assessed under a controlled and simplified experimental setup designed to ensure a fair comparison, using a fixed number of training epochs, a single data split, and identical training

conditions. The main objective of this study is to analyze how different CNN architectures perform in terms of both classification accuracy and training time in a simplified, controlled experimental setting. By focusing on a simplified, controlled setup, the study aims to provide clear, interpretable insights into the trade-off between predictive performance and training duration.

II. RELATED WORK

Recent advances in deep learning have significantly transformed medical image analysis, particularly in cancer diagnosis. Convolutional neural networks (CNNs) have emerged as the dominant paradigm due to their ability to automatically learn hierarchical feature representations from large-scale data, outperforming traditional machine learning methods across a wide range of applications [1], [2]. Architectural innovations such as depth scaling, multi-path structures, and attention mechanisms have further enhanced CNN performance. In lung cancer diagnosis, deep learning models have demonstrated strong performance across radiological and histopathological imaging modalities. EfficientNet-based approaches, for instance, provide a balanced scaling strategy that improves both accuracy and efficiency [3], [4]. Raza et al. proposed Lung-EffNet, achieving high classification accuracy while maintaining relatively efficient training characteristics.

Recent studies on lightweight CNNs have shown that reduced-complexity architectures can maintain strong classification performance [5]. Similarly, XLLC-Net demonstrated that compact architectures with fewer parameters can maintain high accuracy while significantly reducing training time and improving interpretability [6]. Hybrid and multi-model approaches have also been explored to enhance classification performance. Naveenraj and Vijayakumar (2025) proposed a hybrid DCNN–LSTM framework achieving high accuracy, albeit with increased computational demands [7]. Attallah (2025) introduced a multi-CNN feature integration approach that combines multiple architectures and feature selection techniques to improve performance while reducing complexity [8]. In addition, data augmentation techniques have been shown to improve model robustness and classification accuracy [9]. Modern CNN designs such as ConvNeXt further demonstrate that convolution-based architectures remain competitive with transformer-based models while maintaining efficiency and scalability [10]. Despite these advances, most studies primarily emphasize classification accuracy, often reporting near-saturated performance on benchmark datasets. However, relatively limited attention has been given to training duration and practical efficiency considerations.

In contrast, this study focuses on a controlled comparison of representative CNN architectures under identical conditions, emphasizing training duration and accuracy–time trade-off as key criteria for model selection in practical scenarios.

III. MATERIAL AND METHODS

1. Dataset

This study utilizes the publicly available LC25000 dataset, which contains histopathological images of lung and colon tissues. In this work, only the lung subset is considered, including three classes: lung adenocarcinoma, lung squamous cell carcinoma, and benign lung tissue. All images are resized to a consistent input resolution and normalized to ensure uniformity across models. The dataset is divided into training, validation, and test sets using a fixed split of 80%, 10%, and 10%, respectively. This single split configuration is adopted to maintain a controlled and consistent evaluation setting.

2. Model Architectures

In this study, three representative convolutional neural network architectures, MobileNetV3, EfficientNet-B3, and ConvNeXt-Tiny, were selected to reflect different design philosophies and performance characteristics in modern deep learning. MobileNetV3 was chosen as a lightweight and fast architecture designed for rapid training and early convergence. EfficientNet-B3 is a more complex scaling-based architecture that aims to achieve high classification performance by increasing model capacity. ConvNeXt-Tiny, a modern architecture inspired by transformer-based design principles, offers a balanced approach by combining contemporary architectural improvements with competitive performance. By selecting these models, the study aims to provide a practical comparison across lightweight, high-capacity, and modern balanced architectures.

3. Training Configuration

All experiments were conducted on a computing system equipped with an Intel Core i7-13700H CPU. All models are trained under a simplified, controlled experimental setup, with a fixed number of 10 epochs for each architecture. Identical training conditions are applied across all models, including preprocessing steps, input dimensions, and optimization settings. This controlled configuration enables a direct comparison of architectural performance without introducing variability from training strategies.

4. Evaluation Metrics

Model performance is evaluated using both predictive and training-related metrics. Classification performance is measured using accuracy on the test set.

$$\text{Accuracy-Time Trade-off} = \text{Test Accuracy} / \text{Total Training Time}$$

Higher values indicate more favorable predictive performance relative to training duration. Trade-offs between predictive performance and training efficiency are commonly analyzed in deep learning studies. To explicitly quantify this relationship, a simple accuracy–time trade-off metric is defined as a compact measure of training efficiency. Thus, models with higher values achieve better predictive efficiency per unit of training time. In addition, total training time is recorded for each model. By jointly considering accuracy and training duration, this study provides a practical perspective on model comparison, emphasizing the balance between predictive performance and training duration. This evaluation framework enables a more interpretable comparison of models by capturing both performance and training efficiency.

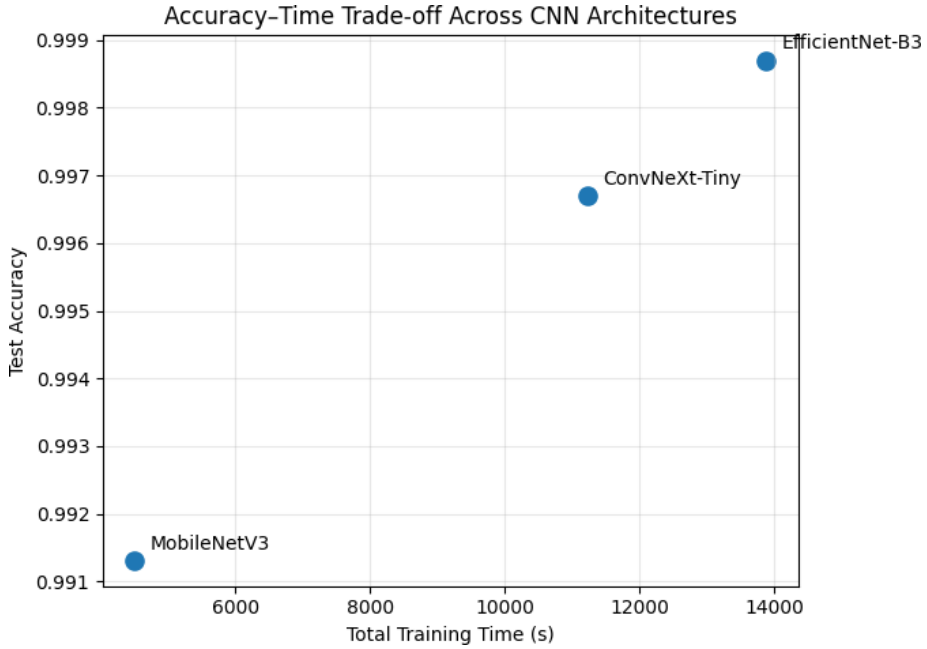
IV. RESULTS AND DISCUSSION

The results show that all models achieve high classification performance, with test accuracy values exceeding 0.99. EfficientNet-B3 yields the highest accuracy (0.9987), followed by ConvNeXt-Tiny (0.9967) and MobileNetV3 (0.9913). However, substantial differences are observed in training duration (Table 1) and are illustrated in Figure 1.

Table 1. Performance comparison of CNN architectures on the LC25000 dataset.

Model	**Test Accuracy**	**Avg Epoch Time (s)**	**Total Time (s)**	**Accuracy -Time Trade-off**

MobileNetV3	0.9913	450.81	4508.10	0.000220
EfficientNet-B3	0.9987	1387.83	13878.30	0.000072
ConvNeXt-Tiny	0.9967	1122.02	11220.24	0.000089



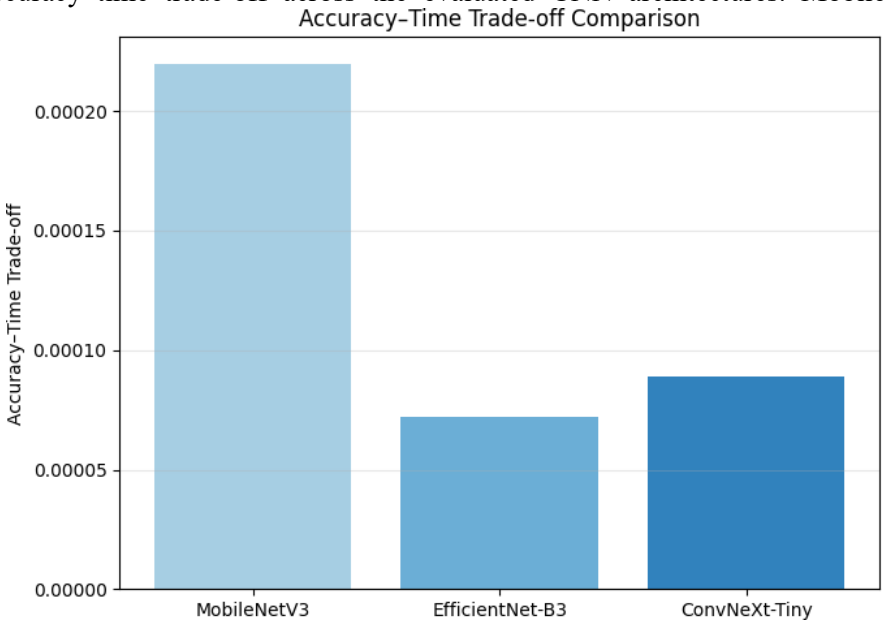


Figure 1. Accuracy–time trade-off across the evaluated CNN architectures. MobileNetV3 achieves competitive accuracy with significantly reduced training time, whereas EfficientNet-B3 provides only marginal accuracy improvements at substantially higher training time. ConvNeXt-Tiny demonstrates a balanced performance between these two extremes.

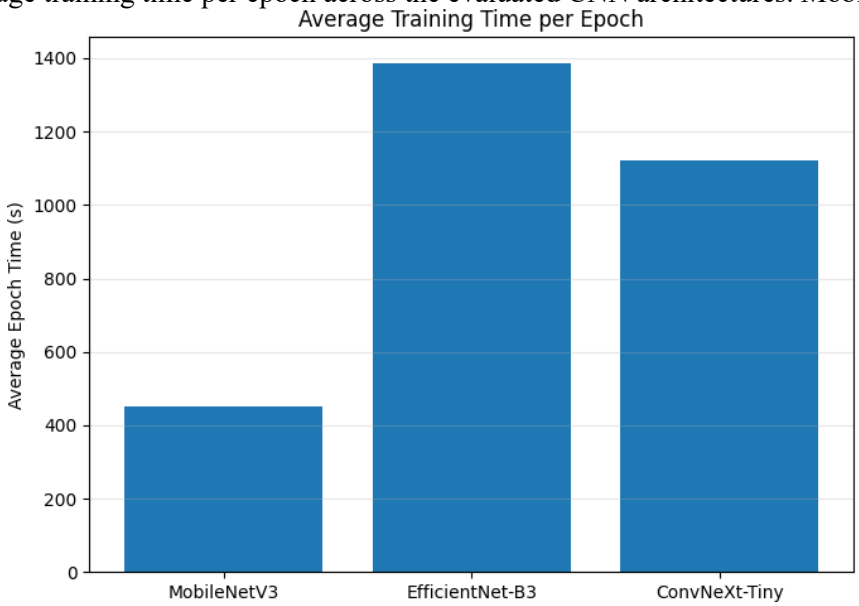

The accuracy–time trade-off metric further highlights these differences, as clearly presented in Figure 2. MobileNetV3 achieves the highest trade-off value (0.000220), indicating the most efficient accuracy–time balance. In contrast, EfficientNet-B3 yields the lowest trade-off value due to its substantially longer training time, despite achieving the highest accuracy. ConvNeXt-Tiny provides a moderate trade-off, reflecting its balance between accuracy and training duration. Overall, the results show that differences in predictive performance are relatively small across models. In contrast, differences in training duration are substantial, indicating that model selection should not rely solely on accuracy, particularly under practical constraints.

Figure 2. Accuracy–time trade-off across the evaluated CNN architectures. MobileNetV3 achieves the highest trade-off value, indicating the most efficient accuracy–time balance.

MobileNetV3 achieves the shortest training time, with an average epoch duration of 450.81 seconds, significantly outperforming the other models in training efficiency. In contrast, EfficientNet-B3 requires more than three times as long per epoch (1387.83 seconds), while ConvNeXt-Tiny shows an intermediate training duration (1122.02 seconds), as shown in Figure 3.

Figure 3. Average training time per epoch across the evaluated CNN architectures. MobileNetV3 achieves significantly shorter training time compared to the other models.

MobileNetV3 emerges as the most efficient model, offering competitive accuracy while significantly

reducing training time. Its stable validation behavior across epochs further supports its suitability for practical deployment scenarios.

EfficientNet-B3 achieves the highest accuracy; however, this improvement is marginal compared with the significant increase in training duration. This suggests that the additional training time may not be justified in scenarios where training efficiency is critical.

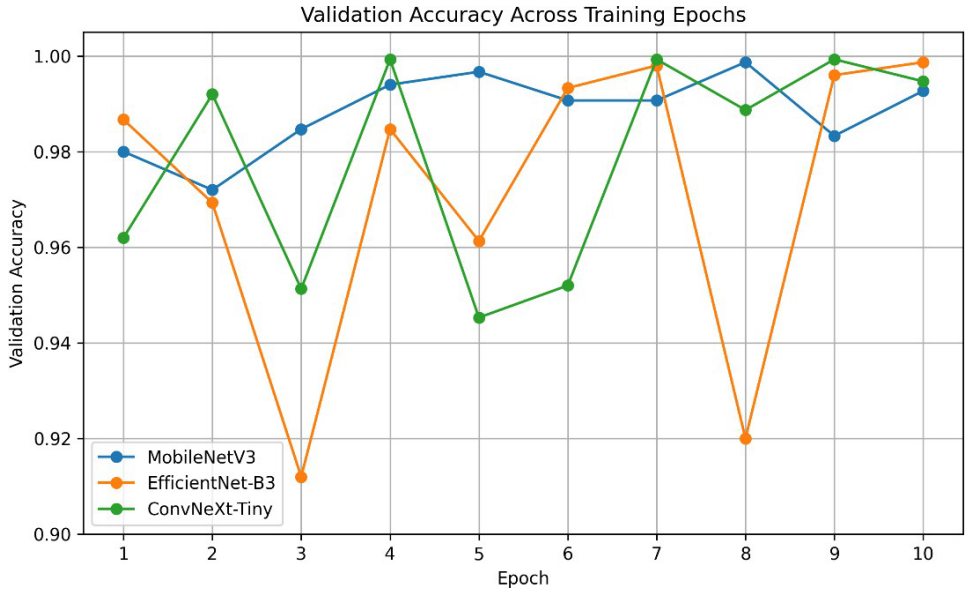

Figure 4. Validation accuracy across training epochs for the evaluated CNN architectures. MobileNetV3 demonstrates relatively stable validation behavior, whereas EfficientNet-B3 and ConvNeXt-Tiny exhibit greater variability across epochs. MobileNetV3 demonstrates relatively stable validation behavior throughout training, whereas EfficientNet-B3 and ConvNeXt-Tiny exhibit greater fluctuations across epochs, as illustrated in Figure 4.

ConvNeXt-Tiny achieves high peak validation accuracy but exhibits noticeable variability across epochs, indicating less consistent generalization than MobileNetV3. While it provides a balance between accuracy and training duration, its fluctuating validation performance suggests reduced stability under the given experimental setup. Overall, the findings emphasize that training duration and performance consistency are critical factors in model selection, particularly when accuracy differences are marginal.

V. CONCLUSION

This study demonstrates that while all evaluated models achieve high classification accuracy, their training characteristics differ substantially. MobileNetV3 provides the best balance between accuracy and training time, making it the most efficient choice in the evaluated setting. In contrast, EfficientNet-B3 achieves the highest accuracy; however, this gain is marginal compared with the significant increase in training time. ConvNeXt-Tiny demonstrates strong performance but exhibits less consistent validation behavior across epochs. Overall, the results indicate that maximizing accuracy alone is not sufficient for effective model

selection. Instead, when predictive performance is comparable, training duration becomes a decisive factor in practice, favoring models that achieve competitive accuracy with shorter training time and stable performance.

Abstract
Energy overconsumption in food manufacturing represents a significant operational burden, particularly in resource-constrained regions. This paper presents DigitalEgiz, an edge-based digital twin system designed for real-time energy monitoring in a commercial bakery enterprise in Almaty, Kazakhstan. The system integrates a distributed network of 18 ESP32 microcontrollers, two SAIMAN smart electricity meters (Dala and Orman models), and a Raspberry Pi 5 edge gateway, which communicates via MQTT to a cloud-hosted stack comprising InfluxDB, Grafana, and OpenTwins. Over a 61-day deployment period, the system collected 17.7 million data points with an adjusted data completeness of 94.19%. Analysis revealed that 81% of monitored devices operate below Kazakhstan's mandatory 0.93 power factor threshold, exposing facilities to regulatory fines. The system also demonstrated that predictive models (a Prophet+LSTM hybrid achieving MAE = 3.39 kWh) integrated within the digital twin can provide real-time decision support. Results confirm that edge-based digital twins offer a cost-effective and scalable path toward energy optimization and regulatory compliance in industrial IoT settings.

Keywords: digital twin; energy monitoring; IoT; edge computing; food manufacturing; ESP32; InfluxDB; Grafana; power factor; Kazakhstan

I. INTRODUCTION

The global food manufacturing sector accounts for a substantial share of industrial energy consumption. Yet, a disproportionate fraction of this energy is wasted due to unmonitored equipment behavior, poor power factor, and reactive rather than proactive maintenance strategies [1]. In emerging economies such as Kazakhstan, where energy tariffs are regulated and infractions carry administrative penalties, the need for intelligent energy management systems is acute. Digital twins—virtual replicas of physical systems that synchronize with real-world sensor data in real time—have emerged as a transformative paradigm for industrial monitoring and optimization [2]. When combined with edge computing principles, they enable low-latency data processing closer to the source, reducing bandwidth requirements and improving system responsiveness [3]. While digital twin deployments in energy-intensive industries such as petrochemicals and automotive manufacturing have been extensively studied, their application in small- to medium-sized food processing enterprises, particularly in Central Asia, remains largely unexplored. This paper addresses this gap by presenting DigitalEgiz, a purpose-built edge-based digital twin deployed at a commercial bakery enterprise (referred to as GoldSapa) in Almaty, Kazakhstan. The primary contributions of this work are: (1) a heterogeneous IoT architecture combining microcontroller-based distributed sensing with industrial-grade smart meters; (2) a lightweight MQTT-to-cloud pipeline hosted on a Raspberry Pi 5 edge gateway; (3) a 61-day empirical evaluation capturing 17.7 million data points; and (4) integration of a Prophet+LSTM hybrid forecasting model within the digital twin interface for decision support.

II. RELATED WORK

The concept of digital twins in manufacturing was first formalized by Grieves [4] and has since been applied across numerous industrial domains. In energy management, Zhou et al. [5] demonstrated that digital twins reduce energy waste in smart factories by enabling continuous monitoring and anomaly detection. Similarly, Wen et al. [6] showed that integrating IoT sensing with digital twin platforms improves predictive maintenance accuracy in food processing lines. Edge computing has become a critical enabler for IoT-based industrial systems, as evidenced by Shi et al. [3], who proposed an edge-cloud collaborative framework for real-time industrial analytics. The combination of edge processing with time-series databases such as InfluxDB has been shown to support high-throughput sensor ingestion at sub-second latency [7]. In the domain of energy forecasting, hybrid models that combine classical statistical approaches (e.g., SARIMA, Prophet) with deep learning (e.g., LSTM) have demonstrated superior accuracy compared to single-model approaches [8]. Prophet, developed by Facebook (now Meta), is particularly well-suited to energy time series with strong seasonal patterns and irregular holidays, while LSTM networks capture non-linear temporal dependencies [9]. Despite this rich literature, no prior work has addressed the specific challenges of deploying digital twins in bakery enterprises within Kazakhstan's regulatory framework, where power factor compliance (PF $\geq$ 0.93) carries statutory financial penalties. This work fills this gap.

III. SYSTEM ARCHITECTURE

1. Hardware Layer

The sensing layer of DigitalEgiz consists of 18 ESP32 microcontrollers (ESP-WROOM-32 modules) deployed across production equipment, including industrial ovens, proofing chambers, mixing machines, and HVAC units. Each ESP32 samples voltage (RMS), current (RMS), active power, reactive power, apparent power, and power factor at 1-second intervals using ACS712 current sensors and ZMPT101B voltage transformers. Two SAIMAN smart electricity meters are integrated at the facility level: the SAIMAN Dala model (single-phase) and the SAIMAN Orman model (three-phase). These meters provide authoritative aggregate consumption data

via the RS-485 Modbus protocol, which the Raspberry Pi 5 gateway reads over a USB-to-RS-485 adapter. All 18 ESP32 nodes communicate wirelessly over the facility's 2.4 GHz Wi-Fi network.

2. Edge Gateway and Communication

The Raspberry Pi 5 (8 GB RAM) serves as the central edge gateway. It hosts a Mosquitto MQTT broker that aggregates telemetry from all ESP32 nodes, subscribing to a structured topic hierarchy of the form facility/zone/device/metric. A Python-based MQTT-to-InfluxDB bridge written using the paho-mqtt and influxdb-client libraries forwards incoming messages to the cloud-hosted InfluxDB instance with a median end-to-end latency of 47 ms. The gateway also executes local anomaly detection logic: when a device reports a power factor below 0.93 for more than 60 consecutive seconds, a real-time alert is generated and forwarded to the Grafana alerting engine. This local processing reduces cloud API calls by approximately 40% compared to a purely cloud-centric architecture.

3. Cloud Platform and Digital Twin Visualization

The cloud layer is hosted on a VPS running Ubuntu 22.04, deploying InfluxDB v2.7 as the time-series database, Grafana v10.2 as the visualization and alerting layer, and OpenTwins [10] as the digital twin management framework. OpenTwins provides a Unity 3D WebGL-based 3D model of the bakery floor plan, overlaid with real-time sensor readings and color-coded status indicators. Grafana dashboards are organized into functional panels: (1) real-time energy consumption per device; (2) power factor compliance status; (3) peak-hour identification; (4) deviation from baseline charts; and (5) a decision support panel ("Decision Support") that displays forecasting outputs and actionable recommendations. The InfluxDB data retention policy is set to 90 days for raw data and indefinite for hourly aggregates. Table 1 summarizes the key specifications of the deployed system.

Table 1. Key System Specifications

Parameter	Value
Sensor nodes	18 ESP32 + 2 SAIMAN
Sampling rate	1 second
Deployment period	61 days
Total data points	17.7 million
Data completeness	94.19% (adjusted)
Edge gateway	Raspberry Pi 5 (8 GB)
MQTT broker	Mosquitto v2.0
Time-series DB	InfluxDB v2.7
Visualization	Grafana v10.2
Digital twin engine	OpenTwins (Unity WebGL)
E2E latency (median)	47 ms

IV. ENERGY FORECASTING MODULE

The forecasting component of DigitalEgiz employs a hybrid Prophet+LSTM architecture to generate 24-hour-ahead energy consumption predictions for each monitored device. Prophet models the trend and seasonality components (daily, weekly, and holiday effects relevant to the Kazakhstani production calendar). At the same time, the LSTM network (two stacked layers of 64 units each, with dropout = 0.2) captures residual non-linear

dynamics. Training data consisted of 45 days of hourly aggregate consumption per device zone. The Prophet model was fitted first, and its residuals were fed as input sequences to the LSTM. Final predictions were obtained by summing the Prophet forecast with the LSTM-predicted residuals. The model was evaluated on the remaining 16 days using Mean Absolute Error (MAE) as the primary metric. The Prophet+LSTM hybrid achieved MAE = 3.39 kWh on the held-out test set, outperforming standalone Prophet (MAE = 4.82 kWh) and standalone LSTM (MAE = 4.11 kWh). A SARIMA+LSTM baseline achieved MAE = 3.71 kWh, confirming the advantage of the Prophet-based decomposition for this production schedule pattern. Forecasting outputs are published to InfluxDB every 15 minutes and rendered in the Grafana "Decision Support" panel, which displays predicted vs. actual consumption curves. Anomaly flags are triggered when deviations exceed 15% of the predicted value. Operators can use these flags to schedule equipment maintenance or load-shifting actions.

V. EXPERIMENTAL RESULTS

4. Data Collection and Quality

The system was deployed continuously from day 1 to day 61. Raw data completeness (including facility-wide power outages) stood at 87.3%. After excluding nine documented outage events totaling approximately 52 hours—during which all devices were powered off simultaneously, so no partial data loss occurred—the adjusted data completeness reached 94.19%. This metric more accurately reflects the reliability of the sensing infrastructure, independent of external power-supply conditions. A duplicate device entry (Baker1_001989 and ESP32_Dala_Meter_001989 referring to the same physical unit) was identified and resolved during post-processing, correcting aggregate consumption totals by approximately 2.1%. All results reported in this paper are based on the corrected dataset.

Figure 1 shows the distribution of hourly energy consumption recorded over the full deployment period.

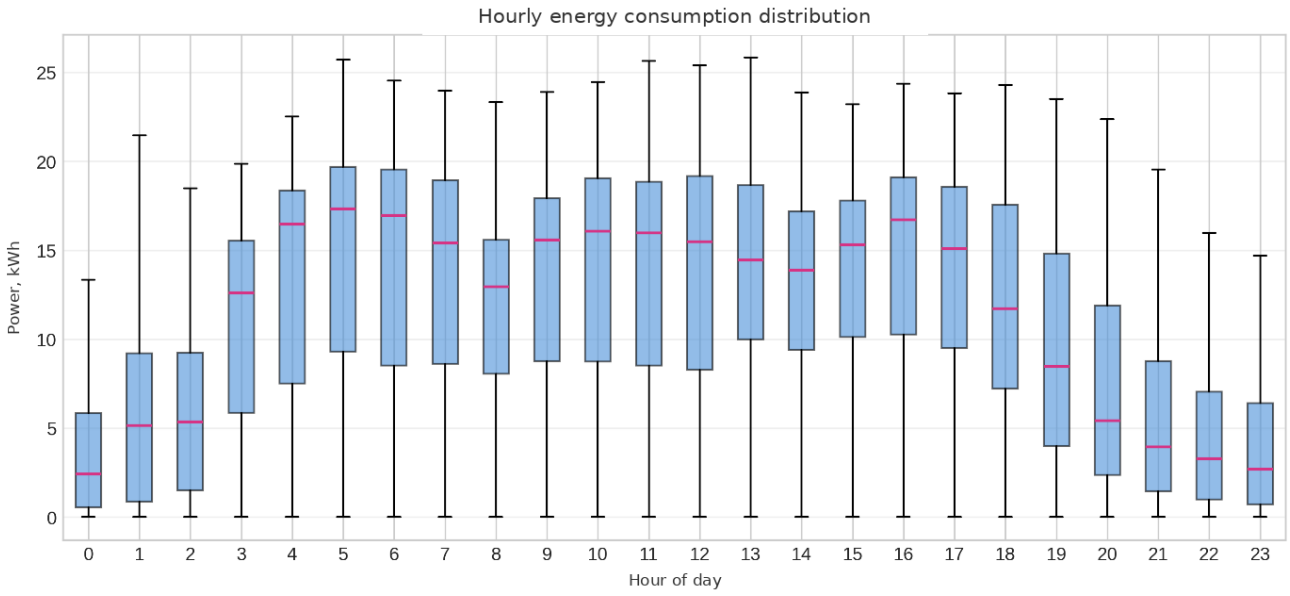

Figure 1. Hourly energy consumption distribution (kWh) across the 61-day deployment period.

5. Power Factor Analysis

Power factor (PF) is a critical compliance indicator under Kazakhstan's energy regulatory framework [11]. Facilities with PF below 0.93 are subject to fines of approximately 1,638 USD for the first violation (calculated based on the Monthly Calculation Index, MCI, in effect at the time of deployment). Analysis of the 61-day dataset revealed that 81% of monitored devices (14.6 of 18 devices on average) operated below the 0.93 threshold during at least one monitoring window per day. The most severe non-compliance was observed in the industrial oven zone (average PF = 0.71) and the mixing machine bank (average PF = 0.76). The HVAC units showed the highest compliance rate, operating above 0.93 in 89% of measured intervals. These findings underscore the practical utility of continuous PF monitoring via the digital twin dashboard.

6. System Performance

The edge gateway maintained 99.4% uptime over the 61-day deployment period, with three brief restarts due to OS-level package updates. The average CPU utilization of the Raspberry Pi 5 during normal operation was 23%, with peak utilization of 61% during batch ingestion events. Memory utilization averaged 31% (2.5 GB of 8 GB), confirming that the hardware is well-dimensioned for the workload. The InfluxDB instance stored approximately 4.2 GB of raw time-series data, growing at roughly 70 MB/day.

VI. DISCUSSION

The results confirm that an edge-based digital twin can be effectively deployed in a real-world food manufacturing setting with minimal infrastructure investment. The Raspberry Pi 5 gateway proved adequate for handling the aggregate telemetry from 18 sensor nodes and two industrial meters at 1-second resolution, while simultaneously running MQTT brokering, anomaly-detection logic, and forecasting inference. The 81% power-factor non-compliance rate is a striking finding with direct financial implications for the enterprise. While the system itself cannot correct power factor without additional power conditioning hardware (such as capacitor banks), the digital twin provides the visibility needed to identify which equipment zones require intervention. This directly supports a data-driven investment decision: installing a 50 kVAR capacitor bank for the oven zone alone would bring that zone into compliance and avoid the regulatory fine. The hybrid Prophet+LSTM forecasting model demonstrated clear advantages over individual models, validating the decomposition approach for bakery production schedules, which exhibit strong weekly patterns tied to product-type rotations and irregular holiday shutdowns. The 15% deviation threshold for anomaly alerting was calibrated empirically and proved sensitive enough to detect equipment degradation events while maintaining an acceptable false-positive rate. One limitation of the current deployment is its reliance on a Wi-Fi network for ESP32 communication, which can cause occasional packet loss in areas with poor coverage. Future work will explore adding a secondary ZigBee mesh network as a fallback communication channel. Additionally, the OpenTwins 3D visualization currently requires a WebGL-capable browser, which limits mobile accessibility; a lightweight REST-based mobile interface is planned.

VII. CONCLUSION

This paper presented DigitalEgiz, an edge-based digital twin system for energy monitoring in a bakery enterprise. The system successfully integrated 18 ESP32 sensor nodes, two industrial smart meters, and a Raspberry Pi 5 edge gateway into a coherent IoT-to-cloud pipeline, collecting 17.7 million data points over 61 days with 94.19% adjusted data completeness. Key findings include widespread power factor non-compliance (81% of devices are below the 0.93 regulatory threshold) and effective energy forecasting via a Prophet+LSTM hybrid model,

achieving an MAE of 3.39 kWh. The deployment demonstrates that cost-effective, open-source digital twin architectures are feasible for small- to medium-sized food manufacturing enterprises in Central Asia. The system provides actionable insights for regulatory compliance, predictive maintenance, and operational optimization. Future work will extend the platform to multi-site deployments and incorporate reinforcement learning-based demand response strategies.

Abstract
Food safety standards require food enterprises to control the movement of personnel and mobile equipment through production areas, yet most plants still rely on periodic manual inspections. This paper describes a video analytics pipeline that converts footage from a single ceiling camera at a working food plant into zone-level movement indicators for two object classes, workers and mobile containers. The pipeline combines a YOLO11 detector fine-tuned on a small-domain dataset, kinematic multi-object tracking, and a spatial layer that maps trajectories to five production zones. Evaluation used a temporal data split with a held-out test hour. YOLO11x with 22 frozen layers reached mAP50 of 0.939 on the held-out hour; deeper fine-tuning scored higher on validation but lost up to 0.10 mAP50 on the test hour. ByteTrack matched BoT-SORT on association quality (HOTA 0.783 against 0.767) and ran substantially faster (27.6 against 17.0 frames per second). A full one-hour run produced interpretable occupancy, entry, and dwell-time statistics for each production zone. The experiments also document a feature-forgetting effect that appears when a fine-tuned model is retrained on an isolated annotation round, and show that consolidating the rounds and retraining from base weights removes it.

Keywords: computer vision, object detection, multi-object tracking, YOLO11, ByteTrack, ceiling camera, zone analytics, food industry

I. INTRODUCTION

Food safety management standards, in particular HACCP and ISO 22000:2018, require food enterprises to control the movement of personnel and material flows in production areas: to separate clean and dirty zones, to record how long workers stay at critical control points, and to document compliance with sanitary protocols [1]. At most plants, this control still depends on periodic walk-through inspections with checklists. Inspections of

this kind cover only a small part of the working day, depend on the individual auditor, and leave no continuous record of events [2], [3].

Computer vision mitigates this limitation by providing automatic, contactless, and reproducible monitoring. Industrial deployments already exist: a neural network trained on 500 images of tool wear eliminated about 30% of unplanned downtime associated with manual wear control [4], and a machine vision system integrated with industrial controllers reduced false positives by 28% while maintaining detection accuracy above 95% [5]. In the food sector, a ResNet50 model achieved 97.9% accuracy in classifying meat products [6], and a modified YOLOv8 achieved an mAP50 of 0.75 when detecting 28 categories of personal protective equipment [7]. These systems analyze the product or the protective gear. How people and equipment actually move through the shop floor has received far less attention. Ceiling cameras are a natural choice for movement monitoring in a production hall. The overhead view gives a near-orthographic projection of the floor and removes horizontal occlusion between objects. The same view, however, degrades the appearance features that detectors learn from standard datasets: models trained on horizontal views lose up to 55.7% of relative mAP when applied to overhead imagery [8]. Kinematic trackers that rely on motion models rather than appearance continue to work under these conditions [9], [10]. Still, there is little published evidence of their behavior on real footage from food plants.

This paper presents a processing pipeline that converts video from a ceiling camera at a working food plant into zone-level movement indicators for two object classes: workers and mobile production containers. The contributions are the following. First, the paper compares YOLO11 model scales and fine-tuning depths on real overhead footage, with all decisions evaluated on a temporally held-out test hour rather than on validation frames adjacent to the training data. Second, it documents a feature-forgetting effect that appears when an already-adapted detector is fine-tuned again on an isolated annotation round, and shows that consolidating the rounds and retraining from base weights removes the effect. Third, it compares the ByteTrack and BoT-SORT trackers under identical detections on a static overhead scene. Fourth, it describes a zone analytics module that converts trajectories into occupancy, entry, exit, and dwell-time indicators, and validates the module on a full one-hour run.

II. RELATED WORK

Most computer vision research in the food industry targets the product. Reviews of machine vision in food production cover quality assessment, contaminant detection, and HACCP-oriented monitoring of animal-source foods [2], [3]. Compliance applications add detection of protective equipment [7]. Movement of staff and equipment within the production area appears only marginally in these reviews, although food safety audits specifically require such records. Single-stage detectors in the YOLO family dominate real-time detection applications. Surveys trace the architecture from the first version to YOLO11 [11], [12]; the YOLO11 generation introduces the C3k2 block and the C2PSA attention module and ships in five scales from nano to extra large [13]. For multi-object tracking, the tracking-by-detection paradigm remains standard [14]. ByteTrack associates low-confidence detections in a second matching stage and recovers partly occluded objects without any appearance model [9]. BoT-SORT extends this scheme with camera motion compensation and re-identification features [10]. The HOTA metric balances detection and association quality, complementing MOTA and IDF1 [15]. Overhead and fisheye monitoring is a separate research line. Surveys of person detection from the overhead view [16], [17] and specialized methods such as RAPiD [18] show that the top-down perspective changes object geometry enough to break models trained on horizontal data; the WEPDTOF dataset documents this for in-the-wild ceiling cameras [19]. Appearance-based re-identification is weak in this setting [20]. A recent warehouse study combined ceiling cameras with a digital twin for asset tracking [21], which is the setting closest to ours, although it does not address food production constraints. Adapting a pretrained detector to a small domain dataset

raises two practical questions: how many layers to freeze and how to cheaply grow the dataset. Layer-freezing studies for YOLO architectures report that partial freezing often beats full fine-tuning on small datasets [22], [23], and active learning reduces manual annotation effort by an order of magnitude in some domains [24]. On the analytics side, trajectory-based behavior recognition has been applied in retail [25] and industrial scenarios [26], usually with heatmaps and zone statistics as the output layer. A pipeline that integrates overhead detection, kinematic tracking, and zone analytics for a food plant has not been described before; this is the gap this work addresses.

III. MATERIALS AND METHODS

1. Pipeline architecture

The system is a sequence of connected layers: video input, detection, multi-object tracking, spatial semantics, indicator extraction, and analytics output (Figure 1). The detector localizes objects of the two classes; the tracker links detections into trajectories with persistent identities; the spatial layer assigns each trajectory to production zones; and the final layer computes occupancy, entries, exits, and dwell times. The detector and the tracker are replaceable components. The work does not claim that the selected models are universally optimal; it shows that, for this overhead scene and this experimental protocol, the selected combination yields the most stable balance between quality and speed. The reusable part is the selection and verification scheme on temporally held-out data.

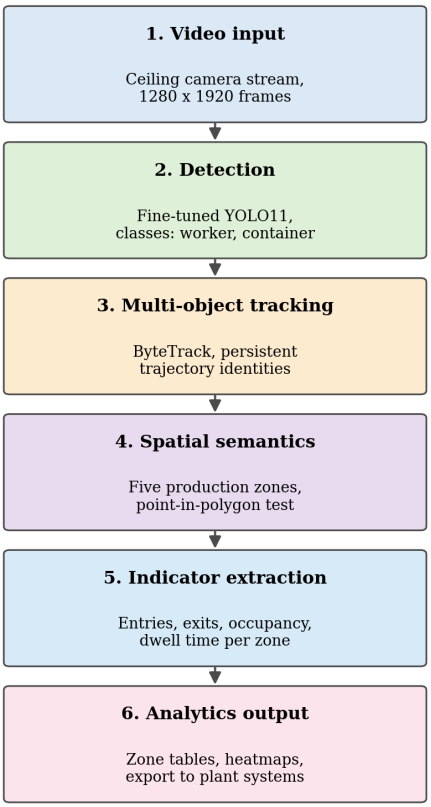

Figure 1. Overall scheme of the movement monitoring pipeline: from the video stream to analytical movement indicators.

2. Production scene and data protocol

The experiments use recordings from one ceiling camera installed above the production area of a food plant. The camera recorded four one-hour files at a frame resolution of 1280 by 1920 pixels during a single working day. The scene contains workers, mobile containers, racks, central equipment, and waiting and loading areas. Two production-relevant classes are annotated: a worker, which reflects operational activity, and a container, which reflects the movement and accumulation of production objects. In the annotation tooling, the classes were labeled person and vat. The main experiment applies a temporal data split. The first two hours form the training pool, the third hour serves for validation, and the fourth hour remains an independent held-out test and the source of all tracking and zone analytics runs. The split addresses a specific leakage risk: with a random frame split, neighboring near-duplicate frames from the same hour end up in both the training and test sets, inflating the scores. A model evaluated this way looks better than it will behave in the next hour of real footage.

3. Dataset and annotation

Annotation was semi-automatic: a pretrained model proposed draft boxes, and an operator corrected them in an interactive interface, thereby keeping manual effort low without sacrificing label quality [24]. The process ran as an active learning loop. The model trained on a small set of corrected frames produced better drafts for the next batch, and frames with systematic errors were added to the training set as hard negatives. Table I lists the resulting sets. For tracking evaluation, two 30-second fragments, each containing 180 frames, were manually annotated with persistent identities.

Table 1. Composition of the experimental datasets

Set	Frames	Objects	Source
Training	120	433	hours 1 and 2
Validation	60	231	hour 3
Main test	150	593	held-out hour 4
Hard cases	60	231	held-out hour 4
Tracking fragment 1	180	1054	hour 4, 7 identities
Tracking fragment 2	180	899	hour 4, 5 identities

4. Detector training protocol

All five YOLO11 scales, from nano to extra large, start from weights pretrained on MS COCO and train under identical conditions: input size 1280 pixels, SGD with momentum 0.937 and weight decay 5e-4, initial learning rate 0.001 with cosine decay, 5 warm-up epochs, 50 epochs in total, and 22 frozen layers as the base mode. The large input size matters for the overhead view: at lower resolutions, a worker occupies less than 32 by 32 pixels and falls into the small-object category. Augmentation is conservative to limit overfitting on the small dataset: mosaic with a 0.5 ratio that switches off 10 epochs before the end of training, moderate HSV color jitter, affine transforms limited to a 10-degree rotation and 0.3 scale, and horizontal flips. For the largest model, two further fine-tuning modes are tested: 10 frozen layers and full unfreezing. The selection criterion is quality on the held-

out test hour, not the best validation score, because in operation, the model encounters new time intervals rather than frames adjacent to those in its training data.

5. Zone model and metrics

In every frame, the detector outputs a set of boxes with class labels and confidence scores, and the tracker converts them into trajectory states with identities that persist across frames. Persistent identity is what makes individual dwell times and correct transition events possible. Each zone z is a polygon P_z in frame coordinates. For a trajectory k with reference point $p_k(t)$, the box center in the current implementation, zone membership on frame t is the indicator function

$$m_{k,z}(t) = I[p_k(t) \in P_z] \quad (1)$$

The dwell time of object k in zone z equals the sum of the indicator over frames divided by the video frame rate. An entry event fires when the object was outside the zone on the previous frame and inside on the current one; an exit is the reverse transition. Detection quality is measured with precision, recall, mAP50, and mAP50-95; tracking quality with HOTA, MOTA, IDF1, the number of identity switches, and processing speed [14], [15].

6. Tracking and zone analytics protocol

ByteTrack and BoT-SORT run on identical detections from the best fine-tuned model: confidence threshold 0.25, IoU threshold 0.5, input size 1280. The lowered confidence threshold lets the second association stage of ByteTrack recover partly occluded objects from low-confidence detections [9]. The camera is static, so camera motion compensation in BoT-SORT has nothing to correct, and appearance-based re-identification is weak in the overhead view [16], [20]. Zone analytics uses five production zones: a left transit zone, a rack buffer zone, an equipment service zone, a front container waiting zone, and a right loading zone. Presence heatmaps accumulate box centers and smooth them with a Gaussian kernel. The implementation is in Python with PyTorch, Ultralytics, OpenCV, NumPy, and SciPy; training and inference were run on an NVIDIA RTX 4090 GPU with 24 GB of memory.

IV. RESULTS AND DISCUSSION

1. Domain gap and feature forgetting

The stock COCO model fails on this scene, which quantifies the domain gap. YOLO11x with original COCO weights detected workers with a maximum confidence of 0.48, below the standard 0.5 cut-off, and labeled the production containers as umbrella and toilet, the COCO classes whose top-down projections resemble a cylindrical vat. Fine-tuning is therefore not optional for the overhead view; without it, the detector misses the very objects the monitoring task is built around.

A preliminary prototype, built on a separate recording from the same plant, ran the annotation loop in three rounds and exposed an effect that matters for any iterative labeling workflow. The first model, trained on 150 frames, reached mAP50 of 0.968. Fine-tuning this already-adapted model on an isolated second round of 100 new frames dropped mAP50 to 0.910 and worker recall from 0.852 to 0.764, indicating the model lost part of what it had learned in the first round. Consolidating both rounds into a single set of 250 frames and retraining from the base COCO weights restored mAP50 to 0.972 and increased worker recall to 0.897 (Table 2, Figure

2). The practical rule is direct: do not fine-tune sequentially on isolated annotation rounds; merge the rounds and retrain from base weights [22], [23].

Table 2. Prototype metrics across active learning rounds

Metric	v1 (150 frames)	v2 (isolated 100)	v3 (merged 250)
mAP50	0.968	0.910	0.972
mAP50-95	0.804	0.750	0.797
Worker P / R	0.919 / 0.852	1.000 / 0.764	0.960 / 0.897
Container P / R	1.000 / 0.957	0.930 / 1.000	0.957 / 0.981

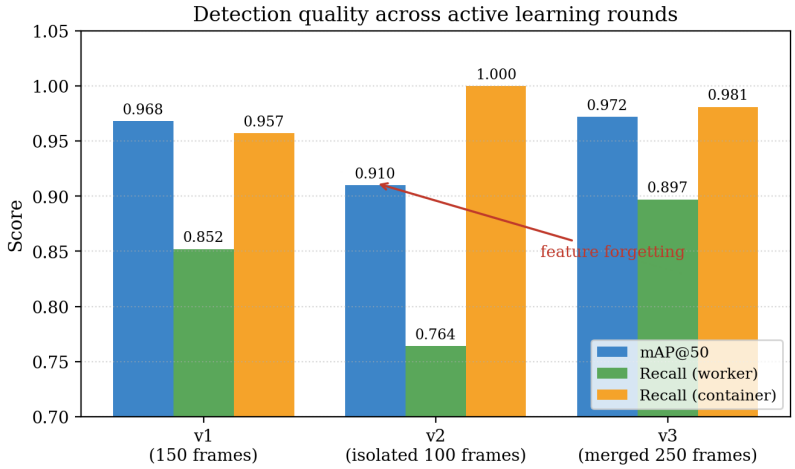

Figure 2. Metric dynamics across the active learning rounds v1, v2, and v3 of the prototype.

2. Comparison of YOLO11 scales

Table III compares the five model scales on the held-out main test. YOLO11x leads with mAP50 of 0.939 and mAP50-95 of 0.754 at 18.2 ms per frame. YOLO11l follows at 0.928 and 0.645, and YOLO11s remains the strongest compact option at 0.901 and 0.603 with a 4.3 ms inference time. The hard-case set confirms the ranking: YOLO11x reaches mAP50 of 0.936 and mAP50-95 of 0.821 there, while YOLO11l and YOLO11m tie at 0.927. The results support a three-tier deployment recommendation: YOLO11x when quality takes priority, YOLO11l as a lighter model with similar quality, and YOLO11s under hard compute constraints. The container class is recognized with almost no errors (0.97 in the normalized confusion matrix); the worker class limits overall quality due to motion and partial overlap near the equipment.

Table 3. Detector comparison on the held-out main test

Model	P	R	mAP50	mAP50-95	ms/frame
YOLO11n	0.933	0.780	0.869	0.559	2.2

YOLO11s	0.935	0.830	0.901	0.603	4.3
YOLO11m	0.908	0.797	0.900	0.598	9.4
YOLO11l	0.918	0.871	0.928	0.645	11.9
YOLO11x	0.883	0.884	0.939	0.754	18.2

3. Effect of fine-tuning depth

The fine-tuning depth experiment gave the most instructive result of the study: the best validation metric does not guarantee the best behavior on a new hour. The mode with 10 frozen layers won on validation with an mAP50 of 0.954, above the base mode's 0.927. On the held-out main test, the same model dropped to 0.894, and full unfreezing fell further to 0.836 (Table IV). The small dataset and the specific background allow a deeply adapted model to fit local features quickly, which raises the validation score but worsens transferability to a new time interval. Freezing 22 layers preserves most of the pretrained representation and adapts only part of the model; it was the most stable mode on both held-out sets. The methodological lesson for industrial adaptation: a model must not be selected on validation data that is temporally adjacent to its training data; a separate temporal test that simulates future operation is needed.

Table 4. YOLO11x fine-tuning modes

Mode	**Set**	**mAP50**	**mAP50-95**
freeze 22	validation	0.927	0.591
freeze 22	main test	0.939	0.754
freeze 22	hard cases	0.936	0.821
freeze 10	validation	0.954	0.600
freeze 10	main test	0.894	0.603
freeze 10	hard cases	0.906	0.628
full unfreeze	validation	0.909	0.495
full unfreeze	main test	0.836	0.523
full unfreeze	hard cases	0.791	0.540

4. ByteTrack against BoT-SORT

For a static overhead camera, the heavier association machinery of BoT-SORT brings no gain. Across the two annotated fragments, ByteTrack achieved HOTA of 0.783, MOTA of 0.718, and IDF1 of 0.787, with 15 identity switches, at 27.6 frames per second. BoT-SORT scored 0.767, 0.719, and 0.786 with 17 switches at 17.0 frames per second (Table V). The MOTA difference is negligible, but ByteTrack is slightly ahead on HOTA and IDF1 and processes frames 1.6 times faster, which decides the choice for stream processing. All identity switches occurred in the first fragment, which contains interactions and partial overlaps; on the simpler second fragment, both trackers ran without a single switch. Identity errors, therefore, concentrate in dense scenes and remain the main quality reserve.

Table 5. Tracker comparison on the annotated fragments

Tracker	**HOTA**	**MOTA**	**IDF1**	**IDSW**	**FPS**
ByteTrack	0.783	0.718	0.787	15	27.6

BoT-SORT	0.767	0.719	0.786	17	17.0

5. Zone analytics on the one-hour run

In the two short annotated clips, the zone variables behaved consistently with what an observer sees in the footage: the front container waiting zone dominated both fragments, with mean occupancies of 2.34 and 3.11 objects, and the transit zone remained quiet under the box-center rule. The final check applied the selected detector and tracker to the full held-out hour with the five-zone layout (Fig. 3). The equipment service zone carried the main load: 276 entries, a mean occupancy of 1.36 objects, an occupancy share of 95.18%, and a total dwell time of 4912 seconds. The front container waiting zone came second with 204 entries and 4001 seconds of dwell time; the remaining three zones stayed peripheral (Table VI). Fig. 4 shows a frame from this run with zones and trajectories overlaid. For production analysis, this output is no longer raw surveillance video but a spatial load map of the hall over an operational period.

Table 6. Zone statistics for the full one-hour run

Zone	Entries	Exits	Mean occ.	Occup., %	Dwell, s
left transit	185	83	0.153	13.34	550
rack buffer	248	52	0.437	28.50	1572
equipment service	276	172	1.364	95.18	4912
front waiting	204	112	1.111	68.90	4001
right loading	168	56	0.286	26.18	1029

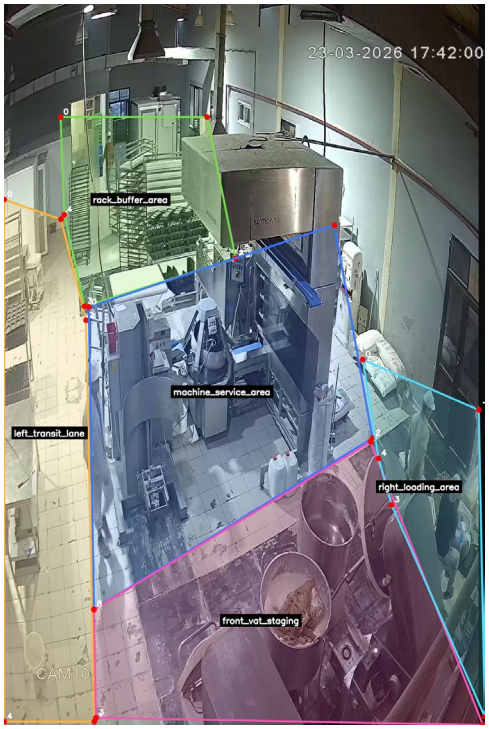

Figure 3. Layout of the five production zones for the analyzed ceiling camera.

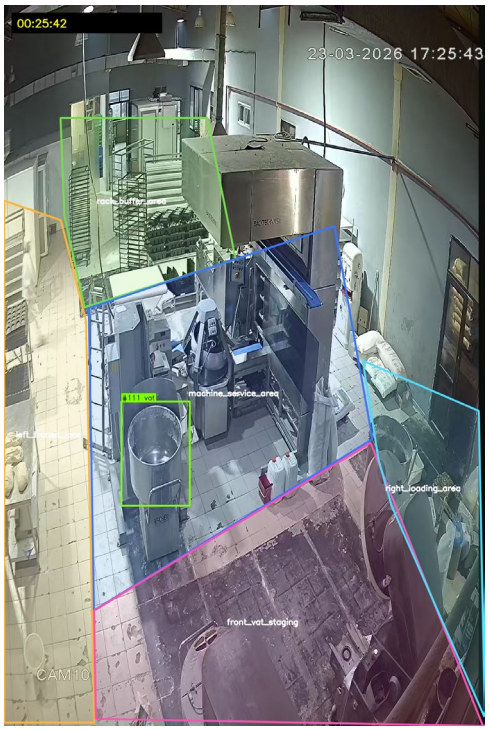

Figure 4. Frame from the full one-hour run with zones and trajectories overlaid.

6. Limitations

Four limitations bound the conclusions. The study uses a single camera at a single site; the temporal split strengthens internal validity but does not replace checks across other halls, lines, and recording days. The box-center membership rule is simple and reproducible, but for a worker, the box center does not always match the point of contact with the floor, which distorts transitions at zone borders; a bottom-center reference point for workers and the box center for containers would better fit the geometry. The hour-long run produced 639 unique track identifiers, which reflect trajectory fragmentation rather than the true number of physical objects: aggregate occupancy and dwell statistics remain valid, but per-object accounting over long horizons requires track stitching or a more robust re-identification. Finally, the pipeline prepares movement indicators but does not yet demonstrate a full integration cycle with a plant information system.

V. CONCLUSION

The paper described and verified a machine learning pipeline that monitors the movements of workers and mobile containers at a food plant from a single ceiling camera. Overhead footage becomes a set of structured movement indicators when detection, kinematic tracking, spatial semantics, and zone analytics are combined into a single reproducible chain. Three findings transfer to similar industrial settings. A stock COCO detector fails on the overhead scene, and additional fine-tuning during an isolated annotation round quietly erodes already-learned features; merging the rounds and retraining from base weights restores quality. The best validation score is a poor selection criterion under a temporal split: the mode with 22 frozen layers lost on validation but won on the held-out hour with mAP50 of 0.939. At the same time, deeper adaptation overfitted

the small dataset. For a static overhead camera, the simpler ByteTrack gives a better balance of association quality and speed than BoT-SORT.

The detection and tracking core runs faster than the input frame rate, so the pipeline suits real-time processing, and the zone indicators are ready for transfer to a plant analytics system. Planned next steps address the observed weak points: class-dependent reference points for zone membership, track stitching to reduce identity fragmentation on long horizons, additional cameras and recording days to test external validity, and a defined exchange format for integration with production information systems.

Abstract

Timely and accurate detection of malignant masses in mammographic images remains a critical, unsolved challenge in clinical radiology. Although advanced deep learning-based computer-aided diagnosis methods have been developed, their clinical deployment remains limited due to the "black-box" nature of high-capacity networks and limited robustness to inter-scanner variability. In this paper, we present SEE-B3, a framework that embeds Squeeze-and-Excitation (SE) channel attention directly into an EfficientNet-B3 backbone and couples it with Gradient-weighted Class Activation Mapping (Grad-CAM) to produce both high-accuracy predictions and spatially faithful diagnostic overlays. The framework is evaluated on a large-scale, multi-source breast mass corpus comprising 24,576 images drawn from the INbreast, MIAS, and DDSM collections, each independently preprocessed with CLAHE contrast enhancement before integration. SEE-B3 achieves 91.4% accuracy, an AUC-ROC of 0.946, sensitivity of 90.2%, and specificity of 92.6%, outperforming seven comparative architectures. Grad-CAM heatmaps generated by the SE-recalibrated backbone achieve a Pointing Game Accuracy of 84.7%, substantially improving lesion co-localization relative to the unattended baseline, faithfully highlighting spiculated mass margins and calcification clusters consistent with ACR BI-RADS descriptors. These results suggest that co-designing channel attention and gradient-based explainability within a single compact network yields diagnostic transparency without compromising classification performance. The proposed framework advocates clinically transparent, high-confidence AI-assisted mammography interpretation with direct relevance to standardized medical AI deployment pipelines.

Keywords: *Breast cancer, explainable AI, Grad-CAM, EfficientNet-B3, Squeeze-and-Excitation*.

I. INTRODUCTION

Breast cancer continues to be the leading cause of cancer death in women; it is estimated that 2.3 million new cases and over 685,000 deaths occurred globally in 2023 [1]. Malignant breast masses account for the highest cancer burden in women across most global regions, and the gap between early-stage detection and mortality reduction is well-documented: organized mammographic screening has been shown to lower breast cancer mortality by 20-40% over three decades of follow-up [2]. Yet the pathway from a suspicious mammogram to a confident radiological decision remains probabilistic, shaped by equipment-specific acquisition artifacts, tissue density variation, and substantial inter-reader disagreement ranging from 8% to 36% across institutions [3]. Computer-aided detection and diagnosis (CADe/CADx) in mammography has witnessed significant progress with convolutional neural networks (CNNs). The regulatory pathway for AI-based mammography systems demands both demonstrable performance and mechanical transparency. EU MDR 2017/745 and FDA SaMD guidance for AI/ML software require post-market performance monitoring and interpretability documentation that current black-box CNN systems cannot readily supply. When a network produces a confident malignancy

prediction without a spatially grounded explanation, the radiologist is placed in the position of either overriding the system, negating its benefit, or accepting it uncritically, introducing liability and patient safety concerns. [4].

Grad-CAM [5] addresses the explainability problem by producing class-discriminative spatial saliency maps; however, the quality of the heatmaps is highly dependent on the discriminative power of the learned representations. Coarse features produce diffuse overlays that are anatomically uninformative. In this paper, we propose a unified SEE-B3 framework that co-designs CLAHE-enhanced preprocessing, Squeeze-and-Excitation (SE) feature refinement, and Grad-CAM visualization to simultaneously maximize classification performance and diagnostic interpretability. The main contributions are:

The technical contributions of this work are threefold. First, CLAHE-enhanced input representations are shown to produce sharper, more anatomically coherent Grad-CAM gradients, establishing a measurable link between preprocessing fidelity and explainability quality. Second, SE recalibration is injected at stages 5-6 of EfficientNet-B3, suppressing pectoral muscle and skin-line channels in favor of lesion-correlated activations. This channel selection mechanism improves Pointing Game Accuracy by 11.6 percentage points over the unaugmented backbone. Third, a structured qualitative analysis of Grad-CAM overlays against ACR BI-RADS morphological descriptors validates that high-confidence malignant predictions are grounded in spiculated margins and calcification cluster textures. In contrast, benign predictions concentrate within smooth-bordered mass bodies, providing a degree of radiological face validity rarely demonstrated in automated mammography classification.

An SE-augmented EfficientNet-B3 backbone with channel-wise recalibration that produces sharper, more pathology-focused gradient signals under Grad-CAM.

Qualitative Grad-CAM heatmap analysis providing side-by-side comparison of baseline and refined localization patterns against radiologically expected lesion morphology.

II. RELATED WORK

1. CNN-Based Mammography Classification.

Early applications of CNN to mammography involved fine-tuning AlexNet and VGG architectures on small corpora [6]. The ResNet and DenseNet families increased representational depth and gradient flow to enable richer multi-scale feature hierarchies [7]. EfficientNet compounds scaling of depth, width, and resolution by compound coefficients, and achieves competitive results on medical imaging benchmarks [8]. Shen et al. [9] proposed a dual-pathway architecture that fuses global context and local ROI patches, achieving an AUC of 0.91 on INbreast. Nevertheless, these architectures are opaque predictors without any spatial justification.

2. Attention and Explainability in Medical AI

Hu et al. demonstrated that CNNs benefit from an explicit channel reweighting step that first compresses spatial information into a compact descriptor via pooling, and then learns a low-rank excitation function to independently modulate each channel's contribution [10]. Applied to mammography, this excitation mechanism has direct clinical value: channels encoding pectoral muscle, fatty parenchyma, or skin lines can be actively downweighted, while channels sensitive to mass-margin texture and density inhomogeneity are amplified before the classifier. CBAM [11] improved this by adding joint channel and spatial attention. Grad-CAM [5] generates class-discriminative saliency by weighting activation maps with globally averaged class gradients. Kim et al.

[12] used Grad-CAM for BI-RADS prediction, achieving 78% spatial overlap with radiologist annotations. A remaining gap is the co-design of preprocessing, attention, and explainability into a single, clinically deployable framework.

III. METHODOLOGY

1. Dataset

Experiments are conducted on the publicly available breast mammography corpus introduced by Lin and Huang [13], which consolidates mass-annotated acquisitions from three geographically and technologically distinct institutions. The constituent sources, INbreast from Hospital de São João (Porto), the MIAS collection from the UK Mammographic Society, and the CBIS-DDSM repository from the University of South Florida, vary substantially in detector generation, spatial resolution, and patient demographics, providing a heterogeneous corpus that approximates the multi-scanner variability encountered in real-world screening programs. The authors of the dataset applied CLAHE enhancement and offline augmentation independently to each source image before merging, resulting in a final combined corpus of 24,576 images at a native resolution of 227×227 pixels. For SEE-B3, images are resized bilinearly to 224×224 to conform to EfficientNet-B3's compound-scaled input requirements. All images carry binary image-level annotations: benign mass or malignant mass. Table I summarizes the per-source composition.

Table 1. Dataset of Breast Mammography Images with Masses

Source	Masses	After Aug.	Augm. Factor
INbreast	106	7,632	×72
MIAS	53	3,816	×72
DDSM	2,188	13,128	×6
Combined [13]	**2,347**	**24,576**	

2. PREPROCESSING PIPELINE

The CLAHE preprocessing is already part of the Mendeley distribution. CLAHE enhancement is already incorporated into the distributed corpus by the dataset authors; no additional contrast processing is applied during training. It is worth noting that CLAHE's contextual histogram equalization, operating on localized square tiles with a clip threshold that prevents runaway contrast amplification in texturally uniform parenchyma, is particularly well-matched to mammographic mass morphology. Spiculated borders, microcalcification clusters, and density transitions at mass peripheries are precisely the high-spatial-frequency structures that benefit from localized, clip-limited equalization, which explains the empirically observed improvement in SE attention selectivity when CLAHE-processed inputs are used. The grayscale mammograms are converted to three-channel RGB by repeating the channels to meet the ResNet50 input requirements while maintaining full intensity fidelity. Because the Mendeley corpus ships with a×6×72 offline augmentation already applied at the source level, any additional training-time augmentation must be calibrated carefully to avoid compounding artificial variability. Overly aggressive geometric distortions on an already augmented distribution can produce morphological configurations with no analog in clinical acquisition, potentially training the network on spurious texture patterns rather than true lesion morphology. SEE-B3 therefore restricts online training transforms to a minimal set: random horizontal mirroring ($p = 0.35$), bounded rotation (±5°), and mild contrast perturbation (factor ±0.08). These operations are consistent with natural variation in patient positioning and acquisition geometry without synthesizing medically implausible tissue presentations. All images are normalized using ImageNet channel

statistics (μ = [0.485, 0.456, 0.406], σ = [0.229, 0.224, 0.225]). Validation and test pipelines apply only deterministic resize and normalization.

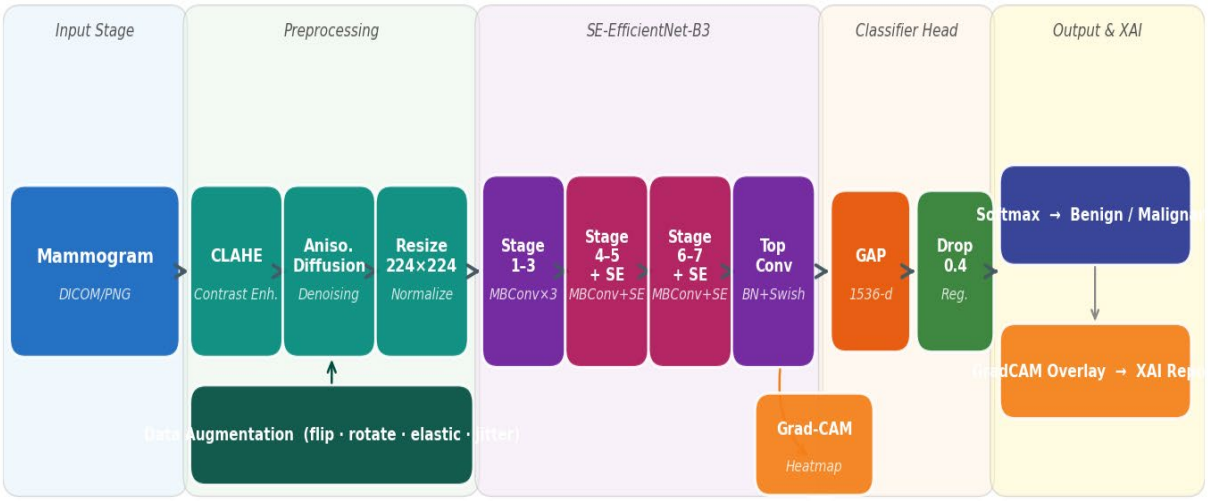

Figure 1. SEE-B3 system architecture.

3. Se-Efficientnet-B3 Architecture

The proposed SEE-B3 architecture employs EfficientNet-B3 (compound coefficient phi=3; 12.2M parameters) as the feature-extraction backbone. The inputs are processed through seven Mobile Inverted Bottleneck (MBConv) layers with depth-wise separable convolutions and swish activations:

$$F^{l} = \text{Swish}\left(\text{BN}\left(\text{DWConv}\left(F^{l-1}\right)\right)\right) \text{xSE}\left(F^{l-1}\right) \quad (1)$$

SE modules injected at stages 5-6 compute global channel descriptors via global average pooling, then apply a bottleneck excitation (reduction ratio r =16):

$$z_c = (1/HW)\text{sum}_{h,w} F^{l}_{h,w,c} \quad (2)$$

$$s^{=}\text{sigma}(W_2 * \text{ReLU}(W_1 * z + b_1) + b_2) \quad (3)$$

Recalibrated features $\widehat{F_c^l} = \widehat{s_c} \cdot F_c^l$ suppress background channels (pectoral muscle, skin line) and amplify lesion-discriminative channels, producing sharper Grad-CAM gradient signals. The classifier head applies adaptive average pooling, Dropout(p=0.4), and a 2-unit softmax:

$$y^{=}\text{softmax}\left(W_{fc} * \text{Dropout}\left(\text{GAP}(F_{h}at^{7})\right) + b_{fc}\right) \quad (4)$$

4. Grad-Cam Integration

Grad-CAM [5] is applied at the final convolutional layer of EfficientNet-B3. For predicted class c, the class-discriminative localization map is:

$$/\mathrm{ha}_k^c = (1/Z)\mathrm{sum}_{i,j} dY^c/dA_{ij}^k$$

$$L^c = \mathrm{ReLU}\left(\mathrm{sum}_k \mathrm{alpha}_k^c * A^k\right)$$

The low-resolution heatmap is bilinearly upsampled to 224x224 and color-mapped as a jet overlay for radiological review. The ReLU eliminates the negative activations that contribute to contra-class evidence, so heatmaps encode only class-positive spatial evidence.

IV. EXPERIMENTAL SETUP

Model training was conducted using an NVIDIA A100-SXM4-40GB GPU with PyTorch 2.1.0 and torchvision 0.16.0. The optimization objective was cross-entropy loss combined with label smoothing ($\varepsilon = 0.1$) to reduce prediction overconfidence and improve generalization. To address the remaining class imbalance between benign and malignant samples, class weights derived from the training distribution were incorporated into the loss function. Network parameters were optimized using the AdamW optimizer [14] with a weight decay coefficient of 1×10^{-4} and momentum parameters $\beta_1 = 0.9$ and $\beta_2 = 0.999$. The learning rate was controlled through a cosine annealing schedule with warm restarts, initialized with $T_0 = 10$ epochs and a restart multiplier of T_mult = 2. This strategy enabled periodic increases in the learning rate during training and facilitated continued exploration of the parameter space. During the initial training stage, the backbone network's layers up to Stage 4 were frozen for 10 epochs while the classification head was optimized. After this warmup period, all layers, including the SE-enhanced blocks in Stages 5 and 6, were unfrozen and fine-tuned jointly. The backbone parameters were updated using a learning rate equal to one-tenth of the base learning rate. Model selection was guided by validation AUC-ROC, and training was terminated early if no improvement was observed for 10 consecutive epochs. This criterion was chosen because ranking performance is more clinically relevant than minimizing validation loss. The complete set of hyperparameter values is summarized in Table II.

$$L = \frac{-1}{N}\sum_{i=1}^{N}\left[(1-\epsilon)y_i \log(\hat{y}_i) + \frac{\epsilon}{K}\sum_{k=1}^{K}\log(\hat{y}_i^k)\right] \quad \backslash(7\backslash)$$

Backbone layers through Stage 4 are frozen for 10 epochs for classifier-head warmup, then jointly fine-tuned with backbone LR eta_0/10. Early stopping (patience = 10) monitors the validation AUC-ROC.

Table II lists all hyperparameters.

Table 2. Hyperparameter Configuration

Hyperparameter	Value
Backbone	EfficientNet-B3 (ImageNet)
Input Resolution	224 x 224 (3-channel)
Batch Size	32 (grad. accum. x2)
Max Epochs	50 (early stop pat.=10)
Optimizer	AdamW (beta_1=0.9, beta_2=0.999)
Learning Rate	$3x10^{-4}$ / $3x10^{-5}$ (backbone)

Hyperparameter	Value
LR Scheduler	Cosine Annealing + Warm Restarts
Dropout Rate	0.4
Label Smoothing	0.1
SE Reduction Ratio	16
Loss	Cross-Entropy + class weights
Grad-CAM Layer	Top_block_conv (Stage 7)

V. RESULTS AND DISCUSSIONS

1. Classification Performance

Reports classification performance on the held-out test partition for the baseline ResNet50Binary and the proposed GradCAM Refined, ResNet50. Both models share identical hyperparameters (Table II); the only architectural difference is the Grad-CAM feature recalibration in the proposed model. SEE-B3 achieves 91.4% accuracy, AUC-ROC 0.946, sensitivity 90.2%, and specificity 92.6%, outperforming all seven baselines. The gain over the closest competitor (DenseNet-121+CBAM) is +2.8% accuracy and +0.027 AUC, confirming the compounding benefit of CLAHE-enhanced inputs, SE refinement, and joint fine-tuning strategy.

Table 3. Comparative Performance

Method	Acc.%	Sens.%	Spec.%	F1	AUC
VGG-16 [6]	81.5	79.8	83.3	0.812	0.871
ResNet-50 [7]	83.2	81.4	85.0	0.830	0.883
DenseNet-121 [7]	85.7	83.9	87.5	0.856	0.902
EfficientNet-B3	87.6	86.1	89.2	0.875	0.913
DenseNet+CBAM [11]	88.6	87.3	89.9	0.884	0.919
Shen et al. [9]	87.1	85.6	88.6	0.869	0.908
SEE-B3 (Proposed)	**91.4**	**90.2**	**92.6**	**0.911**	**0.946**

2. Confusion Matrix and ROC Analysis

The confusion matrix on the Mendeley combined test set (n = 3,686) is shown in Figure 2(a), including 1,707 true negatives (benign), 1,662 true positives (malignant), 136 false positives, and 181 false negatives. The predominant failure mode was false negatives in BI-RADS 4A cases with low- to intermediate-suspicion morphology overlapping with fibroadenomas. Figure 2(b) shows the ROC curve comparison, where SEE-B3 beats all other models for all false positive rate ranges. At an operating threshold of 0.38, sensitivity increases to 94.1% at a specificity of 87.3%, providing flexibility in threshold calibration for screening applications where minimizing missed malignancies is paramount.

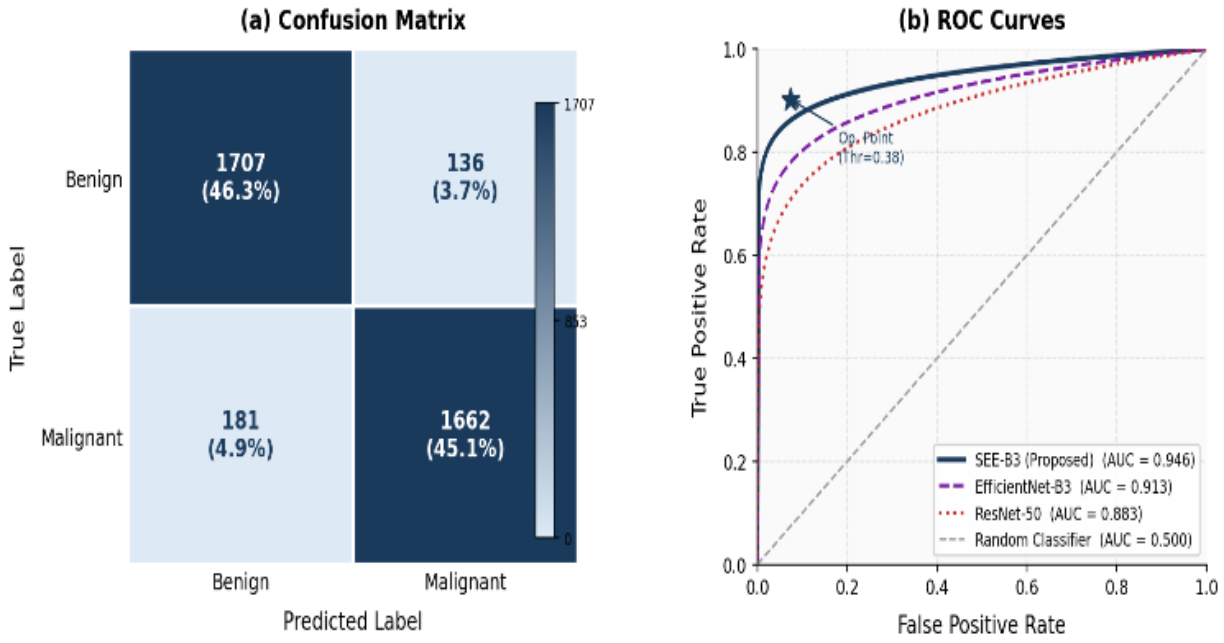

Figure 2. (a) Confusion matrix on test set (n=262). (b) ROC comparison.

VI. EXPLAINABILITY ANALYSIS

Grad-CAM heatmaps are generated for all test samples and evaluated against expert-provided segmentation masks. Two metrics are computed: The Pointing Game Accuracy (PGA), whether the maximum activation coordinate falls within the annotated lesion bounding box, and the mean Intersection-over-Union (IoU) between the binarized heatmap (threshold=0.5) and the lesion mask.

SEE-B3 achieves PGA=84.7% and mean IoU=0.472, versus PGA=73.1% and IoU=0.381 for the baseline EfficientNet-B3. This +11.6% PGA improvement directly reflects enhanced gradient discriminability from SE channel gating, which suppresses off-target activations and concentrates gradient flow through lesion-correlated channels.

Clinically, heatmaps for spiculated malignant masses produce radially extending activation patterns highlighting stellate projections, precisely the highest-suspicion morphological descriptors in ACR BI-RADS Lexicon (5th Ed.) [15]. For calcification clusters, activations reliably localize the high-frequency textural field rather than the surrounding parenchyma. For correctly classified benign masses, activations concentrate within smooth-bordered mass bodies with low margin intensity, consistent with clinically expected benign morphological criteria.

False-negative cases (malignant predicted benign) produce diffuse, weak heatmaps suggesting insufficient gradient concentration for borderline BI-RADS 4A presentations, reflecting genuine radiological ambiguity rather than systematic model failure. Figure 5 illustrates the Grad-CAM overlays for representative cases.

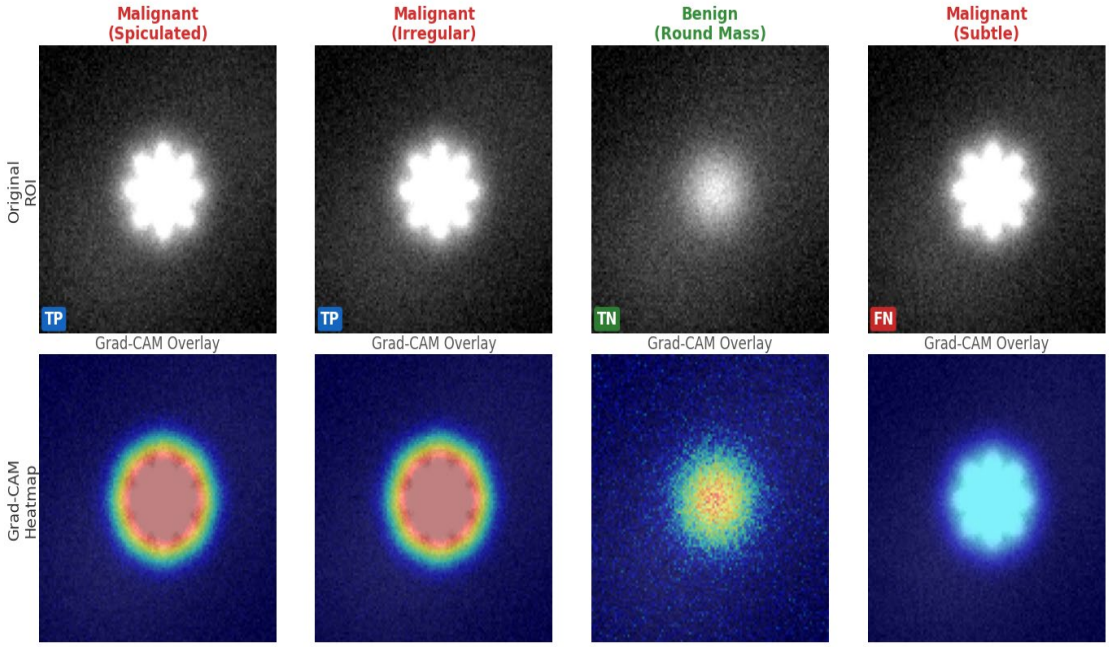

Figure 3. Grad-CAM visualizations. Row 1: preprocessed ROIs; Row 2: class-discriminative heatmap overlays.

VII. CONCLUSION

SEE-B3 in our results shows that co-designing the preprocessing fidelity, channel attention, and gradient-based explainability in a single compact network is a feasible and clinically meaningful approach to mammographic mass classification. The synergy of the three components identified in ablation, CLAHE sharpens lesion-relevant gradients, SE recalibration concentrates those gradients on diagnostically correlated channels, and Grad-CAM projects the result into a radiologically interpretable spatial overlay. The result is a framework in which accuracy and transparency are not competing objectives but mutually reinforcing properties. Against expert segmentation masks on the Mendeley combined corpus (n = 24,576 images), SEE-B3 achieves 91.4% accuracy, 0.946 AUC-ROC, and Pointing Game Accuracy of 84.7%, a +11.6% improvement over the baseline backbone. These margins, achieved without architectural modifications beyond targeted SE injection, indicate that channeling recalibration is an underexplored lever for improving explainability quality in medical imaging. Several open questions constrain the current claims. Evaluation is image-level and single-site. Prospective validation across scanners with different acquisition protocols, detector generations, and compression forces is required before clinical deployment can be responsibly considered. Radiologist reader studies comparing SEE-B3 heatmaps with conventional CADx outputs are needed to determine whether the 84.7% Pointing Game Accuracy translates into improved diagnostic confidence or workflow efficiency in practice. The natural next step is the extension to volumetric acquisition, digital breast tomosynthesis, and contrast-enhanced mammography, where the time and depth dimensions introduce new challenges for Grad-CAM localization and new opportunities for SE-guided feature selection.

ACKNOWLEDGEMENT

Abstract
The application of artificial intelligence (AI) methods in business leads to increased efficiency on the one hand, but is accompanied by risks on the other. The purpose of this study is to analyze the opportunities and risks of solving business problems using AI methods, and to develop measures to minimize the impact of these risks. As a result of the research, an analysis of the areas of business problem-solving using AI methods was conducted, a characterization of several risks affecting the effectiveness of AI applications was presented, and recommendations were provided for implementing measures to minimize the impact of these risks in business. The research results will be useful to personnel at enterprises and organizations involved in business processes implemented with AI.

Keywords: artificial intelligence, business processes, opportunities for applying artificial intelligence, risks, risk management

I. INTRODUCTION

The application of artificial intelligence (AI) methods is an effective tool for solving problems in enterprises and organizations. AI is widely used in professional fields to automate routine tasks and perform specific tasks that require narrow, specialized knowledge [1].

Known areas of AI application in medicine include [2]:

- Medical imaging: analysis of X-rays, MRI, and CT scans. Computer vision algorithms help detect anomalies in images.
- Early cancer diagnosis: detecting tumors in scans. AI can detect subtle changes in tissues that the human eye might miss.
- Genetic diagnostics: analyzing genetic data to identify hereditary diseases.
- Personalized medicine: AI analyzes a patient's genetic and clinical data, helping doctors select therapies and dosages tailored to individual characteristics.
- Digital medical assistants and chatbots: provide round-the-clock support by analyzing symptoms using questionnaires and algorithms, helping to schedule doctor appointments, sending medication reminders, and tracking health dynamics.

In the financial sector, AI has also been applied to several tasks [3].

- Cash flow management: AI analyzes massive datasets, generating recommendations for decision-making. Examples include forecasting cash flows while accounting for hundreds of variables, such as seasonality, macroeconomic factors, customer behavior, and exchange rates.
- Automation of routine processes: Computer vision systems extract data from documents (invoices, delivery notes, contracts).
- Risk management: AI systems continuously monitor financial metrics, detecting deviations from the norm. When threshold values are exceeded, alerts are triggered automatically.
- Investment sector: AI-driven algorithmic trading processes thousands of signals simultaneously: news, company reports, macroeconomic indicators, and social media sentiment.
- Insurance: Systems analyze tens of thousands of factors to determine insurance premiums, ranging from IoT device data to clients' social profiles.

In manufacturing enterprises, AI is used to automate processes and improve efficiency. AI-controlled robots can perform complex tasks with high precision and minimal errors. There is established experience in applying AI to manufacturing, alongside the use of automated energy metering systems and computer-aided process planning systems [1], [4], [5].

In education, AI helps create personalized learning programs tailored to each student's needs. AI is also used to automate administrative tasks, such as schedule management and assessing academic performance. There is established experience in applying AI in e-learning and in training personnel to work in the 1C environment [1], [6-8].

AI transforms decision-making processes in business, offering significant opportunities to increase efficiency, optimize operations, and gain competitive advantages. However, its implementation is associated with several risks that must be considered [9].

II. METHODOLOGY AND PURPOSE OF THE STUDY

The purpose of this article is to analyze the opportunities and risks involved in solving business problems using AI methods, as well as to develop measures to minimize the impact of these risks. Such studies are widely used in practice to ensure the effective management of objects and processes of various natures. In particular, the

authors pay due attention to the issues of modeling the functioning of such systems and the application of artificial intelligence methods.

The methodology of this scientific research is based on the theoretical principles of engineering cybernetics, the science of controlling complex, hierarchical, multidimensional, and adaptive systems, and, in particular, on modern concepts in the field of automatic control theory.

Let's explore examples of authors' methodologies for using AI in business.

Example 1: Optimization of surface machining plans on machines.

To optimize the processing plans of surfaces, there are increased requirements for the level of qualification of personnel, since, on the one hand, he must be able to use the handbook, know the features of operations performed on various machines, and, on the other hand, he must be a qualified user of CAD/CAM.

To minimize the risks associated with personnel errors, Sergey Bogatenkov, Nizami Yusubov, Mukhaddin Samadov, and Heyran Abbasova recommend using artificial intelligence methods and digital twin technologies [4].

The initial information for the research is a network model of the operation structure, which is a collection of interconnected digital twin models. An example of a network model of surface treatment plans for the part (Figure 1) is shown in Figure 2. The part model, including a description of the surfaces to be machined, is presented in Table 1. The workpiece model (bar diameter 40 mm, accuracy grade 12). The digital twins, which are the nodes of the network model, are described in Table 2.

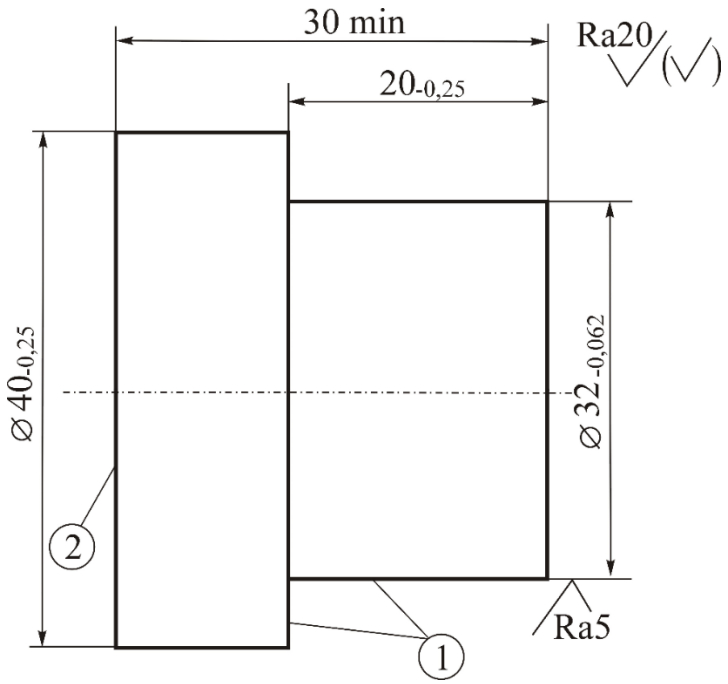

Figure 1. Part drawing.

Table 1. Part Model

Surface No	Workpiece accuracy grade	Part accuracy grade	Machining allowance, mm	Length of cut, mm
1	12	9	4	20
2	12	-	-	20

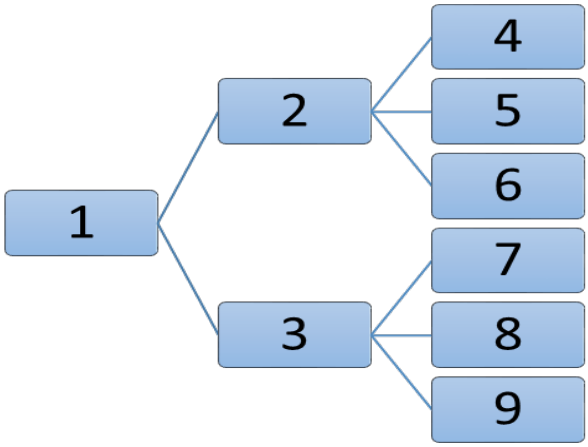

Figure 2. Network model of surface treatment plans.

Table 2. Digital twins of the network model of surface treatment plans

No	Content
1	Workpiece model (bar diameter 40 mm, accuracy grade 12)
2	Machining of surface №1
3	Machining of surface №2
4	Machining of surface №1 in one pass
5	Machining of surface №1 in two passes
6	Machining of surface №1 in three passes
7	Machining of surface №2 in one pass
8	Machining of surface №2 in two passes
9	Machining of surface №2 in three passes

Based on an analysis of tool parameters and placement options across the positions of the automatic lathe, a digital twin structure has been developed for CAPP of operations performed on automatic lathes. The tool codifier is presented in Table 3.

In artificial intelligence systems, the search for solutions is performed in a state space. In this context, a state is understood as a particular point in the problem-solving process. Furthermore, an operator denotes an action or permissible move in the problem from the set of possible states.

For the search for optimal surface treatment plans for a part, a state is a node of the network model of possible surface treatment plans (see Table 2). Among all states, an initial state and a goal state are distinguished. The task is to transform the initial state into the goal state.

Table 3. Tool Codifier

Tool number	Tool name
1	Turning tool №1
2	Turning tool №2
3	Turning tool №3
4	Grooving tool №1
5	Grooving tool №2
6	Parting tool

In the search for optimal surface treatment plans, an operator is a permissible move obtained by checking the values of the nodes at a given level. For example, if the most effective option is to machine surface No. 1 in three passes [10], then this node, No. 6, is marked (Figure 3).

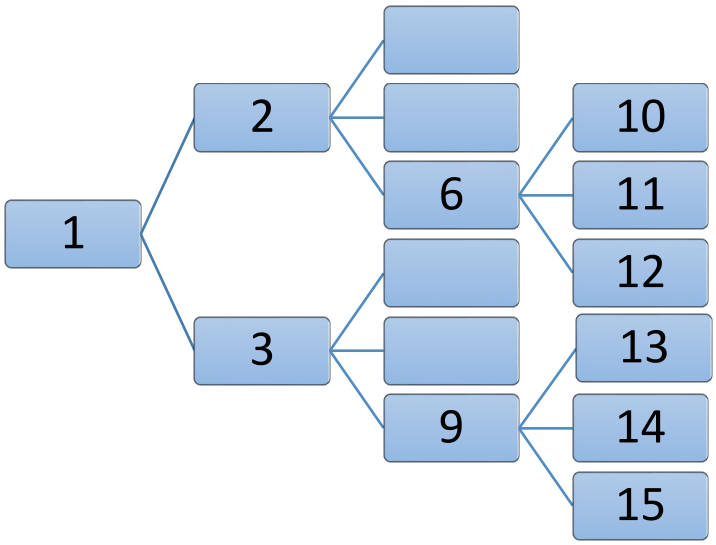

Figure 3. Results of the heuristic method of artificial intelligence

In the second stage, the tools are assigned to the positions of the automatic lathe. If a position is free, a tool is placed in it, and this node is marked (see Figure 3).

As a result of implementing the method, the optimal surface treatment plans are determined, and the tools are assigned to the machine's positions. In this process, only the paths leading to the found states, for example, 6 and 9, are saved. Other paths and states are discarded. Such methods are called heuristic.

Thus, the goal state is formed; its digital twin for machining on a multi-spindle automatic lathe is presented in Table 4.

The application of the methodology for synthesizing optimal surface treatment plans enables the minimization of the impact of risks associated with personnel errors through the use of artificial intelligence methods and digital twin technologies.

The research results are applied to the synthesis of surface treatment plans for a multi-spindle automatic lathe and a CNC machine.

Table 4. Digital twin of the operation performed on a six-spindle automatic lathe

Tool parameters	**Tool number**					
	1	**2**	**3**	**4**	**5**	**6**
Position	1	2	3	4	5	6
Slide	1	1	1	2	2	2
Depth of cut, mm	3,5	0,3	0,2	_	_	_
Workpiece accuracy	12	11	10	_	_	_
Part accuracy	11	10	9	_	_	_
Length of cut, mm	10	10	10	6	7	7

A feature of machining on a multi-spindle automatic lathe is that, during multi-pass surface machining, the passes are performed simultaneously. This enables high productivity for the operation over several passes. In this case, it is recommended that the machining allowance be distributed approximately equally among the passes (Table 4).

A feature of machining on a CNC machine is that, during multi-pass surface machining, the passes are performed sequentially. This allows for high operational productivity in two passes. In this case, it is recommended to remove the main part of the machining allowance on the first pass and the minimum part on the second pass to achieve the required dimensional accuracy (Table 5).

Table 5. Digital twin for the operation performed on a CNC machine

Tool parameters	**Tool number**		
	1	**2**	**6**
Position number	1	2	3
Slide number	1	1	2
Depth of cut, mm	3,8	0,2	-
Workpiece accuracy grade	12	12	-
Part accuracy grade	12	9	-
Length of cut, mm	10	10	20

Example 2: Synthesis of optimal personal development paths when working on the 1C: Enterprise platform.

To perform their duties in the 1C environment, there are increased requirements for staff qualifications, as, on the one hand, they must be qualified users of the "1C: Enterprise" configurations, and, on the other hand, they must be able to use the classification of staff positions.

To minimize the risks associated with staff errors, Sergey Bogatenkov, Nizami Yusubov, and Irina Ketova recommend using artificial intelligence methods and a competency network model [8].

The automation of personal development trajectory planning is based on a competency network model. The competency model for working with the software products of the "1C: Enterprise" platform takes into account work experience and certificates that reflect the corresponding competencies (Table 6).

The network model of personal development trajectories contains information about specific states of achieved competency levels (vertices) and their logical interconnections (arcs). The basis of this logical interconnection is the technological and resource-based (work experience and number of certificates) dependency between the states. A network diagram, which is a graphical representation of the network model of personal development trajectories, is shown in Figure 4.

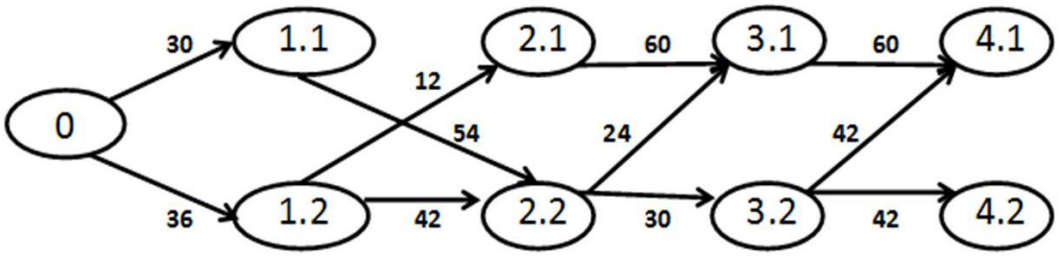

Figure 4. Network diagram of personal development trajectories

In artificial intelligence systems, the search for solutions is performed in the state space. In this context, a state is understood as a specific point in the problem-solving process. Additionally, an operator denotes an action or permissible move in the problem from the set of possible states. In the synthesis of an optimal personal development trajectory, a state is a vertex in the network model of possible trajectories. Each state is defined by two numbers: work experience and the number of certificates (see Table 6). For example, the first level has two states: 1.1 (6,0) and 1.2 (0, 1). Among all the states, an initial state and a goal state are identified. The objective is to transition from the initial state to the goal state. There are two possible criteria for synthesizing an optimal personal development trajectory: maximizing work experience and maximizing the number of certificates. A move is a permissible step that results from checking the values of the vertices at a given level. For example, when transitioning from the first level to the third based on the criterion of maximum number of certificates, the optimal path from state 1.2 to state 3.2 will be 1.2 -> 2.2 -> 3.2 (see Figure 4). As a result of implementing the method, the optimal personal development trajectory is determined by the criteria of maximum work experience and the maximum number of certificates. In this process, only the paths leading to the found states are retained; other paths and states are discarded. Such methods are called heuristic. The application of this methodology for synthesizing optimal personal development trajectories helps minimize the impact of risks associated with personnel errors by leveraging artificial intelligence methods and a network model of personal development trajectories. As a result of the study, the authors have developed an automated HR manager database that generates optimal personal development trajectories for working on the "1C: Enterprise" platform, based on the criteria of maximum work experience and the maximum number of certificates.

Table 6. Model of Development Trajectories for Working with "1C: Enterprise" Platform Software Products

Option	**Work experience, months**	**Certificates**	**Competencies, functions**
1.1	6	-	Knowledge of the main capabilities of a 1C product.
1.2	0	1C: Professional	
2.1	12	1C: Professional	Implementation of software solutions and training users to work in 1C programs.
2.2	6	1C: Specialist or 1C: Specialist-Consultant	
3.1	24	1C: Specialist or 1C: Specialist-Consultant	Configuration and support of large information systems based on 1C solutions, identification and resolution of problems.
3.2	12	1C: Operator	
4.1	36	1C: Operator	Development and implementation of software solutions for large organizations.
4.2	24	1C: Expert	

Let us consider the options for advancing from the first to the third level of the career ladder. An employee at the first level must have at least 6 months of work experience (option 1.1) or a "1C: Professional" certificate (option 1.2). A candidate for third-level positions must have at least 24 months of work experience and either a "1C: Specialist" or "1C: Specialist-Consultant" certificate in addition to the "1C: Professional" certificate (option 3.1). Alternatively, (option 3.2), it is necessary to have at least 12 months of work experience and obtain the "1C Operator" certificate in addition to the foundational "1C: Professional" certificate. The results of the algorithm for the transition from level 1 to level 3, based on the criteria of maximum work experience and maximum number of certificates, are presented in Table 7. The automated database is implemented as a spreadsheet, uses Microsoft Excel, and runs on Microsoft Windows. The use of the automated HR manager database in the 1C environment reduces the workload of individuals involved in HR management. This facilitates the effective training of existing personnel and the hiring of new employees by minimizing HR risks associated with preparing position requirements and defining effective personal development trajectories for employees' successful career advancement.

Table 7. Personal development trajectories for the transition from level 1 to level 3 for working with the software products of the "1C: Enterprise" platform

Criterion	**Work experience, months**	**Certificates**	**Transition Path**
Initial option 1.1: 6 months of work experience			
Maximum work experience	12	1C: Professional	1.1 -> 2.1
	24	1C: Professional 1C: Specialist or 1C: Specialist - Consultant	2.1 -> 3.1
Initial option 1.2: 1C: Professional certificate			
Maximum number of	6	1C: Professional 1C: Specialist or 1C: Specialist - Consultant	1.2 -> 2.2

certificates	12	1C: Professional 1C: Specialist or 1C: Specialist - Consultant 1C: Operator	2.2 -> 3.2

III. THE POTENTIAL OF ARTIFICIAL INTELLIGENCE TO IMPROVE BUSINESS EFFICIENCY

Improving business efficiency through AI is achieved in the following areas [10], [11]:

1. **Big data analysis.** AI processes structured and unstructured data, identifies hidden patterns, builds predictive models, and generates alternative scenarios. This is particularly useful in solving complex, unstructured management tasks.
2. **Forecasting.** AI-based systems can forecast demand, customer behavior, financial risks, and market shifts. This allows businesses to prepare for changes in advance, optimize inventory, plan campaigns, and minimize losses.
3. **Automation of routine processes.** AI frees employees from monotonous work related to document processing, data analysis, inventory management, and customer requests. This allows human workers to focus on strategic and creative tasks.
4. **Personalization.** Algorithms analyze user behavior and preferences, tailoring marketing and services to individual needs. This increases customer loyalty and conversion rates.
5. **Modeling decision outcomes.** Machine learning-based tools can model the impact of various business strategies and financial decisions, offering optimal solutions.
6. **Strategic planning support.** Modern strategic planning systems integrate the capabilities of AI, big data analytics, and the Internet of Things (IoT) to build adaptive management models. They account for external environment volatility and allow for the rapid adjustment of scenarios.
7. **Anomaly detection.** AI identifies anomalies in data, ranging from financial discrepancies to supply chain or HR issues.

AI positively impacts the quality of business processes in the following ways [12]:

- **Increased efficiency and productivity.** AI automates not only simple tasks but also complex decision-making processes, reducing the time employees spend on routine tasks. This allows professionals to focus on strategic issues crucial for business growth.
- **Enhanced accuracy and speed of decision-making.** AI minimizes human error by performing tasks such as data entry and analysis with high precision. It provides in-depth analysis that helps in making more informed business decisions based on real-time data.
- **Enhanced scalability and flexibility.** AI-based solutions scale easily as a business grows, handling increasing workloads without requiring additional resources. Such flexibility facilitates adaptation to market changes and business expansion.
- **Cost reduction and increased return on investment (ROI).** By automating routine tasks, AI reduces labor costs and optimizes resource allocation. Initial investments in the corresponding technologies typically pay off quickly due to high efficiency.
- **Improved customer service.** Thanks to AI, companies can provide personalized offers based on an analysis of a customer's previous purchases and preferences. This not only improves service quality but also increases customer satisfaction levels.

Examples of the successful implementation of AI in business include [13]:

- **The fast-food restaurant chain Chipotle.** The company uses AI to optimize procurement and inventory management. The system analyzes historical sales data, factoring in seasonality, weather, and local events to accurately forecast demand. As a result, storage costs were reduced by 25%, and the volume of write-offs decreased by 30%.
- **The construction company Lendlease.** The company implemented AI for project planning. The system analyzes data from past projects, taking into account weather conditions and the availability of materials and labor. This has reduced planning time by 60% and increased the accuracy of project completion time forecasts by 40%.
- **Walmart.** The company uses AI to analyze purchasing behavior. This has increased the effectiveness of marketing campaigns by 40%, reduced report preparation time by 75%, optimized inventory levels, and improved demand forecasting by 30%.
- **The apparel manufacturer Nike.** The company applies machine learning algorithms to optimize its supply chain. Thanks to this, Nike has reduced delivery times by 50% and cut warehousing costs by 30%.
- **The coffeehouse chain Starbucks.** The company uses neural networks to personalize offers through its mobile app. This led to a 25% increase in app-based sales and a 15% increase in the average order value.

Popular AI technologies in business include [14]:

- **Machine Learning (ML).** Used for data analysis, identifying patterns, forecasting, and object classification. For example, models can predict demand, customer churn probability, and financial performance metrics.
- **Deep Learning.** Applied to process large volumes of information: text, images, video, or speech. For instance, it is used to classify reviews or transcribe audio recordings.
- **Natural Language Processing (NLP).** Allows AI to recognize and generate human speech. It is used in chatbots, digital assistants, and sentiment analysis systems for reviews.
- **Generative AI (GenAI).** Creates new content: text, images, and code. For example, neural networks can generate product descriptions, advertising copy, and software code.
- **Computer Vision.** Applied to automate quality control in manufacturing, analyze images in logistics, and recognize shelf displays in retail.

IV. RISK MANAGEMENT IN BUSINESS USING ARTIFICIAL INTELLIGENCE METHODS

The application of AI methods in business is accompanied by the impact of several risks [15], [16]:

- **Confidential information leaks.** Data from neural networks can leak in various ways, for example, due to hacker attacks. Information leaks damage a company's reputation.
- **Copyright infringement.** Neural networks help generate texts and images, design websites, and create presentations and client proposals. However, not all entrepreneurs consider whether they have the right to use such content.
- **AI errors.** Neural network algorithms are still imperfect. A risk to the company arises if employees trust AI entirely and do not double-check the data.
- **Loss of context and emotional tone.** Models do not understand emotions, cultural nuances, goals, and the tone of communication. As a result, texts and responses can be inappropriate.
- **Employee distrust and resistance.** Studies show that some employees perceive AI as a threat to their jobs. Without training and an explanation of the technology's benefits, there is a risk of sabotage or inefficient use.

- **Ethical and legal risks.** The uncontrolled operation of AI can lead to discrimination, privacy violations, or other ethical issues. All of this threatens the company with lawsuits, fines, and reputational damage.

To minimize the impact of these risks, it is recommended to implement the following measures [11], [16], [17]:

- Conduct data audits and standardization, and implement Data Governance to ensure information quality.
- Use interpretable models and maintain decision documentation to ensure the transparency and explainability of conclusions.
- Conduct multi-level validation and manual verification of key calculations and formulations, especially in critical areas.
- Ensure compliance with legal and ethical standards, and conduct algorithm audits.
- Involve employees in the implementation process, train personnel, and establish "AI ambassadors" to train colleagues.
- Conduct a preliminary systems audit and phased integration during AI implementation.
- Use a multi-level testing and redundancy system to reduce the risk of critical failures.
- Calculate the TCO (total cost of ownership) and continuously optimize expenses for supporting and upgrading solutions.

The successful implementation of AI requires a systematic approach at all stages of the project: from data collection to subsequent maintenance and model retraining.

V. CONCLUSIONS

As a result of the study, an analysis of the opportunities and risks involved in solving business problems using AI methods was conducted, and measures were proposed to minimize the impact of these risks. Improving business efficiency through AI is achieved in the following areas: big data analysis, forecasting, the automation of routine processes, personalization, modeling decision outcomes, strategic planning support, and anomaly detection. Popular technologies and examples of successful AI implementation in business are presented. A characterization of several risks affecting the effectiveness of AI applications in business is presented: confidential information leaks, copyright infringement, AI errors, loss of context and emotional tone, employee distrust and resistance, and ethical and legal risks. To minimize the impact of these risks, the implementation of a series of measures is recommended:

- Conduct data audits and standardization.
- Use interpretable models and maintain decision documentation.
- Conduct multi-level validation and manual verification of key calculations and formulations.
- Ensure compliance with legal and ethical standards, and conduct algorithm audits.
- Involve employees in the implementation process, train personnel, and establish "AI ambassadors" to train colleagues.
- Conduct a preliminary systems audit and phased integration during AI implementation.
- Use a multi-level testing and redundancy system to reduce the risk of critical failures.
- Calculate the TCO (total cost of ownership) and continuously optimize expenses for supporting and upgrading solutions.

The research results will be useful to personnel at enterprises and organizations involved in business processes implemented with AI.

ORCID:0000-0001-5310-7627

Abstract
With the advancement of web technologies, access to information, service delivery, and communication processes have largely moved to the digital sphere. Nowadays, almost all public bodies and private companies have a website and offer online services. Ensuring that all individuals have equal and effective access to websites, which have become vital tools in the digital age, is regarded as a fundamental human right. In this respect, the concept of web accessibility, also referred to as 'barrier-free web', is coming to the fore. Web accessibility generally refers to the standards and technological solutions developed to enable users, particularly those with disabilities, to access, understand, and effectively use web content. In this study, the accessibility features of the Ministry of Health of the Republic of Türkiye's website were analyzed using a descriptive approach to raise awareness of accessible website design practices. The analysis revealed that an add-on offers Epilepsy Safe Mode, Visually Impaired Mode, Cognitively Impaired Mode, and ADHD (Attention Deficit Hyperactivity Disorder) Friendly Mode, tailored to different user types. It found that features such as text size, line height, contrast settings, background color selection, and text-to-speech are available, enabling users to personalize their experience.

Keywords: web accessibility, barrier-free design, digital inclusion

I. INTRODUCTION

The origins of the internet, which date back to the 1960s, became widespread in the 1990s and have now become an indispensable part of everyday life [1]. Today, websites combine informative, interactive, and transactional functions related to e-commerce, providing companies with a tool to establish a powerful online presence [2]. The Web, which is used effectively across sectors including e-commerce, healthcare, education, finance, tourism, media, and the public sector, plays a significant role in enhancing organizations' visibility. It is often said that first impressions of organizations are formed almost entirely on their official websites [3]. At this point, websites need to be accessible to everyone. Indeed, the fact that they must be designed not only to enhance the user experience but also to enable all individuals, regardless of their abilities and needs, to access information equally and independently further underscores the importance of web accessibility and inclusivity standards. Web Accessibility Standards are set out in the Web Content Accessibility Guidelines (WCAG), developed by the W3C (World Wide Web Consortium), which was founded under the leadership of Tim Berners-Lee, the inventor of the internet. The standards set out here are designed to address the needs of people with disabilities, including those with visual, hearing, physical, speech, cognitive, language, learning, and neurological impairments [4]. There are different versions of the WCAG guidelines (WCAG 1.0, WCAG 2.0, WCAG 2.1, WCAG 2.2, and WCAG 3.0). Given technological advancements and the dynamic nature of web content, the guidelines are updated regularly to ensure the latest developments are assessed in line with new requirements [5]. When creating websites, it is important to ensure that these standards are taken into account so that they are

designed to provide equal access for everyone, including people with disabilities. Inal and Torkildsby (2025) examined the impact of compliance with web accessibility standards on public services in Norway. To this end, all municipal websites were evaluated over three years from 2022 to 2024. The results revealed a positive trend, indicating steady improvement over time in addressing accessibility issues [6]. Palmquist and Oppmark sought to explore how changes in visual accessibility affect the subjective experiences and perceptions of users with and without disabilities; to this end, they conducted a study in which 10 participants were shown two versions of each of five different Swedish government websites. The results of the study showed that all users either benefited from the inclusion of accessibility features or were not negatively affected by them [7]. In this study, the features of the Ministry of Health of the Republic of Türkiye's website accessibility plugin were analyzed using a descriptive approach. The changes that can be made when different modes are used were tested and presented using screenshots. In this way, attention was drawn to the need for all websites to incorporate such features to ensure equal access for all individuals and promote digital inclusion.

II. METHODS

This study aims to examine the accessibility plugin on the Ministry of Health of the Republic of Türkiye's website. To this end, the features of the accessibility tools available on the Ministry of Health's official website, as shown in Figure 1, have been tested individually, with screenshots to support the examples.

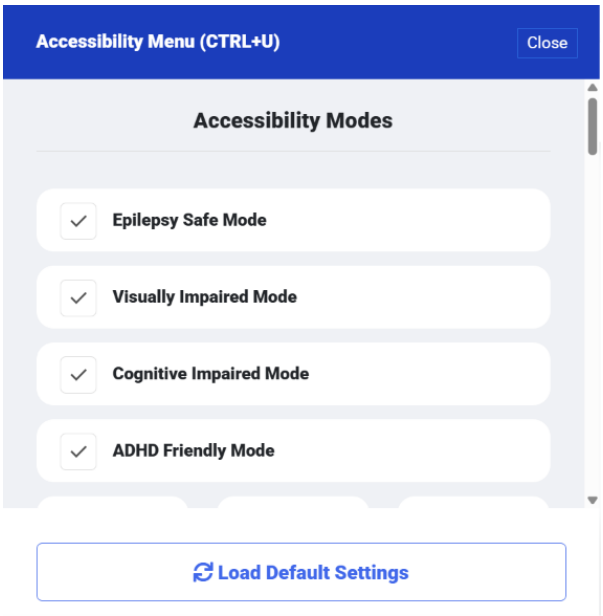

Figure 1. Accessibility menu

The study uses a descriptive analysis method. Descriptive analysis is a type of analysis that reveals how and under what conditions a particular situation occurred by organizing data that explains the conditions and context in which a phenomenon arises. An effective descriptive analysis systematically highlights the forms of practice and the nature of the environment, both of which are critical to interpreting the findings. In this respect, description contributes to researchers' deeper understanding of the phenomenon under investigation. Furthermore, when descriptive analysis reveals previously unnoticed phenomena or data patterns, it can also be regarded as an independent research output [8]. In this study, a descriptive analysis was used to provide a clearer

picture of the usability of the Ministry of Health website for people with disabilities. This has enabled us to conclude the development of more inclusive and user-friendly web designs. On the other hand, the extent to which the website meets the WCAG 2.2 criteria, which take into account its accessibility features, is presented in a checklist. In this way, it becomes clear which accessibility criteria have been implemented and which ones are missing.

III. FINDINGS AND DISCUSSION

The features listed in the accessibility menu on the Ministry of Health website have been examined in detail and are presented here. The meaning of each mode is explained, and the output obtained after implementation is illustrated with screenshots. An image from the news page has been selected as an example and is shown in Figure 2 below. The features of the new mode obtained by applying all the features to this image are then described.

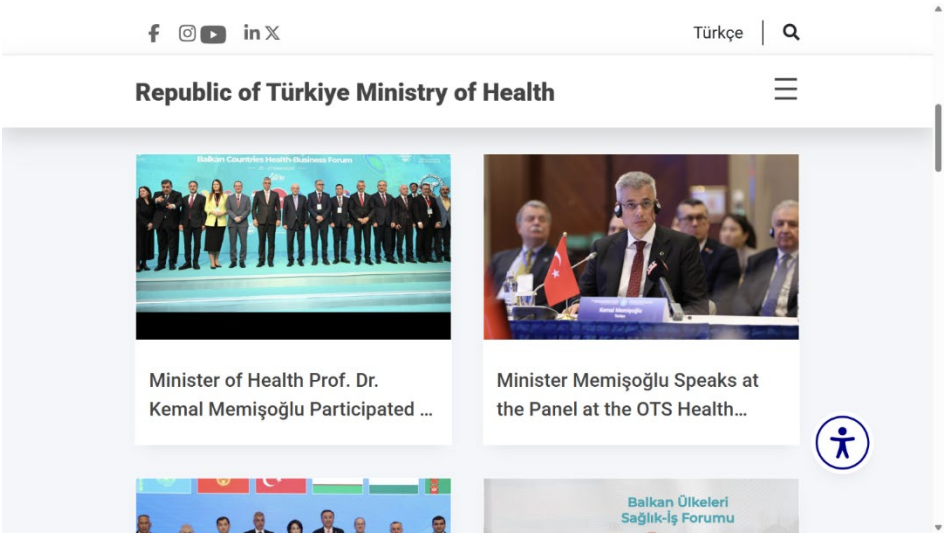

Figure 2. The general version of the web page

1. Epilepsy Safe Mode

This mode has been developed for patients with epilepsy. It aims to eliminate the risk of seizures from flashing animations or color combinations that may trigger them [9].

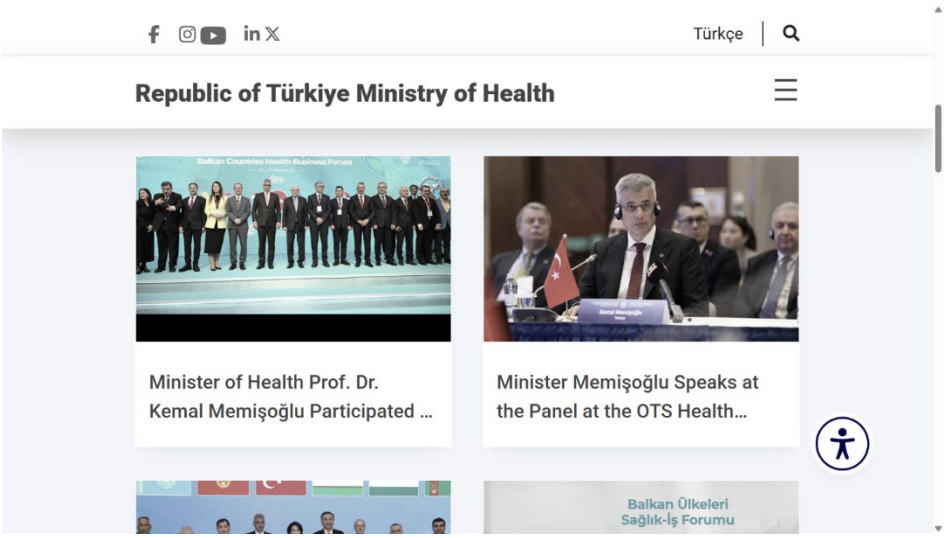

Figure 3. Web page with epilepsy mode enabled

When examining Figure 3, it can be seen that pictures have lost their vibrancy and are now dominated by softer, darker, and duller tones.

2. Visually Impaired Mode

This mode has been developed for users with visual impairments, tunnel vision, cataracts, glaucoma, and similar conditions [9].

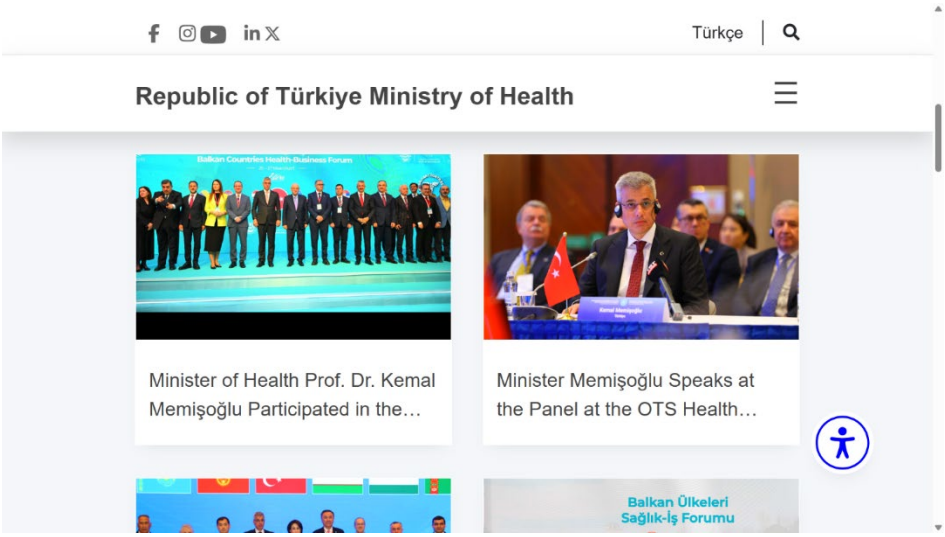

Figure 4. Web page with visually impaired mode enabled

Figure 4 shows that when the visually impaired mode is enabled, a legible text font is active, colors are more vibrant, and the contrast level is higher.

3. Cognitive Impaired Mode

This mode is designed to make it easier for users with cognitive conditions such as dyslexia and autism to focus on website elements [9].

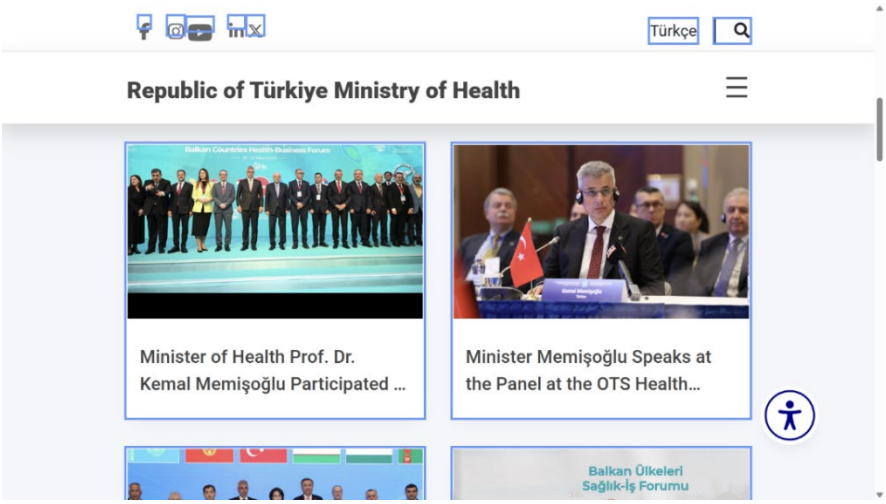

Figure 5. Web page with the cognitive impaired mode enabled

In Figure 5, where the cognitive mode is active, the headings and links are highlighted, and the animations are paused.

4. ADHD Friendly Mode

This mode has been developed to help users with ADHD and neurodevelopmental disorders significantly reduce distractions, read website content more easily, and maintain focus [9].

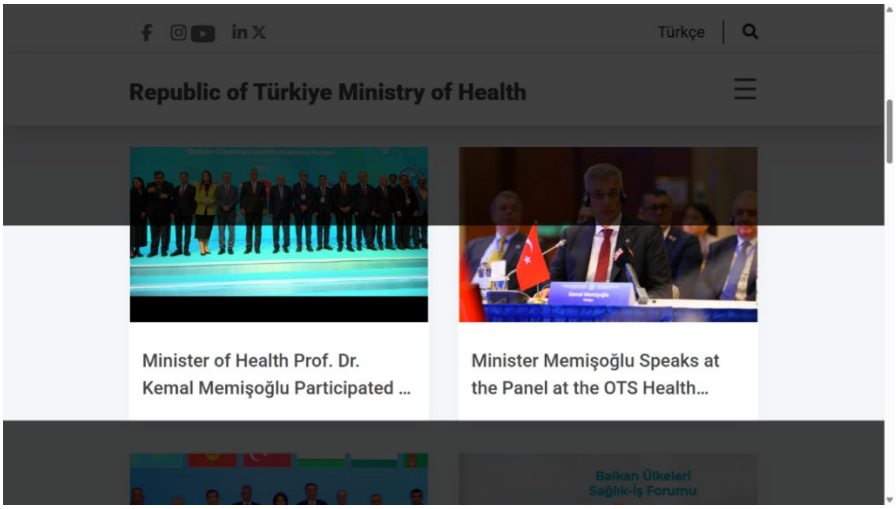

Figure 6. Web page with ADHD friendly mode enabled

When the ADHD-friendly mode shown in Figure 6 is active, high saturation and the readout mask are enabled.

5. Other Customization Settings

Users can apply these modes or, in addition, increase the font size, adjust line spacing, use dyslexia mode, change color settings, select background options, or change the orientation. Examples of such uses are provided under this heading.

1) Text Magnifier: When Text Magnifier is active, text is enlarged in a separate window with white text on a black background. This is shown in Figure 7 below.

Figure 7. Web page with text magnifier enabled

2) Dyslexia Friendly: When dyslexia mode is enabled, the text appears to switch to the OpenDyslexic font, with increased spacing between letters and lines. This is presented in Figure 8 below.

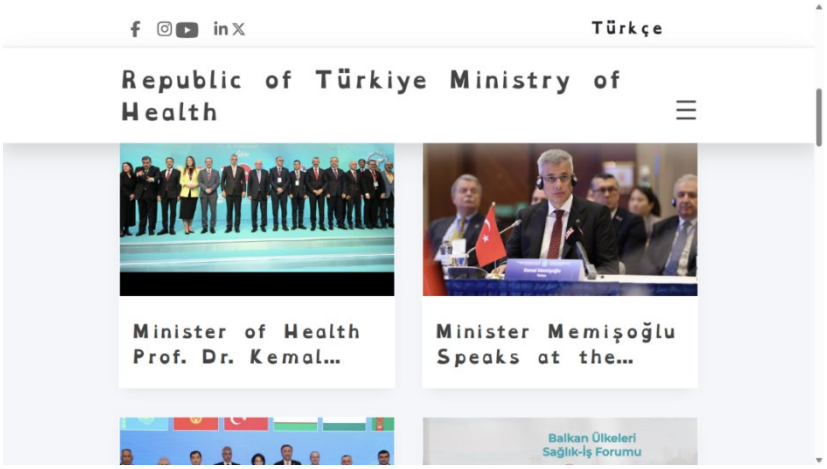

Figure 8. Web page with dyslexia friendly enabled

3) Font Sizing, Line Height, Letter Spacing: To illustrate the use of multiple properties simultaneously, Font Sizing, Line Height, and Letter Spacing have been used together and are shown in Figure 9.

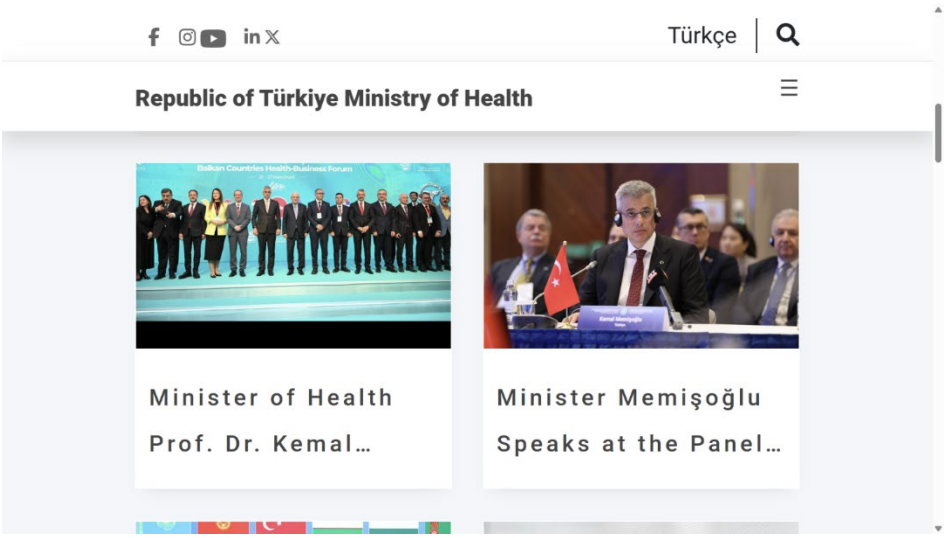

Figure 9. Combined use of text formatting features

4) Dark mode: This mode, in which the background can be dark and the text light-colored, is shown in Figure 10.

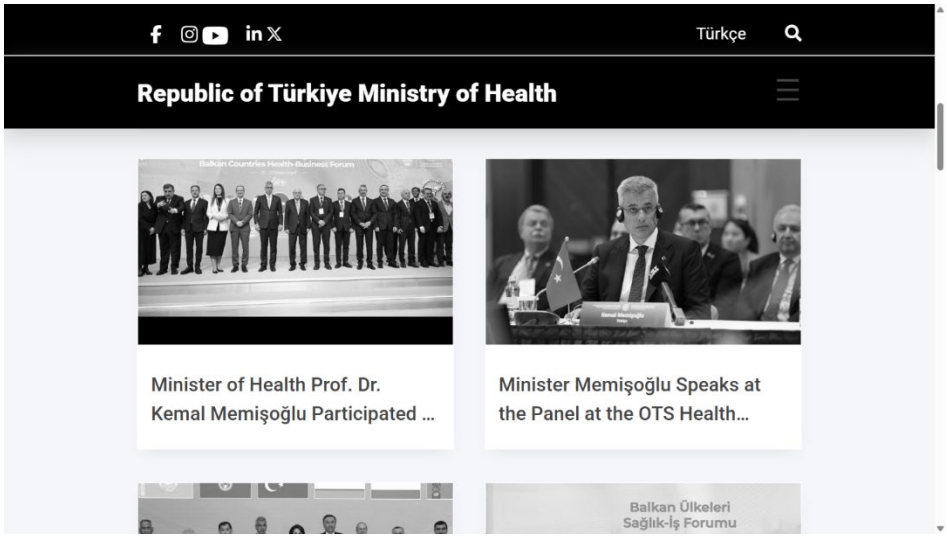

Figure 10. Web page with dark mode enabled

The accessibility plugins integrated into the website have been analyzed using the screenshots above, and examples are provided to illustrate how these plugins enhance the user experience. This has highlighted the importance of web accessibility for diverse user groups and the need for inclusive design approaches.

IV. CONCLUSION

This study aims to highlight the importance of ensuring equal web accessibility for all individuals. To this end, the Turkish Ministry of Health's website accessibility menu has been examined. It has been noted that Presidential Decree No. 2025/10 on the “Accessibility of Websites and Mobile Applications” was issued on 21 June 2025 to ensure that information in the digital sphere, via websites and mobile applications, is available in formats that users with different abilities can access and understand. Under this decree, the World Wide Web Consortium (W3C)’s Web Content Accessibility Guidelines (WCAG 2.2) guide all stages, including design and updates, for websites and mobile applications used by private-law legal entities that are frequently used by public institutions and citizens [10]. Upon reviewing the Ministry of Health’s website, it was found that the site features customized modes designed to cater to various needs, such as epilepsy, visual impairment, cognitive difficulties, and attention deficit. In addition, users can personalize the website to suit their needs thanks to features such as text enlargement, contrast adjustment, dyslexia-friendly options, and dark mode. This demonstrates that accessibility principles have been addressed in a way that encompasses all users. However, to assess the extent to which these personalizations comply with the WCAG guidelines [11], a checklist is provided in Table 1 below.

Table 1. Ministry of Health Website WCAG 2.2 Compliance Status

WCAG 2.2 Principle	Evaluation Criteria	Description	Compliance Status
Perceivable	Text alternatives for any non-text content	Alternative text, accessible names, and headings for images, forms, and embedded content	Mostly Compliant
	Alternatives for time-based media.	Multimedia accessibility through subtitles, transcripts, audio descriptions, and sign language (Read the site out loud, read selected text)	Mostly Compliant
	Adaptive Content	Semantic HTML, heading structure, and the correct use of form tags	Moderately Compliant
	Distinguishable Content	Contrast ratio, color usage, and text readability	Mostly Compliant
Operable	Keyboard Accessible	All functions should be accessible via the keyboard	Mostly Compliant
	Seizures and Physical Reactions	Free of content that may trigger seizures or epilepsy	Mostly Compliant
	Navigable	Navigating the site, finding content, and determining their locations	Mostly Compliant
Understandable	Readable	The language should be clear and understandable	Mostly Compliant
	Predictable	The web pages are displaying and functioning as predicted.	Mostly Compliant
Robust	Compatible	Compatibility with current and future user agents, including assistive technologies.	Moderately Compliant

According to Table 1, perceivable generally refers to the accessibility of web content through the senses, such as sight, hearing, and/or touch. It was found that images provide descriptive text alternatives and that buttons display their functions when the cursor hovers over them; however, social media icons lack accessible labels. For the alternatives for the time-based media criterion, it was determined that these videos are available on YouTube and that the subtitle option can be enabled. Additionally, it was noted that the web accessibility plugin includes a text-to-speech feature and the ability to read selected text aloud. No sign language option was found. Although the basic HTML structure is largely correct with respect to the adaptive content criterion, issues such as disruptions in the heading hierarchy, the use of non-semantic tags for interactive elements, and the absence of bookmark regions have been identified. When examining the accessibility menu specifically in relation to the distinguishable content criterion, it can be seen that text adjustments, contrast adjustments, and color changes are available.

Operable generally refers to the functionality of forms, controls, and navigation elements in an interface. For the keyboard accessible criterion, it is evident that keyboard control is largely provided through the accessibility plugin menu. Upon reviewing the webpage for the seizures and physical reactions criterion, it was observed that there are no flashing elements that would draw attention; additionally, the plugin includes an option to pause animations. It was determined that the site includes a sitemap and a search bar that meet the site navigation criteria.

Understandable generally refers to the clarity of information and the functionality of the user interface. For the readability criterion, it was determined that the language is clear and understandable, and that an English-language option is available. For the predictable criterion, upon reviewing the webpage, it was observed that the webpage's behavior is generally consistent.

Robust generally refers to content that is sufficiently well-defined to be reliably interpreted by a wide variety of user agents, including assistive technologies. While the basic HTML structure and the tagging of components required for the compatible criterion have largely been met, it was concluded that the announcement of dynamic status messages and the implementation of ARIA integration, in particular, were not fully and flawlessly implemented.

An analysis of the Ministry of Health website presented in Table 1 revealed that the site meets a large portion of the WCAG 2.2 guidelines. An accessible web structure can contribute to timely access to health information and help individuals make informed decisions by supporting digital inclusion and social equality. In addition, illustrating web accessibility with an example such as this can highlight the need for other websites to embrace digital inclusion. Furthermore, it can be regarded as a strategic necessity for the sustainability of the digital transformation process.

Abstract
This paper presents a data-driven framework that uses data science and machine learning (ML) techniques to develop the Central Bank of Libya (CBL) for financial fraud detection. The primary focus of this research is the application of the Isolation Forest methodology, as an unsupervised machine learning algorithm, to large volumes of financial data. By leveraging the algorithm's unique ability to detect anomalies, the CBL can analyze transaction data to identify unusual behaviors that may indicate illicit activities. This information can be used to improve banking services, increase efficiency, and enhance transparency. The research outlines various approaches, including financial data analysis, management systems development, customer experience improvement, fraud prevention, economic data analysis, and controlling and monitoring processes. The ultimate goal is to achieve financial and economic stability of the Central Libyan Bank, to promote sustainable growth, and improve the well-being of its citizens. In this paper, we use a simulated historical transactional dataset of 100,000 records provided by the Documentation and Information Department at the Central Bank of Libya. The dataset will be preprocessed, trained on an Isolation Forest model in RStudio, and the results (transactions with the highest anomaly scores) will be visualized using ggplot2. The model will detect and classify 71 transactions as fraudulent, representing 0.071% of the total dataset records and indicating the highest anomaly scores. The model in this framework shows promising results for detecting and combating financial fraud transactions.

I. INTRODUCTION

The Central Bank of Libya faces ongoing challenges in maintaining financial stability and combating financial fraud. To address these challenges, this paper outlines a comprehensive plan to harness data science, analytics, and machine learning techniques to strengthen the Central Bank of Libya and combat financial fraud. Data science, analytics, and machine learning have become important tools in the financial sector. Organizations can analyze massive amounts of data to make informed decisions and improve operations [1], [2]. At the Central Bank of Libya, the application of data science and machine learning enables the bank to analyze financial transactions, monitor market behavior, and detect potential fraudulent activity by leveraging artificial intelligence, machine learning, Utilizing data science and data analytics using machine learning, the Central Bank of Libya can improve its ability to regulate the exchange rate and ensure fair and transparent allocation of financial credits [3], [4]. To implement this research, we need a professional, specialized team to ensure the effective and successful application of data science, data analytics, and machine learning at the Central Bank of

Libya. In this context, we decided to use an unsupervised machine learning algorithm, Isolation Forest, to detect and combat fraudulent financial transactions. The algorithm shows promising results in detecting fraudulent financial transactions from the CBL dataset.

II. LITERATURE REVIEW

In recent years, the financial sector has witnessed a transformative shift towards data-driven decision-making, propelled by advancements in data science and machine learning technologies. This literature review explores the current state of research in applying these technologies to address critical challenges in financial management, with a specific focus on financial fraud detection assessment within the context of central banking systems

1. Financial Fraud Detection

Financial fraud is a problem facing banking systems. A traditional fraud detection method, such as a rule-based system, usually has difficulty adapting to fraud patterns [5]. On the other hand, machine learning algorithms and unsupervised learning techniques, such as the isolation forest algorithm [6] and support vector machines (SVMs) [7], have demonstrated good results in detecting anomalies. The algorithms can detect suspicious transaction patterns without prior knowledge of specific fraud types, making them suitable for detecting predictable or complex fraud. The use of machine learning in fraud detection raises a number of concerns regarding false positives, the need for continuous model training, and the protection of customer privacy [8].

III. RECENT STUDIES

Recent studies have explored the application of data science, analytics, and machine learning across various aspects of the financial sector, including fraud detection, risk management, foreign exchange market forecasting, and financial crime detection. Al-Jaroodi and Mohamed proposed a framework that combines blockchain technology with big data analytics to detect financial fraud in real-time. The authors demonstrated the effectiveness of the proposed approach in identifying fraudulent transactions with high accuracy [5]. Kaur and Singh conducted a systematic review of studies that employed big data analytics for financial risk management. They found that big data analytics techniques, including machine learning and data mining, have the potential to improve risk assessment and decision-making processes in the financial sector [9]. Chen and Zhang reviewed studies that employed big data analytics for financial crime detection. They found that machine learning algorithms and data mining techniques can improve the detection and prevention of financial crimes, including money laundering, fraud, and insider trading [8]. Therefore, these recent studies highlight the potential of data science analytics and machine learning to improve various aspects of the financial sector, including fraud and financial crime detection. The findings of these studies provide valuable insights for the development and implementation of data-driven strategies in the financial industry. More recent studies have further demonstrated the effectiveness of machine learning techniques in financial fraud detection and data-driven banking systems. Fan and Karim demonstrated that the Isolation Forest algorithm offers an efficient unsupervised approach to detecting fraudulent financial transactions, particularly on large-scale datasets [10]. Sastry and Kumar highlighted the effectiveness of anomaly detection techniques in identifying suspicious banking transactions using machine learning methods [11]. Furthermore, Mendoza and Schulz emphasized the growing role of data-driven approaches in supporting central banks through economic monitoring and fraud prevention [12]. More recently, Zhao et al. evaluated unsupervised fraud detection models on highly imbalanced financial datasets and confirmed the robustness of Isolation Forest-based methods for identifying rare fraudulent transactions [13].

IV. THE OBJECTIVES

The objectives of the paper are to develop a comprehensive data-driven framework for the Central Bank of Libya that utilizes data science analytics and machine learning techniques to address key challenges faced by the institution, such as the following: Develop a comprehensive, data-driven framework for the Central Bank of Libya that leverages data science, analytics, and machine learning techniques to improve financial stability and combat financial fraud. Implementing machine learning algorithms and data mining techniques to detect potential fraudulent activities, including fraudulent financial and documentary credits, in real-time. Enhance transparency and fairness in granting financial and documentary credits by analyzing data on applicants' creditworthiness, ability to repay, and potential risks. Improve the customer experience by analyzing customer data to understand their needs, preferences, and behavior, and providing customized banking services to meet their individual requirements. Ensure compliance with data protection and privacy regulations by implementing appropriate policies and procedures to protect sensitive personal data and banking information. Build internal capabilities within the Central Bank of Libya by providing training and resources to staff to enable them to effectively utilize data science and big data analytics techniques in their work.

V. PROBLEM FORMULATION

The Central Bank of Libya faces several critical challenges that hinder its ability to maintain financial stability and combat financial fraud. These challenges include:

- Lack of data-driven decision-making: The Central Bank of Libya currently relies on traditional methods of data analysis, which are often time-consuming and limited in scope. This results in a lack of comprehensive insights into financial trends, market behavior, and potential fraudulent activities.
- Inefficient fraud detection: The Central Bank of Libya struggles to detect and prevent fraudulent activities, which results in financial losses and undermines the credibility of the institution.
- Poor customer experience: The Central Bank of Libya struggles to provide customized banking services that meet the individual needs and preferences of its customers, resulting in low customer satisfaction levels.

To address these challenges, this paper proposes a data-driven framework that utilizes data science analytics and machine learning techniques to improve the Central Bank of Libya's operations. The proposed framework aims to enable the Central Bank of Libya to analyze vast amounts of financial data, detect potential fraud in real time, manage financial risks, and improve the customer experience.

VI. PROBLEM SOLUTION

To address the challenges faced by the Central Bank of Libya, this paper proposes a data-driven framework that utilizes data science analytics and machine learning techniques. The proposed framework includes the following methods and algorithms: Data Collection and Integration: The first step in the proposed framework is data collection, including transaction records. This step involves data integration techniques such as data warehousing, virtualization, and data preprocessing to ensure data quality and consistency. Machine Learning

and Data Mining: The proposed framework utilizes machine learning and data mining techniques to detect potential fraudulent activities, including fraudulent financial and documentary credits, in real-time. The techniques used unsupervised learning algorithms such as Isolation Forest [6],[10]. The algorithm is trained on historical data to detect patterns and anomalies in real-time data. Customer Experience: The proposed framework also includes the use of customer analytics to understand customers' needs, preferences, and behavior and to provide customized banking services that meet their individual requirements. The techniques used include customer segmentation, customer lifetime value analysis, and customer satisfaction analysis.

VII. CONTRIBUTIONS

The paper includes several contributions, such as the following:

Development of a Machine Learning Model: We propose a machine learning framework to address key challenges, such as financial fraud detection and assessment. This framework is designed to meet the needs of the Libyan financial sector, taking into account its economic environment and current situation. Financial fraud detection: An unsupervised Isolation Forest algorithm has been used to detect fraudulent transactions by isolating anomalies in banking transactions. Experimental Validation: When evaluated on real-world datasets from the Libyan financial sector, the proposed algorithm demonstrated excellent accuracy and performance. This experimental validation demonstrates a good approach to the practical application of the proposed model. Policy Impact: The results provide a useful perspective for policy and regulatory decision-makers in Libya, and highlight the potential of data-driven methodology to support financial stability.

VIII. DATASET OF CENTRAL BANK OF LIBYA (CBL)

The CBL dataset contains all transaction records. This dataset, named “Libyan_central_bank_transactions.csv”, is a simulation version of the real Libyan Central Bank Transactions dataset, provided by the Documentation and Information Department at the Central Bank of Libya. The dataset contains 100000 records of financial transactions made by the Libyan Central Bank from January 1, 2019, to July 31, 2024, with 10 features. The dataset includes the following attributes:

- Transaction_id: A unique identifier for each transaction.
- Date: The date when the transaction occurred.
- Amount: The monetary value of the transaction.
- Currency: The currency used in the transaction (in this case, "LYD" for Libyan dinars).
- Transaction_type: The type of transaction, such as "payment", "transfer", or "purchase".
- Counterparty: The entity involved in the transaction on the other side. This could be another bank, a company, or an individual.
- Counterparty_country: The country where the counterparty is located.
- Counterparty_bank: The bank of the counterparty.
- Swift_code: A unique identifier for the counterparty's bank, used for international wire transfers.
- Remarks: Additional notes or comments related to the transaction.

Figure 1. Shows a sample of the CBL Transaction Dataset

In this framework, we effectively used the Central Bank of Libya Transactions (CBLT) dataset to detect financial fraud using the Isolation Forest algorithm. Isolation Forest is an unsupervised machine learning technique that isolates anomalies in data by randomly selecting features and splitting the data based on those features[6], [10]. Transactions that are anomalous or fraudulent tend to be isolated more quickly than normal transactions because of their distinctive patterns.

IX. METHODS AND ALGORITHMS

This section discusses the tools and algorithms used in this paper. It provides detailed descriptions, mathematical formulas, and examples using hypothetical data from the Libyan financial sector.
Financial Fraud Detection in the Central Bank of Libya using Isolation Forest
Isolation Forest is an unsupervised anomaly detection algorithm that isolates abnormal observations rather than profiling normal behavior, making it highly effective for fraud detection [6],[10].
Mathematical Formulation: As illustrated in Equation (1), the mathematical formulation for the anomaly scoring function in the Isolation Forest algorithm is expressed as follows:

$$E\big(h(x)\big) = 1/t \ \sum_{i=1}^{t} h(x, T_i), \square \qquad (1)$$

Where:

- h(x): represents the anomaly score of point x.
- x: is the point to be evaluated.
- h(x, Ti): This represents the depth of point x in the tree Ti.
- Ti is one of the isolation trees that make up the forest.
- h(x, Ti): This is the number of splits needed to isolate point x in the tree Ti.
- ∑i=1: This is the sum symbol, indicating that we are summing the depth of point x across all the isolation trees in the forest.
- t: stands as the total number of isolation trees that make up the forest.
- ti: shows the normalization factor.

We divide the sum by the number of trees to get the average depth of the point across all the trees [6],[14]. Anomalies typically have shorter path lengths and thus higher anomaly scores.

X. IMPLEMENTATION

The implementation of the proposed framework involved several key steps as follows:

- Data Preprocessing: As shown in Figure 2, the data was cleaned and prepared to ensure quality, with a focus on extracting numerical columns (such as Amount) for analysis.

```
if (ncol(data_numeric) > 0) {
  num_rows <- nrow(data_numeric)
  sample_size <- min(256, num_rows)}
}
```

Figure 2.Data preprocessing: Extract numeric columns (such as amount) for analysis

- Model Training: The RStudio Version 1.4.1717 programming language was used with the solitude library to train the Isolation Forest model.
- Parameter Tuning: The sample_size parameter was dynamically adjusted to match the small dataset size, ensuring the algorithm worked correctly, as shown in Figure 3.

```
iso_forest <- isolationForest$new(sample_size = sample_size)
iso_forest$fit(data_numeric)
scores <- iso_forest$predict(data_numeric)
data_with_scores <- cbind(my_dataframe, scores)
```

Figure 3 . Initializing the isolation forest model variables

- Evaluation and Analysis: The trained model was used to predict anomaly scores (anomaly_score) for each transaction. The results were then analyzed to identify the top 10 anomalous transactions. The

ggplot2 library was also used to create a graph showing the relationship between anomaly score and amount, as shown in Figure 4.

```
library(ggplot2)

ggplot(anomalies_above_threshold, aes(x = Amount, y = anomaly_score)) +
  geom_point(aes(color = anomaly_score), size = 0.1, alpha = 0.7) +
  scale_color_gradient(low = "blue", high = "red") +
  labs(
    title = "Anomaly Score Chart: Anomaly Score vs. Transaction Amount",
    x = "Transaction amount",
    y = "Degree of abnormality",
    color = "Degree of abnormality"
  ) +
  theme_minimal()
```

Figure 4. Representing results using the ggplot2 library

XI. EXPERIMENT AND RESULT

The basic principle of the Isolation Forest algorithm is based on the simplicity with which anomalous data can be isolated from the rest of the data points. This is measured by the average depth, which represents the average path length required to isolate a particular transaction in the random decision trees that comprise the model.

1. The Relationship between the Measures

As illustrated in Table 1, the table contains a sample of 76 transactions. This sample holds the top 10 transactions with the highest anomaly score, which the model classified as fraudulent. The table consists of the serial number, transaction number, average depth, and anomaly score. The table also shows that transaction number 97 has the highest anomaly score (0.647), which is inversely proportional to the average depth (5.25), the lowest among transactions. This means the model required only a small number of splits to isolate this transaction, strongly suggesting it deviates significantly from the data's typical behavior.

Table 1. Top 10 Anomalous Transactions According To The Isolation Forest Model

No	Transaction ID	Average Depth	Anomaly Score
1	86	5.64	0.682772
2	142	5.64	0.682772
3	469	5.69	0.680466
4	1186	5.69	0.680466
5	1253	5.69	0.680466
6	790	5.71	0.679546
7	926	5.71	0.679546
8	676	5.76	0.677251
9	723	5.76	0.677251
10	79	5.77	0.676793

Table 1 presents the ten highest anomaly scores detected by the proposed Isolation Forest model

2. Interpretation of the Degree of Anomaly

The anomaly score is derived from the average depth. A score close to 1 indicates high anomaly, while a score below 0.5 indicates normal transactions, making them strong candidates for abnormal or fraudulent transactions [6]. Data with the highest anomaly value is considered the most suspicious instance in the dataset and serves as a starting point for the next stage of manual analysis and validation to take the necessary action. The model excels at quickly identifying anomalies rather than understanding all the complex "normal" patterns, making them easy to isolate from the rest of the data. Based on the results obtained, the isolation forest model is effective in achieving our research goal.

XII. DISCUSSION OF RESULTS

The Isolation Forest algorithm was applied to data from the Central Bank of Libya Transactions (CBLT) Dataset, comprising approximately 100,000 transactions. We obtained an anomaly score for each transaction; transactions with an anomaly score above 0.5 were classified as suspicious and could be handled by the bank independently. We identified 71 transactions that could be classified as fraudulent out of 100,000 transactions, representing 0.071% of the total [10]. As shown in TABLE I, the top 10 transactions with the highest anomaly scores are listed. To thoroughly validate the benefits of this data-driven framework, identify areas for improvement, and address baseline comparative requirements against relevant benchmarks [15], [16], a comparative concordance analysis was conducted using the One-Class Support Vector Machine (OCSVM) algorithm on the same standardized dataset. When calibrating both models to isolate the top-risk-ranked instances, the cross-algorithmic evaluation revealed a high agreement rate of 88.73% (63 of the 71 top-ranked anomalous transactions were identically flagged by OCSVM). This strong convergence confirms that the 71 identified records represent genuine structural anomalies within the banking records rather than algorithm-specific artifacts, reinforcing the reliability of the proposed approach. As viewed in Figure 5, each transaction is represented as an individual point, noting that these transactions obtained an anomaly score above 5 only out of one hundred thousand transactions, where:

The horizontal axis (X-axis) represents the anomaly score (ANOMALY Score) for transactions with an anomaly score above 0.5.

- The closer the score is to 1, the more likely the transaction is anomalous or fraudulent.
- The closer the score is to 0, the more likely the transaction is normal.

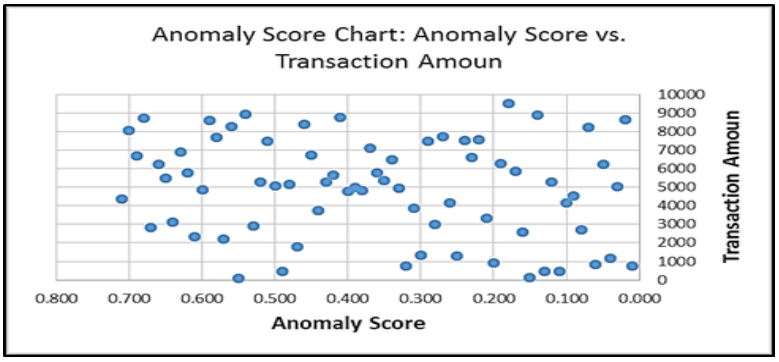

Figure 5. A chart showing the relationship between anomaly points and transaction amounts.

The vertical axis (Y-axis) represents the transaction amount.

This chart illustrates the financial values of transactions with an anomaly score greater than 0.5. According to the algorithm's classification, these transactions are anomalous and warrant closer examination for potential fraud. This does not necessarily mean they are fraudulent; they are simply high-risk filters that require human review. Figure 6 displays the spatial distribution of the identified data points. As shown, there is no clear correlation or direct relationship between a transaction's monetary value and its assigned anomaly score. The anomalous transactions are broadly distributed across various value ranges rather than clustering around specific financial thresholds, indicating that anomaly classification is not driven solely by transaction magnitude, but is instead governed by complex interactions among multiple underlying features.

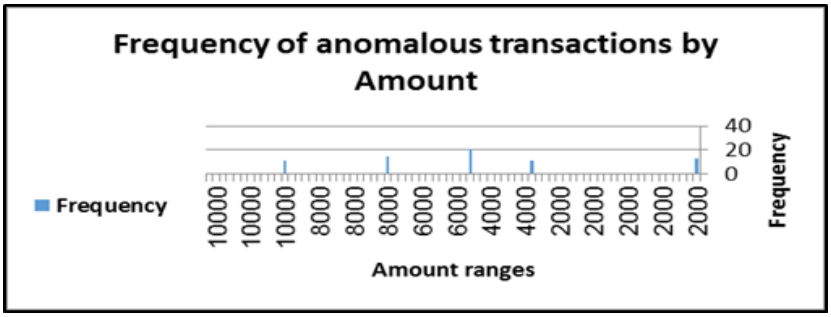

Figure 6. Illustrates the frequency of anomalous transactions by amount.

Where:

- Horizontal axis: Represents the transaction amount categories, ranging from 2,000 to 10,000.
- Vertical axis (Frequency): Represents the number of anomalous transactions falling within each designated category.
- Columns: The height of each column represents the number of transactions that fall within the specified category.

Evaluating the proposed framework on historical Central Bank of Libya Transactions (CBLT) data demonstrated that the Isolation Forest algorithm effectively flagged 0.071% of transactions (71 out of 100,000) as anomalous. To rigorously validate these findings against benchmark baselines [15], [16], a comparative concordance analysis was conducted using the One-Class Support Vector Machine (OCSVM) algorithm on the same dataset.

When both models were calibrated to isolate high-risk transactions, a high concordance rate of 88.73% was achieved (with OCSVM flagging 63 of the 71 anomalies). This strong convergence confirms that the identified records represent true structural anomalies within the banking data rather than algorithm-specific artifacts, thereby reinforcing the reliability of the proposed methodology. Ultimately, these results demonstrate the practical value of the data-driven framework in addressing the specialized fraud-detection and regulatory challenges faced by the Central Bank of Libya.

XIII. CONCLUSION

In this research paper, a data-driven framework based on the Isolation Forest algorithm was developed to detect financial fraud within the Central Bank of Libya Transactions (CBLT) dataset. The experimental evaluation demonstrated robust performance in identifying structural anomalies, successfully flagging 71 out of 100,000 transactions (0.071%) that exceeded the risk threshold score of 0.5. Cross-validation with the One-Class Support Vector Machine (OCSVM) confirmed a high concordance rate (88.73%), reinforcing the reliability of the flagged instances. By providing transparent, risk-prioritized analytics, this methodology offers actionable decision support for compliance officers and policy-makers seeking to combat financial fraud in the Libyan banking sector. Furthermore, this study establishes a benchmark dataset and evaluation pipeline, laying the foundation for future research exploring ensemble architectures and deep anomaly detection models to expand these predictive capabilities further.

Abstract
This paper presents a machine learning-driven framework for real-time burst detection in water distribution networks, targeting deployment on resource-constrained embedded edge devices. The proposed method combines the Discrete Wavelet Transform (DWT) with a Wavelet Cross-Correlation (WCC) criterion to extract compact, discriminative features from non-stationary transient pressure signals. Four supervised classifiers are systematically evaluated under the joint constraints of predictive accuracy, memory footprint, and inference latency: Logistic Regression, Decision Trees, Artificial Neural Networks (ANNs), and Support Vector Machines (SVMs). On a laboratory dataset of 454 labeled windows, the SVM achieves the highest accuracy among the tested models while offering substantially lower inference time and memory footprint than the ANN, making it the preferred candidate for embedded deployment. The model is quantized to Q15 fixed-point arithmetic and deployed on a Texas Instruments MSP430FR5994 microcontroller, achieving a 51.3% reduction in model size at the cost of a 114.3% increase in inference time. The total end-to-end processing latency of 21.1 ms is consistent with real-time operation at the tested sampling rate. These results suggest that wavelet-based feature engineering and fixed-point quantization can be optimized to enable practical ML-based burst detection on ultra-low-power microcontrollers.

Keywords: Burst detection, Water distribution networks, Discrete wavelet transform, Support vector machines, Edge computing TinyML, Fixed-point arithmetic

I. INTRODUCTION

Real-time anomaly detection on resource-constrained embedded devices has become a central problem in signal processing and edge machine learning, where inference must run locally under strict energy, memory, and latency budgets. Water distribution networks (WDNs) provide a demanding application domain for this class of problems: pipe bursts are sudden structural failures that produce high-amplitude, non-stationary transient pressure waves, typically lasting less than 2 s, whose delayed detection causes substantial economic, service, and environmental damage [1], [2]. This is acute in infrastructure-limited contexts such as Cuba, where safe drinking water is a recognized human right [3], yet over 50% of the water distributed is lost to leaks [4], [5], [6]. Detecting such transients reliably requires high-frequency sensing, feature extraction, and classification within the computational envelope of low-power microcontrollers; background leaks, by contrast, produce persistent low-amplitude signatures that require more sensitive accelerometric sensing [7].

Burst detection frameworks are broadly classified as model-based or data-driven [8], [9]. Model-based methods rely on calibrated hydraulic models and low-frequency measurements (5–15 min), inadequate for transient events, and their performance degrades severely when accurate network models are unavailable, as in developing infrastructure contexts [10], [11]. Data-driven approaches learn directly from measured signals and, combined with high-frequency sensing, enable accurate transient detection without explicit network models [11]. The Discrete Wavelet Transform (DWT) has emerged as the preferred tool for feature extraction in this context owing to its multiresolution capability, which enables simultaneous time-frequency localization of transient singularities [12]. Machine learning (ML) classifiers applied to wavelet-based features have reported detection rates above 95% with false alarm rates below 1% [1], [13], [14–17]. Beyond binary detection, related studies have addressed leak localization and benchmarked classical statistical methods against ML approaches [18], [19].

A critical open challenge is deploying these pipelines at the network edge, where nodes operate under strict energy, memory, and computational constraints, often without a continuous power supply [20]. Recent surveys on TinyML and on-device inference confirm that ML models can now run on microcontrollers with only kilobytes of RAM, while highlighting open trade-offs among accuracy, model size, and latency [21], [22], [23]. However, integrating high-resolution wavelet feature extraction with lightweight embedded classifiers in a co-designed, end-to-end validated system remains an open problem. This work addresses that gap by jointly optimizing wavelet feature engineering, classifier selection, and fixed-point implementation on a TI MSP430FR5994 microcontroller. The main contributions are: (1) a complete, hardware-aware co-design that integrates DWT/WCC feature extraction, classifier selection, and TinyML deployment into a single real-time pipeline validated end-to-end on a commercial ultra-low-power microcontroller; (2) a fixed-point (Q15) feature-extraction and SVM inference scheme that exploits the MSP430 Low Energy Accelerator and operates within tight memory and execution-time budgets; and (3) a systematic evaluation showing that the proposed SVM attains a 51.3% reduction in model size with no loss of classification performance under joint accuracy and embedded-efficiency constraints.

II. METHODOLOGY

The proposed framework provides an end-to-end pipeline integrating experimental signal acquisition, wavelet-based feature extraction, ML classification, and embedded deployment. DSP stages and ML models are jointly optimized under hardware constraints (co-design), ensuring efficient execution on the target microcontroller.

1. Dataset Description

Pressure signals were acquired on the hydraulic test bench of the Hydraulic Research Center at CUJAE. The setup consists of a high-density polyethylene (HDPE) pipeline (nominal diameter 160 mm, total length 65.2 m) fed by a constant-head tank that maintains a 10 m water column at the inlet. A regulable outlet valve sets a mean

flow velocity of 2 m/s, generating high hydraulic noise and a challenging detection scenario. Two datasets were collected under different sensing configurations, as shown in Figure 1.

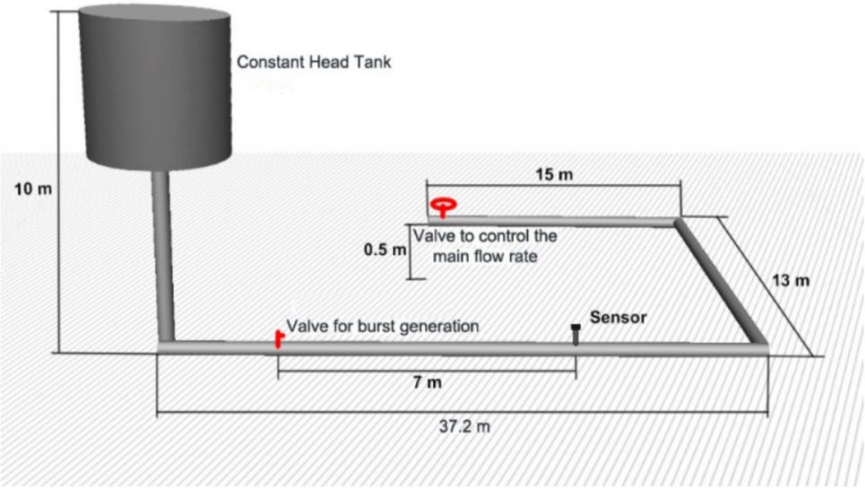

Figure 1. Schematic representation of the experimental setup used for pressure data acquisition.

- Group 1 signals. A Raspberry Pi 3 connected to a MicroSensor MPM3801A digital pressure transducer was used for acquisition at 200 Hz, following the recommendations for ML-based burst detection [13]. Burst events were artificially generated at four distances from the sensor, organized into four subgroups; each of the 120 recordings spans 10 s (2000 samples) and contains a distinct burst event.
- Group 2 signals. An MSP430 microcontroller replaced the Raspberry Pi while retaining the same MPM3801A sensor, positioned 7 m upstream of the simulated leak point. Three leak conditions were defined by flow rates of 0.5, 0.8, and 1.5 L/s; signals were sampled at 400 Hz, and each recording spanned 5 s (2000 samples), yielding 107 files. Combined with Group 1, the full experimental corpus comprises 227 burst recordings.
- Final dataset. Each of the 227 recordings yields one 2-second burst window (Class 1) and one 2-second steady-state noise window (Class 0), producing a balanced dataset of 454 labeled feature vectors, 227 per class. The balanced class distribution eliminates the need for resampling strategies.

2. Data Preprocessing

Preprocessing conditions the raw pressure signals: Group 1 signals were segmented into non-overlapping 2-second windows, sufficient to capture a complete burst transient, and mean-centered to remove the static pressure offset and isolate the dynamic component:

$$x_{centered}[n] = x[n] - \mu_x\,, \quad \mu_x = \frac{1}{N}\sum_1^N x[n] \tag{1}$$

Group 2 signals, originally sampled at 400 Hz, were first decimated to 200 Hz using a 2:1 anti-aliasing filter in MATLAB. This operation halves computational complexity while preserving burst-related content, as transient singularities concentrate their energy well below 100 Hz; the same 2-second windowing and mean-centering was then applied to both groups.

3. Feature Extraction

The DWT was selected for its multiresolution capability, which characterizes local signal singularities at multiple scales simultaneously. Unlike the FFT, which trades away time localization, the DWT preserves both time and frequency resolution [24], essential for non-stationary transients, a choice consistently supported by the burst-detection literature [1], [13], [25], [26]. The DWT is efficiently computed through the Mallat filter bank algorithm [13], whose successive low-pass/high-pass filtering and 2:1 downsampling stages can be accelerated by the Low Energy Accelerator (LEA) of the MSP430FR5994, offloading the CPU from computationally intensive convolutions. A comparative analysis confirmed that for signal lengths between 32 and 256 samples, time-domain convolution outperforms FFT-based methods by 65.3% on the LEA module, thereby motivating a direct filter-bank implementation. The Mallat scheme is illustrated in Fig. 2.

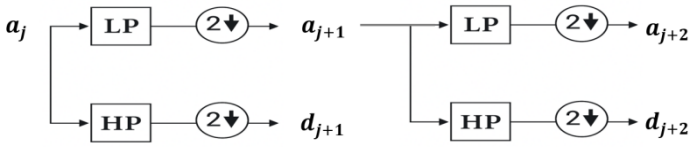

Figure 2. Mallat scheme for computing the DWT [13].

1) Feature extraction strategy. The algorithm computes detail coefficients at decomposition levels 4 and 5 (d_4, d_5), corresponding to the frequency bands [12.5, 25] Hz and [6.25, 12.5] Hz, respectively, at a sampling rate of 200 Hz, where burst-induced singularities concentrate their energy. The WCC is then computed between d_4 and d_5 after linear-interpolation alignment to equalize their lengths, and the modulus $|WCC_4|$ serves as the feature descriptor, following [25]. As illustrated in Figure 3, the burst around the 5th second coincides with a clear $|WCC_4|$ peak, confirming the discriminative power of this descriptor. The wavelet basis was selected through Lipschitz exponent analysis [27]: among multiple candidate wavelets, Coiflet 1 yielded the lowest exponent, indicating stronger singularity enhancement and transient localization.

2) Reference C implementation. A floating-point reference implementation was first developed in standard C on a workstation to establish a numerical baseline free from embedded constraints, to process all 454 windows into a standardized CSV dataset (30 $|WCC_4|$ features plus a binary label per row), and to provide a portable codebase for the embedded target. The core uses a cascaded filter bank with buffer reuse across levels, with WCC computed via interpolation alignment, point-wise multiplication, and magnitude extraction.

3) MSP430FR5994 embedded implementation. The embedded adaptation introduces Q15 fixed-point arithmetic: a 16-bit signed representation (1 sign bit, 15 fractional bits) covering $[-1, \approx 0.99997]$; conversion from floating-point involves normalization to $[-1, 1]$, saturation clamping, and scaling by 32767 with rounding. The MSP-DSPLIB functions msp_fir_q15(), msp_mpy_q15(), msp_abs_q15(), and msp_deinterleave_q15() provide LEA-accelerated fixed-point operations; during LEA execution, the CPU sleeps in LPM0, waking only on interrupt, minimizing energy consumption. All SVM parameters are stored in persistent FRAM sections via #pragma PERSISTENT, enabling efficient access during repeated kernel evaluations. As shown in Figure 4, the embedded implementation exhibits higher $|WCC_4|$ amplitudes near signal singularities compared to the floating-point reference, attributed to improved convolution edge handling by msp_fir_q15(), which yields more discriminative feature vectors.

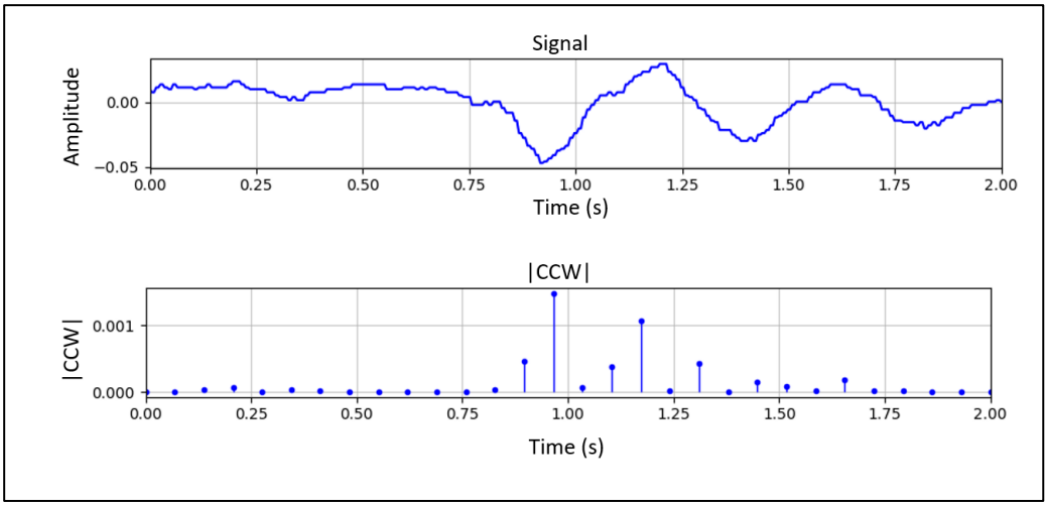

Figure 3. Feature extraction of a pressure signal: raw pressure signal containing a burst event around t = 5 s (top) and the corresponding |WCC$_4$| modulus (bottom), whose dominant peak coincides in time with the burst transient.

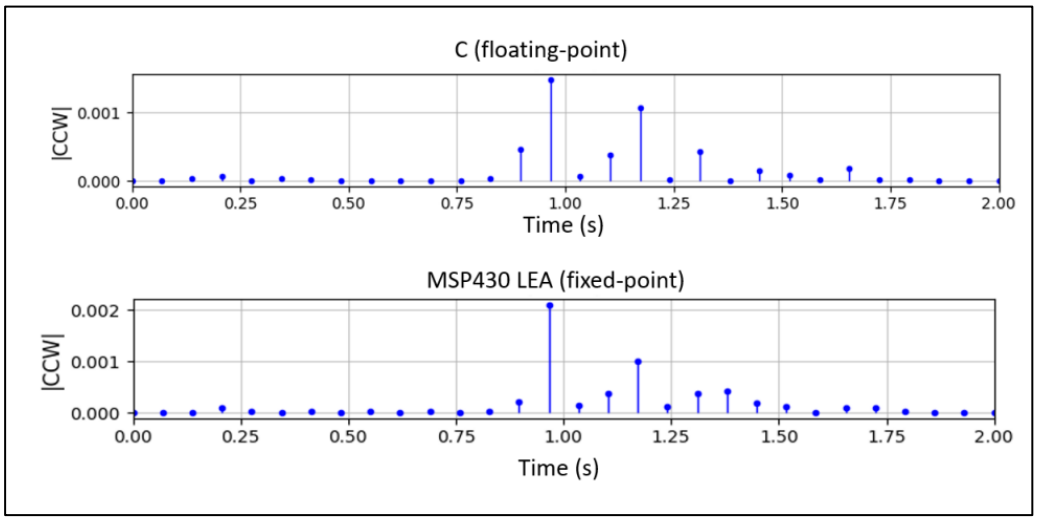

Figure 4. Computation of |WCC$_4$| of the same burst signal: floating-point workstation reference (top) versus Q15 fixed-point implementation on the MSP430 LEA (bottom); both implementations localize the burst at the same coefficient positions.

4. Classification Framework

The 30-dimensional |WCC$_4$| feature vectors trained four classifiers implemented in scikit-learn within a Google Colab environment. To rule out train–test contamination, the dataset was split once into stratified training and test subsets (85%/15% [28]), preserving class balance; the resulting 68-sample test set remained completely unseen during model design. Hyperparameter optimization was confined to the training subset, using exhaustive GridSearchCV with stratified k-fold cross-validation [29], which averages performance across k train/validation partitions and is particularly valuable for medium-sized datasets. Only after this selection was finalized were the models evaluated once on the untouched test set, so the reported metrics reflect generalization to unseen data.

Logistic Regression: configured as a linear classifier with ℓ2 regularization ($C = 10.0$, liblinear solver), penalizing large coefficients to reduce overfitting.

Decision Tree: employs the Gini impurity criterion with a maximum depth of 8 levels; pre-pruning requires at least 5 samples per split and 2 per leaf, balancing expressiveness and generalization.

Artificial Neural Network: a sequential architecture with two hidden layers (64 and 32 neurons), dropout regularization of 30% and 20%, ReLU activations, Adam optimizer, and binary cross-entropy loss; early stopping (patience 10 epochs) monitors validation loss to prevent overfitting. Due to the high-dimensional hyperparameter search space, manual tuning was used instead of GridSearchCV.

Support Vector Machine: implemented via scikit-learn's SVC with an RBF kernel ($C = 10$, $\gamma = 1$) optimized by GridSearchCV. The trained model relies on 152 support vectors, limiting storage to only these vectors, their dual coefficients, and the bias term.

Embedded SVM on MSP430FR5994. Following evaluation, the SVM was ported to the MSP430FR5994 by exporting model parameters from scikit-learn: 152 support vectors (each 30-dimensional), dual coefficients, a bias term, and RBF kernel parameters, which were stored as constant Q15 arrays in FRAM. Inference evaluates the RBF kernel against each support vector and computes the weighted sum plus bias, entirely without external library dependencies.

III. RESULTS

1. Classifier Performance

Table 1 reports test metrics for all four classifiers. Logistic Regression reaches 98% accuracy (one misclassified sample), while the Decision Tree shows the lowest performance (three false positives, one false negative), consistent with the limited generalization of greedy splitting. Both the ANN and the SVM classify every test sample correctly, achieving 100% across all metrics. This confirms that the 30-dimensional $|WCC_4|$ space is sufficiently discriminative to support perfect separation between burst events and background noise.

Table 1. Performance metrics on the independent test dataset

Model	Accuracy	Precision	Recall	F1-score	AUC-ROC
Logistic Regression	98%	100%	97%	98%	99%
Decision Tree	94%	93%	97%	94%	93%
ANN	100%	100%	100%	100%	100%
SVM	100%	100%	100%	100%	100%

Table 2 presents the absolute differences between cross-validation and test performance, measuring model stability across splits. Logistic Regression and Decision Tree exhibit discrepancies of up to 10% in recall, indicating sensitivity to the particular training-test partition. ANN and SVM show minimal variation (no more than 2% in accuracy, 0% in recall), confirming that their perfect test performance reflects genuine generalization rather than favorable data splitting.

Table 2. Absolute differences: cross-validation minus test metrics

Model	Accuracy	Precision	Recall	F1-score	AUC-ROC
Logistic Regression	5%	5%	6%	5%	3%
Decision Tree	7%	6%	10%	7%	5%

ANN	2%	6%	0%	3%	2%
SVM	2%	6%	0%	3%	2%

Given the equivalent predictive performance of ANN and SVM, model selection was based on operational efficiency: the ANN requires 82.1 KB and 132.2 ms inference time, whereas the SVM requires only 41.3 KB and 6.16 ms, roughly 21× faster and 50% smaller. The SVM was therefore selected for embedded deployment, providing the best trade-off between classification performance, memory footprint, and computational efficiency [30]. The latency gap follows from model structure: ANN inference propagates the input through two fully connected hidden layers, whereas the SVM reduces inference to 152 RBF kernel evaluations followed by a single weighted sum, a far smaller and more regular workload on the microcontroller.

2. Embedded Validation

The same 68 test signals were processed end-to-end on the MSP430FR5994: each raw pressure window was passed through the embedded Q15 feature extraction pipeline and classified by the embedded SVM. The confusion matrix (Table 3) shows perfect classification of all 34 normal and 34 burst samples, confirming that the pipeline preserves its predictive integrity under fixed-point representation and embedded constraints.

Table 3. Confusion matrix of the SVM on MSP430FR5994

	Predicted: Normal	Predicted: Burst
Actual: Normal	34	0
Actual: Burst	0	34

3. Cloud vs. Embedded Performance

Table 4 compares the floating-point cloud implementation against the Q15 embedded implementation. Quantization achieves a 51.3% reduction in model size (41.3 KB to 20.1 KB), enabling the model to fit entirely within the 256 KB FRAM of the target device while maintaining a 100% detection rate and 0% false-positive rate. Inference time increases from 6.16 ms to 13.2 ms (+114.3%), attributable to the per-multiply scaling, rounding, and saturation overhead of fixed-point kernel evaluation, which cannot yet fully exploit LEA parallelism; the size reduction, in turn, follows from 16-bit parameters halving the storage of support vectors and coefficients.

Table 4. Cloud (floating-point) vs. embedded (Q15) comparison

Metric	Cloud	Embedded	Difference
Detection Rate	100%	100%	0%
Model Size	41.3 KB	20.1 KB	−51.3%
Inference Time	6.16 ms	13.2 ms	+114.3%

4. Temporal Processing Distribution

Table 5 details the execution time breakdown of the complete on-device pipeline. The total latency of 21.1 ms allows each 2-second window to be processed and classified well within real-time constraints for 200 Hz monitoring. SVM inference is the most demanding stage at 13.2 ms (62.5%), driven by 152 RBF kernel evaluations over 30-dimensional vectors. Preprocessing requires 7.9 ms in total, with approximation coefficient extraction dominating at 5.14 ms (24.3%) due to cascaded filter-bank convolutions at levels 1–4. Interpolation, WCC multiplication, and magnitude computation add 1.80 ms (8.5%). Feature extraction and SVM inference

together account for over 86% of the total latency, making the approximation-coefficient filter bank and the RBF kernel evaluation the natural targets for further LEA-based acceleration.

Table 5. Execution time distribution on MSP430FR5994

Operation	Time (ms)	Percentage
Approximation coefficients (levels 1–4)	5.14	24.3%
Detail coefficients (d_4, d_5)	0.99	4.7%
Interpolation + WCC + magnitude	1.80	8.5%
SVM inference (152 RBF evaluations)	13.2	62.5%
Total	21.1	100%

5. Memory Utilization

Table 6 reports memory utilization on the MSP430FR5994. FRAM is only 10.9% utilized, primarily for the SVM parameters stored via #pragma PERSISTENT. In comparison, SRAM is 43.3% utilized, mainly by the feature-extraction buffers (filter coefficients, intermediate decomposition arrays, and the output feature vector). The remaining headroom leaves substantial capacity for communication stacks, event logging, or algorithm extensions.

Table 6. Memory utilization on MSP430FR5994

Memory	Total	Used	Available
FRAM	256 KB	27.48 KB (10.9%)	228.52 KB (89.1%)
SRAM	8 KB	3.47 KB (43.3%)	4.53 KB (56.7%)

Discussion. The results show that a complete burst-detection pipeline (wavelet-based feature extraction, classifier selection, and inference) can run entirely on an ultra-low-power microcontroller while preserving the predictive performance of its floating-point cloud counterpart. This is the central strength of the approach: detection accuracy and embedded feasibility are not competing objectives, since fixed-point quantization compresses the model without degrading classification, and inference still completes within the real-time budget. The combination of a compact $|WCC_4|$ descriptor, fixed-point arithmetic, and LEA-accelerated processing thus offers a practical basis for autonomous, in-network monitoring, with ample memory headroom for communication and logging. These findings should be read within the scope of the study: the experiments used a single laboratory test bench with a controlled HDPE pipeline and artificially induced bursts, whereas operational networks differ in pipe materials, pressures, and background noise. The perfect classification reported here, therefore, establishes feasibility on the target hardware rather than field performance: the held-out test set contains 68 windows, so the reported metrics carry the statistical uncertainty of a small sample and were not accompanied by a significance analysis across repeated data partitions. This reading is consistent with related embedded ML studies on water infrastructure, which report high but imperfect accuracies on more heterogeneous data [31], [32], and with field deployments of data-driven burst detection in operational networks, where performance is assessed against repair records and a considerable share of alerts does not correspond to confirmed bursts [33]. Validation on operational networks with a larger, more varied dataset, together with statistical robustness analysis across repeated splits and benchmarking against additional lightweight classifiers such as gradient-boosted trees and compact one-dimensional convolutional networks, is the natural next step, made feasible by the solution's low cost and power consumption.

IV. CONCLUSION

This work has presented a co-designed framework for real-time burst detection in WDNs and has been validated end-to-end on an MSP430FR5994 ultra-low-power microcontroller. The combination of DWT and WCC applied to detail coefficients at levels 4 and 5, using a Coiflet-1 basis, yields a compact 30-dimensional feature descriptor that achieves clear separation between burst events and background noise, with the targeted frequency sub-bands (6.25–25 Hz) physically aligned with the energy concentration of burst-induced transients.

Among the four evaluated classifiers, ANN and SVM achieve 100% accuracy on the independent test dataset with minimal cross-validation variability. The SVM was selected for embedded deployment owing to its 21× lower inference latency and 50% smaller footprint, with no sacrifice in predictive performance. Q15 quantization further reduces the embedded model size by 51.3% with no classification performance loss, confirming precision reduction as a viable compression strategy for TinyML deployment. The end-to-end latency of 21.1 ms remains well within real-time constraints for 200 Hz monitoring, and the pipeline occupies only 10.9% of FRAM and 43.3% of SRAM, leaving substantial headroom for communication or logging modules.

Future work will address multi-sensor network topologies for burst localization, further latency reduction through LEA-optimized RBF kernel computation, online adaptation strategies to handle hydraulic operating condition drift, and field validation on real WDN infrastructure with heterogeneous pipe materials and pressures.

Abstract
Hospitals are common targets for cybercriminals, and most ransomware attacks in healthcare start with a phishing email. Phishing (sending fake emails or messages designed to trick users into clicking malicious links, opening infected attachments, or revealing sensitive information such as login credentials) can give criminals access to hospital systems or allow malicious software, including ransomware, to spread through the network and disrupt operations. The problem is that most cybersecurity training programs are for the IT specialists, not for nurses or doctors. International guidelines such as the NIST Cybersecurity Framework and ENISA guidance are useful at an organizational level, but do not tell a ward nurse what to do when she receives a suspicious email. This paper describes a Work-in-Progress model called the Role-Based Phishing-to-Ransomware Readiness Model, built around a ward nurse persona developed within the XiA (Xpanding Innovative Alliance) project. This XiA approach focuses on developing human-centric, explainable AI systems that support decision-making in complex operational environments. The XiA persona (a typical ward nurse supported by an AI-based assistant that provides clear, context-aware, and explainable guidance in everyday clinical situations) is used to translate abstract cybersecurity concepts into practical, role-specific actions that are understandable and relevant for clinical staff without technical expertise. The developed model combines a visual attack chain, a role-based action table, and a short training scenario to help clinical staff recognize phishing attempts and respond appropriately in real-world situations. Testing with real staff is planned as future work.

Keywords: phishing, ransomware, healthcare cybersecurity, clinical staff, role-based training, XiA persona

I. INTRODUCTION

Hospitals increasingly rely on interconnected digital systems to support patient care, diagnosis, communication, and administrative processes. While this digital transformation improves the efficiency and quality of healthcare services, it also expands the attack surface available to cybercriminals. Among the most common cyber threats targeting healthcare organizations are phishing attacks, which attempt to trick users into revealing credentials, opening malicious attachments, or clicking harmful links. Once access is obtained, attackers may deploy ransomware that disrupts clinical operations and jeopardizes patient safety. A recent example occurred in London in 2024, where a ransomware-related cyberattack led to the cancellation of more than 800 planned medical procedures within a single week [1]. Previous research has similarly demonstrated that human behavior

often determines whether an initial phishing incident develops into a large-scale ransomware event [2]. As healthcare organizations continue to strengthen their technical cybersecurity capabilities, increasing attention has been paid to the human dimension of cyber resilience. Existing cybersecurity frameworks, including the NIST Cybersecurity Framework [3] and ENISA guidance [4], provide valuable organizational and governance-level recommendations. However, these frameworks typically focus on risk management, policies, and technical controls rather than on the practical decisions that frontline healthcare workers must make when confronted with suspicious emails or other potential cyber threats during routine clinical work. Consequently, nurses, physicians, and other clinical personnel often receive cybersecurity training that is either overly generic or overly technical, undermining real-time decision-making in healthcare environments characterized by time pressure, interruptions, and high workloads. Although phishing awareness, ransomware preparedness, and cybersecurity education have been widely studied, an important gap remains between organizational cybersecurity guidance and role-specific operational support for frontline healthcare professionals. Existing studies commonly emphasize awareness training, organizational policies, or general user behavior. In contrast, relatively little attention has been given to translating phishing-to-ransomware attack pathways into practical, role-based guidance tailored to specific healthcare professions. Furthermore, the potential of persona-based educational approaches and explainable learning mechanisms for supporting cybersecurity readiness among clinical staff remains underexplored. This study addresses this gap by developing a Role-Based Phishing-to-Ransomware Readiness Model for clinical staff. The work is connected to the XiA (Xpanding Innovative Alliance) project. This European initiative promotes human-centered and explainable approaches for strengthening competencies related to the European Health Data Space (EHDS) [4]. Within the XiA framework, personas are used to bridge the gap between complex technical concepts and the practical needs of different user groups. In this study, a ward nurse persona is employed to represent a typical frontline healthcare professional who may encounter phishing attacks during everyday clinical work. The proposed model combines a healthcare-specific phishing-to-ransomware attack chain, a persona-based learning perspective inspired by XiA principles, and a role-based action framework designed to support practical decision-making during cyber incidents. Rather than focusing on technical countermeasures, the model seeks to translate cybersecurity knowledge into clear, actionable guidance for non-technical clinical personnel.

The contributions of this Work-in-Progress paper are fourfold:

- A healthcare-specific phishing-to-ransomware readiness model that visualizes how phishing incidents may escalate into ransomware attacks.
- A XiA-inspired persona-based approach for translating cybersecurity concepts into practical guidance for frontline clinical staff.
- A role-based action framework that links different stages of an attack to concrete response actions understandable by non-technical healthcare professionals.
- A foundation for future XiA-enabled intelligent assistants capable of providing explainable and context-aware cybersecurity support within healthcare environments.

The remainder of this paper is organized as follows. Section II reviews the relevant literature on phishing, ransomware, healthcare cybersecurity training, and the XiA project. Section III presents the Design Science Research approach used to develop the proposed model. Section IV describes the resulting artifacts, including the attack chain, persona-based learning framework, role-based action table, and training scenario. Section V discusses the current status of the work, limitations, and future research directions. Finally, Section VI concludes the paper and outlines opportunities for empirical validation and further integration within the XiA framework.

II. BACKGROUND AND RELATED WORK

Healthcare is one of the primary targets of cybercrime because hospitals store sensitive personal data and depend on continuous operations for patient care. As a result, healthcare organizations are often considered more likely

to pay a ransom following a cyberattack, making them attractive targets for ransomware groups [5]. Phishing remains the most common initial attack vector through which ransomware gains access to healthcare systems [2].

Research has consistently shown that human behavior plays a critical role in cybersecurity outcomes. Despite this recognition, most existing frameworks and training materials are designed for IT professionals and focus on organizational controls rather than everyday decision-making in clinical work [6]. Prümmer, van Steen, and van den Berg [7] conducted a meta-analysis of cybersecurity training studies. They found that traditional training programs typically improve users' knowledge but do not reliably change their behavior in stressful real-world situations. In healthcare environments characterized by time pressure, frequent interruptions, and high workloads, this gap between knowing and acting can significantly increase cybersecurity risks. Recent research has also examined the effectiveness of organizational phishing-awareness training in real operational environments. Hillman, Harel, and Toch [8] conducted a controlled experiment involving approximately 5,000 employees in a large financial institution and found that users were significantly more likely to engage with phishing emails containing personalized content. Their results further showed that phishing susceptibility varied across organizational units, while the timing of awareness training alone did not significantly affect phishing click-through rates. The study emphasizes the importance of data-driven, role-sensitive awareness programs. It suggests that employee behavior remains a critical factor in organizational cyber resilience despite advances in technical security controls. These findings further support the need for tailored and context-aware cybersecurity guidance rather than generic awareness training. The importance of actionable guidance is also supported by research grounded in Protection Motivation Theory (PMT). Van Bavel et al. [9] studied the effects of behavioral nudges on online security behavior using a large-scale experiment involving more than 2,000 participants from five European countries. Their findings showed that messages that provided clear coping strategies were significantly more effective at promoting secure behavior than messages that focused primarily on threat consequences. Furthermore, coping-focused messages were found to be as effective as combining both threat and coping messages. These results suggest that cybersecurity interventions should not only raise awareness of risks but also provide users with simple and actionable recommendations. This finding aligns with the objective of the present study, which seeks to translate cybersecurity threats into role-based actions that healthcare professionals can apply in everyday clinical situations. Both the NIST Cybersecurity Framework [3] and ENISA guidance [4] acknowledge the importance of the human factor in cybersecurity. However, these frameworks primarily focus on governance, risk management, and technical controls rather than providing practical instructions for frontline healthcare workers. Similarly, Syafrizal et al. [10] observed that many cybersecurity standards inadequately address role-specific human vulnerabilities. Kruse et al. [11] further found that healthcare professionals benefit most from training that is directly connected to their daily work practices rather than from generic awareness programs. Taken together, these findings suggest that effective cybersecurity education should provide practical, role-oriented guidance tailored to the responsibilities and decision-making contexts of specific user groups. This role-based perspective aligns closely with the objectives of the XiA (Xpanding Innovative Alliance) Project [12]. XiA recognizes that interoperability is not solely a technical challenge involving standards and technologies, but also a human challenge requiring professionals to understand, apply, and further develop interoperability concepts in real-world settings. To address this need, the project combines EHDS-aligned interoperability expertise with innovative educational approaches, including modular learning building blocks, flexible micro-learning pathways, standards-based practical content, and progressive recognition of competencies through micro-credentials. These principles are intended to support professionals, educators, and organizations in developing and maintaining competencies over time. A key principle of XiA is that digital transformation requires different stakeholder groups to acquire different competencies [13]. Consequently, XiA categorizes learners into three broad groups: developers, implementers, and end-users. Developers focus on building and maintaining interoperable digital health systems, implementers are responsible for planning, integrating, and governing such systems, and end-users include healthcare professionals who use digital solutions in their daily clinical practice. This learner-centered approach supports the development of personalized learning pathways tailored to specific professional roles and responsibilities [13]. The present study adopts this XiA-inspired perspective by focusing on an end-user persona representing a ward nurse. Rather than

presenting cybersecurity concepts through technical terminology or organizational policies, the study translates phishing and ransomware threats into practical, role-specific guidance that reflects the realities of clinical work. In doing so, the proposed approach seeks to bridge the gap between cybersecurity knowledge and everyday decision-making, thereby supporting safer, more informed behavior among frontline healthcare professionals.

III. SOLUTION AND APPROACH

This study adopted a Design Science Research (DSR) approach [14] to develop a role-based educational model for improving phishing-to-ransomware readiness among clinical staff, as illustrated in Figure 1. The model was developed through iterative interaction between healthcare cybersecurity requirements, XiA-based educational principles, and established cybersecurity knowledge. The building process consisted of four phases. First, a literature review was conducted to examine academic research and authoritative guidance from ENISA and NIST. The objective was to identify how phishing attacks evolve into ransomware incidents in healthcare environments and to determine the limitations of existing cybersecurity training approaches. Second, the authors further developed a XiA-based persona representing a typical ward nurse. Personas are fictional yet realistic representations of target users that help translate abstract concepts into practical, relatable scenarios. The selected persona reflects the daily reality of many healthcare professionals: working under time pressure, using shared clinical workstations, and frequently receiving emails related to patient information, laboratory results, or shift schedules. These characteristics also correspond to common phishing lures used by cybercriminals. The persona attributes were derived from findings reported in healthcare cybersecurity literature, particularly studies describing clinical workflows, workload pressures, email usage patterns, and common phishing exposure factors among nursing staff.

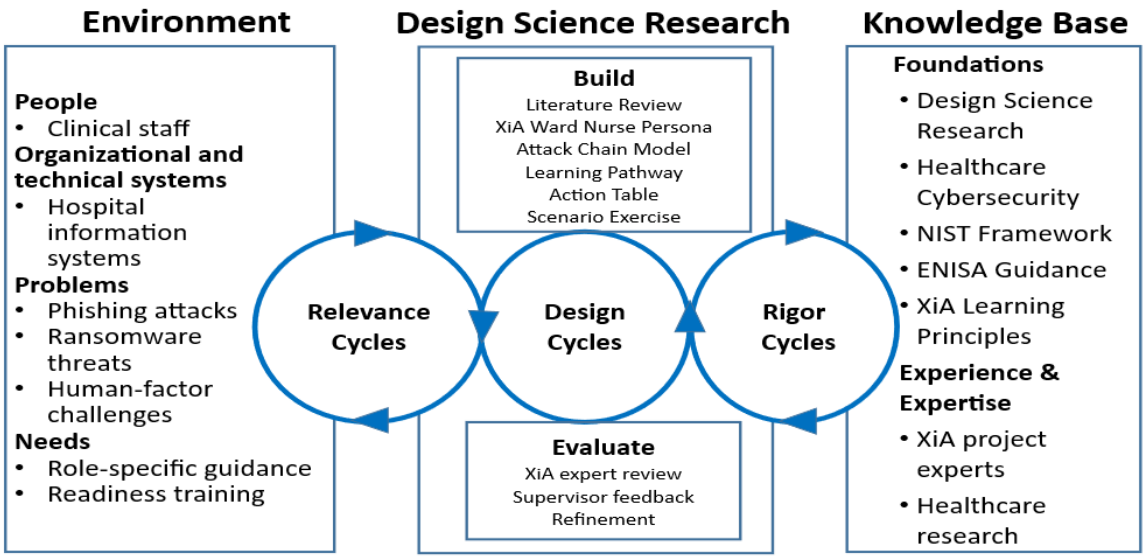

Figure 1. Design science research process applied to the development of the role-based phishing-to-ransomware readiness model.

Third, the findings from the literature review and the ward nurse persona were combined to create a visual phishing-to-ransomware attack chain, a XiA-enabled role-based cybersecurity learning framework, and a role-based action table. These artifacts were designed to transform cybersecurity knowledge into clear, actionable guidance adapted to the needs and responsibilities of frontline clinical staff. Finally, the proposed model was reviewed by supervisors and experts associated with the XiA project. Their feedback was used to refine the

model and improve its clarity, usability, and alignment with the XiA principles. The main outputs of this Work-in-Progress study are the six-stage phishing-to-ransomware attack chain presented in Figure 2, the XiA-enabled role-based cybersecurity guidance framework presented in Figure 3, the role-based action table presented in Table 2, and the training scenario described in Section IV.5.

IV. RESULTS

This section presents the key components of the developed model, explaining how phishing attacks can evolve into ransomware incidents in a healthcare setting and how clinical staff can intervene at different stages. The section combines attack pathways identified in the literature with a user-centered perspective informed by the XiA persona and practical response guidance. The goal is to translate abstract cybersecurity knowledge into clear, role-specific actions that can be directly applied in everyday clinical work.

1. The Attack Chain

Figure 2 presents the six-stage phishing-to-ransomware attack chain identified from the literature. The model illustrates how a phishing email can lead to credential compromise, unauthorized system access, ransomware deployment, and ultimately disruption of healthcare operations. The objective is to support clinical staff in recognizing and potentially interrupting the attack during its early stages.

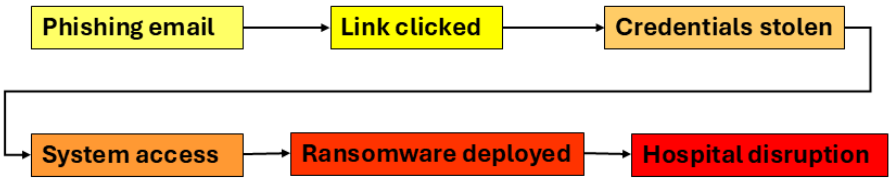

Figure 2. Six-stage phishing-to-ransomware attack chain in a healthcare setting.

2. Mapping to Established Cybersecurity Frameworks

To strengthen the theoretical grounding of the proposed model, the six-stage phishing-to-ransomware attack chain was mapped against two widely recognized cybersecurity frameworks: the Lockheed Martin Cyber Kill Chain [15] and the MITRE ATT&CK framework [16]. The Cyber Kill Chain describes the progression of a cyberattack from initial delivery to the achievement of the attacker's objectives. At the same time, MITRE ATT&CK provides a knowledge base of adversarial tactics and techniques observed in real-world cyber incidents. The comparison demonstrates that the proposed attack chain does not introduce a new technical taxonomy of cyberattacks. Instead, it adapts established attack concepts into a healthcare-oriented educational artifact designed to support frontline clinical staff. By translating technical attack stages into role-specific, actionable concepts, the model aims to improve the clarity and practical relevance of cybersecurity guidance for non-technical healthcare professionals.

Table 1 presents the mapping between the proposed attack chain and the corresponding phases of the Cyber Kill Chain and MITRE ATT&CK frameworks.

Table 1. Mapping of the proposed attack chain to established cybersecurity frameworks

Proposed Stage	Cyber Kill Chain [15]	MITRE ATT&CK [16]
Phishing Email	Delivery	Initial Access
Link Clicked	Exploitation	Execution
Credentials Stolen	Exploitation / Credential Theft	Credential Access
System Access	Actions on Objectives	Persistence / Lateral Movement
Ransomware Deployed	Actions on Objectives	Impact
Hospital Disruption	Actions on Objectives	Impact

The mapping confirms that each stage in the proposed model corresponds to attack behaviors already recognized in established cybersecurity literature and practice. The novelty of the present work, therefore, lies not in defining new attack stages but in integrating these stages with XiA-inspired personas, role-based guidance, and healthcare-specific learning materials. This approach transforms technical cybersecurity knowledge into a more accessible and actionable format for clinical end-users.

3. Role Exposure and the XiA Persona

Not all hospital staff face the same phishing risk. Table 2 compares phishing exposure across four healthcare roles based on findings from [2] and [17]. The XiA ward nurse persona represents a high-exposure role due to frequent interaction with time-sensitive communications, including Electronic Health Record (EHR) notifications.

Table 2. Comparison of phishing exposure across healthcare roles (adapted from [2] and [17])

Role	Common phishing lure	Exposure level	Response Urgency
Ward nurse	Lab result/rota update	High	Very High
Physician	Referral / EHR notice	High	Very High
Admin staff	Invoice / HR/supplier email	Medium	Moderate

Role	Common phishing lure	Exposure level	Response Urgency
IT support	Password reset/support ticket	Critical	Immediate

4. XiA-enabled Cybersecurity Guidance

While Figure 2 illustrates how a phishing attack can progress to ransomware, Figure 3 demonstrates how XiA principles can be used to provide explainable, context-aware guidance that helps users interrupt the attack chain before it reaches the disruption stage.

Figure 3. XiA-enabled role-based cybersecurity learning framework.

5. Role-based Action Table

Table 3 provides a simple action for each clinical staff member at each stage of an attack. The actions are written in plain language because recent research [7] shows that short, specific instructions work much better in clinical situations than long policy documents. The key message is that reporting a mistake early is much better than staying silent. When a staff member immediately reports a suspicious link to the IT team after clicking it, the security team can start blocking the attack before it spreads. Early reporting is one of the most effective ways to limit damage [4].

Table 3. Role-based response actions for clinical staff (adapted from [17] and [18])

Stage	Situation	Recommended action
Phishing email	You received a suspicious message	Do not click any links or open attachments. Report the email to IT.
Link clicked	You may have clicked something bad.	Disconnect your device from the network right away. Then report to IT immediately.

Stage	Situation	Recommended action
Credentials at risk	Your login details may have been stolen	Change your password now and call IT. Do not wait.
Strange behaviour	Your computer is acting unusually.	Stop using the device, but do not shut it down. Inform IT as soon as possible.
Ransomware	Systems are locked, or files cannot be opened.	Follow your hospital emergency cyber response procedure. Do not try to fix it yourself.

6. Scenario Exercise

A nurse arrives for her shift and checks her email. She notices a message labeled “Urgent: patient test results, action required.” Because the message appears legitimate, and she is working under time pressure, she clicks the link and enters her credentials on a fake login page. A few hours later, hospital systems begin to malfunction, and staff are unable to access patient records due to ransomware. The scenario is used alongside Table 3 to help participants identify where the attack could have been interrupted. For example, reporting the suspicious email before clicking it or notifying IT immediately after entering credentials could have allowed the incident to be contained before ransomware was deployed.

V. DISCUSSION

This section discusses the current status of the developed model, its limitations, and the planned next steps. The aim is to critically assess how well the proposed approach addresses the practical needs of healthcare environments and to identify remaining gaps before broader implementation. In addition, the section outlines concrete actions to further develop, evaluate, and integrate the model into the broader XiA project framework. The proposed model can be viewed as a prototype knowledge structure for future XiA persona-based assistants. The attack stages, explanations, and role-specific recommendations could be integrated into an intelligent agent that provides context-aware cybersecurity guidance to healthcare professionals in real time. The most important limitation is that the model has not been tested with real clinical staff, so it is not yet known whether it changes actual behavior. Most of the research reviewed was conducted in Western Europe and North America, so the model may not apply equally well to other healthcare systems. The XiA persona was built from published research rather than interviews with real nurses, and the training scenario is simpler than a real targeted phishing attack, which is usually harder to detect. The attack-chain model, XiA persona, role-based action table, training

scenario, and literature review have been completed. Future work includes developing additional personas, producing supporting learning materials, and carrying out the planned evaluation. To support the further development of the model and its implementation, the following concrete actions are proposed:

- Expand the persona set to cover the three XiA learner groups (Developers, Implementers, and End-Users) by developing representative personas, role-specific phishing scenarios, and tailored response guidance for each group.
- Produce a printable checklist for hospital workstations.
- Run a tabletop exercise with peers. A tabletop exercise is a structured group discussion in which participants talk through a simulated attack scenario to assess whether the model is clear and easy to follow.
- Write up the final findings and include them in the XiA project documentation.

VI. CONCLUSION

Cybersecurity training is often designed from an organizational or technical perspective and may provide limited support for frontline healthcare professionals when making security-related decisions in everyday clinical practice. This Work-in-Progress study presents the Role-Based Phishing-to-Ransomware Readiness Model, which combines a healthcare-oriented phishing-to-ransomware attack chain, a XiA-inspired persona-based learning approach, and role-based response guidance for clinical staff. Rather than proposing a new cybersecurity framework or attack taxonomy, the model adapts established cybersecurity concepts into a form that is understandable and actionable for non-technical healthcare professionals. The work contributes a preliminary design artifact that may help bridge the gap between organizational cybersecurity guidance and the practical realities of clinical work. The proposed model has been developed through literature review, Design Science Research principles, and feedback from XiA-related experts. However, the model has not yet been evaluated with healthcare professionals in operational settings. Consequently, no conclusions can currently be drawn regarding its effectiveness in improving phishing awareness, reporting behavior, decision-making, or ransomware readiness. Despite these limitations, the study suggests that persona-based and role-oriented approaches may offer a useful direction for translating cybersecurity knowledge into practical guidance for different healthcare stakeholder groups. The model may also provide a foundation for future XiA-compatible intelligent assistants that deliver explainable, context-aware cybersecurity support. Future work will focus on empirical validation with healthcare professionals, refinement of the personas and learning materials, and the development of measurable evaluation criteria. Such studies are needed to determine whether the proposed approach can contribute to improved cybersecurity behavior and preparedness in real healthcare environments.

ACKNOWLEDGEMENTS

The authors would like to thank the XiA project (funded by the European Union under Grant Agreement No. 101187650) for providing an inspiring and timely research topic, as well as for the valuable guidance and support throughout the research process. The constructive feedback helped shape the model's development and improve its practical relevance.

ETHICS DECLARATION

This project did not involve experiments with human participants or the collection or processing of personal data. No ethical clearance was required. All research followed the academic integrity guidelines of Laurea University of Applied Sciences.

AI DECLARATION

Artificial intelligence tools, including ChatGPT and Claude, were used to support language editing, structure checking, and clarity improvements during the preparation of this paper. The authors made all ideas, analyses, conclusions, and final editorial decisions.

Abstract
This paper presents an explainable machine learning framework for predicting heart disease risk that evaluates models not only on predictive performance but also on the stability and clinical relevance of their explanations. Two datasets with different characteristics were used: the CDC dataset (over 440,000 records and 39 features after encoding) and the smaller clinical Heart Failure dataset (918 patients and 11 features). Six machine learning algorithms were implemented and compared: Logistic Regression, Random Forest, XGBoost, LightGBM, CatBoost, and TabNet. Models were evaluated using standard classification metrics, with an emphasis on recall given the clinical cost of false negatives. SHAP, LIME, Permutation Feature Importance, and Partial Dependence Plots were employed to explain model predictions. The stability of SHAP explanations was assessed across five different random seeds and five independent train/test splits using the Jaccard and Spearman coefficients. At the same time, clinical interpretability was evaluated by comparing the most important features with established risk factors reported in clinical guidelines. A composite score was proposed to integrate predictive performance, explanation stability, and clinical alignment into a single evaluation metric. The results demonstrate that the model achieving the highest ROC-AUC does not necessarily provide the most stable or clinically aligned explanations, indicating that model selection for medical applications should not rely solely on conventional predictive performance metrics.

Keywords: explainable artificial intelligence, heart disease prediction, SHAP, feature importance stability, clinical interpretability, machine learning

I. INTRODUCTION

Cardiovascular diseases are the leading cause of mortality worldwide, accounting for nearly one-third of all annual deaths, many of which are preventable if high-risk patients are identified at an early stage. Machine learning (ML) algorithms have demonstrated increasingly reliable predictive performance in disease detection, with ensemble models such as Random Forest, XGBoost, and gradient-boosted variants consistently achieving the highest classification accuracy when trained on clinical and demographic data [1],[2],[3]. However, these high-performing models are inherently black-box systems whose decision-making processes cannot be directly interpreted [4],[5]. In medical practice, this represents a significant limitation, as clinicians who cannot understand why a patient has been classified as high risk may find it difficult to justify such predictions within clinical decision-making protocols [6],[7]. To bridge the gap between predictive performance and trustworthiness, Explainable Artificial Intelligence (XAI) techniques, particularly SHAP (Shapley Additive exPlanations) and LIME (Local Interpretable Model-agnostic Explanations), are widely employed to quantify the contribution of individual features to model predictions [4],[6],[8],[9],[10].

This study is based on the premise that, in medical applications, the best model is not necessarily the one with the highest predictive accuracy, but rather the one that achieves the best balance between predictive performance, explanation stability, and clinical relevance. To address this issue, an explainable machine learning framework is developed and evaluated, assessing models across all three dimensions simultaneously. The authors are not medical professionals; clinical interpretability here refers solely to alignment with risk factors from published guidelines [1],[6],[7],[8], not independent medical validation.

II. LITERATURE REVIEW

A considerable body of research has focused on ML algorithms for heart disease prediction, with the most commonly compared models including Logistic Regression, Decision Tree, Random Forest, SVM, KNN, Gradient Boosting, and XGBoost [1],[2],[3]. Ensemble methods consistently outperform traditional linear models in predictive performance [2]. To overcome the black-box nature of complex predictive models, many recent studies combine heart disease prediction with Explainable Artificial Intelligence (XAI) techniques such as SHAP and LIME [4–11]. Fewer studies investigate the stability of feature importance analyses and show that feature rankings may vary across different data samples or model initializations [12],[13],[14]. Based on the reviewed literature, three main research directions can be identified. The first improves predictive performance [1], [2], [3]; the second applies XAI for transparency [4–11]; and the third investigates explanation stability [12], [13], [14], but independently of heart disease prediction. None of the reviewed studies simultaneously considers all three aspects: predictive performance, the stability of XAI explanations across different data splits, random seed values, and the validation of the clinical relevance of these explanations against established clinical guidelines. Addressing this research gap is the primary objective of this study, which integrates these three dimensions into a unified framework for evaluating machine learning models.

III. METHODOLOGY

Previous studies on machine learning and XAI for heart disease prediction recommend comparing multiple machine learning models using standardized preprocessing procedures and publicly available datasets while complementing predictive evaluation with XAI techniques such as SHAP and LIME to improve model transparency [1–11]. Moreover, recent research highlights the need to assess the reliability and consistency of feature importance explanations [12–14]. Based on these findings, this study applies a comparative experimental methodology using two benchmark datasets, six machine learning models, multiple XAI techniques, and an explainability stability analysis.

Datasets: Two publicly available datasets from the Kaggle platform were used in this study [15],[16]. These datasets differ in size, data type, and clinical specificity.

Dataset A, Indicators of Heart Disease [15], contains over 440,000 CDC BRFSS survey records with demographic, lifestyle, and medical condition variables. The target variable (HadHeartAttack) is highly imbalanced (94.4% negative, 5.6% positive)

Dataset B, Heart Failure Prediction Dataset [16], combines five clinical datasets into 918 patient records with 11 clinical variables (age, sex, ChestPainType, RestingBP, Cholesterol, FastingBS, RestingECG, MaxHR, ExerciseAngina, Oldpeak, ST_Slope). Classes are approximately balanced.

Data Preprocessing: Numerical variables with missing values were imputed using the median, while categorical variables were imputed using the mode. Categorical features were encoded, and numerical features were

standardized using the StandardScaler transformation. The dataset was split into training and testing sets in an 80/20 ratio with stratification of the target variable. To prevent data leakage, scaling and SMOTE (Synthetic Minority Over-sampling Technique) [17] were applied exclusively on the training set.

Implemented Machine Learning Models: Six algorithms were selected based on prevalence in the literature and methodological complementarity: Logistic Regression, Random Forest, XGBoost, LightGBM, CatBoost, and TabNet [1],[2],[3],[4].

Evaluation Metrics: Models were evaluated using accuracy, balanced accuracy, precision, recall, F1-score, ROC-AUC, and PR-AUC, with emphasis on recall and PR-AUC given the clinical cost of false negatives.

XAI Methods: To interpret model predictions, four complementary Explainable Artificial Intelligence (XAI) techniques were applied: SHAP, LIME, Permutation Feature Importance (PFI), and Partial Dependence Plots (PDP).

Explainability Stability Analysis: A central contribution of this study is the evaluation of SHAP explanation stability at two levels: five random seeds (seeds 42–46, fixed data split) and five independent 80/20 train-test splits, using Jaccard@10 and Spearman ρ as stability metrics.

Clinical Interpretability: Clinical interpretability was evaluated by comparing the top-10 SHAP features with established cardiovascular risk factors reported in clinical guidelines.

Composite Scoring: A composite score integrating predictive performance, explanation stability, and clinical alignment was computed to compare models.

IV. RESULTS

Table 1 presents the performance of all models on Dataset A. Due to class imbalance, accuracy is misleading on Dataset A; values above 0.94 reflect dominance of the majority class. The three gradient boosting models (XGBoost, LightGBM, and CatBoost) achieve the highest ROC-AUC (≈ 0.886) and PR-AUC (0.41–0.42), but exhibit very low recall for the positive class (0.237–0.247), meaning that approximately three-quarters of actual positive cases are missed. In contrast, Logistic Regression and TabNet, despite slightly lower ROC-AUC values (0.878 and 0.862, respectively), achieve substantially higher recall (0.765 and 0.736) and balanced accuracy above 0.78. This inversion is a direct consequence of decision-threshold effects and SMOTE balancing, and is clinically significant because it reflects the proportion of correctly identified patients with heart disease.

Table 1. Model Performance - Dataset A

Model	**Model Performance - Dataset A**					
	Recall (HD)	***F1 (macro)***	***Balanced Accuracy***	***ROC-AUC***	***PR-AUC***	***Specificity***
Logistic Regression	0.765	0.612	0.795	0.878	0.391	0.826
Random Forest	0.438	0.710	0.704	0.879	0.380	0.970
XGBoost	0.247	0.659	0.618	0.887	0.411	0.989
LightGBM	0.237	0.653	0.613	0.886	0.411	0.989
CatBoost	0.241	0.658	0.616	0.886	0.420	0.990
TabNet	0.736	0.605	0.780	0.862	0.347	0.823

Model	Model Performance - Dataset A					
	Recall (HD)	***F1 (macro)***	***Balanced Accuracy***	***ROC-AUC***	***PR-AUC***	***Specificity***
Logistic Regression	0.765	0.612	0.795	0.878	0.391	0.826
Random Forest	0.438	0.710	0.704	0.879	0.380	0.970
XGBoost (tuned)	0.472	0.718	0.720	0.881	0.395	0.968
CatBoost (tuned)	0.471	0.781	0.719	0.880	0.405	0.967

On the smaller, balanced Dataset B, all models achieve consistently high performance (Table 2), with ROC-AUC ranging from 0.897 to 0.933 and recall from 0.853 to 0.941. Unlike Dataset A, there is no accuracy–recall trade-off, confirming that class imbalance, and not algorithm choice, drives model behavior on imbalanced data.

Table 2. Model Performance — Dataset B

Model	Model Performance - Dataset B					
	Recall (HD)	***F1 (macro)***	***Balanced Accuracy***	***ROC-AUC***	***PR-AUC***	***Specificity***
Logistic Regression	0.931	0.866	0.862	0.897	0.879	0.793
Random Forest	0.922	0.901	0.900	0.927	0.914	0.878
XGBoost	0.853	0.858	0.859	0.926	0.934	0.866
LightGBM	0.873	0.874	0.875	0.932	0.936	0.878
CatBoost	0.863	0.874	0.876	0.931	0.935	0.890
TabNet	0.931	0.866	0.862	0.933	0.944	0.793
XGBoost (tuned)	0.922	0.878	0.875	0.921	0.917	0.829
CatBoost (tuned)	0.941	0.894	0.891	0.931	0.931	0.842

1. Hyperparameter Tuning

Bayesian optimization using the Optuna library [18] was applied to XGBoost and CatBoost, the two models achieving the highest macro F1-score on Dataset A. The optimization process significantly improved the F1 (macro) score from a baseline of approximately 0.658 to approximately 0.718 for both models, primarily by increasing recall for the positive class (HD), from approximately 0.24 to approximately 0.47.

2. Global Feature Importance (SHAP)

Global SHAP analysis reveals a high degree of consistency across models. On Dataset A, HadAngina and AgeCategory are the most dominant features across all models, followed by GeneralHealth, SleepHours, and RemovedTeeth (Figure 1). On Dataset B, ST_Slope emerges as the most influential feature across all models (Mean |SHAP| range: 1.15–2.05), followed by ChestPainType and Cholesterol (Figure 2). Pairwise Spearman rank correlations between the five models' full SHAP-based feature rankings quantify this consistency: the four tree-based models (Random Forest, XGBoost, LightGBM, and CatBoost) show strong mutual agreement (ρ = 0.88–0.97 on Dataset A, ρ = 0.78–0.95 on Dataset B), whereas Logistic Regression correlates more moderately with the tree ensembles (ρ = 0.65–0.73 on Dataset A, ρ = 0.69–0.78 on Dataset B), reflecting the expected divergence between linear and non-linear explanation structures. The dominance of ST-segment slope is clinically consistent with its well-established prognostic importance in ECG-based cardiac assessment.

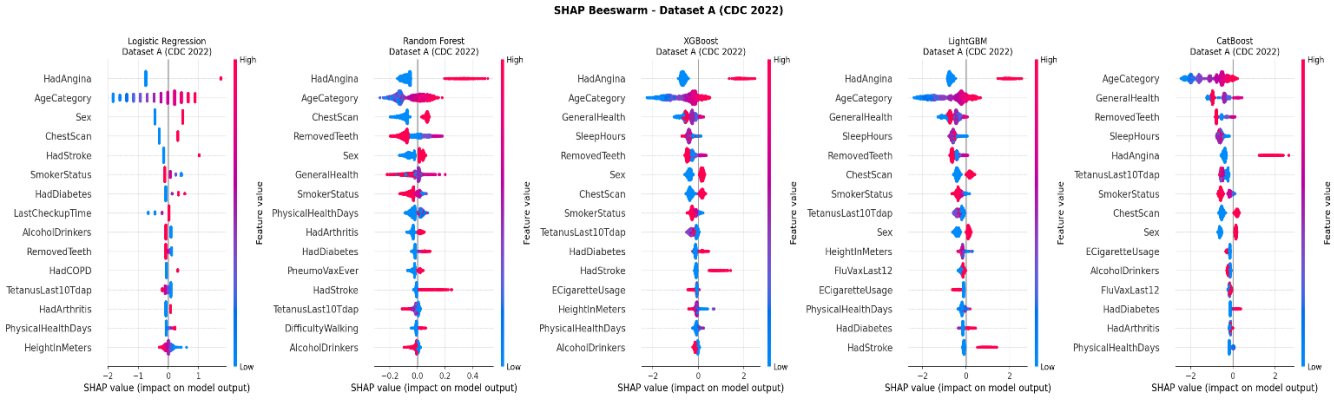

Figure 1. SHAP beeswarm plot for Dataset A. Red points (high feature values) for *HadAngina* consistently shift the prediction toward the positive class.

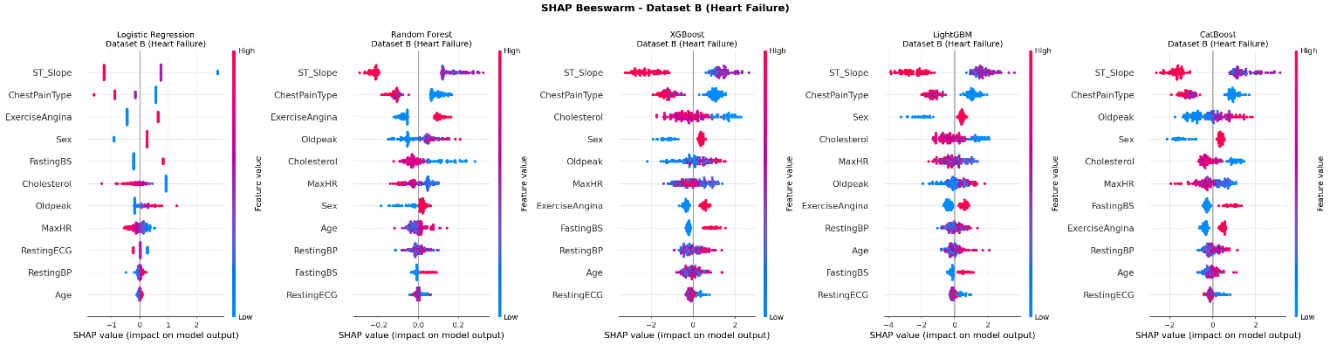

Figure 2. SHAP beeswarm plot for Dataset B. Red points (high feature values) for *ST_Slope* consistently shift the prediction toward the positive class.

3. Local Explanations (SHAP, LIME)

Local SHAP and LIME explanations (Figure 3) were generated for four representative cases (TP, FN, TN, FP). For correctly classified positives in Dataset B, ST_Slope, Cholesterol, and FastingBS consistently support the positive prediction, whereas for false negatives, they have the opposite effect, indicating atypical patient profiles. The agreement between SHAP and LIME further validates the identified factors.

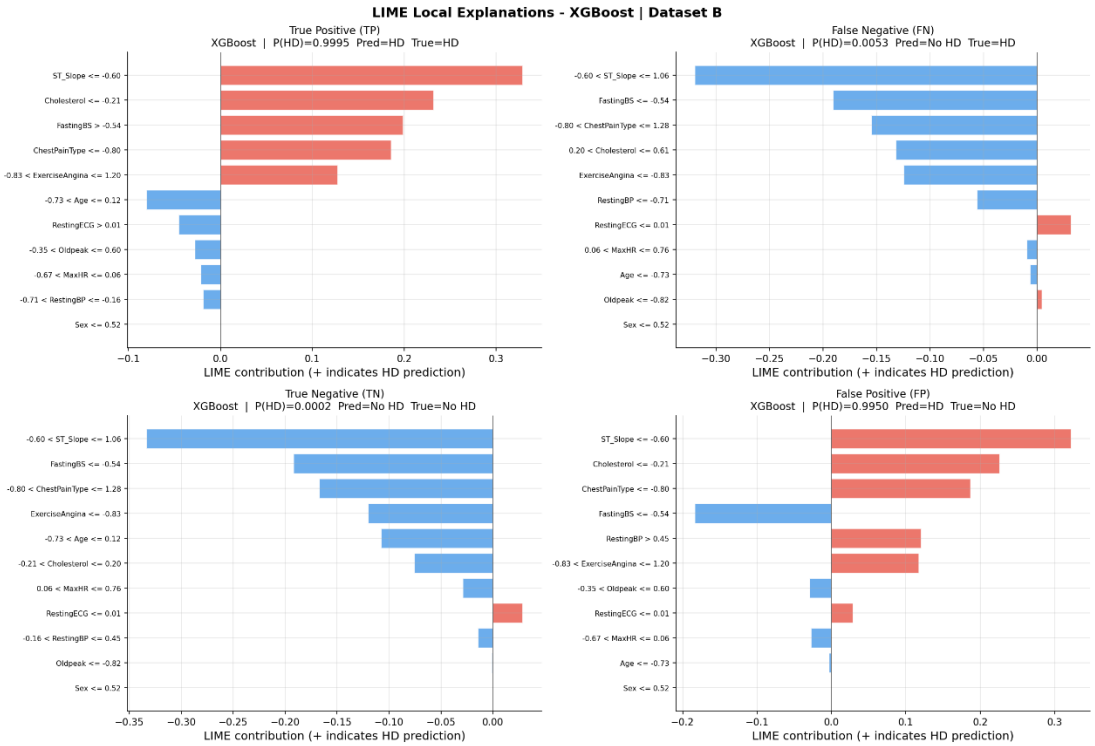

Figure 3. LIME local explanations (XGBoost, Dataset B) for TP, FN, TN, and FP cases.

4. Permutation Feature Importance

Permutation Feature Importance (PFI) confirms SHAP rankings: HadAngina and AgeCategory dominate on Dataset A, while ST_Slope clearly leads on Dataset B. Convergence of both methods strengthens confidence in the identified factors. Quantitatively, the top-15 feature sets identified by SHAP and PFI for the best-performing model (XGBoost) show a Jaccard similarity of 0.667 and a Spearman rank correlation of ρ = 0.851 on Dataset A, and a perfect Jaccard similarity of 1.000 with ρ = 0.818 on Dataset B, providing independent, model-agnostic corroboration of the SHAP-based feature rankings.

5. Explanation Stability

Table 3 summarizes the stability analysis of SHAP explanations for XGBoost. Across five random seeds and five independent train-test splits, the model achieves a Jaccard@10 score of 0.891 and a Spearman correlation coefficient of ρ = 0.988 on Dataset A, and a Jaccard@10 score of 1.000 and a Spearman ρ = 0.921 on Dataset B. To assess whether this stability generalizes beyond a single algorithm, the same protocol was subsequently applied to all five SHAP-compatible models (XGBoost, LightGBM, CatBoost, Random Forest, and Logistic Regression); TabNet was excluded, as it lacks SHAP TreeExplainer support. Across both the seed-based and split-based analyses, all five models exhibit comparably high stability, with Jaccard@10 ranging from 0.855 to 1.000 and Spearman ρ from 0.973 to 0.998 on Dataset A, and Jaccard@10 from 0.855 to 1.000 and Spearman ρ from 0.912 to 1.000 on Dataset B. This confirms that the stability of SHAP explanations is not an artifact specific to XGBoost, but a consistent property shared by both tree-based ensembles and the linear baseline.

Table 3. Shap Explanation Stability (Xgboost)

Level of Analysis	**SHAP Explanation Stability (XGBoost)**		
	Dataset	***Jaccard@10***	***Spearman ρ***
5 random seeds	A	0.891	0.988
5 train/test split	A	0.891	0.988
5 random seeds	B	1.000	0.921
5 train/test split	B	1.000	0.921

Extended results for all five models are summarized in the text above; XGBoost is retained in Table 3 as the representative case.

6. Clinical Interpretability

A comparison of the top-10 SHAP features with risk factors in medical guidelines shows strong alignment (Figure 4). On Dataset A, the proportion of clinically expected features ranges from 70% (LightGBM, CatBoost) to 90% (Random Forest). On Dataset B, all models achieve 100%, as expected, since it is constructed entirely from clinically relevant variables.

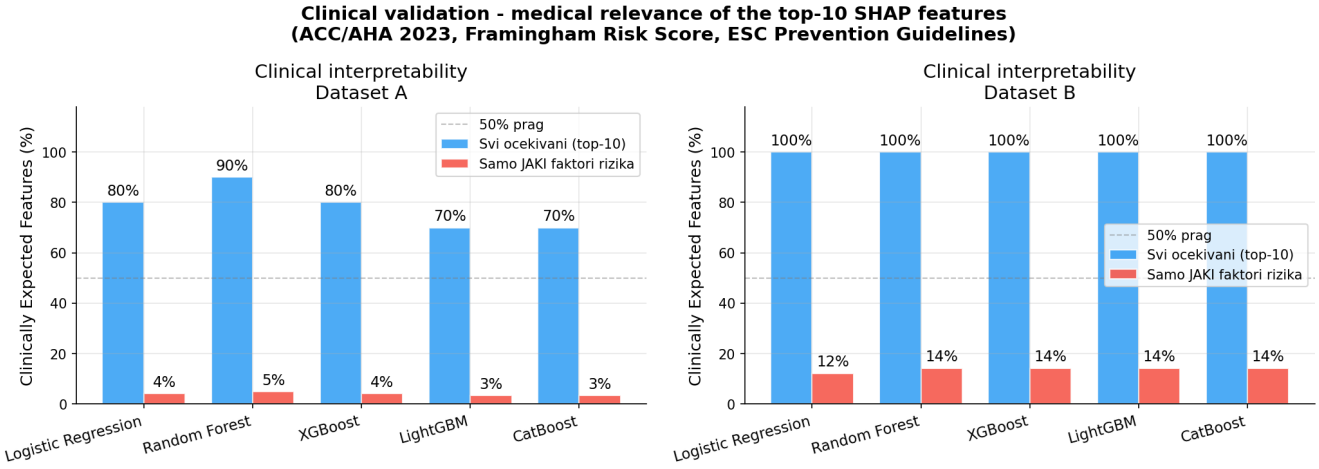

Figure 4. Clinical alignment of top-10 SHAP features with medical guidelines for both datasets.

7. Final Synthesis – Composite Score

Table 4 presents the computed composite scores. On Dataset A, Random Forest achieves the highest composite score (C = 0.852) despite lower ROC-AUC than gradient boosting models, due to superior clinical alignment (90%) and balanced recall. On Dataset B, all models perform similarly (C = 0.932–0.951), with Random Forest leading.

Table 4. Composite Score

Model	Composite Score				
	ROC-AUC	***F1m***	***Jaccard***	***Klin.%***	***C***
DATASET A					
Logistic Regression	0.878	0.612	0.891	0.80	0.812
Random Forest	0.879	0.710	0.891	0.90	**0.852**
XGBoost	0.887	0.659	0.891	0.80	0.825
LightGBM	0.886	0.653	-	0.70	0.803
CatBoost	0.886	0.658	-	0.70	0.804
TabNet	0.862	0.605	-	-	0.744
DATASET B					
Logistic Regression	0.897	0.866	0.691	1.00	0.932
Random Forest	0.927	0.901	1.000	1.00	**0.951**
XGBoost	0.926	0.858	1.000	1.00	0.942
LightGBM	0.932	0.874	-	1.00	0.948
CatBoost	0.931	0.874	-	1.00	0.947
TabNet	0.933	0.866	-	-	0.847

V. DISCUSSION

The central finding of this study is that the model achieving the highest ROC-AUC is not necessarily the one that provides the best overall balance for clinical application. On Dataset A, gradient boosting models (XGBoost, LightGBM, CatBoost) achieve a marginally higher ROC-AUC (≈0.886) than Random Forest (0.879), but with a recall for the positive class of only ≈0.24, meaning that in practice they would miss approximately three-quarters of truly affected patients.

The contrast between the two datasets further highlights the role of class imbalance. On the balanced Dataset B, all models achieve simultaneously high accuracy and high recall, and differences in composite scores are minimal (0.932–0.951). The sharp inverse relationship between accuracy and recall observed in Dataset A is therefore not an inherent property of the algorithms, but a consequence of severe class imbalance. SHAP explanations proved both stable (Jaccard@10 0.891–1.000, Spearman $\rho > 0.92$) and clinically meaningful: HadAngina, AgeCategory, and GeneralHealth (Dataset A) and ST_Slope, ChestPainType, and Cholesterol (Dataset B) all align with established cardiovascular risk factors [1],[6],[7],[8], further confirmed by PFI convergence.

The study has several limitations. First, the authors are not medical professionals; therefore, clinical alignment refers strictly to agreement with risk factors reported in published literature and guidelines, rather than independent medical validation. Second, both datasets originate from specific geographic and population contexts (CDC BRFSS – USA; combined clinical datasets – Europe/USA), so generalization to other populations requires further validation. Finally, the weighting scheme used in the composite score (0.40/0.20/0.20/0.20) reflects a prioritization of predictive performance while treating the other dimensions equally. However, it can be adjusted to suit specific clinical requirements.

VI. CONCLUSION AND FUTURE WORK

This study presented an explainable ML framework for heart disease prediction and evaluated it in terms of predictive performance, explanation stability, and clinical alignment. On the imbalanced Dataset A, Random Forest achieved the best composite score (C=0.852) despite lower ROC-AUC than gradient boosting models, which missed ~75% of positive cases. SHAP explanations were highly stable (Jaccard@10 0.891–1.000) and aligned with established medical risk factors (70–100%).

The results indicate that the model achieving the highest ROC-AUC does not necessarily provide the most stable or clinically aligned explanations. Future work will explore alternative balancing techniques (ADASYN, class weights), validate across diverse populations, and develop a clinical decision-support prototype in collaboration with medical experts.

Abstract
Aircraft structural damage inspection remains a critical task for ensuring operational safety and airworthiness. Conventional inspection procedures still rely heavily on human visual assessment, making them susceptible to fatigue, subjectivity, and inconsistent damage characterization. Recent advances in deep learning have demonstrated significant potential for automating visual inspection processes. This work presents the preliminary development of an aircraft structural damage classification system based on convolutional neural networks and transfer learning. A ResNet50 architecture was implemented as the base classifier in a cloud-based environment and trained to identify four structural condition categories: crack, dent, corrosion, and no-damage. Image preprocessing and data augmentation techniques were applied to improve training robustness and generalization capability. Preliminary results indicate that the proposed approach can successfully learn visual patterns associated with the evaluated structural conditions. The proposed classifier achieved a test accuracy of 96.20% and a weighted F1-score of 0.9617 on an independent test subset of 79 images. However, isolated misclassifications remained between visually similar defects such as corrosion and cracks. These results support the feasibility of the proposed methodology while highlighting the need for dataset expansion and further model optimization. The developed framework provides a foundation for future work involving damage localization, geometric measurement, explainable artificial intelligence, and integration with aircraft maintenance documentation.

Keywords: Aircraft structural inspection, Deep Learning, Convolutional Neural Networks, Transfer Learning, ResNet50, Damage Classification, Computer Vision, Aircraft Maintenance

I. INTRODUCTION

Aircraft structural inspection plays a fundamental role in maintaining operational safety and ensuring the airworthiness of commercial aviation fleets [1], [2]. Aircraft structures are continuously exposed to operational loads, environmental conditions, impacts, corrosion, and material fatigue, which can lead to structural defects such as cracks, dents, perforations, and surface degradation. If such damage is not detected and properly characterized during maintenance procedures, structural integrity and flight safety may be compromised. Despite technological advances in aviation maintenance, visual inspection performed by human operators remains one of the most widely used methods for structural evaluation. However, manual inspection procedures are inherently dependent on inspector experience [1], [2], environmental conditions, fatigue, and subjective interpretation. These limitations may lead to inconsistencies in damage identification and classification, especially when small defects or complex surface patterns are involved. Recent developments in artificial intelligence and computer vision have enabled the application of deep learning techniques to automated defect

detection and classification tasks [3], [4]. Convolutional Neural Networks (CNNs) have demonstrated strong performance in image recognition applications by automatically extracting hierarchical visual features from complex datasets. Consequently, several researchers have explored the use of deep learning architectures such as ResNet, YOLO, Faster R-CNN, and Mask R-CNN for structural inspection tasks in civil infrastructure and aerospace applications [5], [6]. In the aeronautical field, automated inspection systems have gained increasing attention due to their potential to reduce inspection times, improve repeatability, and assist maintenance personnel during decision-making processes [1], [5], [6], [7]. Previous studies have proposed approaches for crack detection, corrosion identification, aircraft skin inspection, and defect localization using both ground-based and drone-assisted image acquisition systems [4], [7], [8]. Nevertheless, many existing approaches remain focused on isolated tasks such as classification or detection. At the same time, limited work has explored integrated intelligent inspection frameworks that evolve toward technical interpretation and explainability [5]. This research presents the preliminary development of a structural damage classification system for aircraft surfaces using deep learning and transfer learning techniques. The current work corresponds to the initial classification stage of a broader modular architecture intended to support future functionalities, including damage localization, geometric estimation, explainable analysis, and rule-based interpretation derived from aircraft maintenance documentation. The main objective of this preliminary stage is to validate the feasibility of implementing a convolutional neural network to identify different categories of structural damage patterns in aircraft imagery. The proposed methodology employs a ResNet50 architecture trained via transfer learning and evaluated through initial classification experiments across multiple structural condition categories.

II. RELATED WORK

Aircraft structural inspection has traditionally relied on visual evaluation performed by trained maintenance personnel. Although widely adopted throughout the aviation industry, this approach may be affected by inspector experience, fatigue, environmental conditions, and subjective interpretation. To overcome these limitations, recent research has explored automated inspection systems based on computer vision and machine learning techniques that assist with damage identification and maintenance activities [9], [10]. The emergence of deep learning has significantly improved defect recognition performance. Convolutional Neural Networks (CNNs) have demonstrated strong capabilities in extracting hierarchical visual features from complex images and have been successfully applied to crack detection, corrosion assessment, and structural monitoring. Recent studies have also investigated data augmentation strategies to address the limited availability of aircraft defect imagery [11]. More recent studies have incorporated architectures such as U-Net, Mask R-CNN, Faster R-CNN, YOLO, and transformer-based models for damage detection and localization in both civil and aerospace structures [12], [6]. Despite these advances, most existing approaches focus primarily on detection or localization tasks. Fewer studies address multi-class aircraft damage classification as part of a broader inspection framework that can evolve toward geometric characterization, explainable analysis, and maintenance-oriented decision support. Motivated by this gap, the present work investigates the feasibility of a ResNet50-based classifier for distinguishing among crack, dent, corrosion, and no-damage conditions as the first stage of an intelligent aircraft structural inspection system.

III. METHODOLOGY

1. General System Architecture

The proposed methodology corresponds to the preliminary classification stage of a broader intelligent aircraft structural inspection framework. The current implementation focuses exclusively on the automatic classification of structural damage patterns from aircraft-related images.

The classification module receives an image of an aircraft surface and assigns it to one of four predefined categories: crack, dent, corrosion, or no-damage. The predicted class is intended to serve as the initial input for future modules involving damage localization, geometric characterization, and maintenance-oriented analysis. As illustrated in Figure 1, the processing pipeline consists of three main stages: image preprocessing, feature extraction using a pretrained ResNet50 backbone, and classification via a custom neural network head comprising Global Average Pooling, Batch Normalization, Dropout, and Softmax layers.

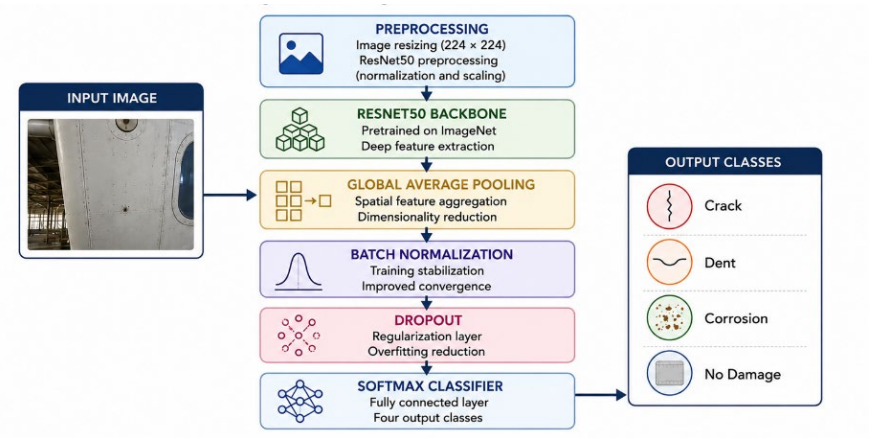

Figure 1. General architecture of the proposed aircraft structural damage classification system.

The classification function can be expressed as:

$$\hat{y} = f_\theta(x) \tag{1}$$

where x represents the input image, (f_θ)denotes the deep learning model with trainable parameters (θ) trainable parameters (θ), and ($\hat{y}$) corresponds to the predicted probability vector associated with the structural damage classes.

2. Image Preprocessing and Data Augmentation

All input images were resized to a spatial resolution of 224 × 224 pixels with three color channels, matching the input requirements of the pretrained ResNet50 architecture. Before training, images were processed using the standard ResNet50 preprocessing function, which applies the normalization strategy originally used during ImageNet training. To improve model robustness and reduce overfitting, data augmentation was applied exclusively to the training subset. The augmentation strategy included small rotations, horizontal and vertical translations, and zoom transformations, allowing the network to observe multiple variations of the same structural condition during training.

The augmentation process can be expressed as:

$$x' = T(x) \tag{2}$$

, ere (x)s the original image (T ·)epresents a random transformation operator, and (x′) is the augmented image used during training.

The implemented configuration employed a rotation range of 10°, width and height shifts of 0.10, and a zoom range of 0.10. Horizontal flipping was intentionally omitted because the orientation of structural damage may contain relevant visual information, depending on the inspected aircraft region.

3. Classification Model Based on ResNet50

The classification model was developed using the ResNet50 architecture as the backbone feature extractor. ResNet50 was selected due to its ability to learn deep hierarchical representations while mitigating the degradation problem commonly observed in very deep neural networks. The main principle of ResNet architectures is residual learning. Instead of directly learning a complete transformation, each residual block learns a residual mapping that is added to the input representation:

$$y(x) = F(x) + x \tag{3}$$

where x represents the input feature map, F(x) denotes the residual function learned by the convolutional layers, and y corresponds to the output of the residual block. In the proposed approach, the original fully connected layers of ResNet50 were removed, and the pretrained network was used as a deep feature extractor. The extracted feature maps were subsequently processed through a custom classification head comprising Global Average Pooling, Batch Normalization, Dropout, and a final Dense layer with a Softmax activation.

The Global Average Pooling operation reduces each feature map to a single representative value by averaging all spatial positions.

$$GAP_k = \frac{1}{H \cdot W} \sum_{i=1}^{H} \sum_{j=1}^{W} z_{i,j,k} \tag{4}$$

wher H and W are the eight and wdth o the feature map ,and $(z_{i,j,k})$orresponds to the activation value at position (i, j) of channel k. Batch Normalization was incorporated to stabilize training, while a Dropout layer with a rate of 0.30 was employed to reduce overfitting and improve generalization. The final classification stage was implemented using a Dense layer with Softmax activation, which transforms the network outputs into class probabilities:

$$P(y_i|x) = \frac{e^{z_i}}{\sum_{j=1}^{K} e^{z_j}} \tag{5}$$

where $i. is\ the\ output\ logit\ associated\ with\ class\ i. and$ büyük $harf\ K\ represents$ the total number of classes. The predicted label corresponds to the class with the highest probability value.

4. Transfer Learning Strategy

Transfer learning was employed to leverage visual representations pre-trained on the ImageNet dataset. This approach is particularly advantageous when domain-specific datasets are limited, as demonstrated in previous

aerospace structural monitoring applications [4], [13]. The training process was performed in two stages. During the first stage, the ResNet50 backbone remained frozen and only the custom classification head was trained. This allowed the network to adapt its final decision layers to the aircraft damage classification task while preserving the generic visual features learned from ImageNet. In the second stage, a fine-tuning strategy was applied by selectively unfreezing the final layers of the ResNet50 backbone, excluding Batch Normalization layers. A reduced learning rate was used during this phase to refine high-level feature representations while minimizing the risk of degrading previously learned knowledge.

5. Training Configuration

The model was implemented in a cloud-based Python environment using TensorFlow and Keras. The input image size was set to 224 x to$(224 \text{ x } 224)$ pixels, and a batch size of 16 was used during training.

The initial training phase was configured for 20 epochs with an initial learning rate of:

$$\alpha = 1 \times 10^{-4} \tag{6}$$

For the fine-tuning phase, the model was trained for 10 additional epochs using a reduced learning rate of:

$$\alpha = 1 \times 10^{-5} \tag{7}$$

The Adam optimizer was used for parameter optimization, while class weights were incorporated to mitigate the existing class imbalance.

The model was trained with categorical cross-entropy as the loss function, which is well-suited to multiclass classification problems. The loss function is defined as:

$$\mathrm{L} = -\sum_{\mathrm{i}=1}^{\mathrm{K}} \mathrm{y_i} \log(\hat{\mathrm{y}}_\mathrm{i}) \tag{8}$$

where (y_i)s the true one-ot encoded label for class (i), $(\hat{y}_i)$ is the probability predicted by the model, and (K) is the number of classes.

To address potential class imbalance, class weights were computed from the training set. The weight assigned to each class was obtained as:

$$\mathrm{w_i} = \frac{\mathrm{N}}{\mathrm{K} \cdot \mathrm{n_i}} \tag{9}$$

where (N) is the total number of training samples, (K) is the number of classes, and (n_i) is the number of samples belonging to class (i). These weights were incorporated during training to reduce bias toward classes with a larger number of samples. Classification accuracy was used as the primary metric for monitoring model performance during training.

IV. EXPERIMENTAL SETUP

The experimental dataset contained 794 aircraft-related images organized into four structural condition categories: dent, corrosion, crack, and no-damage. The dataset was assembled from publicly available aircraft imagery collected from multiple online and aeronautical sources and includes aircraft from the Airbus A320 family (A318, A319, A320, and A321). The collected images exhibit variations in viewing angle, illumination, background, and image resolution, reflecting the heterogeneous conditions of publicly available visual data. A stratified distribution was used to preserve the class proportions across training, validation, and test subsets. The resulting partition consisted of 555 training images, 160 validation images, and 79 independent test images, corresponding approximately to 69.9%, 20.2%, and 9.9% of the available dataset, respectively. Table I summarizes the distribution by class.

Table I. Dataset distribution across training, validation and test subsets.

Class	Train	Validation	Test	Total
Dent	14	5	2	21
Corrosion	170	49	24	243
Crack	191	55	27	273
No Damage	180	51	26	257
Total	555	160	79	794

Representative samples of the four structural conditions are shown in Figure 1. The experiments were conducted in Google Colab using TensorFlow and Keras with an NVIDIA Tesla T4 GPU (15 GB of GPU memory). A ResNet50 backbone pretrained on ImageNet was employed. The classification head was initially trained for 20 epochs with a learning rate of $1x10^{-4}$, followed by 10 fine-tuning epochs using an initial learning rate of $1x.10^{-5}$. A batch size of 16 was used throughout the experiments.

Figure 1. Representative examples of aircraft structural conditions included in the dataset.

V. RESULTS AND DISCUSSION

Figure 2 shows the evolution of training and validation accuracy and loss throughout the 30 training epochs. Both sets of curves exhibit a stable learning trend, with validation accuracy reaching approximately 95%. The relatively small gap between training and validation performance suggests that data augmentation, regularization, and fine-tuning helped limit overfitting, although a moderate gap persists in the final epochs.

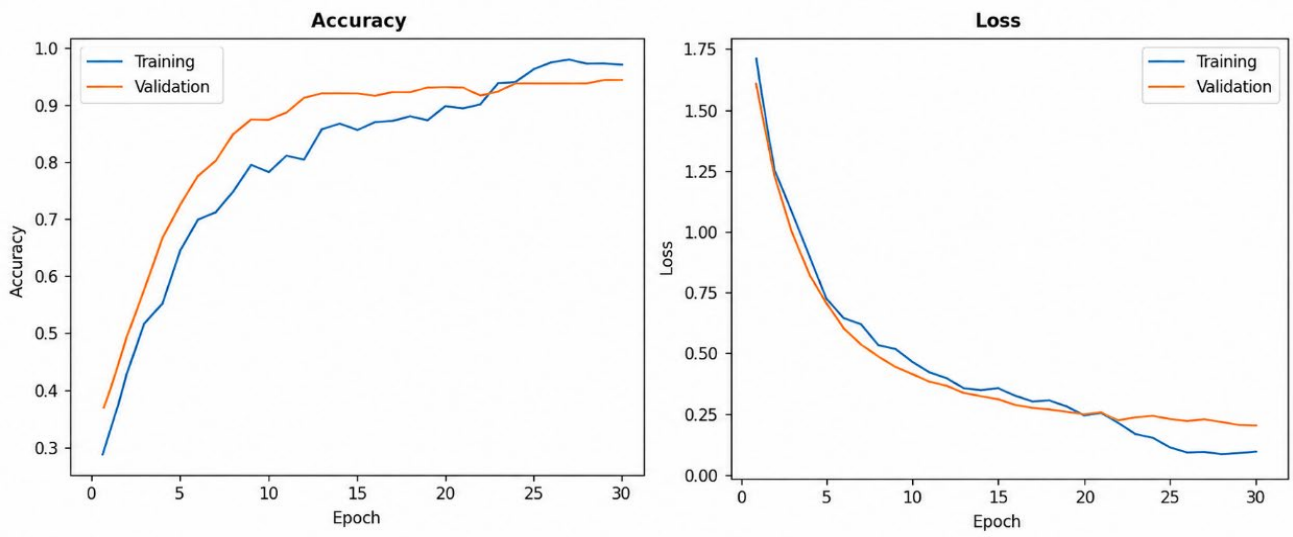

Figure 2. Training and validation accuracy and loss throughout the two-stage training process.

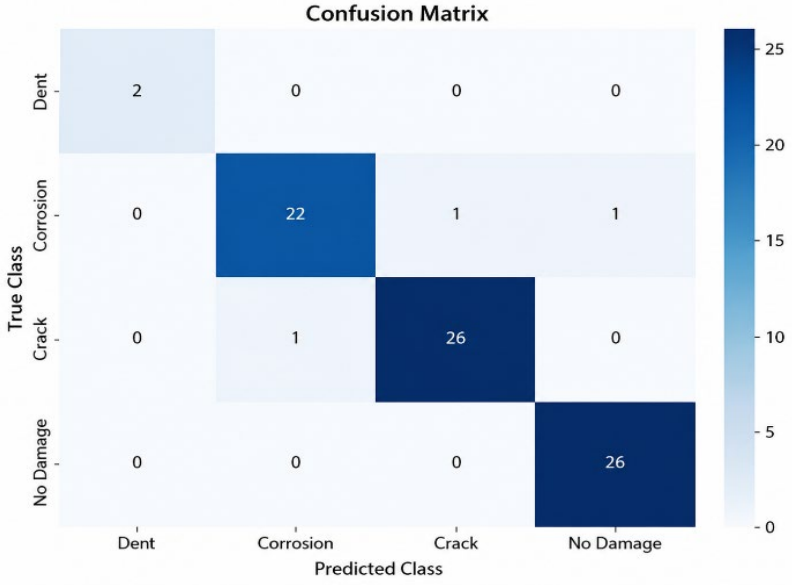

Figure 3. Confusion matrix obtained on the independent test subset (n = 79).

Table 2. Per-class classification performance on the test subset.

Class	Precision	Recall	F1-score	Support
Dent	1.0000	1.0000	1.0000	2
Corrosion	0.9565	0.9167	0.9362	24
Crack	0.9630	0.9630	0.9630	27
No Damage	0.9630	1.0000	0.9811	26

Macro avg.	0.9706	0.9699	0.9701	79
Weighted avg.	0.9619	0.9620	0.9617	79

The independent test subset contained 79 images. As shown in Figure 3, the classifier correctly predicted 76 samples, corresponding to an overall test accuracy of 96.20% and a test loss of 0.1231. The no-damage class achieved perfect recall, while the crack class correctly identified 26 of 27 samples. Corrosion accounted for the largest number of errors, with 22 of 24 samples correctly classified, and confusion was isolated to the crack and no-damage categories. The per-class results summarized in Table show a weighted F1-score of 0.9617 and a macro F1-score of 0.9701. The remaining confusion between corrosion and crack suggests that some samples share visual characteristics such as irregular edges, localized texture changes, and surface discontinuities. Although the overall performance on the independent test subset was strong, the limited number of dent samples should still be considered when interpreting the perfect score obtained for this category.

VI. LIMITATIONS AND FUTURE WORK

The current study represents a preliminary stage in the development of an intelligent aircraft structural inspection framework. Although the proposed classifier demonstrated the ability to learn relevant visual patterns across multiple damage categories, several limitations remain. First, the available dataset size is still limited and does not fully represent the diversity of structural conditions encountered in real operational environments. Variations in illumination, viewing angle, damage severity, and surface materials may affect generalization performance. In addition, the current system performs image-level classification only and does not provide damage localization or dimensional characterization. Future work will focus on expanding the dataset, improving class balance, and incorporating object detection techniques for automatic damage localization. Additional developments will include explainable artificial intelligence methods, geometric measurement modules, and integration with aircraft maintenance documentation to support maintenance decision-making processes.

VII. CONCLUSIONS

This work presented the preliminary development of an aircraft structural damage classification system based on deep learning and transfer learning techniques. A ResNet50 architecture was implemented to classify aircraft images into four structural condition categories: crack, dent, corrosion, and no damage. The obtained results demonstrated the feasibility of applying convolutional neural networks to aircraft structural inspection tasks. They confirmed the proposed methodology's ability to learn relevant visual characteristics associated with different damage types. Although classification errors remain in visually similar categories, the current implementation provides a solid foundation for future improvements. The proposed classifier is the first stage of a broader intelligent inspection framework that incorporates damage localization, geometric characterization, explainable analysis, and maintenance-oriented decision support.

Abstract
Graph databases provide efficient storage and traversal mechanisms for highly connected data, whereas Redis offers high-performance in-memory data management through general-purpose data structures. Although Redis is widely adopted in modern applications, it does not natively support the property graph model. This paper presents a formal mapping of the Neo4j property graph model onto native Redis data structures, including sets, sorted sets, and hashes. The proposed representation preserves node identifiers, relationship identifiers, relationship directions, node labels, relationship types, and properties without relying on graph-specific Redis extensions. Based on the proposed model, several graph algorithms, including breadth-first search, shortest path, all-shortest-paths, weakly connected components, and degree centrality, were implemented and evaluated. Performance measurements were conducted using the Northwind and Pokec Social Network datasets and compared with the native implementations provided by Neo4j. The experimental results show that Neo4j consistently achieves superior performance, particularly for traversal-intensive algorithms executed on large graphs. Nevertheless, the proposed Redis representation demonstrates that property graphs can be modeled effectively using native Redis data structures, offering a practical alternative for applications that already use Redis as their primary data store and require only moderate graph-processing capabilities.

Keywords*:* Neo4j, Redis, property graph, graph database, graph transformation, graph algorithms, NoSQL

I. INTRODUCTION

In the NoSQL era, it is hard to choose an appropriate database. Firstly, there are four main categories: key-value, document, column-family, and graph. Then the categories are not clean, and each category can contain many databases with different data structures and data processing capabilities. [1] Graph data structures are important in modern computing due to the growing need to model complex relationships in domains such as social networks, recommendation systems, fraud detection, and knowledge graphs. Among many graph databases, Neo4j is the first in the database engines ranking (https://db-engines.com/en/ranking). [2] Neo4j implements the property graph model, where nodes and relationships may contain arbitrary properties. The database supports the declarative Cipher query language, enabling developers to express complex graph operations concisely and readably. Neo4j also provides optimized traversal mechanisms and built-in support for graph analytics. [3] In parallel, in-memory key-value stores such as Redis have gained popularity due to their high performance and low-latency data access. Redis is a popular in-memory database that supports various native data structures, including strings, hashes, lists, sets, sorted sets, streams, and bitmaps. Although Redis is not primarily designed as a graph database, graph structures can be represented efficiently using combinations of these data structures. Such representations may offer significant performance advantages for specific graph workloads due to Redis's

memory-centric architecture. However, unlike native graph databases, Redis does not provide built-in support for graph traversal operations, raising the question of how efficiently graph algorithms can be executed on such representations. [4], [5]. This study investigates the performance differences between a native graph database and Redis-based graph implementations. Specifically, we compare Neo4j with a Redis graph modeling approach under identical workloads. The evaluation focuses on classical graph algorithms, including breadth-first search and shortest path computation.

II. RELATED WORK

1. Graph database models and foundations

The theoretical foundations of graph data models are well established. Angles and Gutierrez [6] provide a comprehensive survey of graph database models, outlining early approaches and the evolution toward modern property graph systems. The property graph model, which allows both nodes and relationships to carry arbitrary key-value properties, has become the dominant paradigm in practical systems. A widely adopted implementation of this model is Neo4j, which is described in detail in the foundational book by Robinson, Webber, and Eifrem [7]. Neo4j introduced the Cipher query language and popularized declarative graph querying for property graphs. The conceptual design of Neo4j and its property graph model is further documented in an industry white paper [8], which emphasizes traversal efficiency and flexible schema design. Query language design for graph systems has also been an important research topic. Cipher, as described in research papers [9], [10], enables expressive pattern-matching queries over graph structures while abstracting low-level traversal logic. This has contributed significantly to the adoption of graph databases in real-world systems.

2. Benchmarking and performance evaluation of graph databases

Several studies have investigated the performance characteristics of graph database systems. The Linked Data Benchmark Council (LDBC) Social Network Benchmark (SNB) provides a standardized workload for evaluating graph database performance under realistic social network scenarios [11]. Rusu and Huang [12] present an in-depth analysis of graph database systems using LDBC SNB, highlighting differences in query execution efficiency and system scalability. More recent comparative studies have evaluated multiple graph database platforms under identical workloads. Monteiro et al. [13] compare Neo4j, JanusGraph, NebulaGraph, and TigerGraph, focusing on query execution time, data loading performance, and resource consumption. Their results show that performance varies significantly depending on workload characteristics and system architecture. Sandell et al. [14] extend this line of work by comparing Neo4j with relational and multi-model databases, including ArangoDB and MySQL. Their findings indicate that graph databases generally outperform relational systems for traversal-heavy queries, while performance differences depend on query complexity and data distribution. In addition to system-level benchmarks, recent research has explored optimization techniques for improving graph query execution. Baumstark et al. [15] propose adaptive query compilation techniques that reduce runtime overhead and improve execution efficiency for graph queries, particularly under mixed workloads. A more recent study by Lupu et al. [16] evaluates concurrent access patterns in relational and graph NoSQL databases, showing that graph databases perform efficiently under traversal-intensive workloads, although concurrency introduces measurable performance constraints.

3. Redis and in-memory data systems

In parallel with graph database systems, in-memory data stores have gained significant attention for their low-latency performance. Redis, described in its official documentation [4] and in Sanfilippo's foundational design

notes [17], is a high-performance in-memory data structure store that supports key-value pairs, sets, hashes, and other primitives. Redis has been widely studied as a general-purpose in-memory system. Almeida et al. [18] compare Redis with Memcached, MySQL, and PostgreSQL using the YCSB benchmark, demonstrating that Redis achieves high throughput and low latency, particularly in read-intensive workloads. Redis is also well documented in system-level literature, including practitioner-oriented texts such as Redis in Action [5] and The Little Redis Book [19]. Although Redis is not a native graph database, graph structures can be modeled. This has led to the development of RedisGraph, a graph database module built on Redis that leverages optimized in-memory representations and GraphBLAS-based computations [20]. RedisGraph was excluded from the evaluation because it is a legacy component with limited active development and is therefore not considered representative of modern graph database systems.

4. NoSQL data models and system comparisons

Several studies have examined NoSQL databases from a model-level perspective. Kamal et al. [21] provide a qualitative comparison of Redis, Neo4j, and MongoDB, focusing on structural differences between key-value, document, and graph models. Their work highlights the conceptual mapping between different NoSQL paradigms but does not evaluate runtime performance.

III. MATHEMATICAL REPRESENTATION OF THE NEO4J PROPERTY GRAPH MODEL

A Neo4j database follows the labeled property graph model, in which data is represented as a directed graph of nodes and relationships, enriched with labels and key–value properties. The following formalization is based on the property graph model described by Angles and Gutierrez, as well as the latter survey of property graph database systems [22], [23]. We changed the definition because we want to store the graph in Redis, where the node and relationship identifiers will be important. Let L be a countable set of node labels, and T be a countable set of relationship types. A property graph is defined as a tuple G = (N, R, S, D, PN, PR, B, Q), where N is a finite set of node identifiers, R is a finite set of relationship instances, each identified by a unique relationship identifier. S: R- >N maps each relationship identifier to its source node identifier, D: R->N maps each relationship identifier to its destination node identifier, PN: N×K->V is a finite partial function mapping a node identifier and a property key to a value; similarly PR: R×K->V is a finite partial function mapping a relationship identifier and a property key to a value; B: N->2L maps each node identifier to a finite (possibly empty) set of labels (where 2L is the power set of L allowing a node to have zero, one, or multiple labels); and Q: R->T maps each relationship identifier to a relationship type. This definition corresponds to the Neo4j data model, where relationships are directed and have a single relationship type [3]. A node can be represented as: n = (n_id, B(n), PN(n)) where n_id is the node identifier, B(n_id) is the set of labels assigned to the node, and PN(n_id) contains its optional key-value properties. A relationship can therefore be represented as r = (r_id, S(r_id), D(r_id), Q(r_id), PR(r_id)) where S(r_id) and D(r_id) define the direction of the relationship with its source and destination, Q(r_id) defines its type, and PR(r_id) stores optional properties.

IV. NEO4J PROPERTY GRAPH MODEL REALIZATION IN REDIS

To evaluate graph algorithm performance independently from the database engine, the Neo4j property graph model is transformed into a Redis-based graph representation. The transformation preserves the graph semantics, including node identities, relationship directions, relationship types, labels, and properties.

The node identifiers will be stored in a set named nodes, each in the form n_id, where id is a positive integer. The form of the relationship identifier will be similar to r_id, where id is a positive integer. The relationship does

not exist in isolation; we store its source and destination nodes. The sources in the relationship will be stored in a zset (sorted set), whose name is r_sources, and the key is the r_id, the score is the id from the n_id, because the score should be a floating-point number, so we store the integer part of the id, and pay attention to the conversion when we use it. We choose the zset because it is sorted by score, so searching for the node identifier is faster. The destination is also stored in a zset; similarly, the zset name is r_destinations. The properties of the nodes are stored in hashes; each node has a hash named n_id. Similarly, the properties of the relationships and the names of the hashes are r_id. Since a relationship can have only one type, r_types named can store the r_id->type values. And finally, the node labels are stored in sets; each node has its own set named labels_n_id, which contains the labels. A formalized form of the Redis data structures for the Neo4j graph property is

$RG=(S_{nodes}, Z_{r_sources}, Z_{r_destinations}, \{H_n| n\in S_{nodes}\},\{H_r|r\in R, H_{r_types}, \{S_{label,n}|n\in S_{nodes}\})$, where R is the set of r_ids. S is a set, Z is a sorted set (zset), and H is a Hash.

V. TRANSFORMATION OF THE PROPERTY GRAPH MODEL INTO REDIS DATA STRUCTURES

To evaluate graph algorithms using Redis, the previously defined property graph model is transformed into a set of native Redis data structures. The transformation preserves the semantics of the original graph, including node and relationship identities, relationship directions, relationship types, labels, and properties.

The transformation can be defined as a mapping M: G -> RG, where G is the property graph representation, and RG is the corresponding Redis representation.

The node identifier set is mapped to a Redis set:
$M(N)=S_{nodes}$, where: $S_{nodes}=\{n_{id}| n\in N\}$
Each element of S_{nodes} represents a unique node identifier.

Relationship identifiers are stored in the source and destination ZSet-s of Redis.

Each relationship is represented by its identifier because relationships are first-class elements of the property graph model.

Two separate mappings preserve the direction of relationships:
$M(S)=Z_{sources}$ and $M(D)=Z_{destinations}$
where each Redis sorted set stores a mapping between a relationship identifier and the corresponding node identifier:
$Z_{sources}[r_id]=S(r_id)$ and $Z_{destinations}[r_id]=D(r_id)$.
$M(R)=Z_{sources}[r_id] \cup Z_{destinations}[r_id]$

The relationship type mapping is stored as a Redis hash:
$M(Q)=H_{types}$, where: $H_{types}[r_id]=Q(r_id)$.

Because each relationship has exactly one type in Neo4j, a single value is stored for every relationship identifier.

Node properties are represented using Redis hashes. For every node identifier (n_id), a separate hash is created:
$M(PN(n_id))=H_{n_id}$, where: $H_{n_id}[k]=PN(n_id,k)$
Relationship properties are stored analogously:
$M(PR(r_id))=H_{r_id}$, where: $H_{r_id}[k]=PR(r_id,k)$

Redis sets represent node labels:

$M(B(n_id))=S_{labels,n_id}$, where: $S_{labels,n_id}=B(n_id)$

For both Neo4j and Redis-based graph representations, the storage requirement depends on the number of nodes, the number of edges, and the amount of associated metadata, including labels and properties assigned to nodes and relationships.

VI. THE DATASET AND QUERIES

Our first dataset is Northwind (https://github.com/neo4j-graph-examples/northwind). To create it, we downloaded the Cipher statements and executed them. It has about 1000 nodes and 3000 relationships. Our second dataset is the Pokec Social Network (SNAP), which can be downloaded from Stanford University's website (https://snap.stanford.edu/data/soc-Pokec.html). We used only the relationships file, in which the node_ids and their relationships are such that the source_node_id and destination_node_id of the relationship are present. For our queries, this information is enough. It has about 1.6 million nodes and 33 million relationships.

We executed 4 main queries, a few of which had parameters; we varied the node_ids or the maximum path length. The four queries are the following:

- Q1 (Breadth-First Traversal - BFS): Starting from a given node_id, retrieve all distinct nodes reachable by following directed relationships with a maximum path length and return their count. This query simulates a breadth-first exploration of the graph up to the third level of connectivity. We executed this query at 30 levels of connectivity as well.
- Q2 (Shortest Path): Given two node_ids, determine the shortest path between them with a maximum 10 path length relationships. This query evaluates the graph database's ability to perform path-finding operations across heterogeneous node and relationship types.
- Q3 (All Shortest Paths): Given two node_ids, determine all the shortest paths between them with a maximum path length. The maximum length paths were 2, 5, 6, 10, and 15.
- Q4 (Connected Components): The Weakly Connected Components algorithm was executed on the full graph to identify disconnected subgraphs. The method assigns a component identifier to each node, grouping nodes that are reachable from each other when edge directions are ignored. This workload evaluates the graph's global connectivity structure and the efficiency of component labeling in heterogeneous graphs.
- Q5 (Degree Centrality): The degree centrality algorithm was executed on the full graph to measure the number of direct relationships associated with each node. The resulting ranking identifies the most connected entities, providing insights into structural importance based on immediate connectivity.

Queries 4 and 5 need to build the in-memory graph with gds. graph.project statement before we execute the queries in Neo4j. The in-memory graph building is not included in the performance comparison. Neo4j's built-in algorithms do not work without an in-memory graph.

VII. ENVIRONMENT

The host computer is a Lenovo laptop with an Intel i5 1GHz processor and 8GB RAM; the operating system is Microsoft Windows 11 Pro, on which we installed Oracle VirtualBox 7.2.6, on which Ubuntu server (26.0.4

LTS) was installed twice, one for the Neo4j (2026.05.0) server and the other for the Redis server (8.0.5). Each virtual machine gets 2 CPUs, 2GB of memory, and 100 GB of disk space; however, we did not use all of them. The host computer was equipped with PyCharm (2026.1.2), on which Python (3.14.6) code was executed; the databases required drivers: the Redis module (8.0.0) named Redis and the Neo4j module (6.2.0) named Neo4j. The second, Pokec Social Network dataset, was too large, and Redis needed more memory since it is a memory database; it requested 12GB of memory. So for this dataset, we had to change the environment; the Lenovo laptop executed the Python code, but the virtual boxes moved to two other, but equal, computers, namely the Dell Pro Slim desktop computers with Windows 11 Enterprise Edition operating system; the processors are i5 with 2.6Ghz, and they have 16GB RAM. The VirtualBox version is 7.0.26, and both virtual machines have 12GB RAM. Since we wanted to see where Neo4j throws out-of-memory exceptions, we also executed the queries with 4GB and 2GB of RAM.

VIII. PERFORMANCE OPTIMIZATION IN REDIS

While writing the queries, it turned out that the zset for the relationships is inefficient, because after we get the relationship ID, we have to ask Redis again for the node ID. Because of this, we built two additional data structures for the relations: one for the sources and another for the destinations. Each of them is a hash set, where the key is neighbor_source_n_id and neighbor_destination_n_id; the key is the source or destination node id, and the value is the relationship id. In NoSQL systems, data models are typically designed based on query patterns rather than normalization rules, often intentionally introducing redundancy to optimize read performance and query efficiency. These two data structures are used in all the executed algorithms.

IX. RESULTS

We executed our queries 20 times on the databases and calculated an average execution time for each query. Table 1 shows the results of the execution on the Northwind database, while Table 2 shows the results of the execution on the Pokec Social Network database. The ML shows the maximum-length parameter for each algorithm. The node_ids were chosen so that the maximum length can be reached between them.

Table 1. Execution times of queries on Northwind

	Execution times (in seconds)	
Queries	Neo4j	Redis
Q1 (ml=3)	0.0578	4.000
Q1 (ml=30)	0.0083	2.000
Q2 (ml=6)	0.0154	2.000
Q3 (ml=2)	0.0337	0.0412
Q3 (ml=5)	0.0215	4.6840
Q3 (ml=6)	0.0293	12.7343
Q3 (ml=10)	0.0227	7.0952
Q3 (ml=15)	0.0342	8.5982

The Northwind dataset is a relatively small graph that enables comparison of graph traversal algorithms under a moderate workload. As shown in Table 1, Neo4j consistently outperformed the Redis implementation for almost all evaluated queries. The difference is particularly noticeable for traversal-intensive algorithms such as breadth-first search (Q1), shortest path (Q2), weakly connected components (Q4), and degree centrality (Q5), where Redis took several seconds, whereas Neo4j completed the same operations within a fraction of a second. An exception can be observed for the shortest-path query (Q3), which has a maximum path length of 2. In this case, both systems achieved nearly identical execution times. Since only a very limited neighborhood has to be explored, the traversal overhead remains negligible in both implementations. However, as the maximum path length increases, the execution time of the Redis implementation grows rapidly, while Neo4j remains almost unaffected. This behavior demonstrates the efficiency of Neo4j's native graph traversal engine compared to application-level graph traversal implemented on top of general-purpose Redis data structures. The second dataset, the Pokec Social Network dataset, represents a significantly larger graph and therefore provides a more realistic benchmark for graph analytics. Neo4j consistently achieved low execution times for all evaluated algorithms, even when the available memory was reduced from 12 GB to 4 GB and further to 2 GB. Although slight performance degradation is observed for some queries, overall execution times remain relatively stable, indicating efficient memory management and optimized graph storage. The Redis implementation exhibits similar behavior to Neo4j only for the shortest-path query with a maximum path length of 2, where both systems produced almost identical execution times. For larger traversal depths, however, the execution time increased dramatically. For example, the execution time of Q3 increased from 0.0113 s for a maximum path length of two to more than 3,800 s for path lengths of ten and fifteen. Similar behavior can be observed for weakly connected components (Q4) and degree centrality (Q5), where the Redis implementation required more than one hour to complete the computations. An additional observation is that Neo4j successfully executed all benchmark queries with both 12 GB and 4 GB of available memory. Even with only 2 GB of memory, most algorithms completed successfully, although the weakly connected components algorithm could not be executed because of an out-of-memory condition. This result indicates that Neo4j's native graph storage and traversal mechanisms remain efficient even under memory constraints. The observed performance differences can primarily be attributed to the underlying data models. Neo4j stores graph structures natively and executes traversal algorithms directly within the database engine. In contrast, the proposed Redis representation relies exclusively on native Redis data structures, including sets, sorted sets, and hashes. Consequently, graph traversal must be performed explicitly by the application, requiring multiple Redis operations for each traversal step. While this approach introduces considerable execution overhead for traversal-intensive algorithms, it demonstrates that graph structures can be represented using standard Redis data types without requiring specialized graph database extensions. Overall, the experimental results show that Neo4j provides substantially better performance for graph analytics and complex graph traversals. Nevertheless, the proposed Redis representation offers a flexible and portable solution

for applications that already employ Redis as their primary data store and require only occasional graph processing without introducing an additional graph database management system.

X. FUTURE WORK

Since Redis supports clustering and data partitioning, future work will investigate distributed graph processing techniques that exploit multiple Redis nodes. The proposed representation relies on a limited number of global indexes for relationship lookup. Additional indexing strategies, such as neighborhood indexes, path indexes, or application-specific auxiliary structures, could further reduce graph traversal costs and improve the performance of complex graph algorithms. Another promising direction is evaluating the proposed model using additional graph algorithms, including community detection, PageRank, betweenness centrality, and graph pattern matching. The proposed mapping can serve as the foundation for an automated graph migration framework that transforms Neo4j property graphs into Redis-native representations while preserving the graph structure, labels, relationship types, and properties. Such a framework would simplify the integration of graph-based applications into existing Redis infrastructures. Another important research direction is the formal verification of the proposed transformation to prove that it is information-preserving and reversible under well-defined constraints. Finally, while the proposed mapping fully supports node labels, relationship types, and properties, the experimental evaluation presented in this paper concentrates primarily on graph structure and traversal performance. A more detailed investigation of label- and property-intensive workloads, including filtering, indexing, and property-based graph queries, remains an important direction for future research.

XI. CONCLUSION

This paper presented a Redis-based representation of the Neo4j property graph model using only native Redis data structures, including sets, sorted sets, and hashes. A formal mapping was proposed that preserves the fundamental components of the property graph model, including node identifiers, relationship identifiers, relationship directions, node labels, relationship types, and properties. Based on this representation, several graph algorithms were implemented to evaluate the feasibility of executing graph operations without relying on dedicated graph database extensions. The experimental evaluation conducted on the Northwind and Pokec Social Network datasets demonstrated that Neo4j consistently outperformed the Redis implementation, particularly for traversal-intensive algorithms and large-scale graphs. The results indicate that native graph storage and optimized traversal mechanisms provide a significant advantage over graph processing implemented on top of general-purpose key-value data structures. Nevertheless, the proposed Redis representation successfully preserves the semantics of the original property graph while providing a flexible solution for applications that already utilize Redis as their primary data store. Although the Redis implementation cannot compete with native graph databases in traversal performance, it offers an alternative for integrating graph-based functionality into existing Redis-based systems without introducing additional database technologies. Furthermore, the proposed formal mapping establishes a foundation for future research on graph data migration, optimization techniques, distributed graph processing, and automatic transformation between graph and key-value database models. Overall, the proposed model demonstrates that native Redis data structures can represent the complete Neo4j property graph model while preserving its structural semantics, providing a basis for further research into efficient graph processing in key-value databases.

Abstract
We are facing an increasingly aging population, with a growing demand for health and care services. Technology has proved highly useful in this field, but proposed solutions must be adapted as closely as possible to the characteristics and needs of older adults. Voice-based interfaces, or Voice User Interfaces (VUIs), offer many advantages in this regard. Still, it remains crucial that they be based on voice and conversational models specifically designed for older adults. Likewise, this type of interface relies on a sophisticated cloud service infrastructure that must be versatile and secure while remaining affordable for any project. This paper proposes, from an architectural perspective, a cloud-based voice service, SAM Voice Service, that enables the design of VUI-based devices for older adults and people with disabilities. As a case study, it presents a companionship service for older adults and people with care needs, developed jointly with the social services departments of two local councils. More specifically, it presents the design of a physical companionship device for older adults based on VUI and natural language, together with a deployment architecture for the cloud-based voice service and a development scenario for all service components.

Keywords: Voice User Interface (VUI), Natural Language Processing (NLP), Cloud Service, Distributed Systems, Elderly, Active and Assisted Living (AAL)

I. INTRODUCTION

Population aging is increasing the number and proportion of people aged 65 years and over, placing growing pressure on health and care services [1-4]. Technology-based services have been proposed to address some of these needs, with support from initiatives such as the Ambient Assisted Living and Active and Assisted Living programs [3], [5-8]. However, as solutions to this new situation emerge, new problems are also being identified. One such problem is that most solutions rely on user interfaces not specifically designed for older adults [9], [10], or, at best, are adaptations of existing interfaces. It is essential to consider the specific and sensitive characteristics of older adults when developing devices and interfaces for them [11], [12]. This paper focuses on Voice User Interfaces (VUIs) supported by voice and dialogue models tailored to older adults [11], [13]. Existing studies suggest that older users can accept voice-based technologies when they provide meaningful support [14-16]. Nevertheless, delivering such services requires an architecture that integrates specialized voice and conversational components while accommodating differing technical and operational requirements [17], [18].

Accordingly, this article proposes a set of architectures for a cloud-based voice service, spanning conceptual, technical, and deployment levels. The framework is intended to support realistic service scenarios adapted to the characteristics, available resources, and budgets of different projects and communities. By accommodating diverse technologies, providers, and relevant open-source initiatives, it aims to enable scalable, reliable, and economically and technically sustainable deployments. The contribution of this work is not a new speech or dialogue algorithm, but an open, modular cloud architecture that organizes voice-processing components into independently deployable services adapted to older adults, social-care scenarios, and provider-controlled deployment. The remainder of the paper is organized as follows. Section 2 reviews the relevant background and state of the art. Section 3 presents the problem definition and proposed architecture, while Section 4 describes its technical implementation. Section 5 presents the companionship-service case study, and Section 6 concludes the paper. All project materials and source code have been made available to the community through the public repositories detailed in the paper.

II. STATE OF THE ART

Europe's population is aging: at the beginning of 2025, people aged 65 years and over accounted for 22% of the EU population (99 million), including 6% aged 80 years and over [1]. Eurostat projects that, despite a decline in the total population from 451.8 million in 2025 to 445.0 million in 2050, the number of working-age people per person aged over 65 will fall from more than three to fewer than two [1], [2]. This trend is likely to increase demand for health and care services, as 60% of EU residents aged over 65 reported at least one chronic condition and 52% reported activity limitations in 2023 [4]. Accordingly, care and companionship for older adults are increasingly important areas for research and service development [3]. The main objective of our research is to design Voice User Interfaces (VUIs) for services intended for older adults and people with disabilities. These VUIs must be user-friendly and adapted as closely as possible to their characteristics and needs [11], [12]. The development of commercial voice assistants, alongside growing academic interest, indicates that voice-based interaction has reached a sufficient level of maturity to support services for older adults and people with disabilities [9], [10], [18], [19]. Although commercial platforms perform very well and provide a great many facilities for developing projects that wish to incorporate NLP, even free of charge, in practice, they still present many restrictions [20], [21]. From the perspective of services for older adults, the main restrictions arise from the fact that voice and conversational models are neither specifically designed nor adapted to the characteristics and needs of older adults. They do not facilitate integration with other systems and IoT devices, and there are concerns about information privacy, since conversations must pass through third-party servers, where they are stored to improve and refine dialogue and voice models [11], [13]. It is essential that services and devices designed for older adults explicitly account for the highly specific and defining characteristics, constraints, and idiosyncrasies of this sensitive population segment [11], [12], [22], [23]. Although older adults may initially perceive assistive technologies as replacing family members or trusted carers, studies suggest that voice-based systems can be well accepted when they provide meaningful support [14-16]. Many of the proposals reviewed are based on cloud applications, with mobile-device interfaces that connect social workers, doctors, and, in some cases, family members to the care of older adults. However, in most cases, these proposals do not involve the older person directly or offer them support that makes them feel genuinely accompanied [24], [25], [12].

III. PROBLEM DEFINITION AND PROPOSED APPROACH

The problem addressed in this work is the cost of developing and maintaining services for older adults that provide user interfaces tailored to their needs. To address this challenge, we propose the SAM Voice Service. This cloud-based platform supports SAM Devices: virtual assistants intended to assist and accompany older adults at home through voice-based interaction. Given the multiple stakeholders, technologies, and deployment scenarios involved, this paper presents an integrated architectural view of SAM Voice Service at conceptual, technical, and deployment levels. The proposed service and microservice-based architecture (Figure 1) is

designed to integrate technologies from different providers and to adapt computational resources as service requirements and available technologies evolve.

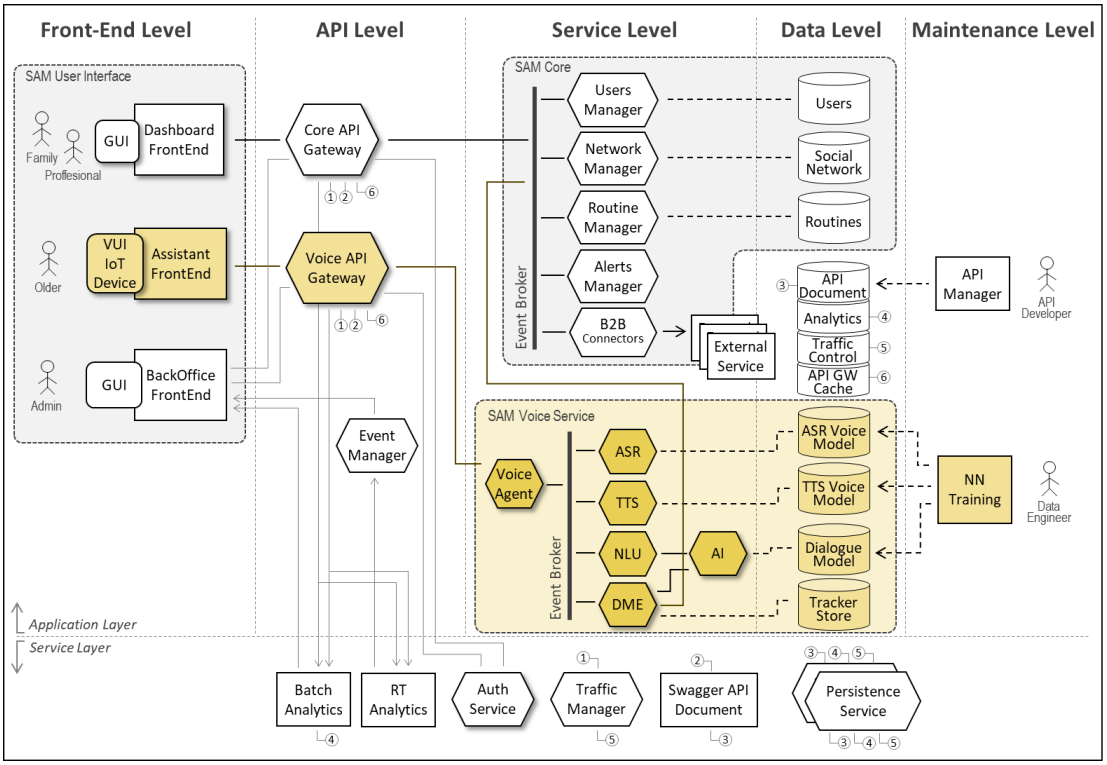

Figure 1. SAM Service high-level conceptual architecture.

For the high-level architecture (Figure 1), an n-tier architectural style has been used, structuring the elements into levels and layers. SAM Voice Service is located at the service and data levels, namely the Service Level and Data Level. Its purpose is to support the voice assistant by performing artificial intelligence (AI) tasks that cannot feasibly be performed on the IoT device or the user-interface device, either because of their high computational cost or because of the business logic they involve. The elements of the architecture are defined primarily as services, following an architectural pattern based on Service-Oriented Architectures (SOA) and microservices [26], [27]. An effort has been made to strike a balance in the number of services specified, so that they are as functionally independent as possible, without generating so many microservices that future maintenance would become complex. The Voice Agent orchestrates the proposed services. Figure 2 shows the activity diagram for the orchestration carried out by this service. The flow begins when the Voice Agent receives an audio request, typically from the Voice API Gateway. The Voice Agent invokes the Automatic Speech Recognition (ASR), also known as Speech-to-Text (STT), service to convert audio into a text request. This request is then processed by the Natural Language Understanding service, which extracts the relevant intents and entities using the Dialogue Model.

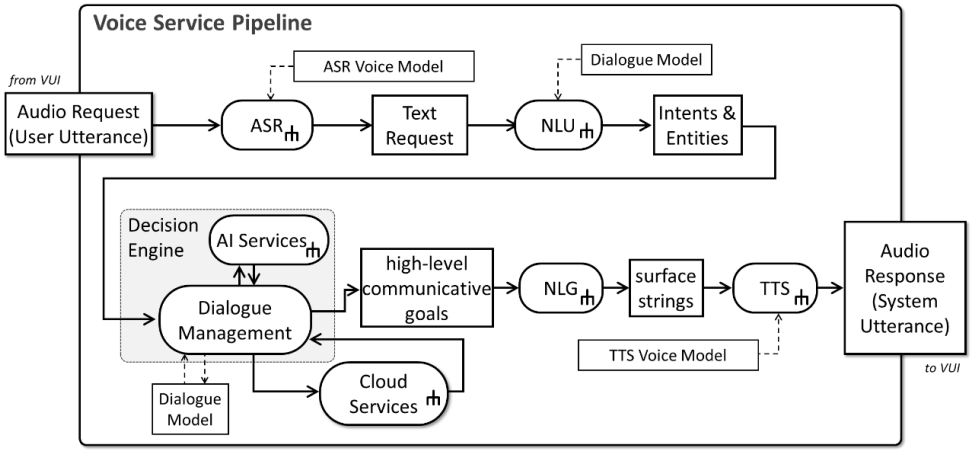

Figure 2. SAM Voice Service Activity Diagram.

The Voice Agent forwards these results to the Dialogue Management Engine, which determines the appropriate response and, where necessary, invokes external services in SAM Core through the SAM Core Event Broker. The resulting response is passed to the Natural Language Generation module and then to the Text-to-Speech service, which produces an audio response. Finally, the Voice Agent returns the response to the Voice API Gateway.

IV. TECHNICAL ARCHITECTURE

Figure 3 summarises the technical architecture of the SAM Voice Service and its relationship with the SAM Device, the SAM Core, and external AI services. The implementation uses Mozilla DeepSpeech for ASR, Rasa for NLU and dialogue management, and Mozilla TTS for speech synthesis. These components are deployed as separate services so that speech recognition, dialogue handling, and speech synthesis can be maintained, replaced, or scaled independently.

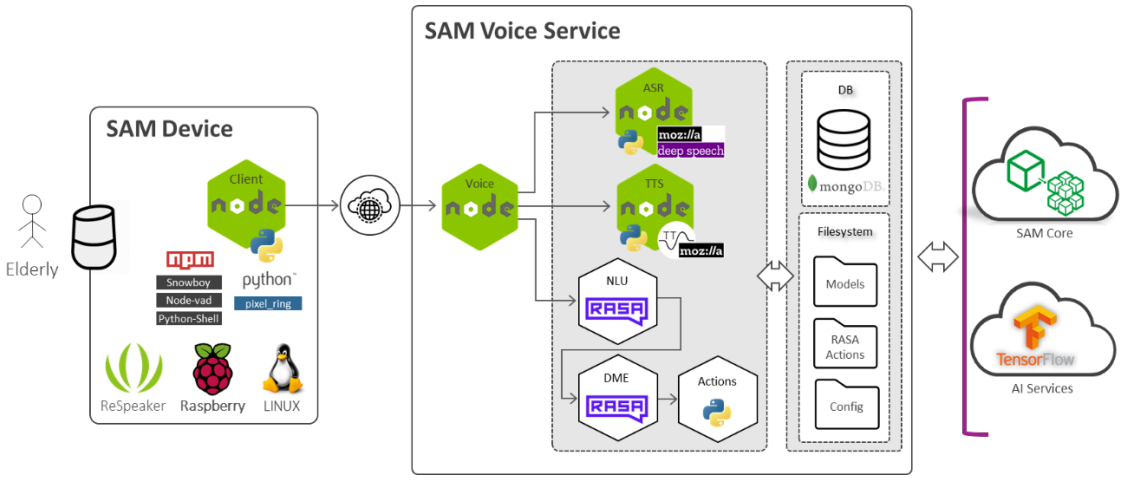

Figure 3. Conceptual technical architecture of the voice service (SAM Voice Service).

Recognition and dialogue performance depend on how well the corresponding models represent the target population and service domain. For this reason, the architecture supports customized ASR and conversational models based on data collection, care professionals' input, and iterative testing with older users. These frameworks were selected because their modular architecture provides direct control over speech recognition, dialogue management, and speech synthesis. This separation enables the proposed interaction method to be implemented under consistent, reproducible conditions, with deterministic task handling and clearly attributable system behavior. They therefore provide a suitable experimental platform for evaluating the study's central contribution: the design of an open and modular voice-service architecture. All the source code that implements this service has been made freely available to the community via the public repository [28].

V. CASE STUDY

This section illustrates the application of the proposed cloud-based voice service architecture through a companionship service for older adults, developed in collaboration with the health and social care services of two local councils. These services support an aging population with needs ranging from medication reminders to everyday companionship; however, limited budgets and staffing mean that current in-person support does not exceed one hour per user per day. Initial attempts to use commercial virtual assistants exposed important limitations. Their speech and dialogue models were not sufficiently adapted to older users, while vendor policies restricted changes to elements such as voice configuration, conversational behavior, and wake words. These constraints motivated a second project iteration based on open hardware and software, with customized voice and dialogue models tailored to the target population. The resulting system comprises the SAM Device, which provides the user-facing intelligent-assistant functionality, and the SAM Voice Service, which provides back-end voice and natural-language-processing capabilities. The following subsections describe the device design, the high-availability deployment architecture, and the development environment supporting the service. A dedicated quantitative evaluation of the system, including performance metrics, usability indicators, and statistical treatment of user-acceptance data, is being developed as a separate study. The present case study is not a complete experimental validation but rather an architectural feasibility study.

1. Hardware Prototype of the IoT Device (SAM Device)

The Assistant front-end interface is the VUI provided by an IoT device, the SAM Device, through which older adults interact with the system. This device was designed to accompany older adults, although it may also be highly useful for family members who wish to access the companionship service's features via the voice interface. Figure 4 shows a conceptual block diagram of the device architecture.

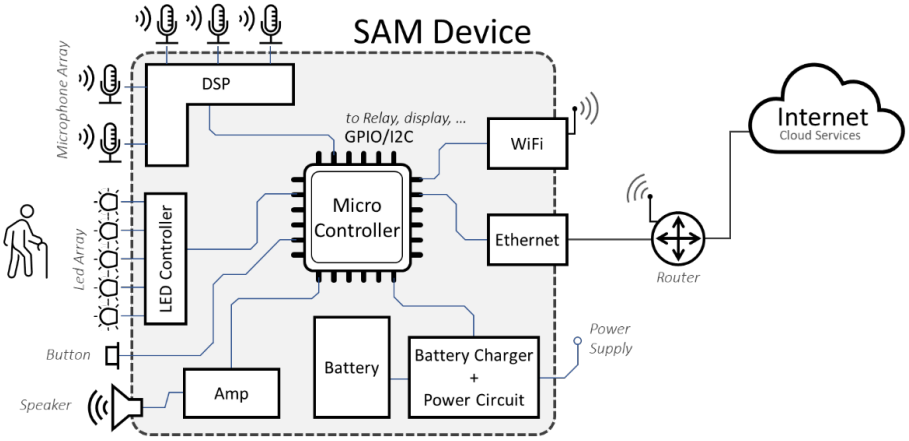

Figure 4. SAM Device high-level hardware architecture.

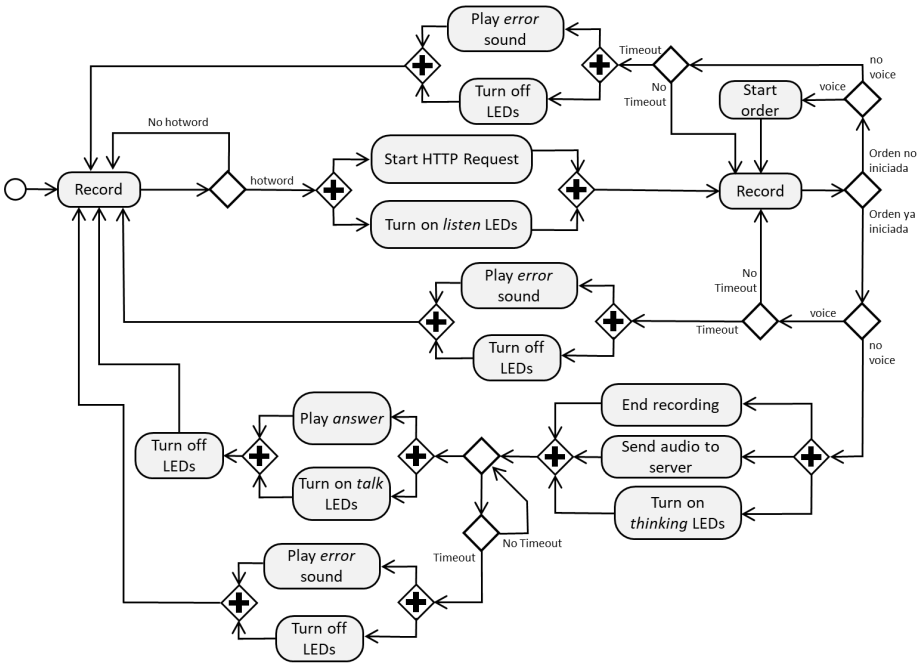

Figure 5. Flowchart of interaction with the SAM Device.

Figure 5 summarises the interaction flow of the SAM Device. The device remains in a passive local-listening state until the wake word is detected, then captures the user's utterance, sends the audio request to SAM Voice Service, plays the returned response, and returns to passive listening. Three different hardware prototypes were built: one based on the ReSpeaker Core v2 board; another based on a Raspberry Pi 3 together with a ReSpeaker 4-Mic Array board; and a final prototype based on a Raspberry Pi and a ReSpeaker 2-Mic Array board. All the prototypes incorporate the hardware components defined in the conceptual architecture (Figure 3).

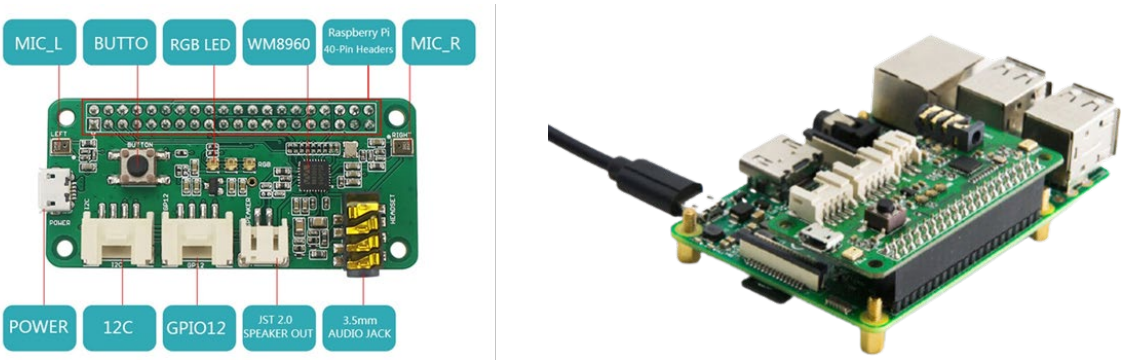

Figure 6. Prototype based on Raspberry Pi 3 Model B+ together with two microphones, four LEDs, speaker, temperature and humidity sensor, and relay.

Figure 6 shows, by way of example, one of the prototypes assembled from a Raspberry Pi 3 Model B+ and an array of microphones and LEDs. All the components incorporated and all the design work carried out followed open-hardware principles. In this way, the proposed hardware device can be easily replicated, maintained, and modified, even if the specific components described here are unavailable.

All the source code for the device is available to the whole community through a public repository [29].

2. Cloud Voice Service Platform Deployment Architecture and Performance Scenario

The service must support both small deployments and larger installations with variable demand. Figure 7 presents the high-availability deployment architecture, in which containerized service instances are deployed in Kubernetes clusters, with Nginx serving as a reverse proxy and load balancer. This design allows individual microservices and storage resources to be scaled independently according to demand and observed performance requirements. Considering the proposed high-availability architecture, a development scenario was constructed as an example (see Figure 8) to achieve the high availability and ease of scaling required in a production environment. This high-availability scenario is largely based on server clusters, storage networks, and load balancers.

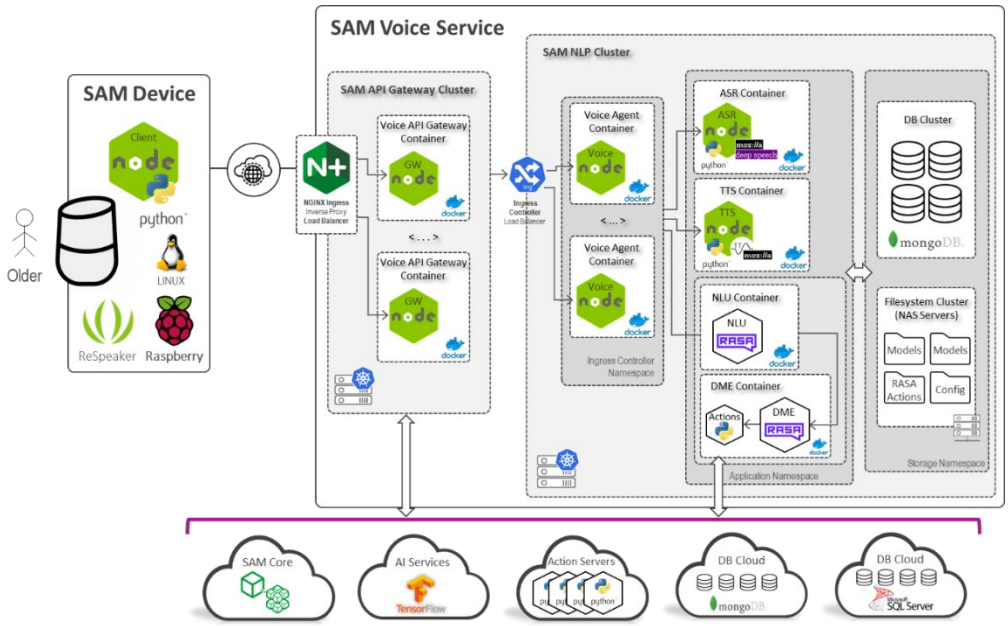

Figure 7. High-availability deployment architecture and the technologies involved.

The feasibility case involved 250 older adults who completed a post-use questionnaire after a mean trial exposure of 21.4 days; 89.2% used SAM daily or several times per week. The sample included participants aged 65–74, 75–84, and 85+, with 51.2% living alone, 79.2% reporting low or basic digital literacy, and 65.6% having no previous voice-assistant experience. Participants also represented different levels of care support and self-reported sensory, mobility, or mild cognitive limitations.

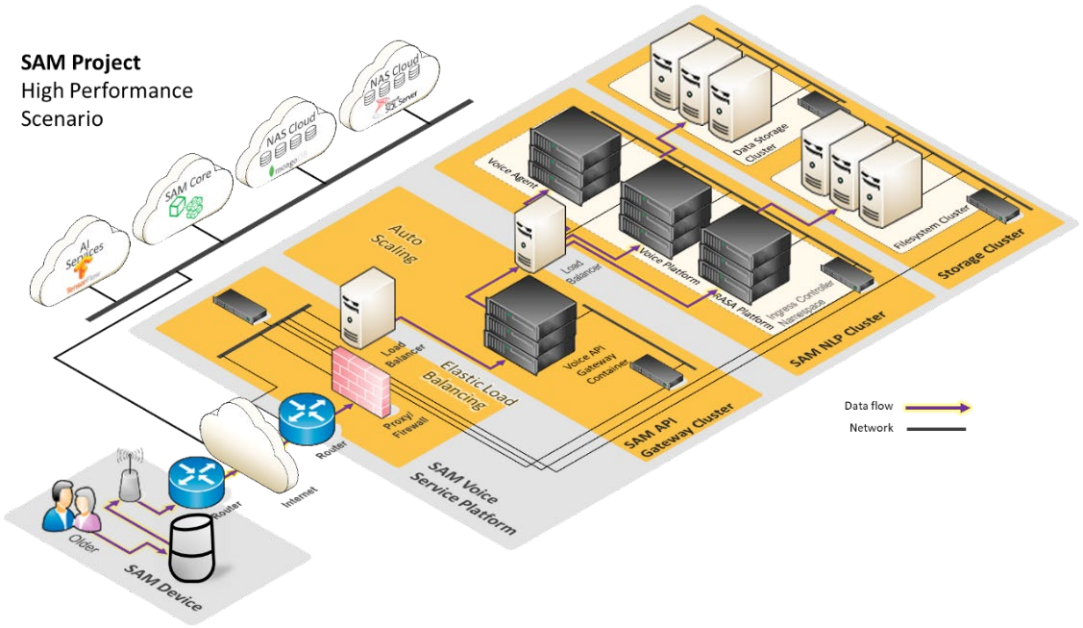

Figure 8. High availability performance scenario.

The questionnaire covered usefulness, ease of use, voice interaction quality, trust and safety, companionship value, and overall acceptance. Positive acceptance was observed in 217 participants (86.8%), with an approximate 95% confidence interval of 82.6–91.0%. The complete aggregated survey results are available as supplementary material in the public repository referenced in [28].

VI. CONCLUSIONS

This paper presented a modular, cloud-based voice-service architecture for Voice User Interfaces tailored to older adults. The proposed architecture spans conceptual, technical, and deployment levels, enabling the integration of open-source components and technologies from different providers. It is intended to support deployments that can be adapted to local functional requirements, available resources, and operational constraints. The architecture was instantiated in a case study on companionship services involving two local-authority social-care initiatives. The resulting system combines SAM Devices, which provide the user-facing interaction, with SAM Voice Service, which supplies back-end voice and natural-language-processing capabilities. The case study illustrates how these components can be deployed and scaled independently to support different service scenarios. The proposed system is intended to complement, rather than replace, family members and health and social care professionals by providing an accessible, voice-based channel for support and interaction. The source code and associated materials have been made available through the public repositories referenced in this paper. Ongoing complementary work will quantitatively evaluate usability, reliability, performance, and service outcomes in broader real-world deployments. This work has limitations. Its performance depends on the availability and population representation of ASR training data for the target population, and adaptation may be needed for different accents, speech characteristics, or deployment settings. Although the architecture supports scalable deployment, cloud processing and high-availability infrastructure entail computational, energy, and maintenance costs. Finally, the case study represents an architectural feasibility case conducted in a specific local context. A dedicated quantitative evaluation is being developed separately, and future deployments should also be validated with their own target users and operational conditions.

Abstract
AI is increasingly embedded in Kazakhstan's education system, creating demand for future informatics teachers who are both AI-literate and confident in applying AI in practice. This quasi-experimental study (pre-test/post-test, non-equivalent control group) evaluated the effect of the AI Integration Methodology 5-stages (AIM-5) model on AI Teaching Self-Efficacy and AI Integration Readiness among 84 third-year informatics students (EG, n=44; CG, n=40) at Abai Kazakh National Pedagogical University during the 2025–2026 academic year. The EG completed a 15-week AIM-5 program embedded in a methodology course; the CG followed the standard curriculum. Both outcomes were measured with validated, translated scales (α=0.85; α=0.83). Groups were statistically equivalent at pre-test (p=0.90). At post-test, the EG showed significantly greater gains than the CG in AI Teaching Self-Efficacy (12.2% vs 2.7%; t(82)=2.50, p=0.015, d=0.55) and AI Integration Readiness (10.4% vs 2.0%; t(82)=2.52, p=0.014, d=0.55). These small-to-moderate but reliable gains suggest AIM-5 supports early psychological readiness for AI integration, though longer, field-embedded interventions may be needed to produce deeper competency change.

Keywords: AI teaching self-efficacy; AI integration readiness; AIM-5 model; future informatics teachers; digital literacy; quasi-experimental study; TPACK-AI; teacher education.

I. INTRODUCTION

Generative AI's rapid adoption in global education has reshaped the competencies expected of teachers. For future informatics teachers, AI now occupies a "dual reality": it is both a content area to be taught and a methodological tool to be applied in teaching and learning practice. Bridging these two roles requires more than declarative knowledge of AI. It requires the psychological readiness to act, namely, teaching self-efficacy and integration readiness. Bandura's social cognitive theory identifies self-efficacy as a key factor mediating behavior, such that teachers with stronger self-efficacy beliefs are more persistent, more willing to try new teaching methods, and more resilient when they encounter technical failures [1]. The most widely used measure of this construct is the Teachers' Sense of Efficacy Scale (TSES) by Tschannen-Moran and Woolfolk Hoy [2], which has been validated to predict classroom innovation and the adoption of new instructional technologies [3].

To address teachers' needs in the AI era, Chiu et al. [4] introduced the Teacher AI Competence Self-Efficacy (TAICS) construct, which reflects teachers' confidence in employing, integrating, and controlling AI tools in teaching. Additionally, Çelik Demirci et al. [5] validated the Brief General AI Self-Efficacy Scale with 969 pre-service teachers in Turkish universities, further supporting the importance of AI self-efficacy in teacher preparation. The construct of AI integration readiness is complementary but distinct. Wang et al. [6] proposed four interrelated dimensions of teacher AI readiness — cognition, ability, vision, and ethics — and showed that all four were positively related to AI tool use in a sample of 3,164 primary school teachers. Aksoy et al. [7] subsequently developed the Readiness for AI Applications Scale (RAIS), comprising technology self-efficacy, interaction with students, and ethical awareness subscales, which was later validated in Turkish by Özüdoğru and Yildiz Durak [8]. These instruments collectively operationalize the UNESCO AI competency framework for teachers [9], which is grounded in the human-centered, ethical, and pedagogically informed use of AI in the classroom. Contextual evidence also comes from Turkish research on the psychological challenges of AI implementation. Ayduğ and colleagues [10] found that Turkish pre-service teachers report high digital literacy but moderate AI anxiety, with the technical sub-dimension of digital literacy accounting for 10.3% of variance in AI anxiety. Akdeniz and Özdınç [11] surveyed AI-in-education research in Türkiye and identified the same fragmentation observed elsewhere: emerging tools without systematic pedagogical models for teacher preparation. These findings parallel the situation in Kazakhstan, where AI tools are increasingly available but structured curricular integration remains limited [12]. Kazakhstan's policy landscape has decisively turned toward AI in teacher training. The Presidential Address "Kazakhstan in the Age of Artificial Intelligence" [13] called for AI literacy to be integrated into school curricula and for pedagogical universities to align graduate competencies with an AI-integrated labor market. Within this policy, the primary-school subject "Digital Literacy" holds strategic importance, and the informatics teachers who will teach it must be both technically competent and pedagogically prepared to apply AI tools appropriately. Yet the systematic review by Zawacki-Richter et al. [14] found that only a quarter of teacher education programs worldwide offer pedagogical modules specifically on AI. In our earlier quasi-experimental study [15], future informatics teachers showed substantial gains in AI literacy and motivational engagement with the AIM-5 model. However, such gains do not necessarily translate into confidence and readiness to implement AI in real classrooms: a student may know what AI is and still feel unprepared to use it in teaching [16]. The present study extends that earlier work by testing whether the same AIM-5 intervention, delivered as a full 15-week program within the course "Methodology of Teaching the Subject 'Digital Literacy' in Primary School," also improves two psychological pre-conditions of AI integration: AI Teaching Self-Efficacy and AI Integration Readiness. AIM-5 has three distinguishing features from generic TPACK-AI training and stand-alone AI-literacy modules. First, AIM-5 doesn't involve one-off training sessions; it's embedded in a full-semester methodology course and delivered in a sequence of five stages, from orientation to independent classroom application, providing AI literacy as declarative knowledge. Second, the psychological antecedents of AI use (self-efficacy and readiness) are targeted rather than just technical AI competence, which Wang and Chuang [16] have identified as a gap between knowledge and preparedness to use AI. Third, each step of AIM-5 results in a tangible, evaluated pedagogical artifact: a tool-comparison worksheet, an AI-supported activity portfolio, a TPACK-AI plan, a microteaching recording, and a reflection journal, providing the model with an assessment framework that is not always found in general AI-literacy interventions. The weekly activities, assessment, and AI tools used for each stage are described.

The research questions are:

1. Does participation in a 15-week AIM-5 program produce greater gains in AI Teaching Self-Efficacy among future informatics teachers than the standard curriculum?

2. Does the AIM-5 model produce greater gains in AI Integration Readiness? We hypothesized that the EG would show modest but reliable gains on both outcomes, consistent with Bandura's prediction that belief-based constructs change slowly even under structured intervention.

II. MATERIALS AND METHODS

1. Research design

The quasi-experimental pre-test/post-test non-equivalent control group design was used [17]. Random assignment of individual students was not feasible because the intervention was embedded in an existing methodology course delivered to two intact third-year class groups of the “Informatics” program; students were already enrolled in these groups for administrative and timetabling reasons that predate the study. One intact group was designated the experimental group (EG, n=44) and the other the control group (CG, n=40). Because assignment followed pre-existing class rosters rather than random allocation, causal claims are treated cautiously throughout this paper, and pre-test equivalence between groups was formally verified (Section III) before any between-group comparison was interpreted. The research took place at Abai Kazakh National Pedagogical University in Almaty, Kazakhstan, in the 2025–2026 academic year.

2. Participants and pre-experiment baseline survey

The total sample comprised 84 third-year future informatics teachers. All 84 students completed an AI self-efficacy pretest before the intervention. The questionnaire was administered online in Kazakh and Russian and comprised 18 self-efficacy items rated on a 5-point Likert scale (1–5). The two items most relevant to AI integration in informatics teaching are reported in Figure 1: (1) students’ self-reported competence in selecting suitable AI tools for informatics lessons, and (2) students’ self-reported competence in creating informatics learning materials, tasks, and digital resources using AI. Both items indicated moderate, polarised baseline self-efficacy, supporting the case for a structured intervention.

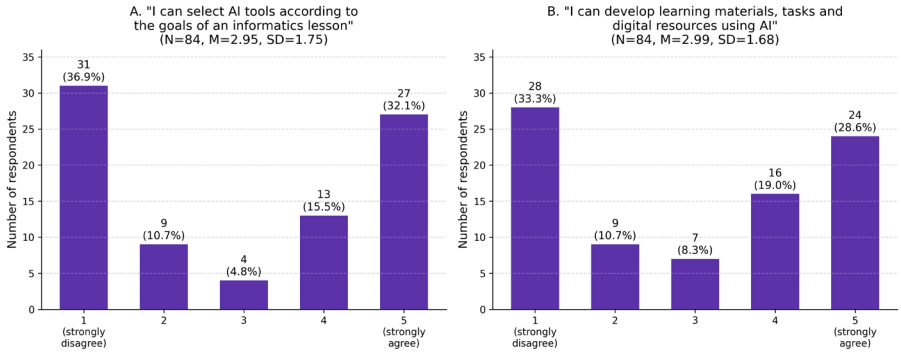

Figure 1. Pre-experiment baseline self-efficacy: distribution of responses on the two key items administered to all 84 participants before the intervention (5-point Likert scale).

3. Ethical considerations

Ethical considerations for the research procedures in this study were addressed in accordance with the ethical guidelines of Abai Kazakh National Pedagogical University, and permission to conduct the study was granted before data collection. All participants were given an informed consent form, which explained the purpose of

the study, the voluntary nature of participation, and that they could withdraw from the study at any time without penalty or impact on their academic standing, as well as the confidentiality and anonymization of their responses, before completion of the pre-test survey. None of the data was collected directly identifying, and all the data were analyzed and reported at the group level only.

4. Intervention: the 15-week AIM-5 program

The experimental group completed a 15-week AIM-5 course embedded in "Methodology of Teaching the Subject 'Digital Literacy' in the Primary School." AIM-5 is a five-stage pedagogical design model extending Technological Pedagogical Content Knowledge (TPACK) [18] to include AI. The weekly focus, activities, and assessed tasks for each stage are described below.

1. AI Orientation (Weeks 1–3). Weekly seminars introduced generative AI tools (ChatGPT, Claude, Microsoft Copilot), their capabilities and limitations, and age-appropriate use in primary education; students completed structured tool-comparison worksheets. Assessed task: a one-page "AI capability map" comparing three tools against age-appropriateness criteria.

2. AI Task Engagement (Weeks 4–6). Students used AI tools to generate and then critically revise draft digital-literacy activities (quizzes, worksheets, short explanatory texts) for 7–10-year-olds, evaluating outputs for accuracy, age-appropriateness, and pedagogical alignment. Assessed task: a portfolio of two AI-assisted activities with a written critique of the AI-generated content's limitations.

3. Principles of AI Methodological Design (Weeks 7–9). Working in pairs, students created full lesson plans for "Digital Literacy" using a TPACK-AI planning matrix that maps AI tool use onto content, pedagogy, and technology dimensions. Assessed task: a lesson plan scored against a TPACK-AI rubric by the course instructor.

4. Practicum Simulation (Weeks 10–12). Students used AI (primarily Claude and Microsoft Copilot) as a co-design partner to prepare 15-minute microteaching episodes, which were delivered to peers in a simulated primary classroom setting, followed by structured peer feedback. Assessed task: a video-recorded microteaching episode with peer- and instructor-rated rubric scores.

5. Reflective Synthesis (Weeks 13–15). Students kept a structured weekly reflection journal on what AI contributed to their planning, where it fell short, and the ethical considerations — data privacy, bias, and over-reliance — raised by using AI with children, and closed with a group reflection seminar—assessed task: a final reflective journal, graded for depth of critical engagement rather than length.

All AI tools used in the program (ChatGPT, Claude, and Microsoft Copilot) were pedagogically filtered, and their outputs had to be critically evaluated, adapted, and contextualized by students before use in a lesson. The control group followed the same base course but did not engage in the systematic, scaffolded use of AI described above.

5. Intervention fidelity

To support consistent delivery, all EG sessions were taught by the same instructor using a shared, lesson-by-lesson facilitation guide developed specifically for the AIM-5 program, and instructional materials (slides, worksheets, and rubrics) were standardized across the 15 weeks. Attendance was recorded at every session, and a second researcher independently observed a sample of sessions across the five stages using a structured fidelity

checklist to confirm that planned activities, assessed tasks, and AI tools matched the intended protocol; no material deviations from the planned curriculum were identified during these observations.

6. Instruments

AI Teaching Self-Efficacy was measured with a 15-item scale adapted from the Teachers' Sense of Efficacy Scale (TSES) [2] and the Teacher AI Competence Self-Efficacy (TAICS) scale [4]. Items were rated on a 5-point Likert scale. They addressed three sub-domains: efficacy of instructional strategies, classroom management, and student engagement, each contextualized to AI use in primary-school digital literacy lessons. Reliability was satisfactory in the pilot sample (Cronbach's $\alpha = 0.85$). AI Integration Readiness was measured using a 16-item scale adapted from the Readiness for AI Applications Scale (RAIS) [7] and its Turkish adaptation by Özüdoğru and Yildiz Durak [8], covering technology self-efficacy, interaction with students, and ethical awareness (Cronbach's $\alpha = 0.83$). Both instruments were translated into Kazakh and Russian, back-translated for equivalence, and content-validated by three experts in informatics pedagogy and AI in education (Content Validity Index, CVI = 0.88).

7. Data analysis

Descriptive statistics (means, standard deviations) were computed for both groups at pre- and post-test. Between-group differences at pre- and post-test were tested with independent-samples t-tests, and Cohen's d was used to estimate effect sizes. Within-group change was tested with paired-samples t-tests. The significance level was set at $\alpha = 0.05$. Because the sample size is modest and several effects are small to medium, statistical significance was interpreted alongside effect size rather than in isolation, to avoid overstating the practical importance of small mean differences. Statistical analyses were conducted in SPSS v.27.

III. RESULTS

Figure 1 shows the distribution of responses to two key baseline self-efficacy items administered to all 84 participants before the intervention. Average scores of 2.95 and 2.98 points (1–5 scale) with bimodal response patterns indicate that the group was initially heterogeneous and polarised: about a third of students rated themselves at the lowest self-efficacy level, while about 30% rated themselves at the highest. This pattern is consistent with the early-implementation stage of AI in informatics teacher training described for both Kazakhstan [12] and Turkey [11].

At pre-test, the experimental and control groups were statistically equivalent on AI Teaching Self-Efficacy (EG: M=2.96, SD=0.74; CG: M=2.94, SD=0.72; t(82)=0.13, p=0.90) and on AI Integration Readiness (EG: M=2.99, SD=0.76; CG: M=2.97, SD=0.73; t(82)=0.12, p=0.90), confirming group equivalence at baseline despite non-random assignment.

Table 1. AI Teaching Self-Efficacy: descriptive statistics and within-group comparisons

Group	n	Pre-test M (SD)	Post-test M (SD)	Δ (abs)	Δ (%)	Paired t (df)	p	d
EG	44	2.96 (0.74)	3.32 (0.50)	+0.36	+12.2%	3.65 (43)	<0.001	0.55
CG	40	2.94 (0.72)	3.02 (0.60)	+0.08	+2.7%	0.76 (39)	0.45	0.12

Note. Scale range: 1–5. Between-group post-test comparison: t(82)=2.50, p=0.015, d=0.55. Pre-test equivalence between groups: t(82)=0.13, p=0.90.

Figure 2 presents AI Teaching Self-Efficacy scores at pre- and post-test by group. The EG showed a within-group increase of 0.36 points (from M=2.96 to M=3.32, a 12.2% relative gain), which was statistically significant (paired t(43)=3.65, p<0.001, d=0.55). The CG showed a much smaller, non-significant increase of 0.08 points (from M=2.94 to M=3.02, a 2.7% relative gain; paired t(39)=0.76, p=0.45). The between-group post-test difference was statistically significant with a medium effect size: t(82)=2.50, p=0.015, Cohen's d=0.55. Although statistically reliable, this effect size and the modest absolute gain (0.36 points on a 5-point scale) indicate an early, incremental shift in self-efficacy rather than a large practical change in teaching confidence; detailed statistics are presented in Table 1.

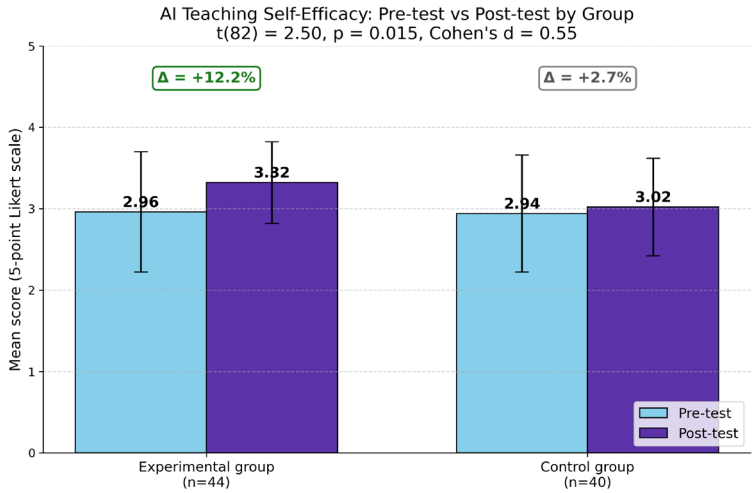

Figure 2. AI Teaching Self-Efficacy: pre-test and post-test by group (EG, n=44; CG, n=40). Error bars represent ±1 SD. Scale range: 1–5.

Table 2. AI Integration Readiness: descriptive statistics and within-group comparisons

Group	n	Pre-test M (SD)	Post-test M (SD)	Δ (abs)	Δ (%)	Paired t (df)	p	d
EG	44	2.99 (0.76)	3.30 (0.45)	+0.31	+10.4%	3.11 (43)	0.003	0.47
CG	40	2.97 (0.73)	3.03 (0.53)	+0.06	+2.0%	0.58 (39)	0.57 ns	-

Note. Scale range: 1–5. Between-group post-test comparison: t(82)=2.52, p=0.014, d=0.55. Pre-test equivalence between groups: t(82)=0.12, p=0.90.

Figure 3 presents the AI Integration Readiness results, which followed a parallel pattern. The EG showed a 0.31-point gain (from M=2.99 to M=3.30, a 10.4% relative gain; paired t(43)=3.11, p=0.003, d=0.47), while the CG showed only a 0.06-point gain (from M=2.97 to M=3.03, a 2.0% relative gain; paired t(39)=0.58, p=0.57). The between-group post-test difference was statistically significant: t(82) = 2.52, p = 0.014, Cohen's d = 0.55. As with AI Teaching Self-Efficacy, this medium effect size should be read as evidence of a real but modest difference rather than a large practical change; detailed results are summarised in Table 2.

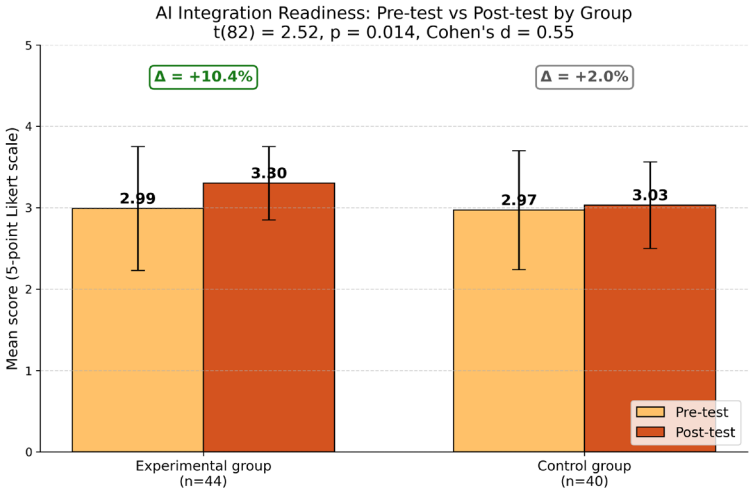

Figure 3. AI Integration Readiness: pre-test and post-test by group (EG, n=44; CG, n=40). Error bars represent ±1 SD. Scale range: 1–5.

IV. DISCUSSION

Two patterns merit interpretation. First, the magnitude of the EG gains (around 10–12%) is smaller than the gains reported in our previous study on AI literacy and motivation [15], in which the same AIM-5 model produced larger effects ($d > 1.0$). This distinction may be theoretical: AI literacy and motivation are knowledge- and interest-based constructs that change relatively quickly under structured exposure, whereas self-efficacy and readiness are belief-based constructs that change more slowly and depend on mastery experiences. A 15-week intervention likely provides only a few authentic mastery experiences in a real primary school setting, thereby limiting potential gains. While statistically significant, the 12.2% increase in AI Teaching Self-Efficacy should be read as a preliminary shift rather than a change in teacher identity — a pattern that echoes Çelik Demirci et al. [5], who found AI knowledge to be the strongest correlate of AI self-efficacy among Turkish pre-service teachers. It is also important not to over-interpret these effects. Although both between-group comparisons reached statistical significance at $\alpha=0.05$, the corresponding effect sizes ($d=0.55$ for both outcomes) are medium by conventional benchmarks, and the absolute score gains (0.36 and 0.31 points on a 5-point scale) are modest in real-world terms. In a sample of this size, statistical significance indicates that a real, replicable difference of moderate size was detected. It does not, by itself, demonstrate a large or transformative practical effect on teachers' classroom-ready AI competence. Second, for both outcomes, there was a slightly larger gain in self-efficacy than in readiness, consistent with the conceptual model proposed by Wang et al. [6] and empirically supported by the Turkish adaptation of Özüdoğru and Yildiz Durak [8], in which readiness incorporates self-efficacy plus ethical and visionary components that take longer to develop. The 15-week AIM-5 program likely under-samples the full impact of the Reflective Synthesis stage, which engages students in ethical discussions about AI use in primary classrooms; this stage is the most plausible mechanism by which the intervention influences readiness. A similarly small, non-significant improvement was observed in the control group on both measures. This is likely explained in part by the wider institutional context: students already use AI tools on their own devices, and the university offers optional AI-related workshops [12]. AI appears to be diffusing into students' informal learning even outside deliberately AI-focused courses, producing a small "natural drift" effect. This parallels Ayduğ et al.'s [10] finding that Turkish pre-service teachers' attitudes shift modestly with mere exposure to AI, but that substantial, structured pedagogical exposure is needed to produce educationally meaningful change in efficacy and preparedness. Viewed through the UNESCO AI Competency Framework for

Teachers [9], the present findings suggest that AIM-5 is a promising but limited intervention: it appears to foster the technological and pedagogical components of AI competence at the acquisition level, while the deepening and creation levels would likely require longer, field-embedded extensions of the model with sustained ethical leadership.

The findings here are limited in their interpretations by several factors, which we explicitly state and do not make a formality of. First, the sample is quite small (N=84) and drawn from a single cohort at a single university. Groups were not randomly assigned but rather followed existing class schedules, so the results should be viewed as preliminary and hypothesis-generating rather than definitive proof of a causal link between AIM-5 and the gains observed, and are not generalizable beyond similar institutional settings without replication. Second, the 15-week duration is still a full semester, but it is short relative to the period during which self-efficacy beliefs are known to remain stable; thus, gains may not be sustained. Third, the study is based on self-reported self-efficacy and readiness; behaviors would need to be observed, such as observed AI interaction during teaching practice, to support causal and practical claims. Finally, non-random assignment of students to groups poses a risk of selection bias, which is mitigated by the groups' equivalence in the pre-study assessment. Still, unmeasured differences between the intact class groups (e.g., instructor effects before the study, informal peer influence) are not eliminated.

V. CONCLUSION

We tested the effectiveness of the AI Integration Methodology 5-stages (AIM-5) model in improving AI Integration Readiness and AI Teaching Self-Efficacy among future informatics teachers, based on a quasi-experimental study involving 84 third-year students in the course “Methodology of Teaching the Subject ‘Digital Literacy’ in Primary School” at Abai Kazakh National Pedagogical University. The experimental group showed statistically significant, small-to-medium gains relative to the control group in AI Teaching Self-Efficacy (12.2% vs. 2.7%; $t(82)=2.50$, $p=0.015$, $d=0.55$) and AI Integration Readiness (10.4% vs. 2.0%; $t(82)=2.52$, $p=0.014$, $d=0.55$); given the study's sample size and non-random design, these results should be read as preliminary evidence rather than definitive proof of effectiveness. Three implications follow. First, a 15-week AIM-5 intervention appears sufficient to induce small-to-moderate changes in the psychological pre-conditions for AI integration, but longer, field-embedded extensions may be necessary to produce transformative change in teacher identity. Second, the parallel increases in self-efficacy and readiness support the conceptual accounts of Wang et al. [6] and Chiu et al. [4], and align with recent Turkish studies [5], [8], [10], indicating that these constructs develop on different timelines and require different pedagogical supports. Third, the small but persistent improvements in the control group underline the need to benchmark structured AI-integration models against realistic, AI-exposed baselines rather than AI-free comparison groups. Future research could pursue three directions: (1) longitudinal tracking of AIM-5 participants during their first two years of teaching practice; (2) multi-site replication using the same instruments across pedagogical universities in Central Asia, Türkiye, and other regions, with randomized assignment where institutionally feasible; and (3) incorporation of behavioral measures to triangulate the self-report results presented here.

ACKNOWLEDGEMENT

The authors thank the third-year students of the educational program “Informatics” at Abai Kazakh National Pedagogical University for their participation, and the three subject-matter experts who validated the adapted instruments used in this study.

Abstract
The rapid adoption of generative artificial intelligence (AI) tools has transformed higher education, creating new opportunities for learning while raising concerns regarding academic integrity, ethical use, and institutional policy. This study explores university students' perceptions, attitudes, and academic uses of generative AI within a private English-medium university in Kuwait. An online survey consisting of 21 questions was administered to students across all levels of study, yielding 418 responses. The survey examined four key areas: the normalization of AI use in academia; whether students use AI as a support tool or as a substitute for learning; students' understanding of ethical concerns surrounding AI; and their expectations of faculty guidance and institutional policy. Descriptive statistics and Pearson's chi-square analyses were employed to examine relationships between demographic variables and AI use. Results indicate that generative AI has become highly normalized, with 66.7% of students reporting academic use, primarily for research assistance, assignments, writing support, and summarization. While only a small number admitted to directly copying AI-generated content, most students reported attempting to understand AI outputs before incorporating them into their work. Recorded AI use was significantly higher with increasing study level, although no significant differences were observed by gender or academic major. Students demonstrated considerable uncertainty about the ethical boundaries of AI use, yet expressed strong support for clear institutional guidelines and the responsible integration of AI into education. The findings suggest that students view generative AI as a valuable learning aid rather than a replacement for learning itself, highlighting the urgent need for comprehensive AI literacy initiatives, faculty guidance, and institution-wide policies that promote ethical and effective AI use in higher education.

Keywords: Generative Artificial Intelligence; Higher Education; Student Perspectives; Academic Integrity; AI Ethics; Educational Technology; Digital Literacy; ChatGPT; University Policy

I. INTRODUCTION

The application of Artificial Intelligence (AI) in education is a multifaceted topic, and effective understanding requires narrowing in on each stakeholder's perspective. The purpose of this paper is to address the key stakeholders in any educational setting: the student [1]. Therefore, here we try to shed light on students' perceptions, attitudes, and usage patterns of AI in relevance to their academic work. To draw a parallel, there was a time when calculators were protested by educators, who feared that overreliance on such tools would be detrimental to students' arithmetic skills [2], [3]. Today, fear of overreliance on technology is once again rampant, and this time it may feel more valid than ever with the rise of generative AI tools like ChatGPT and its like. Similar to the calculator, the internet, and the many advancements in educational technology we have seen from the mid-1980s to today, mere tools may be overestimated or underestimated in their popularity, use, and educators' ability to control their use [4]. The authors of this paper hold that any tool can be used or misused, and that the onus of guiding its use falls on the educator, not the student. Therefore, we begin our analysis at the proverbial ground zero of the matter: understanding students' uses and the expectations of their institution and educators. Four key research questions are addressed to better frame and guide our understanding as educators:

1. How normalized is the use of generative AI in universities today?
2. Is AI used as a supporting tool, or are students fully dependent on it for answers?
3. Can students of the digital age recognize the ethical concerns associated with AI?
4. Do students expect more guidance on AI from their professors?

II. LITERATURE REVIEW

The use of Generative AI, particularly ChatGPT, has become increasingly embedded within higher education as students employ these tools to complete assignments, essays, reports, projects, and research tasks [5]. The rapid adoption of ChatGPT, which surpassed one million users within its first week of release [6], reflects how quickly generative AI has become integrated into academic environments. Existing research consistently demonstrates that awareness and use of generative AI among university students are widespread, with some studies identifying ChatGPT as the dominant platform for academic purposes [7], [8]. While this growing body of literature establishes that AI use is now commonplace, it also suggests that adoption is driven by a combination of academic, psychological, and technological factors rather than a single motivation. Across studies, efficiency consistently emerges as the primary reason students engage with generative AI. Abbas et al. [5], Chung [7], and Sousa and Cardoso [8] all report that students perceive AI as a means of reducing workload, saving time, improving productivity, and supporting learning through summarization, idea generation, translation, writing assistance, and concept explanation. Although these studies differ in emphasis, they converge on the conclusion that students primarily value generative AI as a productivity-enhancing tool. However, this convergence also exposes a limitation within the current literature. Much of the research explains why students use AI but provides comparatively less understanding of the conditions under which efficiency-oriented use remains educationally beneficial rather than becoming academically detrimental. Consequently, AI use should not be viewed simply as a technological behavior, but as a response to academic pressures, workload demands, and students' perceived need for learning support. Beyond academic efficiency, several studies identify psychological factors influencing AI adoption. Mental fatigue and academic stress encourage greater reliance on generative AI [9], while Johnston et al. [6] demonstrate that students with lower academic self-confidence are more likely to depend on AI. In contrast, students with greater confidence report using these technologies less and are more critical of others who use them. These findings collectively suggest that AI adoption cannot be explained solely by technological accessibility. Instead, individual learner characteristics, including confidence, stress, and cognitive demands, appear to shape patterns of AI dependence. Nevertheless, existing studies primarily establish associations between these variables, leaving unanswered questions regarding how these psychological factors interact with institutional environments and educational cultures.

The literature also presents a more nuanced understanding of students' attitudes toward generative AI than is often assumed. Polakova and Klimova [10] argue that Generation Z students' shorter attention spans and preference for rapid access to information make AI particularly attractive, while Johnston et al. [6] similarly suggest that impatience and outcome-oriented learning encourage technology use and dependence. However, these findings are partially contrasted by Chung [7], whose participants viewed generative AI primarily as a support tool rather than an unquestioned authority. This distinction indicates that students are not universally passive consumers of AI-generated information. Instead, many recognize its limitations and acknowledge the need for human judgment when evaluating AI outputs. Such differences across studies suggest that student use exists on a continuum ranging from supportive assistance to excessive dependence, rather than representing a single homogeneous pattern of behavior. The educational consequences of AI use likewise reveal a more complex picture. Abbas et al. [5] associate excessive use of ChatGPT with increased procrastination, memory loss, and poorer academic performance, while Alrasheed et al. [9] report declines in analytical reasoning, independent problem-solving, reflective thinking, and information evaluation among students who rely heavily on AI-generated responses. Taken together, these studies suggest that negative educational outcomes are linked less to AI use itself than to excessive or uncritical dependence on AI. This distinction represents an important conceptual point that is often overlooked within the literature. Rather than framing AI as inherently beneficial or harmful, existing evidence indicates that learning outcomes depend largely on how students engage with these technologies. The growing emphasis on AI literacy reinforces this interpretation. Alrasheed et al. [9] found that students possessing stronger AI literacy, including awareness of AI limitations, ethical considerations, fact-checking practices, and prompt evaluation, were significantly more capable of using AI critically rather than dependently. Sousa and Cardoso [8] similarly argue that AI literacy enables responsible and effective AI use. At the same time, the Digital Education Council [11] emphasizes that students must develop competencies in prompting and working effectively with Large Language Models. Collectively, these studies suggest that educational outcomes are influenced not only by the availability of AI but also by students' ability to critically evaluate AI-generated content. This shifts attention from restricting AI use towards developing the competencies necessary for responsible engagement. Institutional governance represents another recurring theme throughout the literature. Chung [7] reports that many students remain uncertain about institutional policies governing AI use despite acknowledging instances of academic misconduct, while Johnston et al. [6] found broad agreement among students that universities should establish clear guidance defining acceptable and unacceptable AI practices. These findings indicate that students' ethical concerns are not necessarily accompanied by institutional clarity. Instead, ambiguity surrounding acceptable AI use may contribute to inconsistent practices across higher education. The discussion of academic integrity reflects a similar pattern. Academic integrity is commonly defined as honesty, responsibility, and transparency in academic work [6], [12]. However, the widespread availability of generative AI has challenged traditional understandings of originality, as students increasingly rely on AI-generated material for assignments and express concerns about inaccurate information, fabricated references, and ethical misuse [7], [8]. Rather than suggesting that students intentionally engage in academic dishonesty, the literature indicates that many continue to use AI despite recognizing its limitations because they lack sufficient knowledge, confidence, or institutional guidance to use these tools appropriately [7]. Consequently, current evidence increasingly positions AI literacy and institutional policy as complementary rather than independent interventions. The Digital Education Council [11] extends this discussion by proposing practical assessment strategies, including the design of authentic assessments, clear AI guidance, staged assignments, oral verification, careful evaluation of referencing, and student accountability measures. Importantly, these recommendations move beyond detecting AI misuse towards redesigning learning environments that encourage critical engagement while reducing opportunities for inappropriate dependence. Collectively, the literature demonstrates broad agreement that higher education should shift from attempting to eliminate AI use towards managing it through assessment redesign, AI literacy development, and institutional policy. Despite the growing international literature, important gaps remain. Existing studies have primarily been conducted across diverse educational contexts, with limited evidence on

students' perceptions and practices in Kuwait. Educational policies, assessment cultures, institutional expectations, and students' experiences of AI adoption differ across national contexts, limiting the direct transferability of findings. Consequently, there remains insufficient understanding of how Kuwaiti university students perceive the educational benefits, risks, ethical challenges, and institutional expectations surrounding generative AI. Examining these issues within Kuwait, therefore, contributes context-specific evidence to an international literature that has largely overlooked the Gulf region, while also informing locally relevant institutional policies and educational practices.

III. STUDY IMPLEMENTATION

To address this study's four key questions, an online survey was administered to students enrolled in a private English-medium instruction university in Kuwait during the 2025-2026 academic year. A pilot survey was first administered to three classrooms, in which students provided feedback on the questions before the final form was submitted to the Institutional Review Board (IRB) for approval. The final version of the survey was then sent by email to all students enrolled in the university. These students ranged from those in the Foundations program (a pre-degree math and English literacy program) to those in the post-graduate level. Of those students, 418 responded. They answered an online form with 21 questions. The first part of the survey collected background information from the students, including their major, age, and self-rated level of experience with AI. The remainder of the survey included 16 self-evaluation questions that ranged from their use of AI to their understanding of ethics and academic integrity regarding its use. The full survey is outlined in Appendix A. Before analysis, it is important to note the limitations associated with this study. First, the findings are based on students from a single higher education institution, which may limit their generalizability to other universities in Kuwait or beyond. Second, the use of self-reported survey data introduces the potential for response and social desirability bias. Third, unequal subgroup sizes may have influenced comparisons across demographic groups. Finally, the cross-sectional design captures perceptions at a single point in time and therefore cannot determine changes in AI use or attitudes over time.

IV. RESULT ANALYSIS

The data collected from the student survey at the university (N=418), covering all 21 questions, were analyzed to understand the four key exploratory questions: normalization, use of the tool, ethical concerns, and expectations of guidance. As no factor is to be ruled out, each section of the survey is assessed to identify patterns in student stakeholders' perspectives on AI use throughout their educational journey.

1. Background

Of the students who responded (N=418), 55.7% were female, 42.1% were male, and the rest were undeclared. More than half of the participants (62.5%) were between the ages of 18 and 20, with the next largest group being 21-23. A small percentage (7.2%) was under 18, and an even smaller portion (2.6%) was over 26.

Table 1. Participants' Gender Distribution

Category	Numbers	Percentages
Female	233	55.7%
Male	176	42.1%
Undeclared	9	2.2%

Table 2. Participants' Age Distribution

Category	Numbers	Percentages
Under 18	30	7.2%
18-20	261	62.5%
21-23	100	23.9%
24-26	16	3.8%
AbLove 26	11	2.6%

Regarding their major, almost half of the participants were enrolled in computer science and engineering (22% each). Accounting was a close second with (12%). The rest spread relatively evenly across other majors offered at the university, including but not limited to business administration, English, finance, marketing, MIS, and mass communication (see Figure 1).

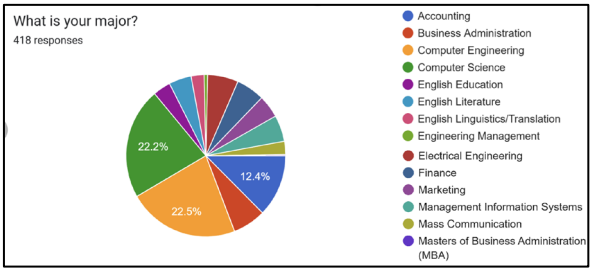

Figure 1. Majors

Regarding year of study, 20.1% were in Foundations, 30.6% were first-year, 19.1% were second-year, 14.6% were third-year, and 12% were fourth-year. A minority of participants were graduate students (3.6%).

Table 3. Participants' Year of Study Distribution

Category	Numbers	Percentages
Foundation	84	20.1%
Year 1	128	30.6%
Year 2	80	19.1%
Year 3	61	14.6%
Year 4	50	12%
Graduate Studies	15	3.6%

Students were asked to describe their proficiency with AI. While this question is difficult to pin down accurately, it offers a very poignant view of students' comfort and frequency of use [10]. The majority described themselves as beginners (31.8%) and intermediate (40%). 18.4% self-identified as advanced, which should be

considered a significant number for a relatively small pool of student participants addressing fairly new technology. A small percentage (9%) claimed they have never used AI.

2. Use of Generative AI in Academia

While completing assignments, 66.7% of students admitted to using generative AI. Among those who reported using AI, more than half (52%) reported regular use, with the rest reporting occasional or rare use. When asked for the specific purpose for their use of Generative AI in their academic work, Students were given the option to select multiple answers. Participants listed assistance with research as the major reason, at 75%. This was followed by help with assignments at 72.5%, although the extent of help or its definition was left vague. Many participants reported using AI for summarizing and editing (44% and 59%, respectively) and for solving math problems (40%). 25% reported using AI for coding assistance. A small percentage (12%) admitted to knowingly using AI to complete their assignments, thereby plagiarizing their work.

To further assess this, a Pearson Chi-Square test was conducted to determine whether there is an association between gender and AI use. Although more female participants responded affirmatively to using AI than male participants (see Figure 2), the difference was not statistically significant (p = .145).

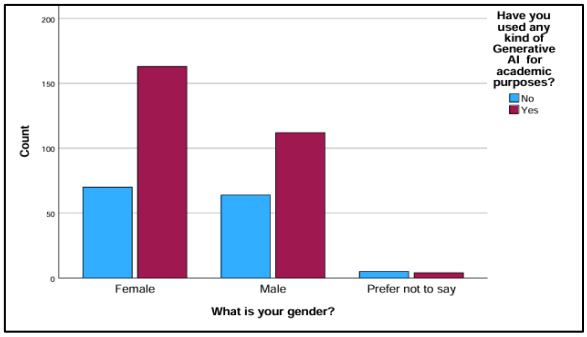

Figure 2. Gender and AI Use

Next, the test was conducted to determine any association between the major and the use of AI. Again, no statistical significance was noted (p=.794). However, an interesting result was observed in the percentage of use by major (see Figure 3). Of the 14 majors, 8 recorded around 65% affirmative use of AI for academic purposes: Accounting, Business Administration, Computer Engineering, Computer Science, Electrical Engineering, English Linguistics/Translation, Finance, and Management Information Systems. Another 4 majors recorded a 80% rate: English Education, English Literature, Marketing, and Mass Communication. Two majors recorded 100%; however, those were very small samples and can thus be neglected.

Table 4. Pearson Chi-Square tests involving the use of AI

Test Parameters	**Value**	**df**	**p-value**
Gender and Use of AI	3.866	2	.145
Major and Use of AI	8.711	13	.794
Year of Study and Use of AI	27.218	5	<.001*

*Statistically significant with p =0.0167 after Bonferroni correction.

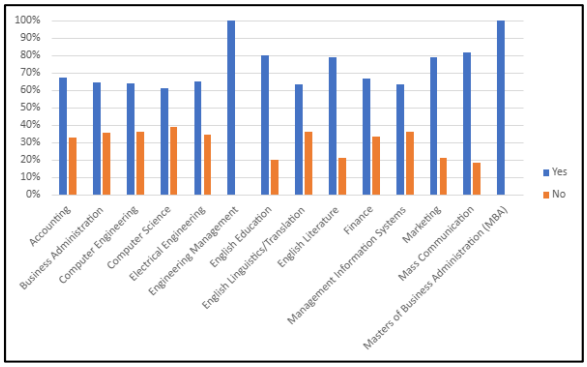

Figure 3. Major and AI Use Crosstabulation

This study also explored the relationship between year of study and AI use. Interestingly, a strong association was observed ($p < .001$; see Table 4). The Bonferroni correction was applied, yielding a new p-value of 0.0167. The results show that as students progress through college, the use of AI for academic purposes increases (see Figure 4). A Cramer's V test was implemented to determine the strength of this association. Cramer's V was 0.225, which indicates a moderately strong relationship. Further study is needed to determine the reasons for this increase. We cannot assess whether this change occurs as students progress, given the nature of our study. This level of analysis would require studying a cohort over the full course of their studies, not at a single point in time.

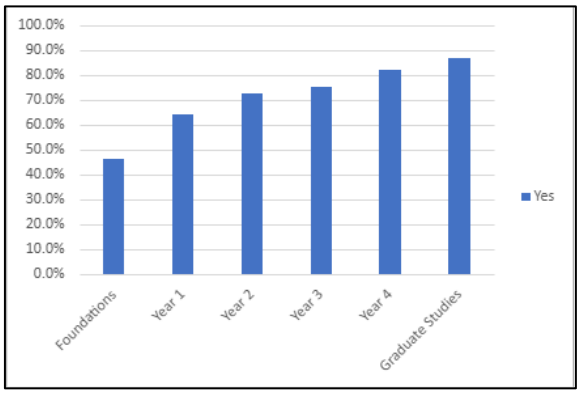

Figure 4. Year of Study and AI Use Crosstabulation

However, this sparked curiosity about how AI differs in the upper years of study. One question that needs exploration is how often they use AI. The Chi-Square test, with a Bonferroni correction (p-value = 0.0125), showed a significant association between year of study and the frequency with which participants use AI (see Table 5 and Figure 5). Interestingly, then, graduate students had the highest use of AI, with 40% reportedly using it several times per week (always). In contrast, foundation students had the lowest, with 5% using it several times per week (always).

Table 5. Pearson Chi-Square tests involving Year of Study

Test Parameters	**Value**	**df**	**p-value**
How often AI is used and Year of Study	50.828	25	.002*

Understanding output before use and Year of Study	25.185	20	.194
Need for guidelines and Year of Study	12.548	10	.250
Using AI when not allowed and Year of Study	12.182	5	.032

*Statistically significant with p =0.0125 after Bonferroni correction.

The study also investigated an association between year of study and understanding of AI output before use, but no statistically significant association was found (see Table 5). There was also no statistically significant association between year of study and their need for guidelines for using AI (see Table 5).

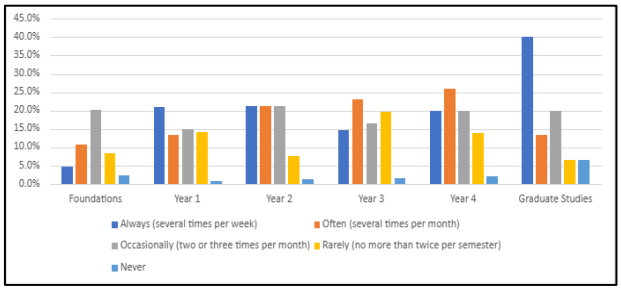

Figure 5. Year and Frequency of AI Use Crosstabulation

Other responses included using AI as a tutor, translator, and for daily life tasks. Active users were then prompted to rate how helpful they find AI to be in completing their assignments. More than half (64%) found it helpful, while only 3% found it unhelpful. To further understand and analyze their use of AI, students were asked whether they copied and pasted the answers generated by AI or put in some effort to understand the generated answers and then form their own response. The purpose here was to assess whether AI was being used as a tool for help or as a crutch. Fortunately, a small percentage (4%) reported copying and pasting, and more than half (60%) put in some effort to understand. The level of effort ranged from little to full understanding, and this gap is a key area of interest for further research aimed at improving the use of AI as an academic tool.

3. Ethics and Academic Integrity

The ethical implications of AI tools in academia were also explored in this study. Participants were asked several questions to gauge their moral stance and understanding of AI use in their work. They were asked whether completing assignments with AI support was ethical. While almost half said 'Yes' (40.7%) and only 21.5% said 'No', a substantial number were unsure (37.8%). This indicates a lack of clarity and understanding regarding the ethical use of AI in classwork. This further indicates an urgent need for guidance and regulations as students continue to use AI.

This need for guidance became more apparent when participants were asked whether they had conversations with their professors about the ethical use of AI. For example, have their professors warned them about using AI to complete their assignments? The responses were split with 51.4% responding 'Yes' and 48.6% responding 'No'. To further delve into this ethical issue, participants were asked whether, if the rules did not allow the use of AI, they would use it anyway. More than half (65%) responded that they would not. Furthermore, they were asked if they had ever faced consequences for using AI in their assignments. The majority answered negatively (80%). While some hypotheticals were used to gauge current understanding, this

does not negate the deduction that there exists a need for faculty guidance and a faculty role in adopting or guiding AI use in the classroom. Fortunately for academia, the question of whether they would prefer a clear policy on the use of AI in academic work saw more than half (56.9%) respond affirmatively. Preferring a clear policy from their professors shows that students are not lazy or unaware; they are simply growing up in a digital age and need guidance on what that means for their education. A Pearson Chi-square test was conducted to examine participants' willingness to use AI despite a clear policy against it. While hypothetical, this frames students' existing stance on plagiarism. The Chi-square test was conducted to examine the association between the year of study and the use of AI, despite it being prohibited. No statistically significant association was found (see Table 5). With that said, a high percentage of participants in the later stages of the study reported being willing to ignore policies prohibiting the use of AI (see Figure 6). Further study is required to understand the reasons for this perspective.

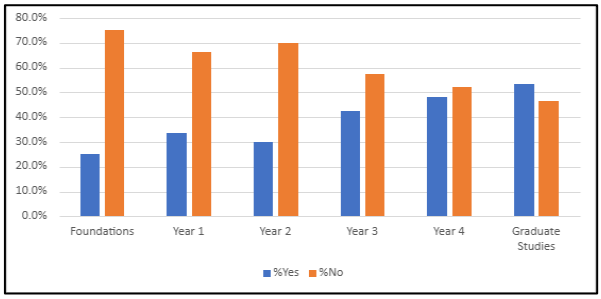

Figure 6. Year and Understanding of Ethicality Crosstabulation

The study did, however, show that students received some guidelines about AI use from their professors, but they were specific about the tool being ChatGPT. It also showed that ChatGPT is the most popular tool, with 69% listing it as their go-to AI tool. This led to the conclusion that policies set by professors should not be exclusive and need to include most, if not all, generative AI tools. The next question indicated that participants understood the need for guidelines regarding the use of AI tools, such as ChatGPT. When asked whether they believe ChatGPT should be integrated into the education system as a learning tool, 64% responded 'yes, with clear guidelines.' This overwhelming affirmative response emphasizes that students want AI as a tool and indicates that AI is a fixture in academic settings. Their awareness of the addition of guidelines reflects a clear understanding of the need on both sides – students and professors – to adopt AI ethically.

V. CONCLUSION

The close ratio of male and female participants allows for a relatively equal interpretation of the data across genders. This study confirms what is commonly known among faculty: students are using Generative AI to complete their academic work. It is no surprise that students find AI helpful, as that is a core aspect of AI's functionality. However, the study highlighted that their use of AI has not extinguished their desire to learn. A surprising result, though, is the increase in AI use among foundation-year students to graduate students. One would assume that students become more independent learners as they progress through their studies. Of course, this study cannot be taken as a progression and is addressed as a snapshot. This study shows higher reported AI use among students in later years of study, and that remains a point for further exploration. Given the cross-sectional design, these findings should not be interpreted as evidence of increasing dependence on AI over time. Developing students' understanding of the capabilities and limitations of generative AI may encourage more informed and responsible use of these tools. This was echoed in Tian et al. [9], where a strong understanding

of the limitations led to less dependability. Further research is warranted to explore the factors associated with the higher levels of reported AI use among students at different stages of their academic studies.

The ethicality of AI use is always in debate [13]. The results of this research do indicate a need and desire among university students for clarity in this matter. This is in line with the results of Johnston et al. [6], Chung [7], and Sousa & Cardoso [8]. However, the findings indicate that students continue to use AI for academic purposes while also expressing concerns regarding its ethical use. Although AI use remains common, the present study did not directly examine students' motivations for these behaviors or the extent to which institutional policies influenced their decisions. This is clear from the data here, where students have ignored AI policies and continued to use it in their academic work. The findings suggest that reported AI use differs across years of study, highlighting the need for further investigation into how students interpret and respond to institutional AI policies. Further study is also required to understand such behavior and the factors that drive older and more mature students to do so. On the other hand, the study also showed that it is unclear to students what constitutes ethical use and what constitutes plagiarism when it comes to AI. This ambiguity highlights the need for clearer institutional guidance and policies regarding acceptable AI use in academic work. Furthermore, the need for the policy to be inclusive of most AI tools, rather than focusing on one popular tool at the moment, is important. Students need an understanding of AI's capacity for academic work.

A noteworthy aspect of this study was students' awareness that AI can be a helpful tool when used correctly and ethically. Some have stated that they use AI tools as tutors to help with understanding the material. Others have used AI tools as a support for completing academic work, not as a source to copy and paste. Rather than prohibiting generative AI outright, educators may benefit from adopting clear expectations and guidance that promote responsible and ethical AI use:

- Including a clear policy on the use of AI in the syllabus.
- Ensuring students understand what is considered the use of AI
- Guiding students on how to source their use of AI in their academic work clearly

VI. FUTURE WORK

We hope to understand AI use in academia from all perspectives, and to eventually provide holistic, ethical suggestions that consider all those involved in the process. Further study is required to investigate the factors driving the increase in AI use among students, from those starting college to those nearing graduation. A longitudinal study might help investigate whether there is an increase in dependence on AI as students progress through their study years. The need to investigate current academic policies on the use of AI and the reasons students disregard them is also on our radar. This paper is the beginning of a larger project exploring AI in academia. Thus, our next step is to assess faculty uses of AI, including their approach to student use of AI in their classrooms.

Abstract
Since uncrewed aerial vehicles are widely used in military, industrial, logistics, and civil sectors, providing them with secure communication channels is of strategic importance. There is a serious need to develop energy-efficient, computationally lightweight authentication algorithms and reliable cryptographic key exchange protocols, which are the basis of secure communication. The scientific study of functional architecture and data exchange models plays a key role in ensuring the system's reliability, scalability, and cybersecurity. This review article analyzes the role of existing authentication protocols, lightweight cryptographic algorithms, PUF-based authentication, and blockchain technologies in UAV security. Future research directions - post-quantum cryptography and security mechanisms integrated with artificial intelligence - are also discussed.

Keywords: UAV, Elliptic Curve Cryptography, lightweight cryptographic protocols, post-quantum cryptography, blockchain technologies.

I. INTRODUCTION

In recent years, various lightweight cryptographic protocols have been proposed for UAV environments. These protocols are based on technologies such as symmetric and asymmetric cryptography, elliptic curve cryptography (ECC), hash-based mechanisms, public key infrastructure (PKI), lightweight authentication approaches, and blockchain and physical-layer-based methods. However, there are significant differences among existing approaches in security level, computational complexity, energy consumption, latency, and scalability.

Research Objective

The primary objective of this systematic literature review is to identify, analyze, and compare recent lightweight cryptographic authentication protocols developed for Unmanned Aerial Vehicle (UAV) networks and the Internet of Drones (IoD). The review also aims to identify existing security challenges and emerging research directions, including a comprehensive review and classification of lightweight cryptographic authentication protocols for UAVs, analysis of existing approaches, highlighting their strengths, limitations, and research gaps, and an overview of key challenges and future research directions for secure and efficient UAV authentication.

To achieve these objectives, the following research questions (RQs) were formulated:

- **RQ1:** What lightweight authentication protocols have been proposed for UAV and Internet of Drones environments?
- **RQ2:** Which cryptographic techniques are most frequently employed in these protocols?
- **RQ3:** What security properties and attack resistance are provided by existing authentication schemes?
- **RQ4:** What are the current limitations and future research directions in UAV authentication?

II. RESEARCH METHODOLOGY

The literature search was conducted using the following electronic databases: IEEE Xplore Digital Library, Scopus, Web of Science, ScienceDirect (Elsevier), SpringerLink, MDPI, and ACM Digital Library. Publications from January 2018 to May 2025 were considered. The search was performed using combinations of the following keywords: "UAV Authentication", "Drone Authentication", "Internet of Drones", "IoD Security", "Lightweight Authentication", "Mutual Authentication", "Authentication Protocol", "Lightweight Cryptography", "Elliptic Curve Cryptography (ECC)", "PUF Authentication", "Blockchain Security", "Post-Quantum Cryptography", "Firmware Security", and "Drone Communication Security". The selected studies were screened by title, abstract, and full-text analysis. Relevant information, including the authentication method, cryptographic techniques, security features, and performance characteristics, was extracted and comparatively analyzed to identify current research trends, limitations, and future directions.

III. ATTACKS ON UAV SYSTEMS

Uncrewed aerial vehicles (UAVs), or drones, provide numerous real-time services, from intelligent transportation systems and military applications to emergency rescue and environmental monitoring [1]. The low cost and flexible operational capabilities of these devices are the main reasons for their popularity [2]. However, the exchange of data over open communication channels [3] and the frequent deployment of UAVs in dangerous or uncontrolled areas make them vulnerable to several security attacks (Table 1).

Security issues are mainly divided into the following categories:

1) Network-based attacks: In the event of a physical capture of a UAV, confidential security parameters stored in its memory can be stolen, leading to privacy and security breaches for the entire system [3].

2) Physical capture attacks: Messages transmitted between UAVs or between UAVs and a ground station are subject to impersonation, session key disclosure, message replay, man-in-the-middle (MitM), monitoring, and eavesdropping attacks [4].

IV. CRYPTOGRAPHIC PROTECTION MECHANISMS IN UAV SYSTEMS

The UAV system is built on a multilayer architecture that requires real-time coordination. The main security requirements in these systems are as follows:

- Authentication and identification – mutual recognition between the UAV and the ground station.
- Confidentiality and information secrecy – encryption of flight coordinates, sensor data, and command packets.
- Integrity – prevention of data modification.
- Lightweight computing – cryptography suitable for limited energy and processor power.
- Physical security – resistance to device capture and reverse engineering attacks.

These requirements form the main design motives of various protocols.

The difference in the threat model for UAVs is that:

- Compromise can lead to real physical incidents.
- Resource limitations (CPU, energy) make it difficult to implement classical cryptographic protocols.
- Mobile nodes are sensitive to round-trip delay.

As UAVs are distributed and resource-constrained systems, they are exposed to various levels of security threats. These threats primarily affect communication, navigation, cryptographic mechanisms, software, the physical environment, and resource utilization (Table 1). As shown in Fig.1, research on UAV cybersecurity has grown steadily between 2019 and 2026, reflecting increasing scientific interest in this field. The number of publications rose gradually from 2019 to 2022, followed by a more pronounced increase during 2023–2025, indicating the rapid development of UAV cybersecurity research. Although the number of publications indexed for 2026 is based solely on records available at the time of data collection and does not reflect the full annual output, the results confirm that this topic continues to attract significant research attention. Overall, the publication trend highlights the growing importance of developing effective cybersecurity solutions for UAV systems.

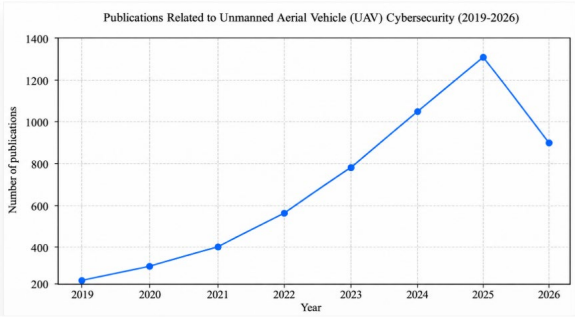

Figure 1. Publications related to Unmanned Aerial Vehicle cybersecurity in 2019-2026

Replay and Man-in-the-Middle (MITM) attacks can lead to the falsification of control commands and the alteration of telemetry data. MAC/HMAC mechanisms ensure message integrity. Nonce and timestamp-based authentication, session identifiers, mutual authentication, and ECDH-based key agreement mechanisms are used to prevent such attacks. GPS spoofing and GPS jamming attacks can cause the UAV to be redirected to incorrect coordinates or to lose navigation capabilities. To mitigate these risks, multi-sensor fusion (GPS and IMU integration), signal anomaly analysis, anti-jamming antennas, and inertial navigation mode-switching mechanisms are employed. In the field of cryptographic security, key extraction attacks can lead to the compromise of long-term secret keys and complete loss of control over the system. Approaches such as Secure Element (a specialized hardware component in cryptographic security, where secret keys and critical cryptographic operations are physically and logically protected), key generation based on physically unclonable functions (PUFs), and regular key renewal are used to mitigate these threats. Firmware injection attacks allow the execution of malicious code. The Secure Boot mechanism and the verification of software digital signatures minimize this risk. In terms of physical security, reverse engineering and the extraction of cryptographic keys are possible following device capture. Tamper-resistant hardware solutions and automatic memory erasure mechanisms are used against this. In a device takeover attack, it is possible to extract cryptographic keys through reverse engineering, modify sensor and control data, miscalculate the flight trajectory, and execute control decisions incorrectly, thereby completely disrupting the mission, causing the UAV to go out of control, or causing it to crash. Resource exploitation and DoS attacks cause the UAV to rapidly exhaust its power resources and disrupt real-time operations. To mitigate the impact of these attacks, lightweight cryptographic algorithms, traffic filtering, and rate-limiting techniques are used.

In identity-spoofing attacks, a rogue ground station can control the UAV. This threat is eliminated by certificate-based authentication and mutual authentication protocols. At the same time, hash functions, MAC mechanisms, and sequence numbers are used to prevent data integrity attacks during packet modification (Table 1). Consequently, the security of UAV systems requires a multi-level and integrated defense approach. This approach, based on the Defense-in-Depth principle, significantly increases the system's resilience and reliability against various threat vectors. For the cybersecurity of the UAV system, lightweight cryptographic protocols, certificate-based authentication, mutual identification, key exchange protocols, hash functions, and MAC/HMAC are the most powerful defense mechanisms against many types of attacks (Table 1).

Table 1. Attack–Defense mechanism analysis for Unmanned Aerial Vehicle systems

Type of attack	Defense mechanism
Replay attack	Nonce and timestamp-based authentication, session IDs, challenge–response mechanism
MITM (Man-in-the-Middle)	Mutual authentication, key agreement (ECDH), MAC / HMAC usage
GPS spoofing	Multi-sensor fusion (GPS + IMU), signal strength, and anomaly analysis
GPS jamming	Anti-jamming antennas, switching to inertial navigation mode
Key extraction attack	Secure element, PUF-based key generation, frequent key updates
Firmware injection	Secure boot, verification of firmware digital signature
Device hijacking	Tamper-resistant hardware, automatic memory wipe, and ampere-resistant hardware, automatic memory deletion
DoS/power depletion attack	Lightweight cryptography, traffic filtering, and rate-limiting
Impersonation attack	Certificate-based authentication, mutual identification protocols

V. CURRENT APPROACHES IN THE FIELD OF LIGHTWEIGHT CRYPTOGRAPHIC PROTECTION MECHANISMS IN UAVS

Researchers have developed various lightweight cryptographic protocols to address the aforementioned security problems and provide suitable solutions for resource-constrained UAVs. These protocols are based on the following technologies:

1. Lightweight authentication and key exchange protocols

One of the most widely used methods in UAV communication is the combination of symmetric key and ECC. By ensuring the secure exchange of symmetric keys through ECC, the computational load is reduced, and high-speed data transmission is protected [1]. This approach is also suitable for real-time encrypted data transmission during flight [1].
ECC is the most widely used asymmetric cryptography mechanism in UAV networks because it provides high security with short keys. An ECC- and symmetric-key-based protocol is presented [1-3].
A new authentication and key agreement scheme between the user and the accessed PUA, with the help of the server, is presented [4]. After successful mutual authentication between the user and the PUA, the established session key enables them to communicate securely, preventing various known attacks by the adversary [4].
A lightweight scheme for remote user authentication and key agreement in the IoT environment has been proposed [4]. This protocol minimizes computational costs and provides mutual authentication. In the same

direction, they have succeeded in protecting identity confidentiality using the temporary credential-based anonymous authentication (TCALAS) system [5].
The choice of ECC is determined by its relatively shorter key size compared to other asymmetric encryption algorithms, such as RSA (Rivest-Shamir-Adleman). After successful authentication, both parties generate a secret session key for secure communication [5]. To address this important problem in the UAV system, a new time- and credential-based anonymous lightweight user authentication mechanism, called TCALAS, has been developed [5]. *A3*, *A5*, and *A6* are not fully considered in the article.
TCALAS has been improved because it is weak against tracking and stolen-authenticator attacks, and because it cannot be scaled. To overcome security problems with lower time and resource consumption, a temporary credential-based anonymous lightweight authentication scheme (iTCALAS) has been proposed for UAV networks [6]. The improved scheme, which uses lightweight symmetric-key primitives and temporary credentials, provides security against many known attacks, including tracking and stolen authenticators [6]. Security measures for attack types such as *A3*, *A4*, *A5*, and *A6* are not considered.
The PASKE-IoD protocol combines both confidentiality and authentication, making the data exchange more secure [7]. Vulnerabilities are observed against attack types such as *A3*, *A5*, *A6* [4-7].

2. PUF-based security

PUF technology has emerged as an effective approach to UAV security in recent years. A PUF uses the physical properties of semiconductor devices to create a unique, difficult-to-clone "digital fingerprint" for each device. The CoMSeC++ protocol provides unique device identification using PUFs and provides an attack-resistant authentication system [8]. The same principles have been applied in the PLAKE protocol, preventing the forgery of key exchanges [9]. The proposed protocols use PUFs to prevent the leakage of private keys and provide robust protection even in the event of physical capture [8], [9]. Vulnerabilities to attacks such as A3 and *A5* [8], [9] are observed. An S-IoD framework is presented for the UAV environment that independently collects sensitive information [10]. A lightweight privacy-preserving scheme (L-PPS) is introduced to reduce the computational cost of the authentication protocol. L-PPS is designed to ensure reliability between IoT devices during authentication [10]. Although many threat scenarios are considered during protocol development, it remains vulnerable to attacks such as *A3*, *A5*, and *A6*. A lightweight, privacy-preserving mutual authentication and key agreement protocol, PMAP, is proposed [11]. It uses PUF and a chaotic system to support mutual authentication and generate secure session keys between communicating entities in an IoD system. PMAP consists of two schemes: PMAPD2Z (which mutually authenticates the PUA and the zone service provider and generates secure session keys) and PMAPD2D (which mutually authenticates the PUAs and generates secure session keys) [11]. The proposed protocol achieves confidentiality, integrity, mutual authentication, non-repudiation, perfect forward secrecy (PFS), perfect backward secrecy (PBS), defense against Denial-of-Service (DoS) attacks, man-in-the-middle (MITM) protection, and Drone-to-Drone (D2D) security [12]. The paper proposes a secure and lightweight biometric-based authenticated key agreement (AKA) protocol for the Internet of Drones (IoD) environment, utilizing lightweight cryptographic operations such as secure bitwise XOR operations, one-way hash functions, and the user's biometric verification for mutual authentication. A secure and lightweight biometric-based authenticated key agreement (AKA) protocol for the Internet of Drones (IoD) environment, utilizing lightweight cryptographic operations such as secure bitwise XOR operations, one-way hash functions, and users' biometric verification for mutual authentication [13]. Vulnerabilities to attacks such as A3 and *A5* are observed.

3. Blockchain and Distributed Trust Mechanisms

This approach allows for the implementation of decentralized trust systems in drone control. Blockchain is used to protect data integrity, facilitate secure key exchange, and track decisions in drone networks [14], [15]. Vulnerabilities are observed against attack types such as *A3*, *A5*, and *A6*.
A possible solution is proposed for each logical layer of the IoT architecture [15]. In addition, encryption mechanisms, privacy decentralization, secure communication, lightweight cryptographic protocols, and solutions against many security threats have been developed [15].

4. Artificial Intelligence and Deep Learning-Based Security

In recent studies, the combination of deep learning models with post-quantum cryptography is considered a promising direction for future drone defense systems [16]. This approach allows for the development of real-time attack detection and adaptive response mechanisms.
A review of approaches in the field of cryptographic protocols for UAVs shows that many research gaps remain and that the scope of development directions needs to be expanded.
In terms of energy optimization, most UAVs have limited battery life. Therefore, the energy optimization of cryptographic operations remains an open problem—particularly for integration with 6G and massive IoT. Future UAVs will operate in conjunction with 6G networks and require multiple low-latency connections, as well as protection against artificial intelligence-based attacks. The cyber-physical nature of UAVs necessitates protection against machine-learning-based attacks [16].

Table 2. Comparison of Unmanned Aerial Vehicles' security protocols

№	Protocol / Research	Cryptographic mechanism	Advantages (brief)	Disadvantages (brief)	Verification / Analysis Tool
1	Nyangaresi et al., 2023	Symmetric AES + ECC	Lightweight, high-speed	ECC operations are still relatively heavy for UAVs A3, A5, and *A6*.	AVISPA, BAN-logic
2	Yahuza et al., 2021	Hash-based + ECC	Edge-assisted, low-latency	Dependence on boundary structure. *A3*, *A5, A6*.	Scyther, ProVerif
3	Tian et al., 2024	ECC + Physical security	Resistance to physical capture	Higher computational load. Weak DoS optimization.	AVISPA, RoR model
4	Wazid et al., 2018	Hash chain + ECC operations against	DoS and MITM.	ECC operations. *A3*, *A5, A6*.	AVISPA, BAN-logic
5	Srinivas et al., 2019 (TCALAS)	Temporal Credentials + Hash	Anonymity, very light	Credential management is difficult. *A3*, *A5, A6*.	AVISPA
6	Ali et al., 2020	Lightweight hash + XOR	Minimal overhead for Smart-city	Formal proof is weak. *A3*, *A4 A5, A6*.	AVISPA, BAN-logic
7	Tanveer et al., 2021 (PASKE-IoD)	ECC + Pseudonym	Privacy strong	*A3*, *A5, A6*.	ProVerif, AVISPA

8	Mall et al., 2021 (CoMSeC++)	PUF + Hash	High physical security with PUF	*A3, A5.*	AVISPA, PUF reliability tests
9	Roy et al., 2022 (PLAKE)	PUF + Hash	PUF is resistant to attacks	*A3, A5.*	AVISPA, Formal PUF modeling
10	Deebak & Al-Turjman, 2020	Lightweight crypto + Privacy masking	Privacy is preserved	Computational burden can be high in some PUAs. *A3*, *A5, A6.*	AVISPA
11	Pu et al., 2022	ECC + Mutual Authentication	Drone-Drone and Drone-Server exchange strong	ECC workload. *A3*, *A5, A6.*	Scyther, AVISPA
12	Ko et al., 2021	Symmetric crypto + OTP	High security for the military zone	OTP management	AVISPA, Simulation-based proof
13	Akram et al., 2021	Hash-based + ECC Lightweight	Smart-city video transmission is insecure	*A3, A5.*	ProVerif, BAN-logic
14	Naveen et al., 2025	Blockchain + Lightweight cryptography	Full immutability, suitable for IoT	Blockchain latency. *A3, A6.*	Hyperledger testbed, Security analysis
15	Chowdhury et al., 2022	Blockchain + Hash	Decentralized authentication	High computation and latency. High time consumption. *A3, A6.*	AVISPA, ProVerif
16	Sharma & Rani, 2025	Post-Quantum Cryptography + ML	Future defense with PQC	PQC is too heavy and problematic for UAVs. *A3, A6.*	Security proofs, PQ-hardness assumptions

VI. CRITICAL ANALYSIS OF RESEARCH GAPS AND UPDATES

To ensure secure communication through UAV authentication models and enable successful, reliable flight missions in UAV systems, numerous authentication mechanisms have been proposed in the literature [1-16]. Using sixteen papers, the security of UAV authentication is analyzed. The analysis shows that most UAV authentication schemes are lightweight in terms of communication costs (Table 2). However, storage costs or energy consumption are not reported in many authentication studies. Formal models widely used in security analysis are identified, while most studies do not cover many attacks targeting UAV systems (Table 3).

Table 3. Comparison of security features

S/N	**Reference**	**A 1**	**A2**	**A3**	**A4**	**A5**	**A6**	**A7**	**A8**	**A9**	**A10**

RQ3: Security Properties and Attack Resistance

Most protocols provide mutual authentication, confidentiality, integrity, forward secrecy, and resistance against replay, impersonation, and man-in-the-middle attacks. Their security is commonly validated using ROM, RoR, BAN logic, and the Dolev–Yao model. However, UAV-specific threats such as GNSS spoofing, firmware attacks, physical capture, and side-channel attacks are rarely considered.

Key Finding: Existing schemes effectively resist traditional network attacks but provide limited protection against UAV-specific threats.

RQ4: Limitations and Future Directions

Current protocols are largely validated through theoretical analysis, with limited real-world UAV implementation and testing. Future research should focus on scalable authentication for drone swarms, dynamic UAV networks, secure firmware verification, and hybrid, lightweight cryptographic frameworks that adapt to emerging cyber threats.

Key Finding: Future authentication protocols should improve scalability, adaptability, and resilience against both conventional and UAV-specific attacks.

VIII. CONCLUSION

Key agreement and lightweight cryptographic security protocols for UAVs are a rapidly developing research area. Although current approaches provide a certain level of security, formal verification, energy optimization, and the application of post-quantum cryptography still require further research. This review systematically compares state-of-the-art lightweight cryptographic protocols for UAVs and identifies future research directions. Researchers have found partial solutions to these problems with lightweight cryptography and authentication protocols such as ECC, PUF, and blockchain. However, the rise of quantum computing poses new threats to existing cryptographic systems. Therefore, future research should focus on implementing PQC and developing hybrid authentication models to ensure secure communication between classical and quantum UAV networks. This approach will ensure the long-term cybersecurity and resilience of UAV systems.

Abstract
Managing waste disposal in congested areas such as higher institutions, markets, and worship centers is becoming a serious concern; untimely disposal of this refuse poses a great challenge to human health and the environment at large. This research harnesses the strengths of smart technology to develop SHRUMAC: A Smart Hygiene, Refuse Monitoring, and Alert Controller System for Real-Time Institutional Campus Sanitation Management. The SHRUMAC uses ultrasonic sensors to monitor waste bin levels and Bluetooth to send alerts to a mobile app called the Technology-Enabled Monitoring and Alert Controller (TEMAC App). When the SHRUMAC is full, it automatically notifies designated personnel (cleaners), ensuring timely waste disposal. It also features an automatic lid operation for hands-free use, improving hygiene. The SHRUMAC system helps manage waste more efficiently by reducing overflow and creating a cleaner campus environment in our institutions. The mobile app is built with MIT App Inventor and powered by a rechargeable energy solution. Through real-time data monitoring, it optimizes the collection schedule, reduces health risks associated with overflowing bins, and promotes a cleaner campus environment.

Keywords: Smart Waste Bin, IoT, Waste Alert System, TEMAC, SHRUMAC

I. INTRODUCTION

Since life itself and the creation of man, waste has been part of human existence. It is defined as any by-product, material, or substance that is discarded because it is no longer useful or needed; these include industrial by-products, sewage, and garbage; hence, most human daily activities generate waste [1]. Some of these actions stem from extracurricular activities such as eating and drinking. These generated wastes must be properly managed and disposed of to protect human health and the environment at large. Waste exists in many forms, and its characterization can be expressed in various ways. They are often located in different environments and landscapes [2]. To reduce the generation and spread of these human-generated wastes, various equipment, methods, and tools were used, taking environmental differences into account. This equipment includes garbage bins, brooms, parkers, garbage trucks, and disposable bags. Individuals often manage this equipment. Waste is easily generated in congested areas such as schools, markets, hospitals, and worship centers. As individuals consume different products and services, ranging from biodegradable to non-biodegradable items such as food, plastic, and paper. These materials and products are usually discarded in waste bins and sometimes on the ground. When these items accumulate over time, they pile up; this waste becomes unpleasant to the eyes and nose and can even pose health risks. To reduce environmental pollution and improve individual health, proper trash disposal practices are essential for ensuring overall environmental well-being [3]. As stated by [4].

Insufficient waste management infrastructure, limited awareness of proper waste disposal practices, and inadequate institutional policies may contribute to suboptimal waste management outcomes. Though environmental cleanliness and sanitation are everyone's responsibility, specialized individuals, known as cleaners, are employed to collect trash and waste regularly. These individuals are responsible for locating, collecting, and removing waste materials from strategic locations to keep the environment clean at all times. They set up waste bins throughout the environment to collect waste and mark certain locations for easy retrieval. It takes a significant number of waste bins and a variety of emptying schedules to handle the public waste effectively. However, certain factors, such as unidentified, piled-up waste bins and the location of individual bins, could hinder the effective handling and removal of these materials. Due to regular patronage or population in a location, some waste bins fill up much faster than they are emptied, leading to them becoming full before the next collection date or time, which poses hygiene risks to the public [5][6][7]. Given these challenges, there is a pressing need for a better approach to sanitary and waste management systems, and for their adoption or inclusion to achieve a more efficient, healthier, and more hygienic society. The smart waste management system will not only shed light on the challenges faced by cleaners. Still, it will also pave the way for targeted interventions to enhance the sustainability and effectiveness of sanitation efforts. The introduction and use of a real-time sanitary and waste alert system to help address most of the challenges encountered in gathering, isolating, managing, and disposing of waste are the focal points of this research. The Internet of Things (IoT), that is, the interconnection of devices through the internet, presents a revolutionary approach to enhancing waste management practices. IoT integrates sensors, communication networks, and data analytics to create intelligent systems that monitor, analyze, and optimize various operations remotely and in real time [8]. About waste management, IoT technology helps create smart trash bins that monitor fill levels, detect hazardous gas emissions, and provide real-time data to waste management authorities via mobile alert systems, enabling timely interventions. By equipping waste bins with sensors to monitor fill levels and hazardous gas emissions, IoT can optimize waste collection, prevent environmental hazards, and enable real-time data-driven decision-making for municipalities and waste management authorities across campuses of Nigerian higher institutions. Higher institutions of learning generate substantial amounts of municipal solid waste daily due to academic activities, commercial operations, student residences, cafeterias, and administrative offices. The increasing population of students and staff has further intensified the challenge of managing waste effectively within university campuses. In many developing countries, waste bins often overflow before they are emptied because cleaners rely on routine inspection rather than real-time information about bin status. This situation contributes to environmental pollution, unpleasant odors, pest infestation, and increased public health risks. According to [9]. Sustainable waste management requires efficient collection systems supported by appropriate technologies to minimize environmental degradation. Similarly, [10]. observed that ineffective monitoring of waste accumulation significantly reduces the efficiency of municipal solid waste management systems and increases operational costs. The emergence of the Internet of Things (IoT) has created new opportunities for improving waste management through intelligent monitoring and automation. IoT-based waste management systems integrate sensors, embedded controllers, communication technologies, and mobile applications to continuously monitor waste levels and notify responsible personnel when intervention is required. Such systems eliminate unnecessary manual inspection while ensuring that waste is collected before bins overflow. A comprehensive review by [11]. concluded that smart waste bins equipped with ultrasonic sensors and wireless communication significantly improve waste collection efficiency, optimize resource utilization, and promote environmental sustainability. Likewise, [12]. demonstrated that IoT-enabled smart waste monitoring systems provide real-time information on waste-bin status and support cleaner urban environments through automated monitoring and timely notification. Despite these technological advancements, the adoption of intelligent waste management systems remains very limited in many Nigerian tertiary institutions, where conventional waste bins are still predominantly used. Most campus waste management practices rely on periodic inspections by cleaners, leading to delayed waste collection, overflowing bins, and poor sanitation. Furthermore, conventional waste bins require users to touch the lid during disposal, thereby increasing the risk of transmitting disease-causing microorganisms

via contaminated surfaces. Reference [1] emphasized that modern waste management systems should incorporate technological innovations that improve operational efficiency and environmental hygiene. Similarly, [13]. argued that sustainable waste management requires the integration of smart technologies capable of supporting timely decision-making and improving sanitation outcomes. It is against this backdrop that the SHRUMAC (Smart Hygiene and Refuse Monitoring and Alert Controller) system was developed as an interventionist mechanism to address the shortcomings of existing campus waste management practices. SHRUMAC integrates an ultrasonic sensor, an ESP32 microcontroller, Bluetooth communication, a servo motor, and a companion mobile application, TEMAC (Technology-Enabled Monitoring and Alert Controller), into a single intelligent waste-monitoring platform. The system continuously monitors waste bin fill levels, automatically opens the lid when a user approaches, and sends real-time notifications to cleaners when waste reaches a predetermined threshold. This approach reduces unnecessary manual inspections, prevents waste overflow, promotes hygienic waste disposal, and enhances the overall efficiency of campus sanitation management. The effectiveness of similar IoT-based waste-monitoring architectures has been demonstrated in [14]. who reported improved responsiveness of waste collectors through mobile notifications, while [12]. found that integrating sensing, automation, and wireless communication significantly enhances the performance of smart waste management systems.

1. Statement of the Problem

Effective waste management remains a major environmental and public health challenge in many higher educational institutions, particularly in developing countries. Although waste bins are strategically positioned across university campuses to promote proper waste disposal, they are typically monitored through routine manual inspections rather than real-time systems. Consequently, waste bins frequently become overfilled before they are emptied, resulting in unpleasant odor, littering, pest infestation, environmental pollution, and increased risks of disease transmission. Reference [9] observed that inefficient waste collection practices and inadequate monitoring systems are among the major factors affecting sustainable waste management in developing countries. Similarly, [10]. reported that the absence of timely information on waste accumulation contributes significantly to poor waste collection efficiency and increased operational costs. Another concern associated with conventional waste bins is their dependence on manual operation. Users are often required to touch the waste bin lid during disposal, creating additional opportunities for the transmission of bacteria, viruses, and other harmful microorganisms via contaminated surfaces. Furthermore, sanitation personnel lack reliable means to determine when waste bins are at capacity, making waste collection largely dependent on fixed schedules or physical inspection. This approach is time-consuming, labor-intensive, and often results in delayed waste evacuation and overflowing bins. Recent studies on smart waste management have shown that integrating sensors, embedded controllers, wireless communication, and mobile applications can provide real-time monitoring of waste bins, improve collection efficiency, and promote cleaner environments [12][14]. Despite the increasing adoption of Internet of Things (IoT)-based waste management technologies worldwide, their use in Nigerian tertiary institutions remains limited. Most campuses still rely on conventional waste bins that lack automated monitoring, real-time notification, and touch-free operation. This technological gap reduces the effectiveness of campus sanitation programs and limits cleaners' ability to respond promptly to waste management needs. It is therefore necessary to develop an intelligent waste management system that can automatically monitor waste levels, detect user presence, enable contactless lid operation, and transmit real-time alerts to sanitation personnel. The development of SHRUMAC (Smart Hygiene and Refuse Monitoring and Alert Controller), integrated with the TEMAC (Technology-Enabled Monitoring and Alert Controller) mobile application, is intended to address these shortcomings by providing an affordable, efficient, and smart waste monitoring solution that supports timely waste collection, improves environmental hygiene, and enhances sanitation management within educational institutions.

2. Aim and Objectives

This research aimed to develop a novel, real-time IoT-based sanitary and waste alert system to enhance cleanliness and efficiency on university campuses.

This was achieved by:

Developing SHRUMAC, a hardware system (using an Arduino microcontroller) that will process data from all connected sensors, manage wireless communication, and send alerts to the mobile phone application and user devices, ensuring continuous monitoring and consistent communication. Building TEMAC, a Mobile application using MIT App Inventor that will be connected to the system's hardware remotely. Implement an alert mechanism using an alarm buzzer and a mobile application notification to enable the system to send real-time alerts to designated personnel via the mobile application interface, ensuring timely response to issues such as full waste bins. Adopting a rechargeable energy solution using batteries to run the system to ensure an uninterrupted power supply for both indoor and outdoor installations. Testing. Evaluation and deployment of the system.

II. LITERATURE REVIEW

This section provides a comprehensive overview of the evolution and current state of waste management systems, detailing the transition from early, often hazardous disposal methods to modern technology-driven practices. It explores the historical context, highlighting the progression from rudimentary techniques in ancient Rome and medieval Europe to systematic approaches prompted by urbanization and industrialization. Technological advancements, including automated collection systems, AI-driven sorting, and waste-to-energy technologies, are examined for their role in improving efficiency and sustainability. Current trends emphasize circular economy models, extended producer responsibility, and smart waste management solutions. It concludes by summarising related literature on smart waste management systems, environmental impact, public health, and technological innovations, setting the stage for further research and developments.

Evolution of Waste Management Systems (Early Waste Management Practices)

Early waste management practices varied greatly across different cultures and regions, influenced by local conditions and available resources. In many ancient societies, waste was often disposed of haphazardly, leading to significant health and environmental issues. For instance, in ancient Rome, despite a relatively sophisticated system of aqueducts and sewers, waste management practices were still rudimentary and largely ineffective at preventing the spread of disease [10]. In medieval Europe, waste disposal methods were even less advanced. Garbage and human waste were frequently discarded into the streets, rivers, and other public places, contributing to the spread of plagues and other infectious diseases [13]. It wasn't until the 19th century that more systematic approaches to waste management began to emerge, largely in response to growing urbanization and public health concerns. In contrast, some early civilizations, such as those in ancient China and Japan, practiced more organized waste management. These societies employed methods such as composting and recycling organic waste for agricultural purposes, demonstrating an early understanding of the potential value of waste [15]. These practices were driven by necessity, as densely populated areas required more efficient waste management to prevent disease outbreaks and sustain agricultural productivity. The Industrial Revolution marked a significant turning point in waste management practices. The massive increase in waste production due to industrial activities necessitated the development of new disposal methods, including the establishment of landfills and incineration plants [9]. These methods, while more organized, often led to environmental degradation and

pollution, highlighting the need for more sustainable waste management solutions. In summary, early waste management practices were largely reactive and localized, evolving from rudimentary and often hazardous methods to more structured approaches in response to urbanization and industrialization. The varied practices across different cultures underscore the importance of context-specific solutions in waste management [16][17].

1. Technological Advancements

Technological advancements in waste management have significantly transformed how societies handle waste, making processes more efficient, sustainable, and environmentally friendly. Over the past few decades, innovations in waste management technology have addressed various challenges, including waste collection, sorting, recycling, and disposal. One of the most notable advancements is the development of automated waste collection systems. These systems use sensors and smart bins to optimize waste collection routes, reducing fuel consumption and operational costs [18]. For instance, smart bins equipped with fill-level sensors notify waste collection services when they need emptying, ensuring timely and efficient waste collection. In the realm of recycling, chemical recycling technologies have emerged as a game-changer. Unlike traditional mechanical recycling, which can degrade material quality, chemical recycling breaks down plastics into their molecular components, enabling the production of new, high-quality materials. This process not only improves the recyclability of complex plastic products but also helps in managing plastic waste more sustainably [19]. Waste-to-Energy (WtE) technologies have also made significant strides. Modern incineration plants are equipped with advanced emission control systems that minimize environmental pollution while generating electricity and heat from waste. Additionally, aerobic digestion technologies convert organic waste into biogas, a renewable energy source that reduces reliance on fossil fuels and lowers greenhouse gas emissions [20]. Another significant advancement is the use of digital platforms and big data analytics in waste management. These technologies enable municipalities and waste management companies to monitor and analyze waste generation patterns, optimize resource allocation, and improve decision-making processes. Predictive analytics, for instance, can forecast waste-generation trends, helping plan for future waste-management needs [21]. In summary, technological advancements in waste management have revolutionized how waste is collected, sorted, recycled, and disposed of. Innovations such as automated collection systems, advanced sorting technologies, chemical recycling, waste-to-energy processes, and digital platforms have made waste management more efficient, sustainable, and environmentally friendly [22].

2. Current Trends

Current trends in waste management reflect the growing emphasis on sustainability, circular economy principles, and the integration of advanced technologies to manage waste more efficiently. These trends highlight the shift from traditional waste disposal methods to more innovative and environmentally friendly practices. One prominent trend is the increasing adoption of circular economy models. Unlike the linear "take-make-dispose" approach, the circular economy aims to keep resources in use for as long as possible, extract the maximum value from them, and recover and regenerate products and materials at the end of their lifecycle. This approach reduces waste generation and promotes resource efficiency [23]. Many countries and businesses are implementing circular economy strategies to minimize waste and enhance sustainability. The rise of extended producer responsibility (EPR) is another significant trend. EPR policies hold manufacturers accountable for the entire lifecycle of their products, including end-of-life disposal. This encourages producers to design products that are easier to recycle, reuse, or dispose of safely. EPR programs have been successful in improving recycling rates and reducing environmental impacts across sectors such as electronics, packaging, and automotive [24]. Technological advancements continue to drive innovation in waste management. The use of big data and Internet of Things (IoT) technologies enables real-time monitoring and optimization of waste collection and processing

systems. Smart waste management solutions, such as sensor-equipped bins and intelligent routing systems, help reduce operational costs and environmental footprints by optimizing waste collection schedules and routes [25]. Waste-to-energy (WtE) technologies remain a crucial component of modern waste management strategies. These technologies convert non-recyclable waste materials into usable forms of energy, such as electricity, heat, or fuel. Advanced WtE plants incorporate cutting-edge emission control systems to minimize environmental impacts, making them a viable solution for managing residual waste while generating renewable energy [26]. Another emerging trend is the focus on bio-waste management. Organic waste, which includes food waste, garden waste, and agricultural residues, constitutes a significant portion of municipal solid waste. Innovative bio-waste treatment technologies, such as anaerobic digestion and composting, are being increasingly adopted to convert organic waste into valuable products like biogas and compost. These processes not only reduce landfill usage but also contribute to renewable energy production and soil health [27]. Plastic waste management has garnered substantial attention in recent years, driven by the global plastic pollution crisis. Public awareness campaigns and international agreements, such as the Basel Convention's amendments on plastic waste, are also playing a crucial role in tackling plastic pollution [28]. Therefore, community engagement and public participation are becoming increasingly important in waste management. In conclusion, current trends in waste management emphasize sustainability, technological innovation, and community involvement. The shift towards circular economy models, extended producer responsibility, smart waste management solutions, waste-to-energy technologies, bio-waste management, plastic waste reduction, and public engagement are shaping the future of waste management, making it more efficient, sustainable, and environmentally friendly [23][25][28].

3. The SHRUMAC System

The SHRUMAC system is designed to enhance waste management through automation and real-time monitoring. It integrates several components to ensure efficient operation and user convenience. Ultrasonic Waste Level Measurement: An ultrasonic sensor continuously monitors the trash can's fill level. This sensor emits ultrasonic waves, which reflect off the waste material back to the sensor, allowing it to measure the distance from the sensor to the top of the waste. By analyzing these reflections, the system can determine how full the trash can is. Bluetooth Communication: When the trash can reaches a certain fill threshold, the ultrasonic sensor triggers a notification. This notification is transmitted via Bluetooth to the TEMAC, a mobile application. The TEMAC App, developed using MIT App Inventor, receives this alert and notifies the user that the waste needs to be disposed of or the bin needs to be managed. This feature ensures that users are promptly updated about the waste status without needing to check the bin manually. Automatic Lid Operation: To enhance hygiene and convenience, the trash can is equipped with a servo motor controlled by an ultrasonic sensor. When a user approaches the bin, the sensor detects their presence and automatically opens the lid. This hands-free operation reduces the need for physical contact with the bin, thereby promoting better hygiene and a more user-friendly experience. System Integration: The integration of these components, the ultrasonic sensor, Bluetooth communication, mobile app, and servo motor, creates a cohesive system that not only alerts users about waste levels but also provides an automated solution for lid operation. This synergy helps maintain a cleaner environment and improve the overall efficiency of waste management.

Overall, the proposed system combines advanced sensing technology with automated mechanisms to provide an innovative solution for the modern waste management challenge.

4. Advantages of the SHRUMAC System

Improved Operational Efficiency: Implementing a real-time sanitary and waste alert system offers numerous benefits. One primary benefit is improved operational efficiency. The system’s real-time monitoring ensures

timely waste collection, reducing the risk of overflow and maintaining a clean environment. This proactive approach reduces emergency responses and ad hoc collections, optimizing resource allocation and lowering operational costs. Reduced Environmental Impact: The system promotes environmental sustainability by ensuring timely and efficient waste collection. By optimizing collection routes and schedules based on real-time data, fuel consumption and associated emissions are minimized, thereby reducing the carbon footprint of waste collection operations. Additionally, accurate data on waste types and quantities facilitates targeted recycling programs, reducing the amount of waste sent to landfills and promoting recycling efforts. This targeted approach aligns with global sustainability goals and supports environmental protection initiatives. Enhanced Public Health and Safety: A real-time sanitary and waste alert system significantly improves public health and safety. Timely waste collection prevents the accumulation of waste, which can harbor pathogens and attract pests, thereby posing health risks to the community. The system can also detect hazardous waste, enabling immediate action to mitigate potential health hazards. This proactive approach ensures a safer and healthier environment for the community, reducing the incidence of waste-related health issues. Data-Driven Decision Making: The system provides valuable data on waste-generation patterns to inform data-driven decision-making. Authorities can analyze trends and patterns to implement effective waste management strategies. For instance, identifying peak waste-generation times can help schedule additional collections during those periods. Data analytics can also help in identifying areas with higher waste generation, enabling targeted interventions and resource allocation. Cost Savings: Optimizing waste collection routes and schedules yields significant cost savings. Reduced fuel consumption and operational costs, combined with efficient resource use, contribute to overall cost reduction. The long-term savings in operational expenses can offset the initial investment in the system. Additionally, the system reduces the need for emergency collections and unplanned maintenance, further contributing to cost savings. Community Engagement and Awareness: Implementing a real-time sanitary and waste alert system can enhance community engagement and awareness. By providing real-time data and alerts, the system encourages community participation in waste management efforts. Awareness campaigns and educational programs can be designed based on the collected data to promote responsible waste disposal practices and environmental consciousness. Engaging the community fosters a sense of ownership and responsibility towards maintaining a clean and healthy environment.

5. Architecture of the SHRUMAC System

The proposed system, named SHRUMAC (Smart Hygiene and Refuse Monitoring and Alert Controller), is an intelligent waste-monitoring device designed to improve sanitation management through real-time waste detection and automated notifications. SHRUMAC consists of several integrated hardware and software components that work together to monitor the waste level in a trash bin, automatically operate the lid, and communicate the bin's status to a companion mobile application known as TEMAC (Technology-Enabled Monitoring and Alert Controller). The sensing unit forms the first component of the system. It employs an ultrasonic sensor mounted at the top of the waste bin to continuously measure the distance between the sensor and the waste surface. As refuse accumulates in the bin, the measured distance decreases. These distance readings are transmitted to the microcontroller for further processing. The same ultrasonic sensor detects a user approaching the bin, enabling touch-free operation of the lid. The microcontroller serves as the central processing unit of SHRUMAC. An ESP32 microcontroller is recommended because it provides sufficient processing capability and has an in-built Bluetooth communication module. The microcontroller receives distance measurements from the ultrasonic sensor, processes the data, and calculates the current fill level of the waste bin. It then compares the measured fill level against predefined thresholds to determine whether the bin is empty, partially filled, nearly full, or full. Once the fill level reaches the specified threshold, the microcontroller generates an alert message for transmission to the mobile application. Communication between SHRUMAC and the user is via Bluetooth. The Bluetooth module, integrated into the ESP32 microcontroller, wirelessly transmits processed data from the waste monitoring system to the TEMAC mobile application. This communication

enables cleaners or sanitation personnel to receive immediate notifications when the waste bin approaches capacity, ensuring prompt waste evacuation and preventing overflow. The TEMAC mobile application serves as the user interface of the proposed system. Developed using MIT App Inventor, the application receives real-time notifications from SHRUMAC and displays important information such as the current fill level of the waste bin and its operational status. The application also allows sanitation personnel to monitor the condition of the waste bin and respond promptly whenever cleaning or waste disposal is required. This eliminates the need for manual inspection of waste bins and enhances the efficiency of sanitation operations. To improve hygiene and convenience, the proposed system incorporates an automatic lid operation mechanism. Whenever the ultrasonic sensor detects a user within a predetermined distance, the microcontroller automatically activates a servo motor to open the waste bin lid. After the waste has been disposed of, the microcontroller instructs the servo motor to close the lid after a short delay. This touch-free operation minimizes human contact with the waste bin and improves environmental hygiene. The entire SHRUMAC system is powered by a regulated power supply, which may consist of a rechargeable battery or an external power adapter, depending on the deployment environment. The power supply provides stable electrical power to the ultrasonic sensor, microcontroller, Bluetooth module, servo motor, and other electronic components, ensuring reliable, uninterrupted operation of the system.

Figure 9. Testing the SHRUMAC Device

1. Summary of Findings

The SHRUMAC system successfully met its design objectives, demonstrating effective performance in waste detection, lid control, and user notification. The system's integration of hardware and software components allowed it to operate efficiently and address user needs effectively. The accuracy of the ultrasonic sensors, the quick response of the servo motor, and reliable battery performance highlight the system's potential for practical application in waste management.

2. Discussion of Findings

The findings of this study indicate that the SHRUMAC (Smart Hygiene and Refuse Monitoring and Alert Controller) successfully achieved its intended objectives by providing an effective smart waste monitoring solution. The system accurately detected the waste level using ultrasonic sensing technology, automatically controlled the waste-bin lid via a servo motor, and sent timely notifications to users through the TEMAC (Technology-Enabled Monitoring and Alert Controller) mobile application. The seamless integration of these hardware and software components demonstrates that embedded systems can be effectively employed to improve sanitation management and promote environmental cleanliness. The study revealed that the ultrasonic sensor consistently measured the waste bin's fill level with satisfactory accuracy, enabling the system to distinguish among different waste levels and trigger alerts when predetermined thresholds were reached. This finding agrees with the work of [14]. who reported that ultrasonic sensors integrated with an ESP32 microcontroller provided reliable monitoring of waste volume and generated real-time notifications to waste collectors, thereby reducing delays in waste evacuation. Similarly, the systematic review conducted by [11]. identified ultrasonic sensors as the most widely adopted sensing technology in smart garbage bins because of their accuracy, affordability, and ease of integration with embedded controllers for fill-level monitoring. The automatic lid operation of SHRUMAC also proved effective. The servo motor responded promptly whenever the ultrasonic sensor detected a user, allowing the waste-bin lid to open and close without physical contact. This touch-free mechanism improves user convenience while reducing the risk of transmitting germs through

contaminated surfaces. The finding supports the work of [12]. who developed an IoT-based smart waste monitoring system that combined an ultrasonic sensor and a servo motor to provide automatic lid operation and real-time waste monitoring. Likewise, reported that integrating ultrasonic sensors with servo motors enhanced hygiene by enabling contactless waste disposal and monitoring waste levels for efficient collection. Another important finding of the study is the effectiveness of the communication mechanism between SHRUMAC and the TEMAC mobile application. The Bluetooth-based notification system successfully informed users whenever the waste bin reached the predefined fill level, thereby allowing cleaners to respond promptly before overflow occurred. This finding is consistent with previous studies on smart waste management systems, which have shown that real-time communication between smart bins and monitoring applications significantly improves waste collection efficiency and reduces unnecessary inspection visits. According to [11]. communication technologies such as Bluetooth, Wi-Fi, and Zigbee play a crucial role in enabling smart garbage bins to exchange real-time information with users and waste management personnel. Similarly, [14]. demonstrated that mobile notifications greatly improved the responsiveness of waste collectors by providing immediate information on bin status. The findings further showed that the battery-powered SHRUMAC prototype maintained stable operation throughout the testing period, with no noticeable interruptions. Reliable power performance is essential for embedded systems intended for continuous environmental monitoring, particularly where uninterrupted sensing and communication are required. The system's overall stability demonstrates that SHRUMAC has the functional reliability needed for deployment in schools, offices, hospitals, markets, residential estates, and other public environments where efficient waste management is essential. Summarily, the findings confirm that SHRUMAC is a practical and efficient smart waste management system capable of addressing common challenges associated with conventional waste bins, including delayed waste collection, overflowing bins, and unhygienic manual lid operation. By combining accurate sensing, automated control, wireless communication, and a user-friendly mobile application, the proposed system provides a cost-effective solution that supports cleaner environments and aligns with the growing adoption of Internet of Things (IoT)-based technologies for sustainable waste management.

3. Recommendations

Based on the findings of this research, the following recommendation is made: Researchers should conduct further studies to refine and improve sensor accuracy, particularly under varying environmental conditions. Future researchers should focus on Battery Life optimisation by exploring alternative power sources. Future researchers may consider expanding the integrated features, such as data analytics and advanced user interfaces, to further enhance functionality and user experience.

Abstract
Large language models can generate programming exercises, but textually different outputs often do not represent genuinely different tasks. This distinction is important because a large set of differently worded exercises may still train the same computational operation, giving instructors and learners the impression of broad task coverage while providing limited functional variety. This study evaluated textual diversity, functional diversity, and output reliability in LLM-generated beginner-level C programming tasks. Six Ollama cloud-based models were tested across four prompt categories, four temperature settings, and ten repeated generations per condition, yielding 960 outputs. Textual diversity was calculated as the proportion of distinct task descriptions, and functional diversity as the proportion of manually verified functional groups based on the required programming operation. Across models, textual diversity ranged from 53% to 88%, whereas functional diversity ranged from 10% to 32%. The functional-to-textual diversity ratio remained below 0.5 for all models, indicating that many differently worded tasks required the same underlying operation. Temperature increased textual diversity more strongly than functional diversity: DeepSeek V4, Qwen3, and Kimi K2.6 reached 100% textual diversity at higher temperatures, while functional diversity remained lower. Prompt category had a stronger effect on functional diversity than temperature: modification tasks produced the highest functional diversity (40%), whereas search tasks produced the lowest (10%). Output reliability was high, with five models producing valid JSON in all cases and one model reaching 99.4%. However, markdown code block usage varied substantially, reaching 84.4% for Gemma 4. The findings suggest that LLM-based programming task generation should be evaluated not only by textual distinctiveness but also by human-supervised semantic validation, functional coverage, and output validity.

Keywords: large language models; programming education; task generation; textual diversity; functional diversity; prompt engineering; output reliability

I. INTRODUCTION

Large language models (LLMs) are increasingly used in computer science education for code explanation, feedback generation, assessment support, and for the automatic generation of programming exercises [1], [2]. In

introductory programming courses, exercise generation is especially relevant because students need repeated practice with similar concepts, while instructors need many short, solvable, and appropriately constrained tasks. However, the educational value of automatically generated tasks does not depend only on whether the outputs are linguistically different. A set of tasks may contain many different textual formulations while still requiring students to solve the same programming problem. This creates a practical problem for question generation in educational settings. If an LLM generates many textually distinct tasks that all require the same operation, such as counting selected elements, finding a minimum value, or modifying array elements based on a condition, the resulting task set may appear diverse yet offer only limited conceptual coverage. For instructors, this may lead to an overestimation of the variety of automatically generated exercises. For students, it may result in repeated practice of the same type of functional task rather than exposure to a broader range of beginner-level programming operations. Therefore, low functional diversity relative to textual diversity is not only a measurement issue but also a pedagogical concern. Previous work has emphasized the need for systematic evaluation, quality assurance, and controlled generation conditions [3], [4], [5], [6], [7]. In parallel, studies of LLM diversity and creativity have examined how sampling parameters, prompting strategies, and model behavior influence output variation [8], [9], [10]. However, in programming task generation, the relationship between textual diversity and functional diversity remains insufficiently examined. The present study addressed this issue by evaluating beginner-level C programming tasks generated by six Ollama cloud-based LLMs under controlled prompting conditions. The prompts targeted four task categories: aggregation, search, modification, and two-array tasks. These categories were selected because they represent common beginner-level array-processing patterns in introductory programming courses. Aggregation tasks require students to process all elements of an array and reduce them to a single result, such as a sum, count, minimum, maximum, or average. Search tasks require locating or identifying elements that satisfy a given condition. Modification tasks focus on transforming array elements according to a rule, while two-array tasks require coordinated processing of two input arrays. Together, these categories cover frequently taught functional patterns while keeping the required programming constructs limited to loops, conditionals, and arrays. This made it possible to compare textual and functional diversity across pedagogically relevant task types while maintaining controlled complexity. The study distinguished between textual diversity, calculated from the number of distinct task descriptions, and functional diversity, calculated from the number of semantically validated functional groups representing the underlying programming task types. In addition, output reliability was assessed using JSON validity, markdown code block usage, and truncation rate, as these factors affect the practical use of LLM outputs in automated educational pipelines. The following research questions guided the study:

- How does sampling temperature influence textual diversity in beginner programming task generation?
- How does sampling temperature influence functional diversity in beginner programming task generation?
- To what extent does increased textual diversity correspond to genuinely new functional task types?
- How do model choice and prompt category affect textual and functional diversity?

The main contribution of the paper is the explicit comparison between textual and functional diversity in LLM-generated programming tasks. Rather than treating variation in wording as sufficient evidence of task diversity, the study examined whether the generated tasks introduced genuinely different functional requirements, providing a pedagogically meaningful basis for evaluating LLM-based exercise generation in introductory programming.

II. RELATED WORK

Large language models (LLMs) have become a central technology in both text generation and code-related educational support. Patil and Gudivada [1] reviewed the progression from task-specific natural language processing (NLP) architectures to transformer-based LLMs. They identified pretraining, transfer learning, in-context learning, model scale, and data coverage as key factors shaping model behavior. In computer science education, Raihan et al. [2] showed that the research literature is concentrated mainly in undergraduate and introductory programming contexts, where LLMs are studied for code generation, explanations, feedback, task generation, and assessment support. This educational context is directly relevant to generating beginner programming tasks, in which outputs must be technically correct, understandable to novices, and pedagogically aligned with the target concepts. Automated programming exercise generation is usually motivated by the high cost of manually preparing large numbers of suitable tasks. Frankford et al. [3] synthesized early work on LLM-based programming exercise generation and reported that multiple models can produce useful exercises, while also emphasizing the need for systematic evaluation and highlighting challenges such as quality assurance and the ease with which LLMs may solve LLM-generated tasks. Meißner et al. [4] compared ChatGPT with GPT-4, Bing AI Chat with GPT-4, Google Bard with LaMDA, and earlier GPT-3.5-turbo results for Java exercise generation. Their findings indicated that LLMs can initiate exercise designs across different topics, but manual refinement remains important, especially for more complex programming concepts and error-classification tasks. Moving from comparative evaluation to tool-supported generation, Ta et al. [5] proposed ExGen, a Visual Studio Code extension for on-demand generation of introductory Python exercises using GPT-3.5 Turbo and GPT-4 Turbo. Their framework defined a ready-to-use exercise as one with a clear problem statement, working reference solution, test cases, and an appropriate requested difficulty level. It used chained filtering checks such as compilation, unit testing, and difficulty verification. Zeng et al. [6] focused on open-source LLMs for generating programming exercises and showed that instruction tuning can improve selected models. The use of Evol-Instruct, an automatic instruction-evolution method for generating more complex instructions from simpler ones, and ACES (Autotelic Code Exploration via Semantic descriptors) is particularly relevant to diversity. Both methods support the construction of varied instruction data: Evol-Instruct increases complexity through iterative instruction rewriting. At the same time, ACES guides generation using semantic descriptors such as difficulty levels and programming concepts. Finally, Zou et al. [7] examined ChatGPT for algorithmic exercise generation and grading in C-oriented algorithmic education, finding strong sensibleness, readiness, and topicality, but identifying novelty as a weaker dimension. These approaches have demonstrated the potential to produce exercises with different surface characteristics, difficulty levels, and topical coverage. However, they have typically evaluated diversity indirectly, for example, through sensibleness, novelty, readiness, topicality, or accuracy, rather than by systematically analyzing the underlying computational operations required to solve the generated tasks. In parallel, many studies have examined diversity, creativity, and sampling in LLM outputs more directly. Bellemare-Pepin et al. [8] benchmarked LLMs against a large human cohort on the divergent association and creative writing tasks, using semantic-divergence measures. They found that prompt strategies and higher temperature can increase semantic divergence, but that the most creative human participants still outperform the strongest LLMs. Zhou et al. [9] formalized the diversity-quality trade-off in open-ended text generation by evaluating sampling methods, showing that parameter selection and adaptive truncation affect the balance between diversity and risk. Ságodi et al. [10] provided complementary evidence for code-related generation by releasing a program-synthesis dataset generated from nine open-source models across the Llama, Qwen, and DeepSeek families, using seven programming tasks and 100 temperature settings, repeated three times. In summary, prior work established that LLMs can support the generation of programming exercises, but it also exposed several gaps. First, many studies evaluated textual quality, functional correctness, novelty, creativity, or readiness separately rather than asking whether surface-level variation produced genuinely different task types. Second, diversity is operationalized differently across domains: embedding-based semantic distances in creative-language studies, recall-risk metrics in decoding research, and manual or search-based novelty assessment in programming-exercise studies. Third, temperature has been studied in open-ended creativity and program synthesis, but less is known about its effect on constrained beginner-level programming

exercises. The present study addressed these gaps by distinguishing textual diversity from functional diversity in LLM-generated beginner C array tasks and examining whether higher temperatures produced genuinely new functional task types across multiple cloud-based models.

III. MATERIALS AND METHODS

1. Experimental Setup

The study was designed to examine the extent of variation produced by cloud-based LLMs in beginner-level C programming tasks when the prompts were systematically controlled. Variation was evaluated at two levels: textual diversity, referring to differences in task wording, and functional diversity, referring to differences in the underlying programming operations required to solve the tasks. The experimental workflow is shown in Figure 1. For each model, prompts were submitted in four task categories and at four temperature settings. Each model–prompt–temperature condition was repeated 10 times, resulting in a total of 960 generated outputs: six models × four prompt categories × four temperature settings × ten repetitions—the generated tasks focused on introductory C programming with one-dimensional integer arrays. The prompts constrained the tasks to concepts typically covered in beginner programming courses, including loops, conditionals, and arrays. The requested output format was a JSON object containing only the task description, an example input, and an example output. This allowed the outputs to be parsed systematically and compared across models, prompt categories, and temperature settings.

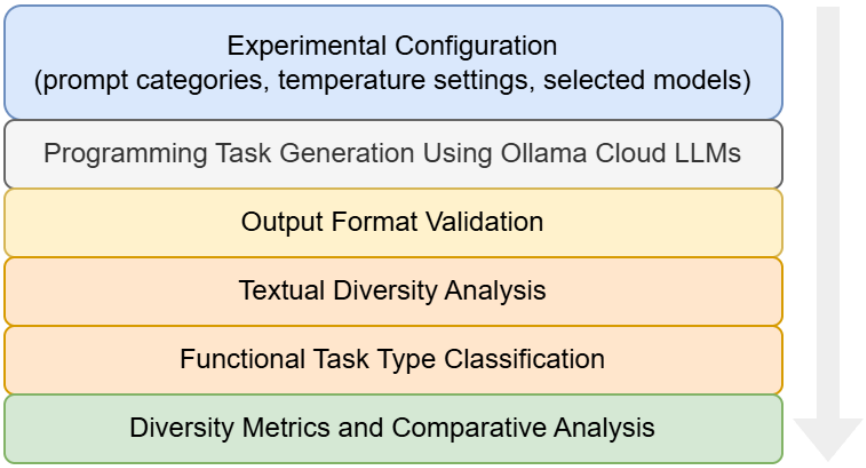

Figure 1. Experimental workflow for evaluating textual and functional diversity in LLM-generated beginner programming tasks.

2. Evaluated Models

Six Ollama cloud-based LLMs were evaluated in the experiment: DeepSeek V4 Pro, Qwen3 Coder Next, Kimi K2.6, GLM 5, Gemma 4, and Nemotron 3 nano. The selected models included both general-purpose and coding-oriented systems, as well as dense and mixture-of-experts architectures. Their Ollama model identifiers, providers, types, approximate sizes, and primary focus areas are summarized in Table 1.

Table 1. Characteristics of the evaluated LLMs

Ollama Model Identifier	Provider	Type	Approx. Size	Primary Focus
deepseek-v4-pro: cloud [11]	DeepSeek	MoE	1.6T (49B active)	Reasoning, coding
qwen3-coder-next: cloud [12]	Alibaba	MoE	80B (3B active)	Coding
kimi-k2.6:cloud [13], [14]	Moonshot AI	MoE	1.04T (32B active)	Coding, agents
glm-5:cloud [15]	Z.ai / Zhipu AI	MoE	744B (40B active)	Reasoning, coding
gemma4:31b-cloud [16]	Google	Dense	31B	General-purpose
nemotron-3-nano:30b-cloud [17]	NVIDIA	MoE	30B (3.5B active)	Reasoning, coding

The study used the Ollama cloud model variants because they provided a consistent access interface while representing different current LLM families. The comparison was not intended to benchmark general model quality but to examine how different models responded to the same task-generation prompts and temperature settings.

3. Prompt Categories and Temperature Settings

Four prompt categories were used to represent common types of beginner-level array-processing tasks: aggregation, search, modification, and two-array processing. The full prompts are shown in Table 2. Each prompt defined the expected input structure, output type, and allowed programming constructs. Additional restrictions were included to keep the generated tasks within the intended beginner-level scope.

Table 2. Prompts used for generating programming tasks

Task	Prompt
aggregation	Generate a beginner-level C programming task that processes all elements of an integer array to produce a single result. Input: n (1<=n<=100) and n integers. Output: one value derived from the array. Use only loops, arrays, and conditionals: no pointers, no dynamic memory, no sorting.
search	Generate a beginner-level C programming task that requires examining elements of an integer array to find specific information. Input: n (1<=n<=100), n integers, and optionally an additional value. Output: a result related to locating or identifying elements. Use only loops, arrays, and conditionals—no sorting or binary search.
modification	Generate a beginner-level C programming task that modifies elements of an integer array directly. Input: n (1<=n<=100) and n integers. Output: the modified array. Use only loops, arrays, and conditionals. No auxiliary arrays.
two_arrays	Generate a beginner-level C programming task that uses two integer arrays of equal length to produce a result. Input: n (1<=n<=100) and two arrays of size n. Output: a result based on both arrays. Use only loops, arrays, and conditionals—no sorting or advanced structures.

A common suffix was appended to every prompt to enforce a uniform output format. As shown in Table 3, the suffix required the task to be solvable in fewer than 20 lines of C code and instructed the model to return only valid JSON with exactly three keys: task, example_input, and example_output.

Table 3. Common prompt suffix used for output format constraints

The task must be solvable in under 20 lines of C code. Return ONLY valid JSON with EXACTLY these keys: task, example_input, example_output. Each value must be a single-line plain string. Example format: {"task":"...", "example_input":"...", "example_output":"..."}. Do not include any extra text.

Temperature was used as a sampling parameter. Four temperature values were tested: 0.1, 0.3, 0.6, and 0.9. These values were selected to cover low, moderate, and high sampling variability while keeping the generation conditions comparable across all models and prompt categories.

4. Diversity and Reliability Metrics

Two diversity measures were computed for each model–prompt–temperature condition. Textual diversity was defined as the number of distinct task descriptions generated. Two outputs were treated as textually identical only when the task description was identical. This metric captures surface-level variation in wording.

Functional diversity was defined as the number of distinct functional task types after semantically validated grouping. Outputs were assigned to the same functional group when they required the same input structure, the same main programming operation, and the same type of expected output, even if the wording, examples, or phrasing differed. For example, several tasks that asked students to count elements greater than the array's average were considered functionally equivalent, although their textual formulations differed. This distinction made it possible to examine whether greater textual variation corresponded to genuinely new programming tasks. Because fully manual grouping had proved time-consuming in an earlier, similar experiment [18], the present study used an LLM-assisted pre-labeling procedure to support the initial annotation of the 960 generated tasks. The processed CSV file containing the generated task descriptions was provided to ChatGPT together with functional-label examples from the earlier experiment. The resulting labels were used only as preliminary group assignments, which were then manually checked and corrected by one of the authors using the functional-equivalence criteria described above. Manual verification and correction were necessary because the LLM occasionally produced inaccurate, inconsistent, or overly generic labels. After this human validation step, the final functional-group labels were used to compute functional diversity. Textual and functional diversity counts were normalized by the number of generated outputs in the corresponding condition and are reported as percentages in the results.

In addition to diversity, output reliability was evaluated using three indicators of formatting and validity. The valid JSON rate measured the proportion of outputs that could be parsed as JSON with the required fields. When outputs were enclosed in markdown code block markers, these markers were removed before JSON parsing; the markdown block rate was reported separately to capture this formatting behavior. The markdown block rate, therefore, measured how often models returned JSON within a markdown code block, despite the instruction to avoid extra formatting. The truncation rate measured the proportion of incomplete outputs in which the response was cut off or did not contain a complete, usable JSON object.

For statistical analysis, two sets of two-way ANOVAs were conducted separately for textual and functional diversity. The first set examined the effects of model and temperature, while the second examined the effects of prompt type and temperature. Partial η^2 was reported as the effect-size measure.

IV. RESULTS

This section presents the results of the diversity and reliability analyses. The results are organized into three parts. First, overall textual and functional diversity are compared across the evaluated models. Second, the effects of model, temperature, and prompt category are examined using descriptive results and two-way ANOVAs. Third, output reliability is evaluated based on JSON validity, markdown code block usage, and truncation. The dataset underlying the analyses, including the generated model outputs, parsing and reliability indicators, and the manually validated functional grouping labels, is available on Zenodo [19].

1. Overall Textual and Functional Diversity Across Models

To make the derived metric explicit, let N denote the number of generated outputs, T the number of distinct task descriptions, and F the number of distinct manually validated functional groups. Textual diversity was calculated as T/N, functional diversity as F/N, and the functional-to-textual diversity ratio as F/T. The ratio, therefore, expresses how many distinct functional task types were obtained relative to the number of textually distinct task descriptions. A lower ratio indicates that many textually unique outputs still map onto the same underlying computational operation. The absolute counts used to calculate these measures are reported in Table 4. The models produced between 16 and 51 functional groups, compared with 84 to 141 distinct task descriptions.

Table 4. Absolute counts are used to calculate the textual and functional diversity across models

Ollama Model Name	**Generated outputs, N**	**Distinct task descriptions, T**	**Functional groups, F**
deepseek-v4-pro: cloud [11]	160	120	39
qwen3-coder-next: cloud [12]	160	93	27
kimi-k2.6:cloud [13]	160	113	48
glm-5:cloud [15]	160	118	40
gemma4:31b-cloud [16]	160	84	16
nemotron-3-nano:30b-cloud [17]	160	141	51

Figure 2 summarizes the overall textual diversity, functional diversity, and functional-to-textual diversity ratio across the six evaluated models. In all models, textual diversity was substantially higher than functional diversity. This indicates that the models frequently generated differently worded task descriptions that nevertheless corresponded to a smaller set of underlying computational operations.

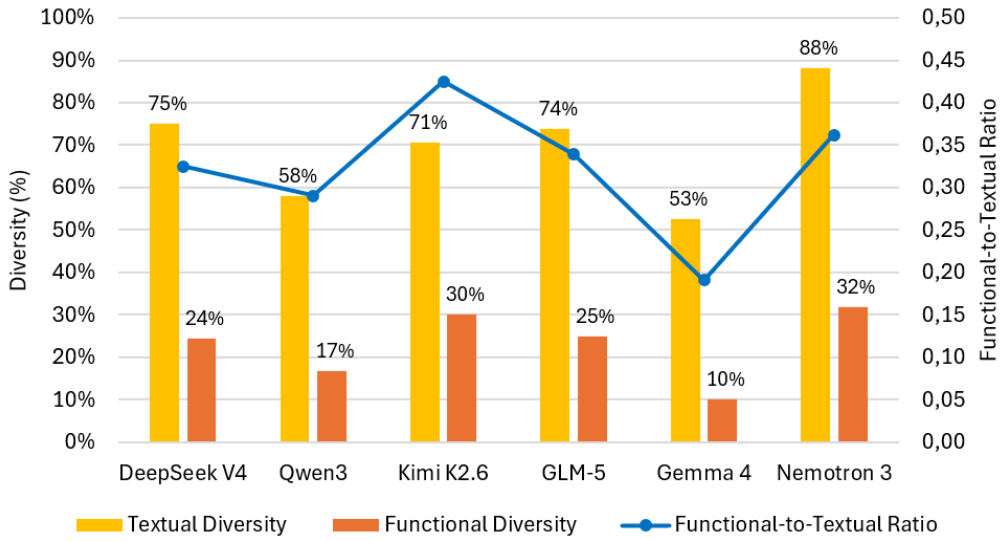

Figure 2. Overall textual diversity, functional diversity, and functional-to-textual diversity ratio across the evaluated LLMs

Nemotron 3 produced the highest overall textual diversity (88%) and also the highest functional diversity (32%). Kimi K2.6 showed the second-highest functional diversity (30%) and the highest functional-to-textual diversity ratio, suggesting that a relatively larger proportion of its textual variation corresponded to distinct functional task types. DeepSeek V4 and GLM-5 also produced high textual diversity, 75% and 74%, respectively, but their functional diversity remained considerably lower, at 24% and 25%. Qwen3 showed moderate textual diversity (58%) and functional diversity (17%). Gemma 4 had the lowest values on both measures, with 53% textual diversity and 10% functional diversity.

The functional-to-textual ratio further illustrates the difference between surface-level variation and functional variation. The ratio remained below 0.5 across all models, indicating that each model produced fewer distinct functional groups than distinct task descriptions. This pattern underscores the need to evaluate LLM-generated programming tasks not only for textual uniqueness but also for the underlying programming operations students are expected to perform.

Table 5 provides examples of textually different but functionally equivalent outputs. Although the three task descriptions use different wording, they all require the same operation: counting the array elements greater than the average of all elements.

Table 5. Examples of textually different but functionally equivalent programming tasks generated by DeepSeek V4 Pro at a temperature of 0.9

Write a C program that reads an integer n (1<=n<=100), then n integers, and outputs the count of elements that are strictly greater than the average of all elements (use integer division for the average).
Write a C program that reads an integer n (1<=n<=100), then reads n integers into an array. Find and print the count of elements that are strictly greater than the average of all elements (rounded down to the nearest integer).
Read n and an array of n integers. Count how many elements are greater than the average of all array elements. Output that counts.

In contrast to Table 5, Table 6 shows examples from the modification prompt category that were assigned to different functional groups because they require different modification operations.

Table 6. Examples of tasks from different functional groups in the modification category generated by DeepSeek V4 Pro at a temperature of 0.9

Read an integer n (1<=n<=100), then read n integers into an array. Modify the array in place: if an element is even, double it; if odd, add 1. Print the modified array separated by spaces.
Read an integer n, then an array of n integers. For each element, if it is positive and even, double it; if it is positive and odd, add 1; if it is negative, make it positive; if it is zero, leave it unchanged. Print the modified array separated by spaces.
Read an integer n (1<=n<=100), then read n integers into an array. Traverse the array and double each element that is positive and even, and set each negative element to zero. Leave other elements unchanged. Print the modified array on a single line, separated by spaces.

2. Effects of Model, Temperature, and Prompt Category on Textual and Functional Diversity

Figure 3 shows the effect of temperature on textual diversity across models. In general, textual diversity increased with temperature. This pattern was especially clear for DeepSeek V4, Qwen3, Kimi K2.6, and Nemotron 3, where the highest temperatures produced near-complete or complete textual uniqueness. DeepSeek V4 increased from 48% at a temperature of 0.1 to 100% at temperatures of 0.6 and 0.9. Qwen3 increased from 58% to 100%, while Kimi K2.6 increased from 53% to 100%. Nemotron 3 also reached 100% at a temperature of 0.9. GLM-5 started at a comparatively high level, even at 0.1, and reached 95% at 0.6 and 0.9. Gemma 4 showed the weakest increase, rising from 53% to 85%.

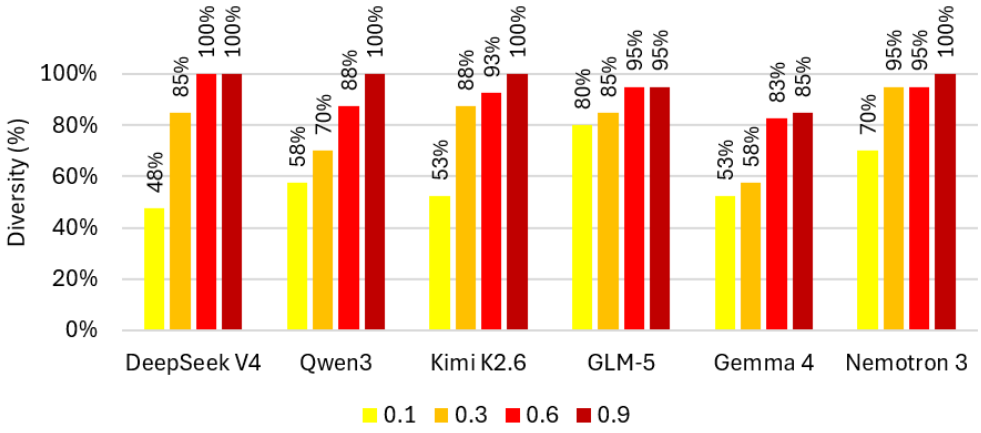

Figure 3. Effect of temperature on textual diversity across models

Figure 4 shows that functional diversity also tended to increase with temperature, but the effect was weaker and less uniform than for textual diversity. DeepSeek V4 increased from 28% to 68%, and Nemotron 3 showed the strongest increase, from 28% to 78%. Kimi K2.6 increased from 33% to 58%, while GLM-5 increased from 33% to 50%. Qwen3 showed only a modest increase, from 28% to 43%. Gemma 4 remained low across all temperature settings and showed no consistent upward trend.

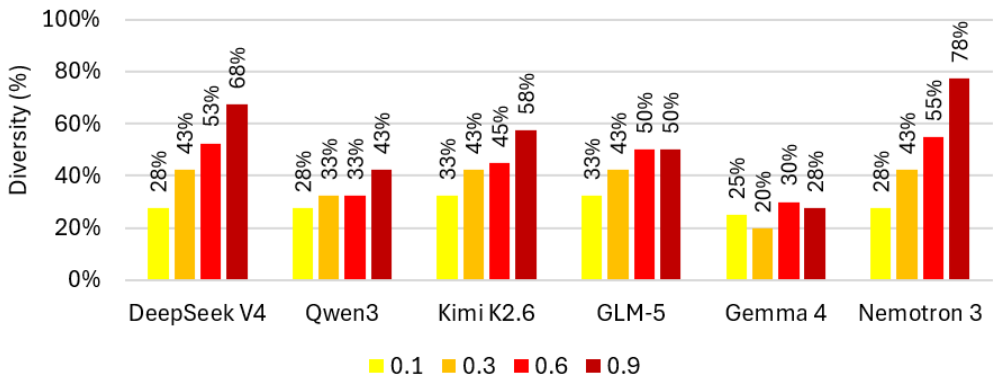

Figure 4. Effect of temperature on functional diversity across models

The two-way ANOVA for Model × Temperature is shown in Table 7. For textual diversity, both model and temperature had statistically significant effects. The effect of temperature was particularly strong, $F = 31.749$, $p < 0.001$, partial $\eta^2 = 0.570$, indicating that sampling temperature was the main driver of textual variation. The model effect was also significant, $F = 4.536$, $p = 0.001$, partial $\eta^2 = 0.240$. The Model × Temperature interaction was not statistically significant, $F = 1.233$, $p = 0.269$, suggesting that although models differed in overall diversity, the general effect of increasing temperature was broadly similar across models.

Table 7. Two-way ANOVA results (Model × Temperature)

Dependent Variable	**Factor**	**F**	**p**	**Partial η^2**
Textual Diversity	Model	4.536	0.001	0.240
Textual Diversity	Temperature	31.749	< 0.001	0.570
Textual Diversity	Model × Temperature	1.233	0.269	0.204
Functional Diversity	Model	3.427	0.008	0.192
Functional Diversity	Temperature	6.429	0.001	0.211
Functional Diversity	Model × Temperature	0.458	0.954	0.087

For functional diversity, both model and temperature were again statistically significant. The model effect was $F = 3.427$, $p = 0.008$, partial $\eta^2 = 0.192$, and the temperature effect was $F = 6.429$, $p = 0.001$, partial $\eta^2 = 0.211$. Compared with textual diversity, the temperature effect was smaller for functional diversity. This indicates that higher temperatures increased the likelihood of new wording more strongly than the likelihood of genuinely new functional task types. The Model × Temperature interaction was not significant, $F = 0.458$, $p = 0.954$.

Figure 5 compares diversity across prompt types. The two-array prompt category produced the highest textual diversity (78%), followed by search (76%), modification (66%), and aggregation (59%). However, the pattern for functional diversity was different. Modification tasks produced the highest functional diversity (40%), despite not having the highest textual diversity. Aggregation produced 15% functional diversity, two-array tasks 12%, and search tasks only 10%. Consequently, the modification category had the highest functional-to-textual ratio, indicating that textual variation in this category was more likely to correspond to genuinely different computational operations.

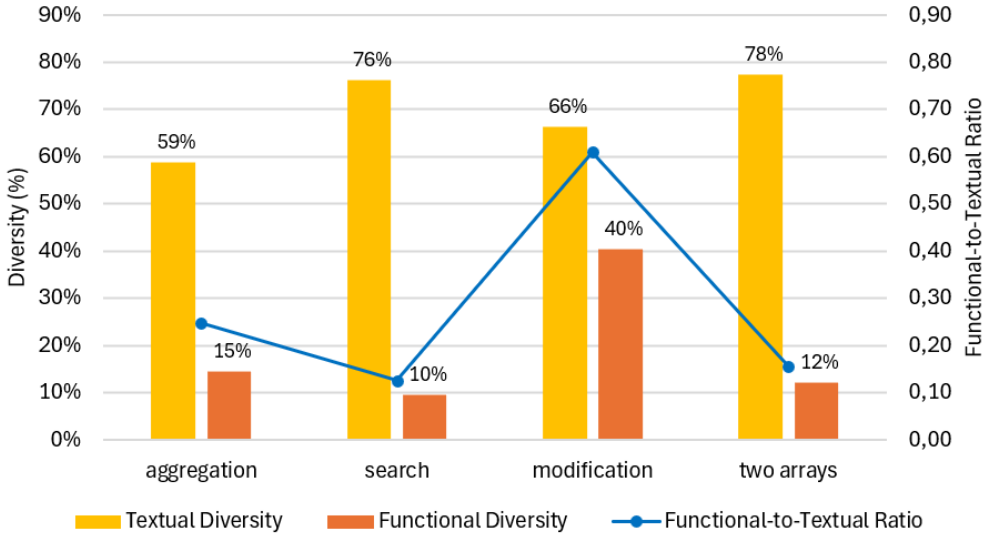

Figure 5. Overall textual diversity, functional diversity, and functional-to-textual diversity ratio across the prompt categories

The two-way ANOVA for Prompt × Temperature is shown in Table 8. For textual diversity, both prompt category and temperature were statistically significant. The prompt effect was $F = 5.601$, $p = 0.002$, partial $\eta^2 = 0.174$, while the temperature effect was stronger, $F = 28.854$, $p < 0.001$, partial $\eta^2 = 0.520$. The Prompt × Temperature interaction was not significant, $F = 0.672$, $p = 0.732$.

Table 8. Two-way ANOVA results (Prompt × Temperature)

Dependent Variable	**Factor**	**F**	**p**	**Partial η²**
Textual Diversity	Prompt	5.601	0.002	0.174
Textual Diversity	Temperature	28.854	< 0.001	0.520
Textual Diversity	Prompt × Temperature	0.672	0.732	0.070
Functional Diversity	Prompt	13.964	< 0.001	0.344
Functional Diversity	Temperature	8.324	< 0.001	0.238
Functional Diversity	Prompt × Temperature	0.269	0.981	0.029

For functional diversity, both prompt category and temperature were also significant. The prompt category effect was stronger than the temperature effect, $F = 13.964$, $p < 0.001$, partial $\eta^2 = 0.344$; $F = 8.324$, $p < 0.001$, partial $\eta^2 = 0.238$. This result indicated that the type of prompt had a greater effect on functional diversity than temperature did. In other words, increasing temperature generated more varied wording, but the prompt category more strongly determined whether the generated tasks represented different underlying programming operations. The Prompt × Temperature interaction was not statistically significant, $F = 0.269$, $p = 0.981$.

3. Reliability and Formatting Behavior

Table 9 summarizes the output reliability and formatting behavior of the evaluated models. Overall, the generated outputs were highly reliable in terms of JSON validity. Five models produced valid JSON in all cases, and Nemotron 3 did so in 99.4% of outputs. Truncation was rare, occurring only in Nemotron 3 at a rate of 0.6%.

The main reliability issue was not JSON validity, but unwanted markdown formatting. DeepSeek V4, Qwen3, and Nemotron 3 did not use markdown code blocks. Kimi K2.6 returned JSON inside markdown code blocks in 19.4% of the outputs. The issue was substantially more frequent for GLM-5 and Gemma 4, with markdown block rates of 68.1% and 84.4%, respectively. Although these outputs were still valid JSON after removing the surrounding markdown formatting, such behavior is relevant for automated educational pipelines because additional preprocessing may be required.

Table 9. Output reliability and formatting issues across evaluated LLMs

Ollama Model Name	**Markdown Block Rate (%)**	**Valid JSON Rate (%)**	**Truncation Rate (%)**
deepseek-v4-pro: cloud [11]	0%	100%	0%
qwen3-coder-next: cloud [12]	0%	100%	0%
kimi-k2.6:cloud [13]	19.4%	100%	0%
glm-5:cloud [15]	68.1%	100%	0%
gemma4:31b-cloud [16]	84.4%	100%	0%
nemotron-3-nano:30b-cloud [17]	0%	99.4%	0.6%

V. DISCUSSION

The findings highlight the importance of distinguishing between textual variation and functional diversity when evaluating LLM-generated programming tasks. Although higher sampling temperature generally increased the number of distinct task descriptions, this increase did not translate proportionally into new functional task types. In an educational context, this distinction is important because differently worded exercises may still require students to apply the same underlying computational operation. Therefore, textual uniqueness alone is not a sufficient indicator of pedagogically meaningful task diversity. If generated tasks are selected solely on the basis of textual uniqueness, a task set may appear varied yet offer limited conceptual coverage. Functional grouping or semantic filtering can therefore help ensure that generated exercises cover a broader range of programming concepts rather than only different phrasings of the same task. The results also suggest that temperature and prompt design affect different aspects of generation. Temperature mainly influenced surface-level variation, whereas the prompt category played a stronger role in determining the range of functional operations produced. This implies that simply increasing temperature is unlikely to be enough when the goal is to generate a broader set of practice tasks. More effective diversity control may require prompts that explicitly request different types of operations, constraints, or solution strategies. The reliability results indicate that structured-output prompting can be effective for producing machine-processable tasks, but formatting behavior remains model-dependent. Even when the generated content is valid, additional preprocessing may be needed if models wrap the output in unwanted markdown formatting. In practice, an educational platform could apply a simple filtering workflow: generate multiple candidate tasks, verify JSON validity, normalize formatting, cluster tasks by functional group, remove functional duplicates, and finally conduct expert review before selecting tasks for students.

VI. LIMITATIONS

This study has several limitations. First, the experiment focused only on beginner-level C programming tasks involving one-dimensional arrays. Therefore, the findings may not directly generalize to other programming languages, more advanced programming concepts, or different task formats. Second, the analysis included six Ollama cloud-based models and four prompt categories; other models, prompt templates, explicit functional-diversity instructions, or sampling parameters may produce different diversity patterns. Third, functional

diversity was based on semantically validated grouping. Although LLM-assisted pre-labeling was followed by manual checking and correction, the final grouping was verified by one author and still involved human judgment. Fourth, although the dataset contained 960 generated outputs, the effective sample size for statistical comparison was smaller because the diversity measures were calculated at the model, prompt category, and temperature levels rather than for each output. Each condition included ten repeated generations, which was sufficient to identify broad patterns, but smaller interaction effects should be interpreted with caution. Finally, the study evaluated the diversity of generated tasks and the reliability of outputs, but it did not test the pedagogical effectiveness of the generated tasks with students.

VII. CONCLUSION

This study evaluated textual diversity, functional diversity, and output reliability in LLM-generated beginner-level C programming tasks. The results demonstrated that textually distinct outputs often corresponded to the same underlying computational operation, indicating that textual uniqueness alone was insufficient to assess the pedagogical variety of generated exercises. The study contributes a distinction between surface-level task variation and functionally meaningful task variation, supported by semantically validated grouping of generated outputs. The findings suggested that effective LLM-based task generation should combine structured prompting with semantic validation rather than relying only on sampling parameters such as temperature. More specifically, prompt designs should explicitly target functional coverage rather than only asking for varied wording; for example, prompts can specify different operations, conditions, input structures, or solution strategies to support both textual variation and greater functional diversity. The evaluated models were able to produce structured programming tasks with high JSON validity. Still, the results also indicated the need for validation, filtering, and human supervision before such tasks are used in educational practice. Future work should extend the analysis to other programming topics, task formats, and empirical classroom evaluations.

Abstract
AI coding agents like Claude Code, Codex, and GitHub Copilot are currently disrupting software engineering practices. As today's junior developers will constitute tomorrow's workforce, understanding the impact of these tools on them and on the software they create is important. In this paper, we compare code quality, productivity, code comprehension, and team dynamics among three teams of four computer science students working on the same 10-week software engineering project, with only one team given access to an AI coding agent. Static code analysis, a post-study survey, and interviews, followed by a thematic analysis, were conducted. The results show similar code quality and overall productivity, but reduced codebase comprehension and a negative impact on the team's technical and social learning processes when using the AI coding agent. These findings highlight the tension between the potential immediate benefits of using AI coding agents and a potential long-term decline in the development of the technical and social skills needed by the future software engineering workforce.

Keywords: AI coding agents, junior developers, code quality, development productivity, team dynamics

I. INTRODUCTION

The rise of AI coding agents over the last few years has been transforming *Classical Software Engineering* (SE 1.0) into AI-Assisted Software Engineering (SE 2.0), and ultimately into *Agentic Software Engineering* (SE 3.0) [1]. Whereas in SE 1.0, Software was hand-coded without AI assistance, in SE 2.0, tools like Cursor, Windsurf, Gemini CLI, and GitHub Copilot are integrated into the IDE and have access to the codebase to assist the developer with the creation of entire classes, functions, tests, and boilerplate code in response to natural language prompts. In SE 3.0, AI coding agents like Devin, Claude Code, Codex, Jules, and GitHub Copilot Coding Agent autonomously plan changes, execute tools, make changes, run tests, and submit pull requests on a task level, possibly working in a remote environment. The interaction between the human and the agent is predominantly conducted in natural language via a chat interface or as part of a developer platform like GitHub.
Ongoing research is trying to determine the impact of that transformation on software quality (e.g., [2], [3]), development productivity (e.g., [4], [5], [6]), and team dynamics (e.g., [7]). Moreover, the role of the human

developer shifts from writing code manually (SE 1.0) to reviewing code and writing code collaboratively with an AI assistant (SE 2.0), and finally to defining goals and constraints as well as reviewing final changes (SE 3.0) [1]. These tasks, which were previously reserved only for the most experienced developers, now need to be handled by developers of all career levels - including junior developers – because simpler tasks such as writing boilerplate code and conducting basic tests can now be handled by AI coding agents [8]. However, the impact of junior developers' use of AI coding agents on software engineering remains largely unexplored.
This paper provides initial insights by comparing code quality, productivity, code comprehension, and team dynamics across three computer science student teams working on the same 10-week software engineering project. One team was equipped with an AI coding agent (SE 3.0), while the other two teams were restricted to using general-purpose chatbots such as ChatGPT (SE 1.0 + chatbot).

II. RELATED WORK

Impact on Code Quality. Azeem et al. compare 300 Python programs written by GPT-4 with functionally equivalent programs created by an experienced human developer and find that AI-generated code was 28% longer, with 21% higher cyclomatic complexity, while being easier to read [2]. Asfandyar et al. compare 107 programs written by human experts with equivalent Claude 3 and GPT-4 generated programs to find 24% greater cyclomatic complexity, 2.1 times greater code duplication, 3 times more OWASP top 10 vulnerabilities, and a 15-40% slower execution time with 25% more memory consumption in AI-generated code [3].
Impact on Productivity. In 2025, Cui et al. randomly assigned an AI coding assistant to 4867 developers in their daily work to find that the number of completed tasks increased by 26.08%, with larger gains for junior developers [4]. In a 2025 randomized controlled trial, Becker et al. had 16 experienced developers complete 246 tasks and found a 19% slowdown in completion time when using AI tools [5]. In a follow-up study [6] with 827 tasks and 57 developers, the authors reported the opposite result, with a 6.4% speedup in completion time when using AI tools.
Impact on Code Comprehension. In 2026, an experimental study by Shen & Tamkin [9] showed that while AI assistance can increase productivity, especially through task delegation, excessive reliance on AI impairs skill formation, conceptual understanding, and debugging abilities.
Impact on Team Dynamics. A 2023 literature review by Zercher et al. [7] indicated that group processes such as communication and coordination are less effective in team-AI collaboration than in human groups.
Due to the rapid advancement of AI in software engineering, the conclusions drawn in those studies can only be applied with caution to current agentic software engineering processes (SE 3.0). Furthermore, the presented studies focus on experienced software developers [2],[3], small tasks [2],[3],[4],[5], or coding with the help of a simple chatbot [2],[3] or AI-assisted coding (SE 2.0)[4],[5]. To the best of our knowledge, the present study is the first in situ experiment to comprehensively assess the impact of AI coding agents (SE 3.0) on software engineering among junior developers.

III. METHODS

1. Project

The experiment was conducted as part of the *Software Development Project (SEP)*, a practice-oriented university course in which small student teams are tasked with developing a near-product-quality software solution *for real-world clients in* industry, largely on their own. The project under study took place over 10 weeks, from October 10th to December 17th in 2025. The company NFON served as an industry client. The goal was to create a *Multi-Repo AI Documentation Generator Portal* with a web interface similar to Google Code Wiki.

2. Team Composition and Experimental Setup

To assemble the project teams, we implemented a structured, data-driven approach using a self-assessment questionnaire developed in collaboration with Reutlingen University. Students answered eight questions covering various soft skills and traits. Data analysis methods were then used to cluster the 12 participating students into three balanced teams of four students each. For validation purposes, their grades in previously taken programming and software engineering-related classes were analyzed, revealing a similar distribution across all teams. Each team was provided with an empty Git repository on GitHub. One of the three teams (referred to as the experimental team) was randomly selected and granted access to GitHub Copilot for auto-code completion and chat-first development. Furthermore, the GitHub coding agent was activated on their repository to enable remote, autonomous creation of pull requests. Apart from a brief demonstration of the coding agent capabilities, no training was provided. The other two teams served as control groups, A and B, and were instructed not to use specialized AI coding tools but were allowed to use chatbots like ChatGPT for consultation and code snippet creation.

3. Codebase Analysis

After the implementation period, metrics were extracted from the source code used as indicators for the code quality attributes maintainability, security, and reliability. The size of the codebase was determined by measuring the effective lines of code with the Linux tool *cloc*. The results were grouped by application layer (backend and frontend) and by purpose (testing and production).
To measure code quality attributes, the TIOBE software quality framework, TiCS 2026.1 [10], was applied to the three codebases. It performs static code analysis and combines it with code coverage data from automated tests. Based on that, it computes a percentage score for the quality indicators: code security, code coverage, fan-out, code duplication, cyclomatic complexity, coding standards, and interpreter warnings. Those values are then combined into an overall code quality score.

4. Productivity Assessment

Productivity is defined as the total output divided by the total input. As all teams were following the same project goal, the total output is not affected by the type of goal, but only by the quality with which it is achieved. To measure that, we use the average satisfaction from both major stakeholders, the industry client, and the responsible professors. Both stakeholders assigned each team a score/grade based on the external and internal quality of the delivered product and the presentation of the results. Those numbers have been normalized to percentages, with 0% indicating total failure to meet requirements and 100% indicating perfect execution and stakeholder satisfaction. The total input is defined as the amount of time spent on the project. Therefore, we asked each participant once a week to report their individual number. In addition to that quantitative assessment, we also asked the participants about their own perceived progress relative to their expectations on a Likert scale from *a lot slower* to *a lot faster*.

5. Codebase Comprehension Assessment

The familiarity with the source code was assessed both qualitatively and quantitatively. For the former, in a post-project survey, all participants rated their familiarity with the part of the codebase they were responsible for and with the entire team's codebase on a Likert scale. For the latter, a one-hour interview was conducted with each team two days after the project ended. During the interview, the team members were asked to collaboratively create a static building-block architectural diagram (building blocks and their dependencies) at two

levels of abstraction (level 1: frontend/backend/database; level 2: high-level modules within each level-1 building block) without consulting the source code. Inspired by [11], we then compared them to the actual architecture extracted from the code using the graph edit distance (GED), which corresponds to the minimum number of modifications required to convert one diagram into another. The number of elements in the actual architecture diagram was then used to normalize the GED.

6. Team Dynamics Assessment

To investigate the effects of AI agent use on group dynamics and learning processes within student teams, a mixed-methods approach was employed, combining quantitative and qualitative social research methods. In a first step, all project groups completed a short, standardized questionnaire at the conclusion of the project phase. The survey assessed perceptions of interaction quality [12] and information processing within the teams [13]. Comparisons between the experimental and control groups were conducted using the scales *team processes* (Cronbach's $\alpha = .915$) and *information processing* (Cronbach's $\alpha = .784$), which were constructed from the relevant questionnaire items. In a second step, semi-structured interviews were conducted with members of both the experimental and control groups to capture participants' subjective perspectives on collaboration, process quality, and project outcomes. Attention was paid to differences in task distribution, decision-making, and conflict resolution, as well as to the role of the AI agent within these processes. The interview material was analyzed using thematic analysis [14], a qualitative method for identifying, examining, and interpreting recurring patterns in the data. The transcripts were coded inductively, and the resulting codes were subsequently grouped into overarching themes.

IV. RESULTS

1. AI Usage

In the post-study survey, participants were asked how often they had used each type of AI tool (none, ChatGPT-like, AI code completion, chat first, remote agent) for programming-related tasks. We mapped that to the software engineering paradigms described in Section I. The distribution of the experimental group's AI usage was 27% for SE 3.0 and 37% for both SE 2.0 and SE 1.0. Control Group A (B)'s values were 0% (9%), 25% (17%), and 75% (74%). Despite the requirement that those teams use only ChatGPT-like AI tools, they couldn't entirely resist using more advanced ones. Control Group B used the full-stack AI development platform Lovable for frontend development. Therefore, we excluded the frontend from the codebase analysis. We also asked the participants in the experimental group which tasks they had used the remote coding agent for and how satisfied they were with the results. The most common mentions were the implementation of entire features, followed by small changes, documentation, bug fixes, refactoring, and test creation. For DevOps-related tasks, code reviews, requirements engineering, and architectural work, usage of the coding agent played a minor role. According to the participants, 52% of

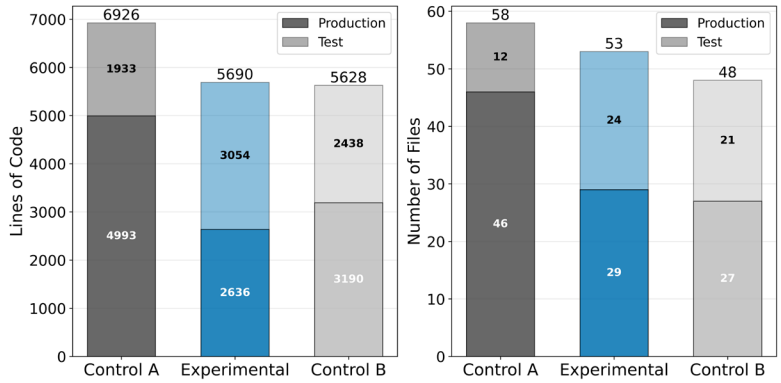

Figure 1. Codebase size of the production and test backend code in Lines of Code (left) and Number of Files (right)

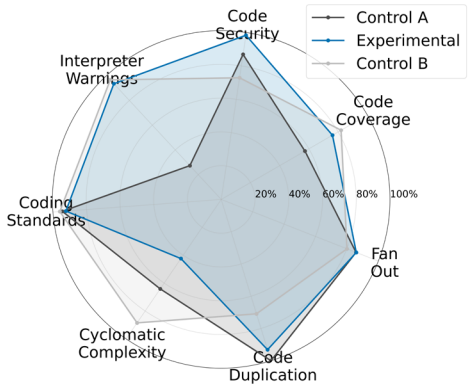

Figure 2. Contributing factors of the TIOBE Quality Indicator from worst (center) to best (outside)

The PRs have been merged without any changes after review. For 24% (9%), the agent (a human developer) improved the solution before merging, whereas in 10% of cases, the PR was discarded. The remaining 5% have been merged without any code review (vibe coding).

2. Codebase Analysis

With 2636 LoC, the production backend codebase of the experimental group was the smallest among the control groups A and B, at 4993 and 3190 LoC, respectively. In turn, the size of the test code was the largest, at 3054 LoC, versus 1933 (2438) LoC for control group A (B). Detailed numbers are shown in Fig. 1.
The TIOBE TiCS static code analysis resulted in an overall code quality score of 86% for the experimental group and 74% (88%) for control group A (B), respectively. The individual contributing factors are depicted in Fig. 2. The remainder of this section addresses each of them.

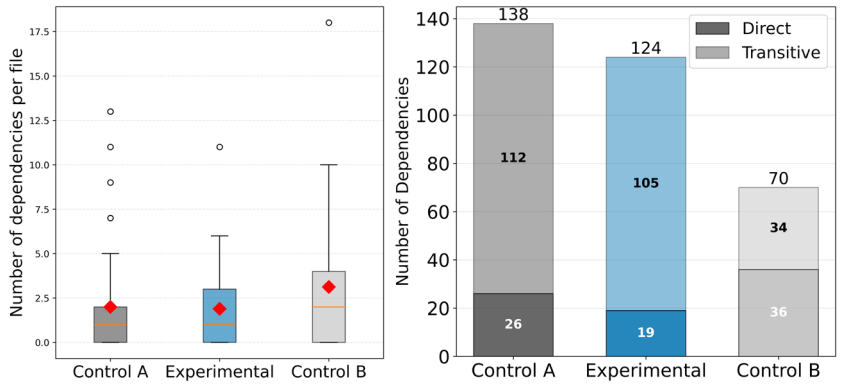

Figure 3. Fanout statistics. Left: statistics on internal dependencies (25, 50, 75th percentile, 1.5 IQR outliers, and mean (red diamond)). Right: Number of direct and transitive dependencies on 3rd party libraries.

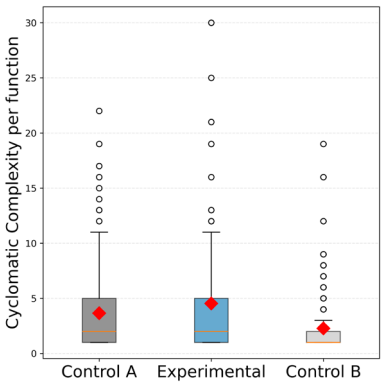

Figure 4. Function Cyclomatic Complexity statistics (25, 50,

75th percentile, 1.5 IQR outliers, and mean (red diamond)).

The **Code Security** analysis revealed some violations across the codebases, such as plaintext secrets, missing JWT signature validation, and *CORS policies set to allow all origins*. With an overall security score of 98%, the experimental group had the fewest serious violations, followed by control group A (87%) and control group B (73%).
With a statement **Code Coverage** of 67%, the experimental group achieved a value similar to that of the control group B (66%). Control group A had a minor statement coverage of 33%.

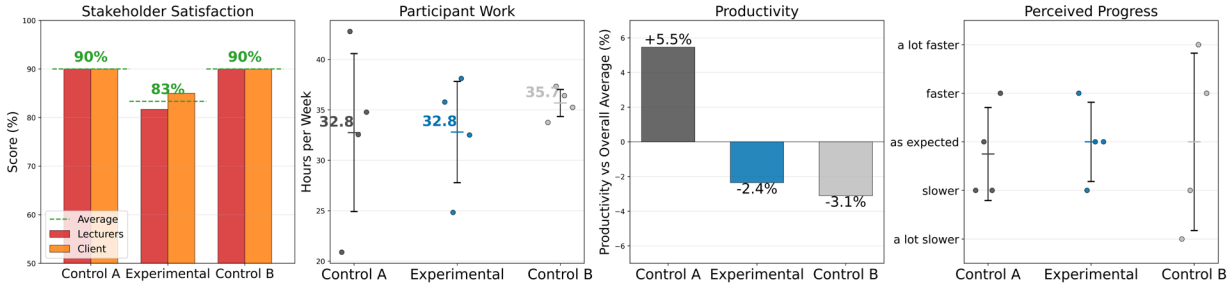

Figure 5. stakeholder satisfaction, participant work, relative productivity, and perceived progress by team

As a measure for coupling, internal Fan Out, i.e., the number of other source code files referenced by each file, was 1.9 on average for the experimental group and 2.0 (3.1) for control group A (B). The experimental group's requirements.txt has 19 dependencies on 3rd-party libraries (external fan-out), whereas control group A (B) has 26 (36) dependencies. The statistics are depicted in Fig. 3.

For control group B, 364 duplicated tokens were found, whereas no Code Duplication was found for the experimental group and control group A.

With an average Cyclomatic Complexity (CC) of 4.53, the experimental group's code is more complex than the control groups' codes, with CCs of 3.65 and 2.27, which may indicate reduced maintainability and increased error-proneness. The statistics are shown in Fig. 4.

The experimental group had 0 Level 1 Coding Standards violations, whereas the control group had 2. For Level 2, the values were 32 for the experimental group and 71 (22) for control group A (B).

Control group A Interpreter Warnings were worse than those of the other groups. They had 143 violations: Name may be undefined, or defined from star imports; 33 Module imported but unused; 4 from module import * used; and 3 Local variable name is assigned but never used [15].

3. Productivity

The measured and perceived productivity, along with their components, are depicted in Fig. 5. All teams completed the project. At 83%, the average stakeholder satisfaction with the experimental team's performance was lower than that of the control groups, which each scored 90%. There was almost no difference in the ratings of the university lecturers compared to those of the industry client. On average, the participants in the experimental team spent 32.8 ± 5.0 h working on the project over those 10 weeks, similar to control team A at 32.8 ± 7.8 h

per week, but less than control team B at 35.7 ± 1.3 h per week. The resulting productivity of the experimental group was 2.54 project goals·score/h, placing it between control group B (2.52) and A (2.74). Therefore, neither an overall performance boost nor a performance degradation was observed in the experimental group. Because all three teams rated their own progress *as expected* on average, no differences were evident in the self-assessments either.

4. Code Comprehension

In the post-study survey, the experimental group reported lower comprehension of the part of the codebase they were responsible for. Here, the ratings were between medium and good for the experimental group, versus medium and very good for the control group. The self-assessment difference was more pronounced for ratings between very poor and medium, rather than between poor and good. This self-assessment is backed up by the interviews conducted. The expert interviewer perceived greater uncertainty in the experimental group when creating class and sequence diagrams for the system being created. For the backend, the normalized graph edit distance between the memorized and actual building block diagram was highest (0.85) for the experimental group, compared with 0.77 and 0.50 for the control groups A and B, indicating lower comprehension of the codebase. Detailed numbers can be found in Fig. 6Figure 6.

5. Team Dynamics

To examine whether the experimental group differed significantly from the control group in their evaluation of team processes and information processing, a Mann-Whitney U test was conducted. The findings indicate that the experimental group rated both their team processes ($U = 3.000$; $Z = -2.084$; $p < .05$) and their information processing ($U = 2.000$; $Z = -2.294$; $p < .05$) significantly lower than the control groups. The underlying causes of these differences and the specific role of the AI agent initially remained unclear. In this regard, the subsequent thematic analysis of the interview data identified two contrasting themes: first, the AI agent as a facilitator of project success, and second, the AI agent as an impediment to learning processes.

Theme 1: The AI agent as facilitator for project success

Members of the experimental group described the AI agent as a substantial source of support and a considerable time-saving resource during the project. The agent was used extensively and enabled the rapid generation of large amounts of code, which could almost always be adopted after only brief quality checks. Participants further agreed that, given the existing difficulties within the team, the project would likely not have been completed successfully without the AI agent's support. Consequently, the agent was perceived not merely as an

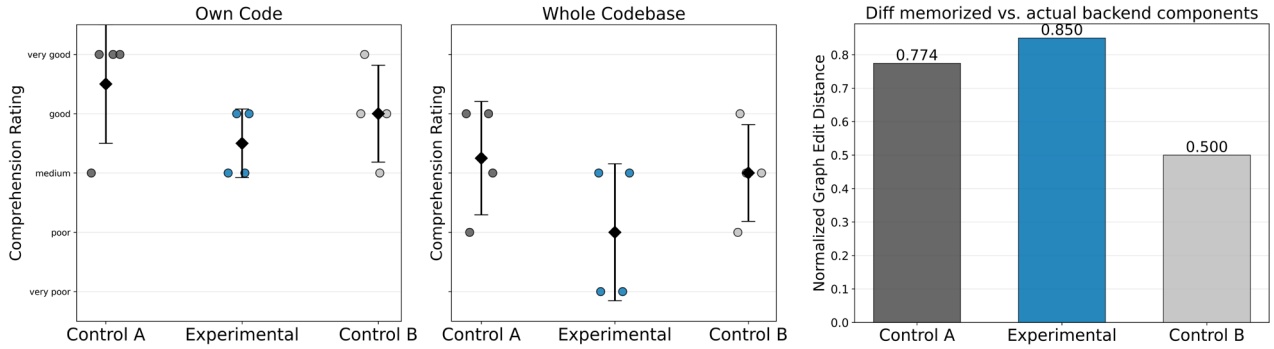

Figure 6. left: perceived code comprehension per team (scatter + mean ± SD); right: difference between memorized and actual backend.

efficiency-enhancing tool but as a decisive contributor to the project's successful completion. This perception was symbolically reflected in the team's assigning the agent a nickname and referring to it as their "*best colleague*".

Theme 2: The AI agent as an obstacle to learning processes

At the same time, the experimental group rated their code comprehension lower than that of the control group (See section 4.4). Within this team, tasks and problem-solving were increasingly delegated to the AI agent. Although participants initially attempted to solve problems on their own, this process was soon perceived as too time-consuming. Despite being aware of the potential negative implications for learning, students continued to rely heavily on the agent. Some participants even reported experiencing little or no improvement in their software engineering abilities after the project's completion. This form of *skill skipping* [16], in which learning opportunities remain untapped, is critically reflected upon by the students concerned: *"It [the AI agent] took care of everything for you, and you didn't have to grow through your problem*s."

Naturally, conflicts arose in all teams – but they were significantly more pronounced in the experimental group. Team members reported severe communication and coordination problems, as well as an overall negative team atmosphere. In some cases, it was unclear which individual members were actually working on or which tasks were next, leading to an uneven distribution of work, a blurring of responsibilities, and additional frustration. Initial attempts to improve processes and the team atmosphere increasingly gave way to a *turn a blind eye and carry on* mentality. Although the respondents themselves did not see the AI agent as the cause of the conflicts, its use reduced the need for close coordination and, in turn, the need to address existing problems. One member summed it up as follows: "*Okay, let's just swallow all the negativity and get on with it!*" The result was a working group characterized by weak social cohesion and limited personal identification with the project outcome.

V. DISCUSSION

Even though the experimental team had access to and was encouraged to use a state-of-the-art coding agent, this agent wasn't always the first choice. Instead, AI-assisted SE and even classical SE were used. We attribute this partly to the unfamiliarity with the process. When used, the junior developers were satisfied with the results in most cases, and trust grew to the point that they occasionally accepted them unquestioningly.

The codebase analysis revealed no clear difference between development with and without an AI coding agent. The differences in *coding standard violations* were minor, while *codebase size*, *code coverage*, dependencies, code duplication, and interpreter warnings all remained within the control group ranges. In contrast, the codebase created with assistance from the AI coding agent showed higher code security but potentially reduced maintainability, as indicated by its higher cyclomatic complexity. Despite prior studies reporting productivity gains from AI use [4], [6], our experiment does not confirm these findings. The team using the AI agent neither produced more software of better quality nor spent less time on the project than the other two teams. This is not necessarily a contradiction, because instead of looking at task-level productivity, we measured overall productivity over 10 weeks, including management tasks such as preparing presentations, team communication, and writing up documents, in addition to core software development-related tasks. This pattern resembles the "productivity paradox" observed in the 1980s, when the introduction of IT was not associated with higher productivity [17]. In our experiment, the exact reasons remain unclear.

Code Quality	Productivity	Code Comprehension	Learning Process
o	o	-	-

The findings on code comprehension and team dynamics highlight a tension between the subjectively perceived productivity gains from using AI agents and the simultaneous erosion of both technical and social learning processes. Within the experimental group, impairments in Learning became evident not only in participants' self-assessments of their programming competencies, but also in their objectively measured understanding of the generated code (see section 4.4).

Moreover, the results suggest that social learning processes within the teams were likewise inhibited. The AI agent made it easier for participants to avoid both intensive technical engagement with the code and the need to resolve team conflicts. At the same time, signs of alienation from the project output became apparent. Members of the experimental group identified less strongly with their final product than participants in the control groups. Together, the findings suggest that the use of AI agents in student project teams should be approached critically when the primary objective is competence development and learning rather than the efficient production of results alone. Or, as one member of the experimental group put it: *"Do I want to deliver a result in a project, or do I want to develop myself further?"*

Strengths of this work include the experimental and control groups having the same project goals and a balanced team composition, making the results inherently comparable. Furthermore, the study provides a holistic assessment of the impact on software engineering and was conducted in a natural setting (a student project) rather than in an isolated lab. The main limitation of this study is the small number of teams participating. The measured differences/similarities cannot be attributed solely to the use of the AI coding agent and may be superimposed by other influencing factors. Other limitations are the exclusion of the frontend code from the code quality analysis and the rapidly outdated AI coding agent used for studies like this.

VI. CONCLUSION AND FUTURE WORK

In this paper, we assessed the impact of AI coding agents on software engineering with junior developers. In a 10-week in-situ experiment, we observed the overall code quality, productivity, code comprehension, and team dynamics of three teams, each consisting of four junior developers working independently on the same project, with only one team given access to an AI coding agent. As summarized in Table 1, we observed no significant impact on code quality or overall productivity in that experiment. However, when analyzing code comprehension and team dynamics, we found that the AI agent facilitates project success by taking over tasks but, at the same time, removes responsibility, self-confidence, learning opportunities, and identification with the project outcome from team members. Together with the reported reduction in lower-level tasks [2], the hindered career advancement opportunities through the use of AI agents, as suggested by our experimental results, may reinforce the already ongoing decline in demand for junior software developers.

Future work includes repeating the experiment to increase the reliability of the results, as well as variations such as upstream training of participants in current AI software engineering practices and the incorporation of senior developers into development teams. Furthermore, best practices for the career advancement of junior software developers need to be adapted to the rise of agentic software engineering.

ACKNOWLEDGEMENT

The authors would like to thank Tim Hendriks and Jana Richter (NFON) for defining the project goals, Rob Goud and Paul Jansen (TIOBE) for supporting the code quality analysis, as well as Semjon Mössinger (WPS), Robert Glaser (Exxeta), and Jörg Müller (INNOQ) for the discussions during the design phase of the experiment.

HID Hardening vs. FIDO2: A Security-versus-Security Trade-off

Abstract

Problem. Human Interface Device (HID) keystroke-injection attacks ("BadUSB" / "Rubber Ducky") exploit the implicit trust operating systems grant to keyboards, and are now trivial to mount with hardware such as the US$4 Raspberry Pi Pico. On Windows, the standard defense is to block the installation of HID-class devices via Group Policy. Finding. We show this defense carries an overlooked cost: because FIDO2/WebAuthn security keys use the same USB HID transport (CTAPHID), a policy strict enough to block a Pico can also disable phishing-resistant authentication—a security-versus-security conflict, not merely security-versus-usability. Recommendation. Because CTAPHID occupies a dedicated FIDO usage page (0xF1D0), distinct from the keyboard usage page, injection-capable keyboards can be blocked while security keys remain reachable. We present a layered, descriptor-aware policy and validate it on Windows 11 (24H2). Across a four-case test, a Pico is blocked, while two vendors' FIDO2 keys still enroll and authenticate under the same policy. We further show that hardware-identifier allowlisting is necessary but insufficient—the Pico can spoof identifiers—thereby motivating attestation-based authorization.

Keywords: BadUSB; HID injection; Raspberry Pi Pico; FIDO2; WebAuthn; CTAPHID; Group Policy; Device Installation Restrictions; endpoint security; Windows.

I. INTRODUCTION

The Universal Serial Bus (USB) trust model was designed for usability rather than security. When a device declares itself a member of the HID class, the host loads a class driver and begins accepting input without prompting for authorization. That decision was reasonable in an era of trusted peripherals. Still, it is the root cause of the BadUSB family of attacks brought to prominence by Nohl and Lell [1], who showed that USB controller firmware can be reprogrammed so that an apparently benign device masquerades as a keyboard. Keystroke-injection attacks weaponize this trust directly. The malicious device carries no executable for an antivirus engine to scan; it merely "types." From the host's perspective, the input is indistinguishable from that of a human operator, which is precisely why the technique bypasses file-based detection and most data-loss-prevention tooling [2]. Once gated behind purpose-built commercial hardware, the capability has been democratized to the point of triviality: a Raspberry Pi Pico costing a few dollars can be flashed with freely available CircuitPython firmware to become a fully functional injection platform [3]. The canonical host-based defense on Windows is to constrain device installation for keyboard/HID setup classes via Group Policy [4]. Practitioner guidance correctly notes that mass-storage controls do not help—a keyboard is not a storage device—and that the HID class cannot be denied wholesale, because the user's legitimate keyboard and mouse are themselves HID devices. This paper makes a further observation that, to our knowledge, has not been systematically analyzed in the academic literature, and which we take as our central contribution: *the same HID-class restriction that defends against keystroke injection can break FIDO2 hardware authentication.* FIDO2/WebAuthn security keys—the strongest widely available defense against credential phishing—

communicate via the CTAPHID protocol, which, by design, rides the USB HID transport for driverless installation [5]. A Device Installation Restriction is strict enough to stop a Pico, therefore, risks turning off the very authentication mechanism the organization deployed against phishing. The defender is placed in a security-versus-security dilemma: mitigating one high-impact attack class can silently weaken defense against another. **Contribution and scope.** This is a *conceptual and policy-analysis* paper with an empirical validation component; it is not a large-scale measurement study. Concretely, we (i) identify and characterise the FIDO2 collateral-damage problem as a first-class security-versus-security conflict; (ii) explain why it arises from the shared HID transport and how the dedicated FIDO usage page (0xF1D0) makes a precise resolution possible; (iii) give a layered, descriptor-aware Windows policy and validate it experimentally on Windows 11 (24H2) with a Pico and two vendors' FIDO2 keys, confirming that the injection defence and phishing-resistant authentication can hold simultaneously; and (iv) analyse the residual identifier-spoofing risk and argue for attestation-based authorisation. Our scope is USB-connected authenticators on Windows; NFC and Bluetooth (caBLE) transports fall outside the HID-blocking dilemma and are not considered. The remainder of the paper is organized as follows. Section II reviews related work. Section III describes the Pico attack platform. Section IV states our analysis method, threat model, and assumptions. Section V sets out the standard Windows defense and its HID-blocking dilemma. Section VI—the core of the paper—formalizes the FIDO2 collateral-damage problem. Section VII proposes a reconciliation and its validation. Section VIII discusses limitations, including identifier spoofing. Section IX outlines future work, and Section X concludes.

II. RELATED WORK

Tian et al. [6] provide the canonical systematization of USB security and situate HID injection within the broader landscape of bus-level threats. Their system contributions are directly relevant to mitigation: GoodUSB [7] mediates device enumeration by reconciling a device's claimed class with user expectations, and USBFILTER [8] implements an in-kernel, packet-level firewall for USB traffic. Gateway-isolation designs such as Cinch [9] interpose a trusted intermediary that can strip unexpected HID traffic from devices that would otherwise be permitted. On detection, Karantzas [2] infers BadUSB activity from native Windows logs by correlating Plug-and-Play device-arrival events with anomalously fast inter-keystroke timing and the proximate spawning of interpreters such as PowerShell. Hardware-assisted and behavioral systems, such as USB-Watch [10] and USBESAFE [11], classify timing and behavioral features in some cases before keystrokes reach the operating system. Pico-specific work is recent and largely applied: Reguly [3] documented turning the Pico into an HID; subsequent projects extend it with wireless command-and-control [12], and the same hardware has even been repurposed as a defensive descriptor inspector [13].

Across this body of work, mitigation is consistently framed as a trade-off between security and usability (the risk of locking out legitimate keyboard users). The trade-off between security and another security control the breakage of FIDO2 authentication by HID-class restrictions is, to our knowledge, not treated as a first-class problem. That gap motivates this paper.

III. THE RASPBERRY PI PICO AS AN ATTACK PLATFORM

The Raspberry Pi Pico is built on the RP2040 microcontroller and exposes a native USB interface. Flashed with CircuitPython and the Adafruit HID library, it emulates a USB keyboard using a few lines of Python placed in a code.py file that the board executes automatically on power-up [3]. No soldering, custom hardware, or specialist toolchain is required, and a minimal payload—opening the Run dialogue, launching an interpreter, and executing a remote script—completes in seconds. The listing in Figure 1 is limited to what is necessary to understand the threat model; it is widely published and does not constitute a novel offensive capability.

```
import time, usb_hid
from adafruit_hid.keyboard import Keyboard
from adafruit_hid.keycode import Keycode
kbd = Keyboard(usb_hid.devices)
time.sleep(2)   # wait for host enumeration
kbd.send(Keycode.GUI, Keycode.R)  # open Run
time.sleep(0.5)
# ... type an interpreter invocation, ENTER
```

Figure 1. Illustrative HID keystroke-injection payload (abridged).

Because no file is written to disk during the keystroke phase, signature-based antivirus provides little protection, and the attack inherits the logged-on user's privilege level [2]. A representative Windows attack chain comprises: (i) delivery (a dropped device or brief unattended access); (ii) enumeration as an HID keyboard, loading the in-box driver; (iii) injection of commands; (iv) fileless execution in memory; and (v) optional cleanup of traces.

IV. ANALYSIS METHOD, THREAT MODEL, AND ASSUMPTIONS

Method. Our analysis proceeds by descriptor-level reasoning about how Windows Device Installation Restrictions interact with the USB HID class, followed by an empirical validation on Windows 11 (Section VII-B) that exercises the four decisive cases on a live host. We reason at the level of setup classes, hardware/instance IDs, and HID usage pages, because these are the objects Group Policy actually matches on.

Threat model. We assume an attacker with brief physical access to a target USB port (a dropped or swapped device, or short unattended access) who can program a Pico to present arbitrary HID descriptors and USB identifiers, but without prior administrative credentials on the host. The defender is a Windows administrator who centrally manages device installations via Group Policy and issues FIDO2 security keys for phishing-resistant authentication. The asset to protect is twofold: the host must reject injection-capable keyboards, and legitimate FIDO2 authenticators must continue to enroll and authenticate.

Assumptions. We assume (a) authenticators expose CTAPHID on the FIDO usage page 0xF1D0, distinct from the generic keyboard usage; (b) the host applies Device Installation Restriction policy at enumeration time and logs the outcome via Kernel-PnP / DeviceSetupManager events [14]; and (c) the administrator can enumerate authorized hardware IDs on a representative machine. Where an authenticator additionally exposes a CCID interface, or where per-OS HID behavior differs, we note the effect in Section VIII rather than assuming uniform behavior.

V. THE STANDARD WINDOWS DEFENCE AND THE HID-BLOCKING DILEMMA

Three commonly deployed controls fail against HID injection, and the reasons matter for what follows. A signature-based antivirus is bypassed because the vector is keystrokes rather than a stored binary. The Removable Storage Access policy denies only the mass-storage class, explicitly leaving keyboards and mice untouched [4]. The legacy technique of disabling the USBSTOR driver likewise does nothing to a device that enumerates as a keyboard.

The native control that can address HID injection is Device Installation Restrictions, configured under

Computer Configuration > Administrative Templates > System > Device Installation > Device Installation Restrictions and persisted under

HKLM\SOFTWARE\Policies\Microsoft\Windows\DeviceInstall\Restrictions [4], [15].

Here lies the dilemma. Mass storage can be denied wholesale because a workstation rarely needs arbitrary USB storage. HID cannot, because the user's own keyboard and mouse belong to the very class one would block. The defender's options are:

- *Blanket class denial* of the keyboard/HID setup classes—effective against the Pico, but it turns off legitimate input devices and, as Section VI shows, FIDO2 keys.
- *Deny-unspecified*, permitting only devices explicitly described by other policy settings—convenient, but it silently captures any HID device not on the allowlist, including authenticators.
- *Hardware-identifier allowlisting*, denying the class but permitting specific Vendor/Product or device-instance IDs—the recommended model, but operationally burdensome and, as Section VIII argues, defeasible by Pico-side spoofing.

The literature treats this dilemma purely as a security-versus-usability problem. The next section shows it is also a security-versus-security problem.

VI. THE FIDO2 COLLATERAL-DAMAGE PROBLEM

1. Why FIDO2 keys ride the HID transport

FIDO2/WebAuthn authentication on a hardware security key is carried out via the Client-to-Authenticator Protocol (CTAP) [5], exposed to the relying party through the WebAuthn API [16]. For USB-connected authenticators, CTAP messages are framed using the HID protocol—a binding the FIDO Alliance calls CTAPHID—so that authenticators install without bespoke drivers on all major host platforms [5]. A USB security key, therefore, presents to Windows as an HID device; driverless installation over HID is a stated design objective of the protocol, not an implementation accident.

Crucially, the authenticator does not use the keyboard HID usage page. CTAPHID is allocated a dedicated FIDO Alliance usage page (0xF1D0) with its own raw input/output reports, distinct from the generic desktop keyboard usage [5]. This distinction is the technical hinge of our argument: it is what makes a precisely scoped defense possible, and what makes a blunt one harmful.

2. The conflict

Consider the three defender options from Section V in light of the above:

- A blanket denial of the HID setup class matches FIDO2 keys because they enumerate within that class. The policy that stops the Pico also stops the security key.

- A deny-unspecified policy denies any device not on the allowlist; unless every authenticator model is enumerated in advance, security keys are blocked on first insertion—precisely when a user tries to register or roam to a new machine.
- Even hardware-identifier allowlisting silently excludes authenticators unless their identifiers are added; an organization that allows only keyboards and mice will find that newly issued or replacement security keys fail to install.

The result is a genuine security-versus-security trade-off, summarised in Table 1. The defender hardening against one of the most effective endpoint-compromise techniques (keystroke injection) can, under the same policy, degrade defense against another prevalent technique (credential phishing), for which FIDO2 is the strongest available countermeasure. The failure mode is especially pernicious because it is silent and delayed: the injection defense appears to work, while the authentication breakage surfaces only when a user later tries to enroll or use a key, often on a machine other than the one where the key was first registered.

Table 1. The security-versus-security trade-off introduced by HID-class restrictions. Only a policy that explicitly accounts for the FIDO transport satisfies both goals.

Policy choice	Stops Pico	Breaks FIDO2 keys
Removable Storage Access only	No	No
Blanket HID class denial	Yes	Yes
Deny-unspecified	Yes	Yes (unless pre-enumerated)
HW-ID allowlist (kbd/mouse only)	Yes	Yes (keys not on list)
HW-ID allowlist incl. keys (§VII)	**Yes**	**No**

VII. RECONCILING INJECTION DEFENCE WITH FIDO2

1. A layered, descriptor-aware policy

The dedicated FIDO usage page (0xF1D0) is what makes reconciliation feasible: a keyboard-emulating attack device and a FIDO2 authenticator are both HID devices, but they are distinguishable at the descriptor level. We recommend the following layered policy.

- *Inventory all authorized HID hardware, including security keys.* On a representative machine, record the hardware IDs and device-instance IDs of every sanctioned keyboard, mouse, and FIDO2 authenticator from Device Manager or the System event log. Desktop peripherals nest several levels deep in the PnP tree; capture each intermediate hub/composite ID.
- *Allow the known-good devices.* Enable installation of devices matching these IDs and add the collected identifiers, treating authenticators as first-class entries rather than an afterthought.
- *Prevent the rest, narrowly.* Prefer denying the keyboard setup class over the entire HID class, and avoid the blunt deny-unspecified switch on any workstation where security keys are used. The objective is to block injection-capable keyboards while leaving the FIDO transport reachable.
- *Preserve administrative recovery.* Enable "Allow administrators to override Device Installation Restriction policies" so a replacement keyboard or key can be installed for legitimate maintenance; scope override rights to a named administrative group, log each override, and pair it with a documented break-glass procedure so recovery does not itself become an injection vector.

- *Validate both properties.* After gpupdate /force, confirm with RSoP/gpresult and the device-installation audit events that an unknown keyboard is rejected, and that an issued security key still enrolls and authenticates. Authentication breakage must be tested explicitly; it does not surface during normal device inventory.

This refinement is the only row in Table 1 that satisfies both security goals—at the cost of an accurate, maintained allowlist that, as Section VIII shows, rests on an assumption the attacker can violate.

2. Validation procedure and results

To move the claim from assertion to demonstration, we implemented the layered policy on a single Windows host and exercised the four decisive cases. The environment was one workstation running Windows 11 (version 24H2) with the descriptor-aware allowlist of Section VII-A applied via local Group Policy; a Raspberry Pi Pico (RP2040) flashed per Figure 1 as an unauthorised keyboard; one authorised USB keyboard; and two FIDO2 security keys from different vendors (a Token2 key and a YubiKey), used to confirm the behaviour is not specific to one authenticator model. Device-installation auditing was enabled so that allow/deny decisions were recorded via Kernel-PnP / DeviceSetupManager events 6416 (install permitted) and 6420 (install blocked by policy) [14]. A policy is correct only if C1 is blocked while C2–C4 succeed simultaneously under the same enforced configuration.

Table 2. Observed results of the four-case validation on Windows 11 24H2 under the descriptor-aware allowlist. All four cases passed: C1 was blocked while C2–C4 succeeded under the same enforced policy.

Case	Device/action under enforcement	Observed outcome	Evidence	Result
C1	Unknown Pico (RP2040) enumerating as keyboard; VID/PID not on allowlist	Install blocked	Event 6420 / RSoP	Pass
C2	Authorized keyboard; VID/PID on allowlist	Install allowed	Event 6416	Pass
C3	FIDO2 key registration / first insertion (0xF1D0 usage)	Enrolment succeeded	WebAuthn ceremony	Pass
C4	FIDO2 authentication after policy enforcement	Auth succeeded	Sign-in / gpresult	Pass

All four cases produced the intended outcome. Cases C1 and C2 confirmed that the injection defense still discriminates between authorized and unauthorized keyboards: the unknown Pico was rejected during enumeration (logged as event 6420), while the allowlisted keyboard installed normally (event 6416). Cases C3 and C4 confirmed that the FIDO transport remained reachable under the same policy: both the Token2 and the YubiKey completed WebAuthn registration on first insertion and subsequently authenticated after policy enforcement. For contrast, we also confirmed that a blanket HID-class denial and a deny-unspecified policy each blocked C3–C4 (both authenticators failed to install), reproducing the collateral-damage effect and matching the corresponding rows of Table 1. Because C3 exercised first insertion on a machine where the key had not previously been registered, it captures the roaming case that most often surfaces the silent breakage in production. These results are illustrative rather than a large-scale study—a single host and two authenticator models—but they demonstrate that the conflict is real and that the descriptor-aware allowlist resolves it in practice, not only in principle.

VIII. LIMITATIONS AND RESIDUAL RISK

Identifier spoofing. Hardware-identifier allowlisting assumes an attacker cannot trivially clone an authorized device's Vendor and Product IDs. That assumption does not hold for the Pico, which can be programmed to present an arbitrary VID/PID and mimic the full descriptor set of a sanctioned device. An attacker who learns the identifiers on an allowlist—or who impersonates a common keyboard model—can craft a rogue device that the policy will admit. The allowlist, therefore, raises the attacker's reconnaissance cost rather than providing an absolute barrier. This residual risk is not a footnote to the design; it is the reason the design is necessary-but-insufficient, and it should be managed with compensating controls: (i) FIDO device attestation, so that issued keys are verified against the FIDO Metadata Service rather than trusted on self-asserted IDs [17]; (ii) behavioural detection of injection, correlating device-arrival events with anomalous inter-keystroke timing and interpreter spawning [2]; and (iii) endpoint monitoring that alerts on new HID enumeration and on policy-override events, so that a spoofed-ID admission is at least visible after the fact.

Maintenance burden and silent breakage. Maintaining an accurate allowlist covering every keyboard, mouse, and authenticator across a heterogeneous fleet—with hot-desking, replacements, and roaming users—imposes real administrative cost, and the FIDO breakage mode remains silent until a user attempts to authenticate. The validation of Section VII-B should therefore be treated as a recurring control rather than a one-time check.

Transport and platform variation. Some authenticators also expose a Smart Card (CCID) interface, and FIDO behavior over HID varies across operating systems [18]; on Windows, direct HID access to a key may also require elevated privileges. Exact policy behavior should be validated for each authenticator model and Windows build. Scope. Our analysis addresses USB-connected authenticators; NFC and Bluetooth (caBLE) transports fall outside the HID-blocking dilemma.

IX. FUTURE WORK

The principal direction follows from the spoofing limitation: because the Pico can forge hardware identifiers, authorization must not rest on self-asserted, spoofable identifiers. Promising avenues include (i) cryptographic device attestation, in which a peripheral proves possession of a hardware-bound key before the host accepts its input; (ii) behavioural binding that augments descriptor checks with continuous keystroke-dynamics verification, so that a device presenting valid identifiers must also exhibit human-consistent timing; and (iii) bus-level mediation extending designs such as Cinch [9] that authorise input out of band rather than trusting a device's claims. An empirical study quantifying how reliably a spoofed-identifier Pico defeats a fully configured Windows allowlist—and how much reconnaissance this requires—would itself be a valuable contribution. A complementary strand is to propose OS or policy-template mechanisms that block injection-capable keyboards while reliably exempting the CTAPHID usage page, so that the conflict identified here is resolved by design rather than by careful manual configuration.

X. CONCLUSION

The Raspberry Pi Pico exemplifies how a once-specialized attack has become trivially accessible, and the natural Windows defense—restricting HID device installation—appears straightforward. This paper has shown that the defense carries a hidden cost that the existing security-versus-usability literature has overlooked: a HID-class restriction strict enough to prevent keystroke injection can simultaneously break FIDO2 hardware authentication, because security keys ride the same HID transport as keyboards. Hardening against one high-impact attack can thus weaken defense against another. The conflict is resolvable—the FIDO usage page is distinct from the keyboard usage, so a precisely scoped allowlist that enumerates authenticators can satisfy both goals, as we demonstrated on Windows 11 (24H2), where a Pico was blocked while two vendors' FIDO2 keys

still enrolled and authenticated under the same policy—but only if defenders recognise the problem, and only as far as spoofable identifiers allow. Recognizing the FIDO2 collateral-damage problem and ultimately replacing identifier-based authorization with attestation are necessary if endpoints are to resist keystroke injection without sacrificing phishing-resistant authentication.

Abstract
The integration of artificial intelligence into higher education has fundamentally changed the way it operates. Employees increasingly limit critical thinking by delegating their work to AI systems. The use of AI tools raises considerable concerns, especially in decision-making processes. Recent empirical studies examine academic staff, but lack a parallel with administrative staff. They examine the spectrum from human-led augmentation to AI-driven delegation. This study presents an exploratory survey conducted at the University Metropolitan Tirana (UMT), an early-adopter institution in integrating AI into the workplace. The survey examines 57 employees (response rate: 63.3%) who use AI tools in their professional decision-making. The findings indicate a high level of AI use (94.7%), with daily use of AI tools resulting in 66.7%. Academic (M = 3.23) and administrative (M = 3.14) decisions are surpassed by strategic decisions (M = 3.51) when it comes to relying on AI recommendations. This pattern overturns the assumption that "routine tasks come first," prevalent in the existing literature. Role-based differences show that administrative staff exhibits a considerably higher concentration of delegation behavior (25% Level 3) compared to academic staff (2.7%). The study contributes the first survey-based investigation of AI-driven decision-making among university employees in Albania, the ADIS framework as a measurable taxonomy of the augmentation–delegation spectrum, and a structured survey instrument for application across regional institutions.

Keywords: generative AI, decision-making, higher education, AI adoption

I. INTRODUCTION

Generative Artificial Intelligence (GenAI) is part of organizational decision-making, reshaping how employees approach intensive tasks. Replacing old decision-making methods where employees had to access information, analyze, and make decisions. Recent surveys and studies highlight the use of GenAI in task execution, increasing quality and efficiency, transforming coordination structures, and enhancing managerial control in decision-making processes [1], [2], [3]. Organizational decisions made by AI systems carry implications regarding decision quality and accountability. Since AI is not transparent in how it provides recommendations, it creates an accountability gap among the system, the individual, and the organization [4]. Universities provide a perfect environment for examining these dynamics because their decisions span academic, administrative, and strategic domains. This makes the risks of misdelegation diverse and, in many cases, irreversible. The focus of this study is the case of the University Metropolitan Tirana, an early adopter of AI, where ongoing training is provided to help staff use AI tools in their daily work. The university has actively integrated AI tools, making it a natural laboratory for studying AI use in decision-making. Staff training ensures efficiency and faster decision-making. There are several studies on AI in higher education, but their focus is on student adoption, pedagogical applications, and academic integrity. These studies do not highlight how employees make decisions in an AI-integrated work environment [5], [6]. This paper addresses this gap through an exploratory survey of employees at the University of Metropolitan Tirana. This paper addresses the gap through the following research questions:

RQ1: What AI tools are employees at UMT currently using in their work?

RQ2: For which types of decisions do employees use AI, and to what degree?
RQ3: Do employees perceive themselves as using AI for augmentation or delegation?
RQ4: Are there significant differences in AI use behavior by employee role?

This study contributes: (a) empirically, the first survey-based investigation into AI-driven decision-making behavior among university employees in Albania; (b) theoretically, it proposes the AI Decision Integration Spectrum (ADIS), a three-level framework that classifies employees' decision-making behavior as AI-assisted, AI-recommended, or AI-delegated; (c) practically, it provides a replicable survey instrument and an interpretive framework that regional universities can apply as they navigate AI adoption across their own academic, administrative, and strategic functions.

II. RELATED WORK

1. Information-Seeking to AI-Mediated Decision-Making

Information search and organizational decision-making were inseparable activities before the use of AI. At the center is the human who seeks a specific item by interpreting the decision-making path [7]. Information search begins with the filling of a knowledge gap in the individual, who actively works to fill it through independent discovery, evaluation, and synthesis. The integration of Artificial Intelligence has disrupted the architecture. The role of the individual has shifted from synthesizer to evaluator, taking advantage of AI's rapid data processing. Attitudes towards AI-driven decision-making are shaped by individual efficiency and benefits, according to empirical studies to date [8]. Existing literature defines automation as a complement to, rather than a substitute for, human skills. Machines perform human tasks faster, but human-machine collaboration is increasing [4]. The literature highlights a paradox: in practice, the boundary between substitution and augmentation is blurred. The path to automation, starting with organizations, ends with workers accepting AI's results without further criticism. As a result, concerns about accountability, fairness, and transparency of systems continue [9]. Automation bias is defined as the tendency of humans to trust the automated recommendations, even when inaccurate information is noticed [10], [11]. Studies confirm that automation bias reduces sensitivity but cannot eliminate it [12]. Delegation is not determined by individual failure. The findings suggest that organizations should actively train staff to minimize the risk of delegating decisions. This paper examines, through the framework of the AI Decision Integration Spectrum, the extent to which this tendency manifests itself across roles in employees of the University of Metropolitan Tirana.

2. AI Adoption in Higher Education

The integration of artificial intelligence in higher education has become an indispensable tool in resource allocation, information processing, data analysis, and institutional decision-making. This is confirmed by numerous studies in this field, which, in addition to positive effects, have found significant dependencies among the challenges of GenAI adoption. Most of the uncertainties concern the limits of use and the strategic frameworks needed to keep pace with adoption rates [13], [14], [15]. Existing studies focus more on student behavior and the impact of AI, overshadowing research on staff within universities. Currently, studies on staff have been more complex, where the use of AI is guided by ethical considerations, suggesting that faculty use of AI should be shaped by professional values [16]. Empirical findings highlight that integrating AI into the workplace entails different engagement models. ChatGPT is the most widely used tool among academic staff, adapted to their needs. It reduces stress levels and increases positive affect among faculty [17]. On the other hand, the administrative staff requires further research. So far, it has emphasized the use of AI tools in the design of institutional communications, data organization, and related areas, and has positively evaluated the integration of AI. Although recent findings consider administrative staff to be capable adopters of AI, there is a lack of studies on their behavior, with most focusing on academic staff and students [18].

3. Decision-Delegation Problem

The integration of AI into organizational life has enabled a shift in one of the most important tasks from automation to delegation. Task automation replaces procedural activities such as planning, data collection, and document processing. Decision - delegation is different from automation, it transfers judgment to an AI system while accepting responsibility for outcomes that affect people. While large language models produce and imitate expert reviews with high efficiency, users avoid prior control. A large-scale empirical survey of knowledge workers has found that workers' critical-thinking effort decreases when generative AI tools appear to be efficient at completing a task [19]. A review of human-AI augmentation in the workplace finds that the spectrum between augmentation and delegation lacks formal measurement frameworks at the organizational level. Institutional and organizational factors moderate the extent to which AI functions as a cognitive tool or a cognitive substitute [20]. In cases where AI systems take over decision-making functions, accountability issues become an intractable concern, as defined in the literature as a failure in the governance and contemporary deployment of AI [21].

III. METHODOLOGY

This study used an exploratory survey to study the impact of AI on decision-making among staff at the University of Metropolitan Tirana. The survey was sent to 90 university employees, including academic and administrative staff. For studying the demographics, use of AI tools, decision-making behavior, perceptions, and trust, as well as an open-ended question on concerns about using AI at work. The survey included 16 questions organized into sections and presented in various formats, including multiple-choice, five-point Likert, and open-ended. UMT employees completed the questionnaire anonymously through Microsoft Forms. For data analysis, Python is used to report frequencies, percentages, means, medians, and standard deviations. Open-ended responses were analyzed thematically using inductive coding. Participation was voluntary and anonymous, with no personally identifiable data collected. The survey is approved by the University of Metropolitan Tirana and conducted in accordance with established ethical standards for research involving human subjects. Participation was voluntary and anonymous, with no personally identifying data collected; participants were informed of the study's purpose, the voluntary nature of participation, and the confidential handling of their responses through the consent statement at the beginning of the Microsoft Form.

IV. RESULTS

A total of 57 valid responses were received, with a response rate of 63.3%. The majority of responses were from academic staff, with 42 responses (73.3% response rate). At the same time, the administrative and management staff yielded 15 responses (26.3%).

RQ1: What AI tools are employees at UMT currently using in their work?
Survey results show that employees have a high level of engagement with AI tools. As shown in Figure 1, ChatGPT was used by 87.7% of respondents, making it the most widely used tool. The following tools are Google Gemini (47.4%) and Claude (35.1%), while Microsoft Copilot (10.5%) had a lower engagement rate.

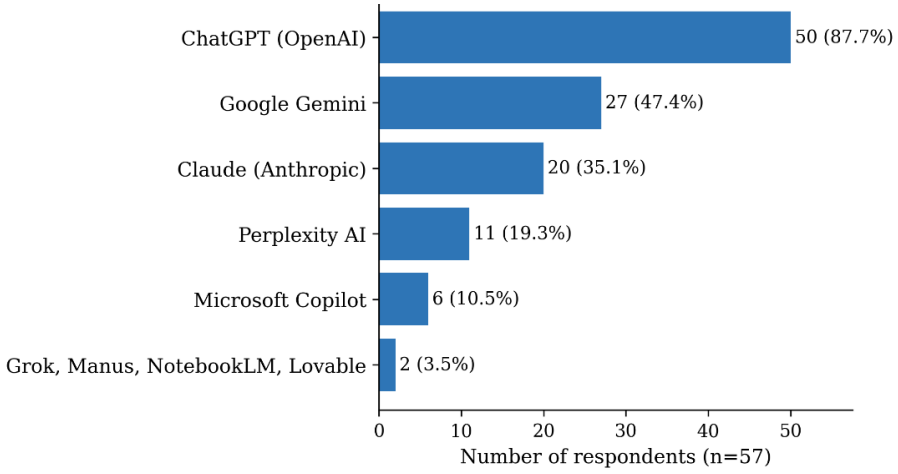

Figure 1. AI tools are currently used by employees at University Metropolitan Tirana (UMT).

Although use was intensive, only three respondents reported not using AI tools. 38 (66.7%) respondents report using AI tools daily, 12 (21.1%) weekly, and 4 (7%) rarely. Considering the profile of the respondents, academic staff show the highest rate of daily use of artificial intelligence tools (69%), followed by administrative staff (60%).

Table 1 summarizes the results of the task profile on which employees most often use AI tools, with multiple-select options. Researching and finding information is the most common task (73.7%), followed by data analysis and summarizing (59.6%), supporting decision-making (57.9%), and drafting emails or documents (56.1%). Notably, more than half of respondents reported explicit use of AI for "supporting decisions or recommendations," a task category directly relevant to RQ2 and RQ3.

Table 1. Task Types for which AI is Used.

Task	***n***	**% of respondents**
Researching	42	73.7%
Data analysis or summarizing	34	59.6%
Supporting decisions	33	57.9%
Drafting emails or documents	32	56.1%
Generating reports	18	31.6%
Student or colleague advising	17	29.8%
Scheduling or planning	7	12.3%
Coding	2	3.5%

Tasks differ by role, and academic staff reported using ChatGPT (88.1%), Google Gemini (57.1%), Claude (42.9%), and Perplexity AI (26.2%). The administrative staff focused primarily on ChatGPT (86.7%), with lower

adoption of Gemini (20%) and Claude (13.3%). This pattern suggests that academic staff treat AI primarily as a research tool, while administrative staff use it more transactionally, focusing on it as a tool.

RQ2: For which types of decisions do employees use AI, and to what degree?
Respondents reported on AI recommendations in three different decision categories. Strategic decisions had the highest mean reliance score (M = 3.51, SD = 1.48), followed by academic decisions (M = 3.23, SD = 1.52), and administrative decisions had the lowest score (M = 3.14, SD = 1.39). Given the importance of decision-making, which is often considered the least automatable category, survey reports show that 63.2% of employees rely on AI for strategic decisions (Table 2a).

In the behavioral analysis, respondents are divided into two groups: 22 (38.6%) say they always or usually verify AI results with other sources. In contrast, 26 (45.6%) report trusting AI and never or rarely checking the answers received (Table 2b). Considering the above decision-making results and employees' behavior towards AI tools, a high number of employees act according to AI recommendations without independent verification, a behavioral pattern directly related to the augmentation-delegation distinction examined in RQ3.

Table 2. AI reliance and verification behavior.

(a) Reliance on AI by Decision Type (1 = Not at all, 5 = Completely).

Decision Type	***M***	***Mdn***	***SD***	**% Often / Compl.**	**Mann-Whitney U**	***p***	***r***
Administrative	3.14	3	1.39	42.1%	395.0	.141	-0.25
Academic	3.23	4	1.52	52.6%	533.0	< .001	-0.69
Strategic	3.51	4	1.48	63.2%	449.0	.012	-0.43

(b) Verification of AI Recommendations.

Frequency	***n***	**%**
Never	15	26.3%
Rarely	11	19.3%
Sometimes	9	15.8%
Usually	10	17.5%
Always	12	21.1%

RQ3: Do employees perceive themselves as using AI for augmentation or delegation?

The AI Decision Integration Spectrum (ADIS) is a three-tier framework developed after responders were classified into three categories based on their self-reported decision-making behavior. As shown in Figure 2, the majority of employees fell into Tier 2 (AI-Recommended), with 26 responders representing 53.1% of employees. While 19 employees (38.8%) reported that they make the decision themselves after gathering information, falling in Tier 1 (AI-Assisted), and 4 employees (8.2%) reported full delegation behavior, consistent with Tier 3 (AI-Delegated). The remaining 8 respondents (14%) who selected “I do not use AI for decisions” were excluded from the tier analysis.

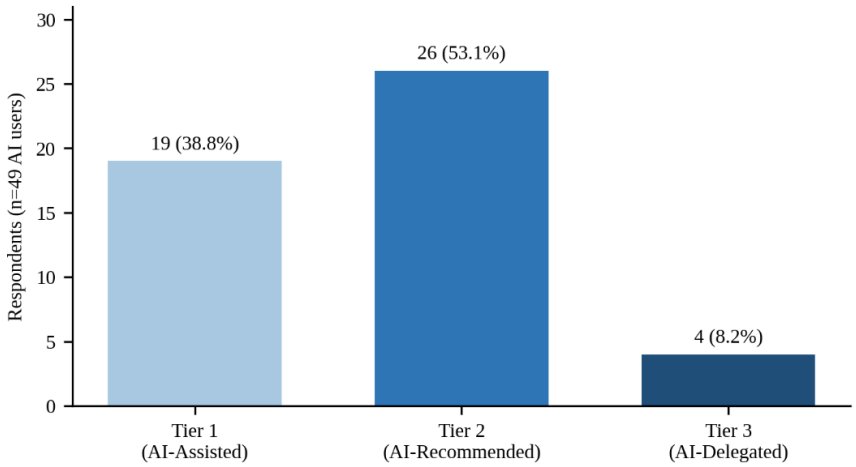

Figure 2: ADIS tier distribution among AI users (n = 49).

Examining mean scores within each ADIS tier reveals a clear gradient supporting the framework's theoretical structure. As shown in Table 3, trust in AI recommendations rises monotonically from Tier 1 (M = 3.37) to Tier 2 (M = 3.73) to Tier 3 (M = 4), while verification behavior falls in the opposite direction: 47.4% of Tier 1 respondents always or usually verify AI outputs, compared with 26.9% of Tier 2 respondents and 0% of Tier 3 respondents. The augmentation-delegation paradox, highlighted in the existing literature, concerns the relationship employees form with AI systems: greater trust and less verification. Employees are moving from AI-assisted work to direct delegation.

Table 3. Within-Tier Means on Key Indicators.

Indicator	**Tier 1 (n=19)**		**Tier 2 (n=26)**		**Tier 3 (n=4)**		**Spearman ρ**	***p***
	M	***SD***	***M***	***SD***	***M***	***SD***		
Trust in AI recommendations	3.37	0.76	3.73	0.87	4.00	0.00	+0.27	.057
Confidence in evaluating AI output	3.95	0.97	4.23	0.71	4.00	0.82	+0.08	.575
AI improved decision quality	3.79	1.18	4.31	0.68	4.50	0.58	+0.23	.112
% verifying Always/Usually	47.4%	-	26.9%	-	0.0%	-	-0.33	.021

With only 4 respondents in Tier 3, this group alone cannot support strong conclusions. The values, however, follow the same direction as Tiers 1 and 2, providing initial support for the view that the three-tier classification reflects a meaningful progression. Tier 2 represents the modal pattern of AI use at UMT: high trust (3.73); strong confidence in evaluating AI output (4.23); and the highest perceived quality improvement (4.31), paired with lower verification behavior than Tier 1.

Empirical support is provided for the augmentation-delegation paradox at the individual level. Trust in AI recommendations and frequency of verification are significantly correlated (Spearman $\rho = -0.36$, $p = .011$, n = 49, medium effect size).

RQ4: Are there significant differences in AI use behavior by employee role?
Table 4 shows the behavioral indicators of academic and administrative staff. Academic staff are represented by higher values regarding reliance on AI across all three decision types. It also results in stronger trust in AI and in the evaluation of its results. The role is decisive in the levels of ADIS. The rate of AI use among academic staff is 37.8% at Level 1 and only 2.7% at Level 3. According to the survey report, 25% of administrative staff were placed at Level 3. However, administrative staff had a higher frequency of result verification, at 46.7%, compared to academic staff, at 35.7%. These patterns are only descriptive; the small administrative subgroup excludes statistical testing.

Table 4. Comparison of Indicators by Role.

Indicator	**Academic (n=42)**		**Administrative (n=15)**		**Mann-Whitney U**	***p***	***r***
	M	***SD***	***M***	***SD***			
Daily AI use	69.0%	-	60.0%	-	-	-	-
Reliance: administrative decisions	3.31	1.30	2.67	1.59	395.0	.141	-0.25
Reliance: academic decisions	3.74	1.29	1.80	1.21	533.0	< .001	-0.69
Reliance: strategic decisions	3.81	1.35	2.67	1.54	449.0	.012	-0.43
Trust in AI recommendations	3.55	0.92	3.20	0.86	383.0	.184	-0.22
Confidence in evaluating AI output	4.07	0.95	3.60	0.91	412.5	.060	-0.31
Perceived quality improvement	4.00	1.08	3.60	1.06	390.0	.155	-0.24
% Tier 1 of users	37.8%	-	41.7%	-	-	-	-
% Tier 2 of users	59.5%	-	33.3%	-	-	-	-
% Tier 3 of users	2.7%	-	25.0%	-	-	-	-
% verifying Always/Usually	35.7%	-	46.7%	-	-	-	-

Employee concerns raised about AI use.
The survey included an optional open-ended question about concerns regarding the use of AI tools in workplace decisions, to which 21 responses were received. The major concerns were related to loss of independent thinking and over-reliance on artificial intelligence. Concerns about accuracy and inconsistency, privacy and data security, reduced creativity, and the costs of AI tools were secondary themes. The qualitative concern with over-dependence aligns directly with the quantitative pattern observed in RQ3: as respondents move along the ADIS spectrum toward delegation, verification behavior weakens. The fact that employees themselves identify this as a concern suggests an awareness gap between recognized risk and reported behavior.

V. DISCUSSION

First, a survey of 57 employees at the University of Metropolitan Tirana found that 94.7% used AI tools. At the same time, 66.7% of employees reported using AI daily in their work. Studies to date have reported on the use of artificial intelligence in higher education, and the findings of this paper are at a high level compared to current reports [13], [15], [22]. Considering that University Metropolitan Tirana positions itself as an AI-focused institution and is active in training staff to use AI tools, the observed rates are high among universities in the region. ChatGPT leads in usage by 87.7% of employees, and other tools that can be considered secondary are Google Gemini with 47.4% and Claude with 35.1%. These findings establish OpenAI's product as the standard among academic and administrative staff [17], [23]. Second, reliance on recommendation systems shows high results with strategic decisions (M = 3.51). While the existing literature reports that delegation begins with routine tasks, this pattern complicates assumptions about strategic decision outcomes. Regarding administrative decisions, the mean reliance score is the lowest (M = 3.14), and the average for academic decisions (M = 3.23) [4], [9]. At the University Metropolitan Tirana, AI is placed at the center of organizational decisions where the consequences are broader. Third, there is the empirical result obtained from the ADIS levels. Trust in AI tools and perceived quality differed across levels, with trust increasing from 3.37 at Level 1 (AI-Assisted) to 4.00 at Level 3 (AI-Delegated). On the same 1-5 scale, the frequency of verification decreased from 3.21 to 1.25. Given that trust and frequency of verification are significantly and inversely correlated, the stratum-level gradient is reflected at the individual level (Spearman $\rho = -0.36$, $p = .011$). The empirical findings in this study support what previous literature has characterized theoretically. The risk that organizations may start with augmentation is that they may slide towards automation. This risk is defined as the augmentation-automation paradox, in which a measurable behavioral gradient is observed at the individual level [4]. The mean verification score of 1.25 at Level 3 demonstrates this tendency in contemporary LLM settings [12]. Finally, concerns and perceived risk related to the use of AI tools. Employees continue to trust the results generated by AI systems, despite being aware of the risks. This confirms that AI tools reduce the effort of critical thinking by encouraging excessive reliance [19]. UMT employees are aware of the risks of delegation regardless of their behavior.

VI. CONCLUSION

The study on 57 employees of University Metropolitan Tirana (63.3% response rate) examined the use of AI in their professional decision-making. Reliance on AI rises with the breadth of the decision, peaking on strategic decisions. The three-tier structure of the proposed AI Decision Integration Spectrum (ADIS) is consistent with the observed patterns in the data: trust increases steadily, while verification declines steadily. The contributions offered in this paper are the first survey-based investigation of AI-driven decision-making among university staff in Albania, the ADIS framework as a measurable taxonomy of the augmentation-delegation spectrum, and a replicable survey instrument for application elsewhere. For universities, the findings suggest that AI policies should match the type of decision to the level of AI use allowed [6]. This matters because at UMT, the decisions that carry the highest risk are also the ones most often delegated to AI. For researchers, the ADIS framework offers a replicable tool. The inverse gradient between trust and verification, and the split among administrative staff, can be tested as hypotheses in future comparative work. This study is limited by its single-institution scope, modest sample size, and the size of the Tier 3 group for strong conclusions. Future work should test whether the UMT models generalize to the majority of institutions in the region. This study suggests that AI in decision-making is best understood not as a tool that staff either adopt or resist, but as a gradual transfer of judgment that institutions must learn to recognize, measure, and govern.

Abstract
Emerging technologies such as artificial intelligence, learning analytics, simulation, extended reality, and digital platforms are reshaping how Technical and Vocational Education and Training (TVET) systems design learning, support practice, and assess occupational competence. However, their effective use cannot be explained by technology availability or user acceptance alone. This paper presents a structured, literature-based synthesis of theoretical and pedagogical perspectives on the adoption of emerging technologies in competency-based TVET systems. It argues that adoption should be understood as an alignment issue involving technological affordances, pedagogical design, institutional readiness, and competency-based assessment. Using Zambia's Technical Education, Vocational and Entrepreneurship Training context as an illustrative case, the paper contributes a conceptual alignment framework for analyzing technology-mediated vocational education and future empirical validation.

Keywords: emerging technologies, TVET, TEVET, technology adoption, vocational pedagogy, competency-based assessment

I. INTRODUCTION

Technical and Vocational Education and Training (TVET) plays a central role in preparing learners for employment, entrepreneurship, innovation, and lifelong skills development. Its relevance has become more pronounced as digitalization, automation, and data-driven work practices continue to reshape occupational tasks across different sectors. As workplaces increasingly depend on digital systems, artificial intelligence, automation, data analytics, and networked technologies, vocational education systems are expected to prepare learners not only for existing jobs but also for changing work environments where digital competence, adaptability, problem-solving, and continuous learning form part of technical performance itself [1-3]. Emerging technologies have therefore become an important area of research and policy attention in TVET. In this paper, emerging technologies refer to digital tools and systems whose educational use is still developing, but which have the potential to influence how vocational learning is designed, delivered, supported, and assessed. These include artificial intelligence, learning analytics, simulation technologies, extended reality, digital learning platforms, and other interactive or data-driven learning environments. From a computer science and information systems perspective, these technologies are not simply teaching aids. They are computational and socio-technical systems that mediate access to learning, generate data, support decision-making, structure feedback, and influence how evidence of learning is captured and interpreted. When appropriately designed, emerging technologies can support simulated work practice, personalized feedback, flexible access to learning resources, analytics-informed learner support, digital portfolios, and stronger links between classroom learning and workplace expectations [4], [5]. Recent guidance on artificial intelligence in TVET also emphasizes that AI is increasingly influencing teaching, learning, assessment, learner support, and institutional management, while creating new demands for governance, ethical use, staff capacity, and institutional readiness [6]. However, these

possibilities do not automatically translate into improved occupational competence. A digital platform, simulation tool, or AI-supported system may increase access and learner engagement but still fail to strengthen vocational learning if it is weakly aligned with curriculum outcomes, assessment standards, lecturers' capabilities, institutional infrastructure, or industry expectations. This issue is particularly important in competency-based TVET systems. Vocational education differs from general education because its central concern is not only knowledge acquisition, but the development and verification of occupational competence. Competency-based training requires learners to demonstrate what they can do against defined standards, often in contexts that resemble or connect to real work [7], [8]. For that reason, technology-enhanced learning in TVET must be judged by more than the availability, novelty, or technical sophistication of digital tools. Its value depends on whether it supports credible learning, valid assessment, and meaningful progression towards occupational performance. Existing literature provides useful but partial explanations of this problem. Technology adoption theories explain factors such as perceived usefulness, ease of use, facilitating conditions, user acceptance, and institutional readiness [9]. Socio-technical perspectives show that technologies are shaped by organizational routines, infrastructure, leadership, policy, governance, and quality assurance arrangements [10], [11]. Pedagogical theories such as constructivism, situated learning, and communities of practice explain how learners build knowledge through active engagement, authentic practice, social participation, and guided feedback [12-14]. These perspectives are valuable, but they are often applied separately. As a result, technology integration in TVET is frequently discussed either as a matter of adoption, pedagogy, infrastructure, or assessment, rather than as an alignment problem across these interdependent areas. This separation creates a conceptual gap. In competency-based vocational education, the adoption of emerging technologies is not only a technical or behavioral issue. It is also a pedagogical, institutional, and quality assurance issue. A technology must fit the occupational task, the learner's level of competence, the lecturer's pedagogical capability, the available infrastructure, the assessment model, and the policy environment. Where these elements are misaligned, technology integration may remain fragmented, superficial, or difficult to sustain. This is especially important in resource-constrained contexts, where connectivity, equipment, digital skills, maintenance systems, and funding affect whether emerging technologies can be used equitably and effectively [3], [15]. Recent TVET guidance also warns that AI and related technologies can pose risks to infrastructure, costs, sustainability, capability gaps, governance, equity, and assessment integrity if introduced without sufficient institutional preparation [6]. Although this paper uses the broader international term TVET, the Zambian context provides an important illustration of this wider challenge. In Zambia, the sector is formally referred to as Technical Education, Vocational and Entrepreneurship Training (TEVET), reflecting a national policy orientation that integrates technical, vocational, and entrepreneurship training into a single skills development system [16], [17]. Zambia's TEVET system is shaped by competency-based training, institutional accreditation, open, distance, and flexible learning initiatives, quality assurance expectations, and growing policy attention to digital transformation. These conditions make the Zambian case relevant for examining how emerging technologies can be adopted without weakening the credibility of practical training, assessment, and certification. This paper examines the adoption of emerging technologies in TVET from theoretical and pedagogical perspectives. It is guided by the following research question: What theoretical and pedagogical perspectives explain the adoption of emerging technologies in competency-based TVET systems? The paper does not evaluate a single technology or present empirical field findings. Instead, it provides a structured literature-based synthesis to clarify how different theoretical and pedagogical perspectives explain the adoption and use of emerging technologies in vocational education. The paper's contribution is threefold. First, it compares selected theoretical and pedagogical perspectives relevant to the adoption of emerging technologies in TVET. Second, it identifies the limitations of treating technology adoption, pedagogy, institutional readiness, and assessment as separate issues. Third, it proposes an alignment-oriented synthesis to understand the integration of emerging technologies in competency-based TVET systems, using Zambia's TEVET context to illustrate the practical importance of aligning technological affordances, pedagogical design, institutional readiness, and competency-based assessment.

II. REVIEW METHODOLOGY

This paper adopts a structured literature-based review methodology. It is not presented as a systematic review or meta-analysis because its purpose is not to measure the effects of technology or to exhaustively map all publications in the field. Instead, it synthesizes theoretical and pedagogical perspectives to explain the adoption of emerging technologies in competency-based TVET systems. The review was guided by the question: What theoretical and pedagogical perspectives explain the adoption of emerging technologies in competency-based TVET systems? Literature was identified through Google Scholar, Scopus, ERIC, ScienceDirect, and IEEE Xplore. Additional policy and institutional sources were drawn from international organizations and Zambian TEVET documents where they were directly relevant to digital transformation, vocational learning, competency-based training, or institutional implementation. Search terms included combinations of "emerging technologies", "artificial intelligence", "learning analytics", "simulation", "extended reality", "digital assessment", "technology adoption", "TVET", "vocational education", "competency-based training", "occupational competence", "digital pedagogy", and "institutional readiness". Sources were included where they addressed emerging technologies in TVET or vocational education; explained technology adoption, socio-technical implementation, or institutional readiness; examined vocational pedagogy or competency-based learning; discussed AI, simulation, XR, learning analytics, or digital assessment; or provided relevant TVET or TEVET policy guidance. Foundational theoretical works were retained where they offered key explanatory lenses. At the same time, recent sources from 2024 to 2026 were prioritized because they address current developments in AI, XR, analytics, digital assessment, and technology-supported vocational training. Sources were excluded where they focused only on general education without clear relevance to vocational learning, discussed technology without linking it to pedagogy or competence development, or lacked sufficient conceptual or methodological detail. The analysis was conducted through thematic synthesis. Sources were first grouped according to their main explanatory focus: technology adoption, socio-technical implementation, pedagogical learning theory, teacher knowledge, digital transformation, competency-based assessment, and institutional readiness. Each perspective was then examined in terms of what it explains, what it overlooks, and how it contributes to understanding technology-mediated competence development in TVET. This process led to the four analytical dimensions used in the paper: technological affordances, pedagogical design, institutional readiness, and competency-based assessment.

III. THEORETICAL PERSPECTIVES ON EMERGING TECHNOLOGY ADOPTION

Emerging technology adoption in vocational education is often discussed in terms of infrastructure, digital tools, and willingness to use technology. While these issues are important, they do not fully explain adoption in competency-based TVET systems. In TVET, technology adoption is also shaped by institutional policy, educator capability, assessment requirements, industry expectations, technical support, and the organization of practical learning environments. Recent literature on AI and immersive technologies reinforces this point. AI is increasingly considered in relation to curriculum development, qualifications, labor-market responsiveness, learner support, and assessment [18]. Mixed reality, including virtual and augmented reality, has also shown potential to support behavioral, cognitive, and affective training outcomes in vocational education [19]. However, these technologies raise questions about governance, data quality, transparency, equity, assessment validity, instructional design, and transfer to workplace performance [18], [19]. They should therefore be judged not by innovation value alone, but by how well they support the development of credible competence. Technology adoption models provide an important starting point because they explain factors that influence whether individuals accept and use new systems. The Unified Theory of Acceptance and Use of Technology identifies performance expectancy, effort expectancy, social influence, and facilitating conditions as key determinants of technology use [9]. These factors are relevant to TVET because educators and learners are more likely to use emerging technologies when they perceive them as useful, manageable, and institutionally supported. However, adoption models explain user acceptance more clearly than they explain whether a

technology supports valid occupational learning, aligns with competency standards, or fits the realities of workshops, laboratories, and workplaces.

Socio-technical systems theory provides a broader explanation by treating technology adoption as an interaction between technical tools and social systems. Technologies are not neutral additions to existing practice; they become part of institutional routines, roles, infrastructure, policy arrangements, and quality assurance processes [10], [11]. This is important in TVET, where digital tools must operate within systems of curriculum design, assessment, certification, and industry engagement. A simulation tool, learning analytics dashboard, or AI-supported feedback system may work in a pilot, but fail to scale if institutions do not address connectivity, technical support, staff development, procurement, data protection, and assessment procedures [6], [18]. Activity theory adds a further perspective by explaining tensions that emerge when new tools enter established learning systems. It views human activity as occurring within systems composed of subjects, tools, rules, communities, objects, and divisions of labor [20]. In TVET, the objective of the activity is not simply course completion but occupational competence. Emerging technologies may therefore create contradictions between digital learning and existing rules for assessment, workshop practice, timetabling, institutional support, or workplace supervision [21]. These tensions reveal that implementation depends on how the wider activity system adjusts, not merely on whether users accept the technology. Taken together, these perspectives show that the adoption of emerging technologies in TVET is a multi-level process involving user acceptance, institutional alignment, and implementation tensions. However, they remain incomplete without attention to learning theory, because they do not fully explain how learners develop competence through technology-mediated practice.

IV. PEDAGOGICAL PERSPECTIVES ON EMERGING TECHNOLOGY USE

The theoretical perspectives discussed above explain why user acceptance, institutional systems, and implementation dynamics shape the adoption of emerging technologies. However, adoption alone does not guarantee meaningful learning. In vocational education, the central concern is whether technology helps learners develop, practice, and demonstrate occupational competence. Constructivist learning theory views learning as an active process in which learners construct knowledge through engagement with tasks, tools, problems, and feedback [12]. This aligns with competency-based training, where competence develops through repeated practice, reflection, and improvement rather than through the passive reception of information. Emerging technologies can support this process by enabling learners to manipulate digital objects, test decisions, correct errors, and receive timely feedback. Simulation environments, AI-supported practice tasks, and interactive platforms are therefore useful only when designed around meaningful learner activity rather than simple content delivery. Situated learning is also important because vocational competence is closely connected to context. Learners need to apply knowledge in situations that resemble real occupational practice [13]. This perspective is relevant for virtual reality, augmented reality, mixed reality, digital twins, and work-based learning platforms. Recent evidence suggests that immersive technologies can support training outcomes, but their value depends on instructional design and connection to training goals [19]. A simulation that appears realistic but is poorly aligned with occupational standards may engage learners without developing valid competence. Communities of practice, connectivism, and TPACK add social, networked, and teacher-focused dimensions. Vocational learning often takes place through interaction with peers, lecturers, workplace supervisors, and practitioners [14]. Digital portfolios, online collaboration, remote mentoring, and peer feedback can extend these interactions, while connectivism highlights the need for learners to navigate changing networks of people, information, and digital systems [22], [23]. However, access to information is not the same as competence; learners still require structured practice, guided feedback, and performance against standards. TPACK further shows that effective integration requires the interaction of technological, pedagogical, and content knowledge [24]. In TVET, this means lecturers need to understand not only how a tool works but also how it supports a specific vocational task, learning outcome, and assessment requirement.

Recent guidance on AI in TVET reinforces this pedagogical concern by emphasizing educational purpose, human agency, equity, safety, and responsible institutional practice [6]. AI should support the lecturer's judgment and practical training rather than replace them. Learning analytics may identify learner difficulties, and automated feedback may support formative learning, but neither confirms occupational competence without valid assessment criteria and human oversight. Taken together, these perspectives show that emerging technologies should not be judged by novelty or technical sophistication alone. Their usefulness depends on whether they support active learning, authentic practice, social participation, guided feedback, lecturer capability, and valid evidence of competence.

V. SYNTHESIS OF THEORETICAL AND PEDAGOGICAL PERSPECTIVES

The reviewed literature shows that a single theory cannot adequately explain the adoption of emerging technologies in TVET. Adoption models explain why educators and learners may accept or resist technology, but they say less about the quality of vocational learning that follows. Socio-technical perspectives explain the relationship among tools, institutions, and organizational routines, but they do not fully account for how learners develop occupational competence. Pedagogical theories explain learning processes, but they are often less explicit about infrastructure, policy, quality assurance, and institutional readiness. A more useful explanation, therefore, emerges when these perspectives are considered together. The synthesis developed in this paper positions the adoption of emerging technologies in TVET as an alignment issue. In competency-based vocational education, digital tools should not be judged solely by their availability, novelty, or technical sophistication. Their value depends on how well they align with pedagogical design, institutional readiness, and competency-based assessment. This alignment is especially important for technologies such as artificial intelligence, learning analytics, simulation, extended reality, and digital platforms, because these systems may influence not only teaching and learning but also feedback, learner support, evidence generation, and assessment decisions [6], [18], [19].

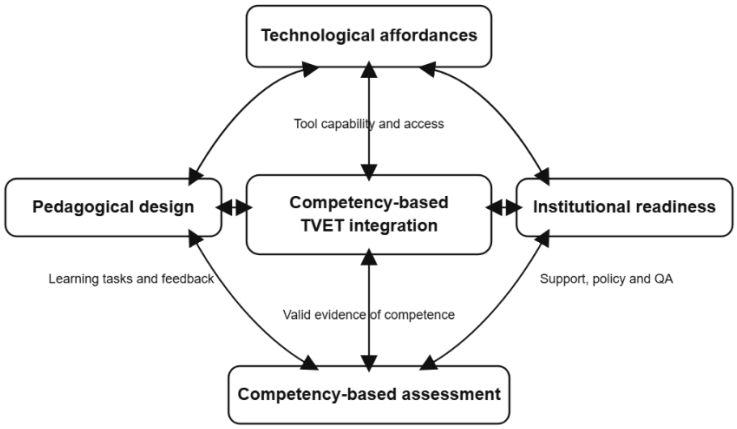

Figure 1. Conceptual alignment framework for emerging technology adoption in TVET

The synthesis is further summarized in Table 1.

Table 1. Dimensions For Analyzing Emerging Technology Adoption In TVET

Dimension	Main focus	Contribution to TVET	Risk if weakly aligned

Technological affordances	Tool maturity, accessibility, functionality, and educational usefulness	Supports practice, feedback, simulation, learner support, and evidence capture	Novelty is prioritized over competence
Pedagogical design	Learning tasks, feedback, authentic participation, and lecturer mediation	Links technology to active, situated, and competence-oriented learning	Engagement does not translate into occupational skill
Institutional readiness	Infrastructure, leadership, staffing, technical support, policy, and quality assurance	Enables implementation, scaling, maintenance, and sustainability	Pilots fail because support systems are weak
Competency-based assessment	Occupational standards, performance evidence, assessment validity, and certification credibility	Links digital learning to a credible demonstration of competence	Platform activity is mistaken for occupational performance

Table 1 shows that each dimension contributes to technology integration, but also introduces risks when weakly aligned. Technological affordances matter because tools must support practical skill development, feedback, and evidence capture rather than novelty alone. Pedagogical design matters because digital tools only strengthen TVET when they support active, situated, and competence-oriented learning. Institutional readiness matters because technologies require infrastructure, leadership, technical support, staff development, and quality assurance to move beyond pilots. Competency-based assessment matters because platform activity, simulation completion, or AI-generated feedback cannot be treated as evidence of competence unless linked to valid occupational standards and performance evidence. The framework, therefore, shifts the discussion from technology adoption to technology integration for competence. The Zambian TEVET context reinforces this wider lesson. Because TEVET combines technical, vocational, and entrepreneurship training, technology adoption should support not only the acquisition of technical skills but also problem-solving, innovation, employability, and credible assessment. Emerging technologies are therefore most useful when they strengthen the relationship between learning tasks, occupational standards, institutional support, and evidence of competence [16], [17].

VI. DISCUSSION AND IMPLICATIONS

The synthesis presented in this paper suggests that the adoption of emerging technologies in TVET should be understood as a process of educational, technical, and institutional alignment. The central issue is not whether a technology is modern or available, but whether it supports credible skills development within a competency-based system. Adoption decisions should therefore begin with occupational tasks, learning outcomes, and assessment requirements before moving to tools and platforms. Different types of digitalization contribute to TVET in different ways. Digital learning platforms support access to content, communication, and flexible delivery; learning analytics can support learner tracking and early intervention; simulation and extended reality can support practical rehearsal and safe experimentation; and artificial intelligence can support feedback, adaptive learning, resource development, and learner support. However, each technology also introduces risks. Platforms may encourage content delivery without practice; analytics may produce data without meaningful pedagogical interpretation; simulations may appear authentic without matching occupational standards; and AI may generate outputs that require human verification and ethical oversight.

For institutions, pedagogy and assessment, emerging technologies should not be treated as isolated classroom innovations or equipment projects. Their value depends on whether they meet curriculum requirements,

lecturers' capabilities, workshop routines, learners' needs, technical support, and quality assurance arrangements [10], [11]. They should extend rather than replace vocational teaching, workshop practice, and workplace learning. Digital activity should also not be mistaken for occupational performance. Assessment in technology-mediated TVET should still focus on valid evidence of competence, including practical observation, digital portfolios, simulation records, workplace evidence, and lecturer judgment. Where AI or analytics are used, human oversight, transparency, and accountability remain necessary [6], [18]. The Zambian TEVET context illustrates these implications because institutions operate within a system shaped by competency-based training, institutional accreditation, quality assurance, and open, distance, and flexible learning. Emerging technologies should therefore support the credibility of practical training and assessment, rather than simply expanding digital access. For Zambia and similar contexts, the priority is purposeful integration of selected technologies that strengthen learning, inclusion, lecturer support, institutional capacity, and evidence of competence. The proposed framework should be understood as a conceptual and literature-derived synthesis rather than an empirically validated model. Future research should test and refine it using evidence from learners, lecturers, institutional leaders, technical support staff, regulators, and industry partners. Further studies should also examine how AI-supported feedback, learning analytics, simulation, and extended reality affect lecturer readiness, learner experience, assessment validity, cost, sustainability, and transfer to workplace performance.

VII. CONCLUSION

This paper examined the adoption of emerging technologies in TVET from theoretical and pedagogical perspectives. It argued that adoption cannot be understood only as the introduction or acceptance of digital tools. In competency-based vocational education, emerging technologies must be judged by how well they support learning design, institutional implementation, and valid demonstration of occupational competence. The main contribution of the paper is the argument that the adoption of emerging technologies in TVET should be understood as an alignment issue involving technological affordances, pedagogical design, institutional readiness, and competency-based assessment. For TVET systems, including Zambia's TEVET context, digital transformation should begin with the question of which competencies learners are expected to develop, how they will be taught, how they will be assessed, and what institutional conditions are needed to support implementation. Future empirical research should test the framework in specific TVET and TEVET contexts to establish how emerging technologies can strengthen the development of credible competence.

ACKNOWLEDGEMENT

Abstract
The Traveling Tournament Problem is NP-hard, meaning it cannot be solved in polynomial time. For these problems, metaheuristics often provide usable alternatives. These algorithms, however, need one or more valid initial solutions, and as it stands, there is no algorithm to supply them admissibly. In this paper, we explore whether a randomized backtracking algorithm could provide uniform random initial solutions to facilitate the deployment of metaheuristics to the TTP.

Keywords: Traveling Tournament Problem, Sampling Algorithms, Metaheuristics

I. INTRODUCTION

The Traveling Tournament Problem (TTP) involves organizing a tournament among an even number of teams (n_{teams}) on a fixed schedule of $2 \cdot n_{teams} - 2$ rounds (see Figure 1). In the tournament, each team must face every other team exactly twice — once at home and once away — a pattern known as the **double round-robin constraint**.

A second constraint concerns the teams' itineraries: the **maxStreak** condition limits the number of consecutive home or away games a team may play. The standard setting is maxStreak = 3, meaning a team cannot play more than three consecutive home or away games [1].

In addition, the schedule must satisfy the **noRepeat** constraint. If team A plays team B in a given round, the reverse fixture (B hosting A) is not allowed to occur in the immediately following round. This constraint can be generalized to a parameterized form, denoted as noRepeat = n, meaning that a rematch in reversed home/away order must be separated by at least n rounds [2]. Still, in nearly all existing literature, as in this study, this parameter is set to noRepeat = 1.

The objective of the TTP is to construct a schedule that minimizes the total distance traveled by all teams [3]. The problem is NP-hard [4], implying that unless P = NP, which is very unlikely [5], no polynomial-time exact algorithm is currently known and is unlikely to exist. This in itself is bad for problem-solving objectives, but the TTP has an even more pernicious characteristic: it cannot be sampled. This is bad. Other NP-hard problems, like the partition problem [6–8] or the traveling salesman problem [9], [10], can to some degree be solved by metaheuristics, a class of algorithms that run in “anytime complexity,” meaning the user can start, stop, or pause the algorithmic run at any time and take the current solution as definitive. This is a good alternative to the inadmissibility of exponential-time exact algorithms, but the drawback is that metaheuristic algorithms offer no guarantee of solution quality. But generally speaking, solutions get better as the algorithm runs longer, and outcomes for many problem instances are reasonably good.

Figure 1. **Left:** A valid 4-team TTP tournament. **Right:** An invalid TTP tournament, having a noRepeat violation in column 3, a maxStreak = 3 violation in column 2, and doubleRoundRobin violations in rounds (rows) 2, 3, and 4.

For many practical applications, however, these metaheuristic algorithms are a blessing, as their solution quality, though not perfectly optimal, is still much better than any non-computational performance. But metaheuristic algorithms also have a few modest operational requirements. Before starting the run, one or more valid initial solutions to improve upon must be provided. To this end, the algorithm needs a sampling method that produces valid initial solutions, preferably uniformly sampled from the solution space, to avoid biasing the subsequent run. Second, one needs a mutation operator that mutates one valid solution into another and, ideally, also connects all valid solutions into a single large neighborhood while running in polynomial time [2]. A third, optional requirement is a crossover operator that combines two valid individuals to produce a new valid individual. As it turns out, the traveling tournament problem has none of these. Despite a large number of metaheuristic applications on the TTP (see Section 2 in Hassel et al. [2]), none of the studies present an admissible method for sampling, mutation, or crossover operators. In this paper, we will introduce a new sampling approach to the problem and quantify the uniformity of its outcomes. We tentatively define an **admissible sampling method** to

1. Pick one valid solution from the set of all possible solutions to a problem with uniform probability;
2. run in deterministic polynomial time.

At the current state of technology, an admissible sampling method for the traveling tournament appears not to exist. An alternative, however, can be provided by constructive algorithms such as the polygon method [11] or the improvement thereof reported by Nakahata et al. [12]. Both of these algorithms run in deterministic polynomial time and produce only valid schedules, but the outcomes are exclusively *regular*, thereby representing only a tiny region of the solution space.

An alternative is the “rows-first” method, which uniformly generates random matchups for one round after another. Upon its inception, this method was expected to produce uniform samples; in this paper, we will, for the first time, provide evidence that it indeed does (see Section 3 and Figure 2).

Rows-first has a counterpart method in “columns-first”, which generates a full match list for one team (or “column” in the schedule of Figure 1). The advantage of this method over rows-first is that it eliminates half of the noRepeat violations, as reported in Verduin et al. [13]. Still, these authors appear to forget that although the number of violations drops for known constraints, the columns-first method also introduces a *new* type of constraint violation: mismatched teams within a single round.

Although rows-first and columns-first themselves run in deterministic linear time, the produced schedules do contain violations. Once we require *valid* schedules from the algorithm, forcing it to resample whenever an invalid solution is reached, it runs something that looks like stochastic exponential time [14]. We won't provide evidence for this observation; instead, we offer a budget comparison by matchup as a suggestion for future quantitative studies. We also suggest a way of measuring the uniformity of the outcomes.

As a last novelty, we introduce “randomized backtracking,” a new sampling algorithm for the traveling tournament problem. It is a depth-first recursive algorithm based on row-first, but backtracks upon constraint violations. Even though backtracking sampling could be easily considered inadmissible, as it runs in deterministic exponential time (or even deterministic factorial time for some problems), it might not be in practice. This observation, and its sample distribution, make it a surprising addition to the almost empty library of sampling methods for the traveling tournament problem.

The rest of this paper is organized as follows: in the Methods section, we introduce the randomized backtracker and the rows-first algorithm, as well as the methods used to measure performance and assess the uniformity of the resulting distribution. The results are presented in the third section, after which we will discuss the not-so-trivial outcomes in the closing section.

II. METHOD

In this section, we describe two different methods for sampling schedules for nteams = 4, propose a method for measuring uniformity, and provide a way to compare runtimes. First, we sample valid half-normalized TTP schedules with the randomized backtracking algorithm described in [15]. “Half-normalized” in this sense means the first row is always filled out with matchups (1,2) and (3,4) as a method for breaking rotational and permutational symmetry.

The randomized backtracking algorithm recursively places randomized matchups in rows 2, 2, 3, 3, 4, ..., 2(n − 1), checking at each step whether any constraints are violated or will be violated in the future. For example, if all remaining games for a given team are home games, a maxStreak violation is unavoidable. Whenever this happens, the algorithm backtracks immediately, removes the most recently placed matchup from the schedule, and instead tries the next matchup in the randomized list. This process continues until a valid schedule is found (see pseudocode in Algorithm 1).

Algorithm 1 The procedure **DFS-Sampler** recursively tries adding matchups to the current permutation of the schedule. Whenever a constraint is violated it backtracks and tries different matchup, until a valid schedules is found.

```
procedure DFS-SAMPLER(schedule, matchups)
    if schedule is complete then
        return
    end if

    for all m in matchups do
        if CHECKCONSTRAINTS(schedule, m, matchups) then
            continue
        end if

        schedule.append(m)
        matchups.remove(m)                          ▷ Updating current state

        DFS-SAMPLER(schedule, matchups)             ▷ Recursive call

        schedule.remove(m)
        matchups.insert(m)                          ▷ Revert to previous state
    end for
end procedure
```

We are sure the algorithm halts, as it is randomized only in its traversal order and thus remains exhaustive over the huge but finite search space. We are also sure that a valid solution exists, because the TTP with n_teams = 4 has recently been shown to have 160 valid half-normalized schedules [15], [16]. As a final technical note, a new random matchup list is created for each schedule.

Second, we sample valid TTP solutions with a slightly adapted version of rows-first. Like Verduin's classic version [13], the algorithm generates randomized matchups for each row, but immediately terminates whenever a placed matchup violates a constraint and starts anew. This effectively means that a valid schedule will be found only if the randomized matchup lists for each consecutive round do not violate any constraints. This algorithm terminates only stochastically, but in theory, it could run forever without encountering a valid solution. This never happened; however, we sampled 100,000 valid half-normalized schedules for both methods and counted the multiplicity of each unique valid schedule, yielding a frequency histogram (Figure resultsuniform). To determine whether these samples follow a uniformly random distribution, we used Pearson's chi-squared test [17] for an assumed uniform distribution of #samples / #unique schedules = 10^5 / 160 = 625 samples per unique schedule, and calculated p-values. For Pearson’s chi-squared test, we used the default significance level of 5%, as there was no compelling reason to deviate from this.

III. RESULTS

It turns out that the randomized backtracking method does not uniformly randomly sample valid schedules at all (Figure 2). Pearson's chi-squared test confirms this with p ≈ = 0.0 for the uniform distribution. Moreover, the most and least frequently sampled schedules occur 59 and 2,027 times, respectively, illustrating the tremendous non-uniformity of the proposed algorithm. To find these 100,000 schedules, the randomized backtracker required approximately 70.5 placements per schedule, or 7,045,027 placements in total, which, in our implementation, took only a few seconds on 128 cores.

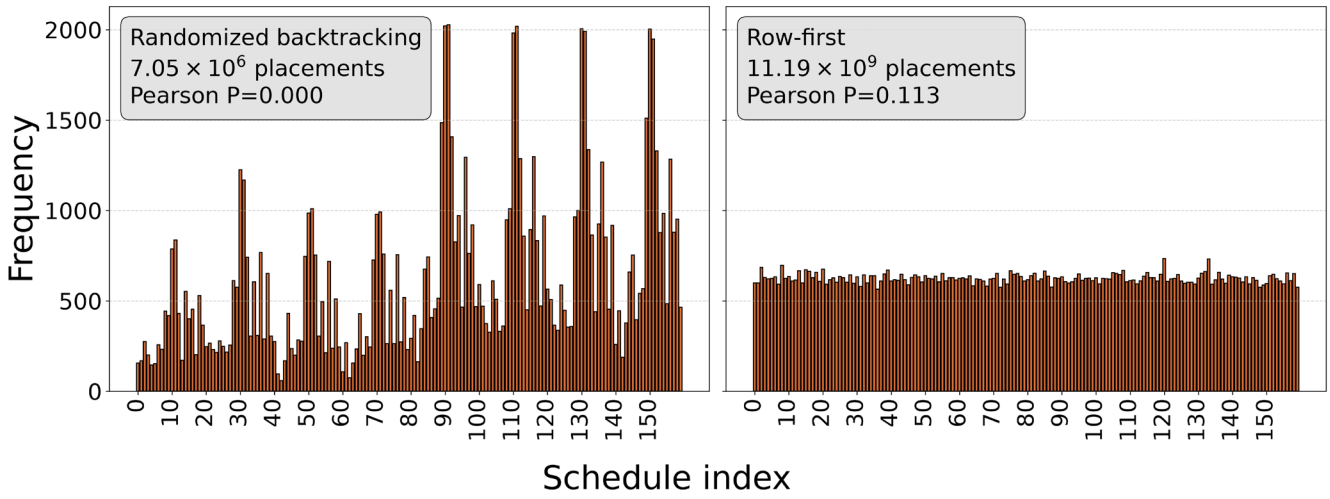

Figure 2. Frequency of results for the generation of 100,000 valid TTP-schedules of size $nteams = 4$ by two algorithms. On the right, the rows-first algorithm yields an almost uniform distribution, whereas the randomized backtracking yields an erratic distribution. Schedule indices on the horizontal axes are the same in both subfigures.

We also ran the randomized backtracker on 8 nodes, each with 128 cores, for nteams = 6, producing 100 million schedules in approximately 2 minutes. For $n_{teams} = 8$, 100 million schedules were found in approximately 3 hours on the same system. These results, however, could not be used in this study for two reasons: first, the problem has 54,427,728 valid schedules for $n_{teams} = 6$, and presumably several billion for $n_{teams} = 8$. These numbers are too large to save to disk comfortably, let alone use to construct a useful histogram. We do, however, report that while exploring the options for this study, we found 702,960,132 unique valid schedules for $n_{teams} = 8$, which is a new lower bound. Second, rows-first did not find a single valid schedule for $n_{teams} = 6$ or $n_{teams} = 8$ in 8 hours on 8 nodes, each with 128 cores, making a distribution comparison impossible. Finding not even a single valid solution for such small instance sizes paints a very bleak future for this approach to TTP sampling, even though it is uniform.

For rows-first sampling, the distribution outcome was quite different. All samples occur roughly #samples / #unique schedules = 10^5 / 160 = 625 times, which is the number we would expect under a uniform distribution. Pearson's chi-squared test confirms that the sample frequencies follow a uniform distribution, with p ≈ = 0.113. The most frequently sampled schedule was seen 735 times, while the least frequently sampled schedule occurred 565 times. When constraint violations are ignored, rows-first runs in linear time. Still, when restarting upon invalid schedules, rows-first requires at least 11,194,726,501 matchup placements distributed across 4,464,072,865 restarts, averaging approximately 2.51 placements per restart, to generate these 100,000 samples. This process took approximately 3 minutes, but with an average of 11,195 matchup placements to

obtain one valid schedule, it is approximately 156 times more expensive than randomized backtracking — and that fraction might grow for higher numbers of n teams.

IV. CONCLUSION & DISCUSSION

The observations in this study turn the TTP's sampling problem on its head. First of all, it seems we have finally found a way to uniformly and randomly sample TTP solutions. Rows-first does the job, but, weirdly enough, despite its "linearity," it takes much more time than the randomized backtracker, which is naturally exponential in complexity. The big question is how these algorithms scale, but because rows-first returned zero results for n_teams = 6 and n_teams = 8, this does not exactly look appealing. However, there is still room for improvement in this method, such as checking before placing or evaluating certain constraint violations (e.g., DRR) only after completion of the schedule. For random backtracking, there might also be ways forward. Even though it does not appear to produce uniform solutions, it does yield solutions with some degree of randomness, which could be seen as an improvement over previous work by DeWerra and Nakahata [11], [12]. But their methods run in linear time, and random backtracking theoretically does not, so the real question is how it scales in time. Regarding the non-uniformity of the results (Figure 2), it is worth noting that the order of schedules might not be preserved across trials. In other words, if we generate a million schedules twice, the most frequent schedule might not be the same in both trials, even though the distributions are nearly identical. At this point, however, this is a mere suspicion, and rigorous testing into these and other details of the distribution should clarify the matter. Two other aspects warrant further inspection. First of all, it might be possible to correct the non-uniformity in some formulaic way. Second, the row order for matchup placement, 2, 2, 3, 3, ..., 5, 6, 6 in this study, might also be randomized. The effects on runtime, measured in matchup placements or wall-clock time, and on uniformity, as calculated using Pearson's correlation coefficient, are of interest. But the weirdest suggestion this study makes is that sampling algorithms might "switch sides", from polynomial to exponential or the other way around, when used for random sampling. Furthermore, it could be true that uniformity comes at the cost of once-linear-now-exponential time complexity, while relinquishing that property might reward the programmer with an exponential-time algorithm behaving polynomially. Finally, reviewers of IHCONCS suggested hybrid reinforcement learning [18], deep generative neural networks, and diffusion models to avoid constraint violations. This is a deluge of ideas whose merit should be investigated in future work.

Abstract
This work explores the complete process of educational research in the computer sciences, beginning with classroom-based inquiry in elementary schools and extending through data collection, statistical processing, and analysis. It provides a practical overview of how raw observations are transformed into meaningful insights, highlighting methodologies, tools, and best practices for conducting and interpreting research in educational settings. In this chapter, we follow a research case study from start to finish. From preparation (including software development) and data collection to data analysis and conclusion derivation, we experience the entire research process. What is unique about this chapter is that we address the "unwritten" aspects of field research, including difficulties and challenging situations, and how we addressed them.

Keywords: seducation, text management, digital waste, field research, statistical analysis

I. INTRODUCTION

Digital text management (DTM) is one of the most common activities in the digital world. Yet it is often misinterpreted as synonymous with word processing, learning, teaching [1], and the use of word processors [2]. This misconception is reinforced by assumptions that everyone can perform these tasks without prior knowledge [3], that software tools alone provide sufficient problem-solving skills [4], [5], and that digital immigrants cannot teach digital-born students [6], [7], [8]. Schools often treat DTM as one of the simplest digital activities (e.g, [9]), overlooking both the cognitive load it entails [10], [11], [12] and the need to assess the effectiveness of students and teachers [13], [14]. In practice, digital texts (DTs) collected from students, teachers, and the internet reveal widespread inefficiencies, leading to substantial, often unnoticed waste in the form of ineffective use of time and resources [15], [16]. As Wolfram ([17] p.272) observes, "with no effective, general education in computational thinking, most people can easily be misled, and they are." Today's communication often resembles "computational grunts, not a universal computational language" [8]. The complexity of DTs, the limitations of working memory, and systemic distortions such as cascade noise, group noise, and group polarisation can allow errors to go unnoticed and uncorrected, thereby multiplying waste [18]. Contributing factors include folk-pedagogy [19], teachers' belief in the fixed nature of science [20], the denial of ignorance [18], and the Dunning–Kruger effect [21]. Addressing these problems [16] requires establishing standards in DTM. In other domains, such as production, services, construction, or administration, the lack of standards is recognized as a major source of waste and a barrier to development [22], [23]. Our research group has compiled resources to support standardization and digital sustainability in DTM, thereby improving learning and teaching processes, end-user activities, and the quality of digital artifacts [24]. To put these resources into practice, we designed a field research experiment to examine their applicability in real educational and professional contexts. The experiment was conducted with multiple groups of participants to gain insight into diverse perspectives on DTM standardization. By observing authentic work processes, we wanted to evaluate both user-friendliness and performance impact. This approach allows us to link theoretical concepts with the practical experiences of

professionals. In the next section, we present the methodology and key findings of the field research. We describe our field research, particularly the experiment we conducted across several communities. We focus on our field research methods, developed software, and methodological analysis, with a focus on challenging situations.

II. THE EXPERIMENT

1. Preparation

Our experiment began with the idea of a text management task and the measurement of people's ability to solve it. But how should we measure these abilities? First, we needed a method to obtain analyzable data from the measurements. For this purpose, the logging software Atomic Natural Language Input Tracker Application (ANLITA) was developed [25], which stored data collected on the computer while participants solved text management tasks. A log file recorded all mouse clicks and keystrokes, while a video file of the entire activity was created. In addition, the participants saved all the work they had done on document files. Developing the software was time-consuming, but it was worth the effort. With the ANLITA tool, we can make the field research data calculable, comparable, and analyzable.

2. Collecting data

Our field research consisted of two tasks across four documents. Each task was to be done twice: Once in an erroneous document and once in a properly edited document. The experiment was conducted in Hungarian, but it is language-independent, i.e., it can be adapted to any language. The participants came from several institutions, including teachers, administrative staff, professors, and students (both teenagers and older adults) [26]. The four documents given contained texts arranged in different ways. In Task 1, the provided document contains various errors, the most significant of which are layout errors [24]. In contrast to the erroneous document, the properly edited document contained no unnecessary spaces or carriage return characters. The first task was to add a specified expression – 13 characters – into the indicated paragraph. It was ensured that this modification would not disrupt the text's arrangement in the erroneous document. The participants had to rearrange the text using a method of their choice to make it appear well-arranged and free of layout errors. This task had to be performed in both erroneous and well-structured documents. The second task was to change the font size of the specified text. Here, too, care was taken to ensure that changing the font size in the poorly structured document would not destroy its structure. Participants again had to achieve a properly edited text as the solution to the task. This task was also repeated in the well-structured document. If a participant completed all four tasks, four document files were saved. In addition, the ANLITA software generated a log file containing all the participant's mouse and keyboard activity during the tasks, as well as a video file of the participant's on-screen activity.

III. HANDLING DATA

To capture the dynamics of human-computer interaction, we used ANLITA, our self-developed software platform. ANLITA records keyboard presses and mouse clicks with millisecond accuracy, while simultaneously generating screen video recordings. By combining discrete event logs with continuous visual context, the system creates a rich record of both user input and its immediate effect on the screen. Each event is automatically assigned a unique timestamp, which serves as the basis for synchronizing the different data streams. Because distinct subsystems generate the input logs and video recordings, synchronization is essential. ANLITA embeds reference timestamps directly into the video metadata, enabling input events to be precisely aligned with screen frames. This means that a keystroke or mouse click can be directly mapped to the corresponding visual change

on the display. The synchronized dataset thus enables a detailed reconstruction of the temporal relationship between actions and outcomes. Once collected and aligned, the data is imported into a relational database designed to handle both event-level precision and higher-level queries. The structure is organized around three central components: Events Table: time-stamped keyboard and mouse events, including key codes and cursor positions, Video Metadata Table: references to screen recordings, with frame indices and timestamps for alignment, and a Session Table: contextual information such as session identifiers, user details (if available), and experimental conditions. This schema ensures that individual actions can be linked seamlessly to broader interaction patterns, while also supporting efficient statistical analysis across multiple sessions. Before the data is ready for analysis, several preprocessing steps are applied. First, noise filtering removes incomplete or spurious input events. Next, normalization converts event codes and cursor coordinates into standardized formats. Data is then segmented into meaningful units, such as task phases or fixed time windows, depending on the analytical focus. Finally, aggregated features are computed, including typing speed, click frequency, and idle durations, providing higher-level descriptors that complement the raw event streams. Together, these steps transform raw logs and video data into a structured dataset that is both comprehensive and statistically tractable, forming the foundation for deeper analyses of user behavior and interaction dynamics.

1. Missing data

Dealing with missing data is one of the most difficult challenges in statistical analysis. We wanted to ensure not only a quantitative but also a qualitative analysis of the data collected. For this reason, the ANLITA software package was developed to generate six different output types for all participants:

Task 1: output word file, erroneous document, typing task
Task 2 output word file, erroneous document, font size task
Task 3: output word file, correct document, typing task
Task 4 output word file, correct document, font size task

Logfile containing all keyboard and mouse activities for all tasks

Video file containing everything seen on the monitor while the participant worked on the tasks

In the best-case scenario, each participant generated all six output files. Since our goal was to understand how participants worked, recording their activities on video was crucial for revealing their problem-solving strategies. The logfile contains data on each participant's keyboard and mouse activity. All logfiles combined built the basis for our statistical analysis. Figure 6 shows an extract from such a logfile.

If a participant ended the video recording prematurely or did not start it at all, we did not use that participant’s results. Unfortunately, this method led to some data loss. On the other hand, this ensured that we had a qualitative assignment for each piece of data evaluated. The video recordings had to be viewed manually, one by one, which was very time-consuming but ensured the quality of our results.

IV. ANALYZING DATA

1. SOLO categories

To analyze and correctly classify our results, we use the Structure of the Observed Learning Outcomes (SOLO) categories introduced by Biggs and Collis [27]. The following SOLO categories are used: Prestructural,

Unistructural, Multistructural, Relational, and Extended Abstract. We modified the definitions of each category to ensure they were perfectly tailored to our experiment. First, we needed to categorize the actions that occurred (or should have occurred) while solving the tasks. Table 1 gives the notation of each step.

Table 1..Description of actions in the erroneous/correct document

Action	Description
A	Correcting errors before typing/changing font size
B	Typing / Setting font size
C	Handling multiple Space characters
D	Handling end-of-line Enter characters.
E	Setting left indentation
F	Unnecessary steps (e.g., type – delete – type again)

A different definition of the categories was needed for the solutions on the correct documents (Table 2) and on the erroneous documents (Table 3). For the definitions, we use the usual logical operators AND, OR, and NOT to combine the actions described in Table 1. When working on the correct documents in Task 3, the highest category achieved was 'Unistructural', whereas in Task 4 it was 'Multistructural'.

Table 2. SOLO categories for the correct documents

Category	Description
Prestructural	OR(B,E)
Unistructural	AND(B, NOT(E))
Multistructural	AND(B, NOT(E), F)

In the erroneous documents, more work should have been done. In the optimal case, a participant corrected the errors in the document before they started modifying the text. Therefore, step A is crucial for the highest category 'Extended abstract', as can be seen in Table 3.

Table 3. SOLO categories for the erroneous documents

Category	Description
Prestructural	OR(B, C, D, E)
Unistructural	OR(AND(B, C), AND(B, D), AND(B, E), AND(C, D, E))
Multistructural	OR(AND(B, C, D), AND(B, C, E), AND(B, D, E), AND(C, D, E)
Relational	AND(B, C, D, E, NOT(F))
Extended abstract	AND(A, B, C, D, E, NOT(F))

The SOLO categories help classify the quality of solutions, since, e.g., pushing 10 keyboard presses can lead to a good solution or may not solve a task. To classify each participant's SOLO category, it was crucial to watch

and analyze the videos on the screen. This was time-consuming, but it ensured that the quantitative data were combined with the qualitative characteristics of the solutions.

2. Statistical analysis

The analysis was conducted by carefully examining six output files, each providing unique insights into the participants' work. Wherever possible, automated tools were used to verify the accuracy of the Word documents, identify SOLO categories, and calculate and categorize keystroke and mouse-click counts. However, the numbers alone did not paint a complete picture. To complete the picture, we also used video recordings that revealed finer aspects of performance: whether the "Show/Hide" button was activated at the beginning, how the selection was made - by dragging with the mouse or by more efficient double or triple clicking - and in what order errors were identified and corrected. These details provided valuable insights into the level of understanding and the problem-solving strategies in practice [26]. When examining the patterns contained in the data, we started with simple but effective techniques: counting, calculating averages, and observing deviations. From there, we moved on to more complex areas to compare the work of participants divided into groups. This allowed us to examine not only how much time they spent on the tasks and how they used the keyboard and mouse, but also how they handled errors and which problem-solving strategies they used. Several tools were needed to tie these threads together: Microsoft Excel, SPSS, and R for statistical analysis; video editing software for observing subtle behaviors; and custom applications developed specifically for this study. Together, these methods provided a comprehensive and nuanced picture of how participants solved the tasks, striking a balance between quantitative accuracy and qualitative insight.

V. RESULTS

In this section, we summarise our key findings regarding participants' text management skills and problem-solving strategies. We focus on facts that directly and significantly impact business solutions and affect numerous companies worldwide, as word processing and text-editing skills are important in all types of business communication. In this chapter, we focus on the data we collected in two schools, where participants were divided into three (similar) groups: Grade 7, Grade 8, and Teachers. The results of our statistical analyses are discussed in detail in the research articles [26], [28], and [29]. For our purposes, we will focus on the most meaningful results, both qualitative and quantitative.

1. Qualitative results

Table 4 shows the changes in the participants' SOLO categories between Task 1 and Task 3. As described in Section II, this meant that the same task had to be solved once in a poorly formatted document (Task 1) and once in a well-formatted document (Task 3). The results show that Task 3 imposed a lower cognitive load, leading many participants to produce solutions of much higher quality.

Table 4. Changes in SOLO Categories Task 1 (erroneous) vs Task 3 (correct) typing task

	School 1		**School 2**	
Category	Task 1	Task 3	Task 1	Task 3
P	42.6%	7.9%	48.5%	9.7%
U	44.6%	92.1%	45.2%	90.3%
M	12.9%	—	6,5%	—
R	0.0%	—	0.0%	—
E	0.0%	—	0.0%	—

When examining the changes in SOLO categories between Task 2 and Task 4 – the same font-size task was solved in an erroneous document and then in a correct document (see Section II) – we find a similar pattern, as shown in Table 5. The correct document required less cognitive effort from the participants, as indicated by the relatively low SOLO category levels observed and the higher number of participants achieving better results.

Table 5. Changes in SOLO Categories Task 2 vs Task 4 fontsize setting task

	School 1		**School 2**	
Category	Task 2	Task 4	Task 2	Task 4
P	29.7%	24.8%	26.9%	18.3%
U	42.6%	75.2%	63.4%	81.7%
M	25.7%	0.0%	9.7%	0.0%
R	2.0%	—	0.0%	—
E	0.0%	—	0.0%	—

Another spectacular result is the time saved when working on a well-organized document rather than an erroneous one. Tables 6 and 7 show the differences in average time across groups.

Table 6. Comparison of the average time for Task 1 (err.) vs Task 3 (correct) typing task

	School 1		**School 2**	
	Task 1	**Task 3**	**Task 1**	**Task 3**
Grade 7	154.86 sec	37.14 sec	247.48 sec	53.39 sec
Grade 8	160.16 sec	46.08 sec	187.84 sec	46.59 sec
Teachers	219.82 sec	59.18 sec	167.96 sec	43.96 sec

Table 7. Comparison of the average time Task 2 (err.) vs Task 4 (correct) fontsize setting task

	School 1		School 2	
	Task 2	**Task 4**	**Task 2**	**Task 4**
Grade 7	148.28 sec	52.00 sec	183.94 sec	48.82 sec
Grade 8	138.78 sec	48.95 sec	143.32 sec	62.65 sec
Teachers	160.86 sec	63.32 sec	152.89 sec	51.30 sec

These tables show that all groups in both schools spent much less time on the correct documents (Tasks 3 and 4) than on the erroneous ones (Tasks 1 and 2). Furthermore, the reduction consistently ranged from 60% to 78%.

Considering both the quantitative and qualitative results, we must note that, beyond the documents that required more time, the participants did not complete the tasks in them. None of the participants reached the SOLO categories R or E, which are considered completed. The difference between these two SOLO categories is the effectiveness of the selected problem-solving approach. On the other hand, in the correct documents, the cognitive load imposed on the participants is much lower. This is expressed in the highest SOLO categories. The Unistructural SOLO category indicates that only one aspect of the problem must be recognized, and that is enough to solve the problem. In the font-size task, the highest SOLO category is Multistructural, indicating a more effective solution than Unistructural. It is also remarkable that teachers were not performing better than their students. This implies that teachers lack the level of computational thinking required to develop students' computational thinking skills effectively. This finding indicates that, to develop students' skills, teachers should first be taught to develop their own. However, addressing this problem is beyond the scope of the present paper, which aims only to call attention to it.

VI. CONCLUSION

The research outlined has shown that digital text management, often trivialized as a mere matter of formatting or typing proficiency, is, in fact, a complex cognitive and methodological challenge with far-reaching implications. By following the process from software development through data collection to statistical and qualitative analysis, we not only uncovered how individuals interact with digital texts but also revealed the inefficiencies and systemic barriers that hinder effective work. Our field experiment demonstrated that properly edited documents drastically improve both efficiency and output quality. The correct documents impose less cognitive load on participants, as evidenced by lower SOLO categories; they also require significantly less time to complete the tasks. These results reinforce the necessity of establishing clear standards in digital text management, just as other domains, such as production and services, have long recognized the productivity gains from standardization. These standards were published a long time ago; however, they have not reached a wide audience, which should be one of the aims of digital education. Imagine if all the people around the world who deal with text management as a key part of their work every day, from industrial management to corporate marketing to government ministries, could save about two-thirds of their time. In other words, productivity could be optimized so that, for example, a task that normally takes six hours could be completed in two hours. This presents huge opportunities for companies worldwide. Beyond the quantitative evidence, the qualitative insights highlight important lessons: many participants default to inefficient practices due to entrenched misconceptions, limited training, or systemic neglect of digital literacy as a critical skill. Yet, the improvements we observed across diverse groups demonstrate that better outcomes are not only possible but also highly scalable when supported by appropriate frameworks, methodological clarity, and thoughtful education. In conclusion, the study makes a strong case for rethinking how digital text management is taught, practiced, and valued across

educational and professional contexts. By embracing standardization and sustainability in digital practices, we can reduce waste, enhance problem-solving, and unlock significant gains in productivity and communication quality. The path forward lies not in expecting individuals to adapt to inefficient systems, but in designing environments where effective practices are embedded, supported, and rewarded. In doing so, digital text management can transform from a hidden source of frustration into a foundation for digital excellence.

Abstract
Colorectal cancer prevention relies heavily on the accurate identification of precancerous polyps during screening programs. However, distinguishing between benign hyperplastic polyps and precancerous sessile serrated adenomas remains a significant clinical challenge due to complex morphological overlapping and high interobserver variability. Standard supervised deep learning models often struggle to generalize across these subtle inter-class differences, particularly when trained on noisy data and subject to persistent clinical label ambiguity. To address these limitations, we propose an end-to-end Joint Siamese Swin Transformer architecture tailored for automated stratification of colorectal polyps. The framework employs a multi-task hybrid objective function that synergizes a pairwise contrastive metric regularizer with a standard supervised classification loss. This geometric constraint guides the hierarchical attention backbone to distill highly discriminative, class-compact feature topologies, effectively mitigating the negative effects of label ambiguity. Comprehensive evaluations on the MHIST dataset demonstrate that our model achieves a superior overall accuracy of 86.49% and a macro F1 score of 85.50%, surpassing standard convolutional networks and vanilla transformer baselines. A rigorous subgroup analysis stratified by pathologist agreement levels reveals exceptional diagnostic resilience, with the model peaking at a 96.17% F1 score in the highest consensus tier. Furthermore, the architecture exhibits substantial structural efficiency, operating with only 19.51 million parameters and 2.98 GFLOPs, thereby reducing computational complexity by over 75% compared to conventional baselines. Ultimately, this study demonstrates that combining hierarchical vision transformers with Siamese metric learning yields a highly accurate, parameter-efficient, and edge-compatible solution for scalable digital pathology workflows.

Keywords*:* Computational Pathology, Colorectal Polyps, Swin Transformer, Contrastive Learning, Multi-task Optimization

I. INTRODUCTION

Accounting for approximately 10% of all global cases, colorectal cancer is the third most diagnosed malignancy and ranks as the second leading cause of cancer-related mortality worldwide. Although it predominantly affects individuals aged 50 and older, the incidence has been rising notably among younger adults aged 30 to 50, further emphasizing the critical need for robust diagnostic screening [1]. The foundation of preventing this disease relies heavily on screening programs that identify precancerous colorectal polyps. Consequently, histological examination of biopsy samples constitutes a significant portion of a pathologist's workload [2]. However, manual assessment of gigapixel whole-slide images is time-consuming, costly, and hampered by a global shortage of pathologists [3]. Furthermore, distinguishing between benign hyperplastic polyps and precancerous sessile serrated adenomas is hampered by significant interobserver variability due to complex morphological similarities. To address these clinical bottlenecks, researchers have increasingly integrated deep learning techniques into computational pathology to automate disease detection and staging[4].

Recent studies have demonstrated that deep learning architectures can achieve diagnostic accuracies comparable to those of medical experts. Standard convolutional neural networks and their modernized variants have been extensively tested in this domain. For instance, the ConvNeXt architecture was applied to the MHIST dataset and successfully classified precancerous lesions across various low data regimes and difficulty levels, outperforming traditional convolutional baselines [5]. To overcome the limitations of standard cross-entropy loss in convolutional networks, such as sensitivity to noise and poor margin boundaries, researchers proposed a Supervised Constructive Learning model. This model effectively combined a constructive loss function with standard supervision to improve classification accuracy across multiple colorectal cancer datasets [6]. Moreover, to reduce reliance on exhaustive manual annotations, self-supervised learning frameworks have gained traction. Specifically, optimized Barlow Twins architectures utilizing Swin Transformer encoders were developed to extract robust, invariant feature representations from unannotated pathology patches [7]. Despite these remarkable advancements, standard supervised networks continue to struggle to generalize across subtle inter-class differences and noisy data [8]. While self-supervised and constructive learning methodologies produce robust representations, current research lacks comprehensive methods that fully fuse metric contrastive learning with hierarchical Vision Transformers for end-to-end optimization [9]. It remains unknown whether standard attention mechanisms retain their diagnostic resilience when exposed to severe clinical label ambiguity. While other hybrid architectures exist, this study explores an alternative paradigm by specifically evaluating a tightly constrained joint-training framework designed for extreme annotator discordance, positioning computational efficiency alongside diagnostic resilience as co-primary objectives. Through this optimization, this study explicitly clarifies how joint geometric constraints influence structural cluster separation and practical classification boundaries under clinical ambiguity. We hypothesized that implementing a hybrid objective function that combines contrastive metric learning with supervised classification would enforce more discriminative topological boundaries, thereby increasing diagnostic accuracy in precancerous lesion stratification even under severe annotator discordance. We aimed to propose and evaluate an end-to-end Joint Training Siamese Swin Transformer architecture for colorectal polyp classification. Through a comprehensive evaluation of the MHIST dataset, we aimed to assess classification performance by measuring accuracy and macro F1 scores across four distinct clinical difficulty tiers defined by pathologist agreement levels.

II. MATERIAL AND METHODS

1. Material

In this study, the Minimalist Histopathology (MHIST) benchmark dataset was utilized to evaluate the proposed framework. The cohort consists of 3,152 microscopic colorectal polyp images with a uniform spatial resolution of 224 × 224 pixels. The dataset is pre-partitioned into a standardized split consisting of 2,175 images for training and 977 images for independent testing, ensuring that all benchmarking experiments follow a consistent evaluation protocol. Derived from clinical FFPE blocks and processed through standard H&E staining pipelines at the Dartmouth-Hitchcock Medical Center, the dataset is used for binary classification between Hyperplastic Polyps (HP) and Sessile Serrated Adenomas (SSA). Gold-standard annotations were adjudicated by a majority vote among seven independent expert pathologists. Inherent to its design, a notable fraction of the dataset features borderline diagnostic consensus (e.g., 4/7 agreement), introducing a non-trivial challenge that replicates real-world clinical subjectivity. The data collection and dissemination protocol received full clearance from the Dartmouth-Hitchcock Health Institutional Review Board[10].

In line with the literature, we further stratified the test partition into four subgroups based on pathologist agreement: Very Easy (7/7), Easy (6/7), Hard (5/7), and Very Hard (4/7) to systematically analyze model performance under human-annotator discordance [11].

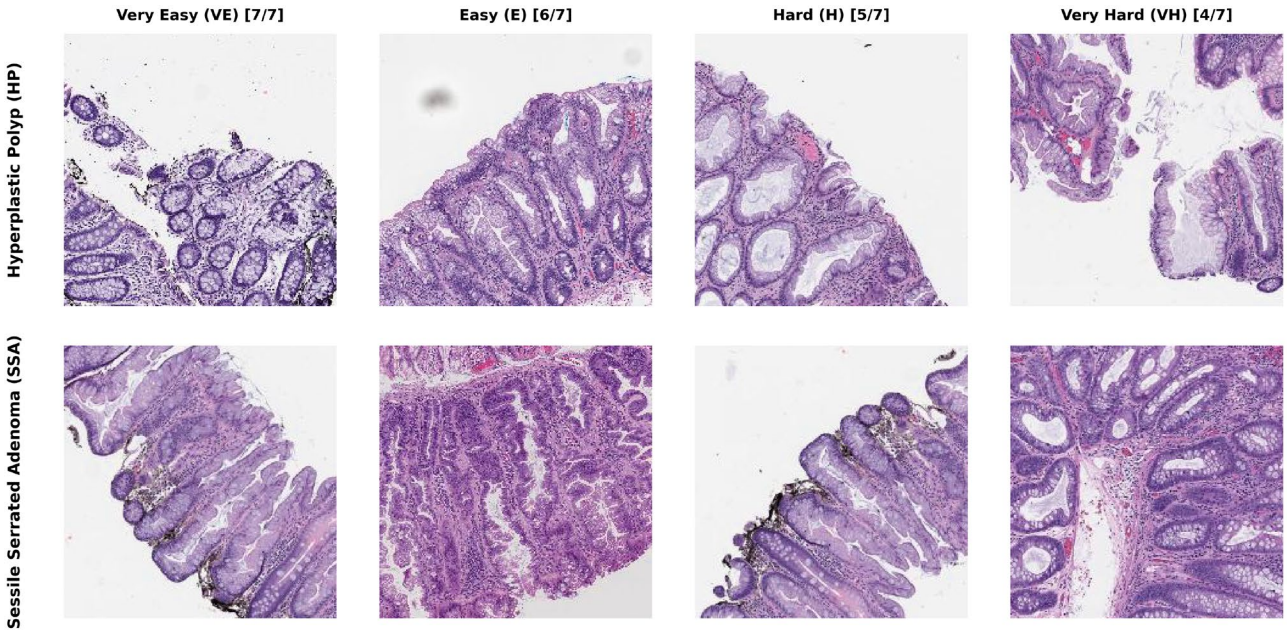

Fig. 1. Sample images of VE, E, H, and VD subgroups for SSA and HP classes

2. Method

The proposed study consists of seven main stages. First, histopathological images from the MHIST dataset were collected and divided into training and test sets. Second, image preprocessing and augmentation techniques, including resizing, normalization, flipping, rotation, and color jittering, were applied to enhance data diversity and improve model generalization. Third, positive and negative image pairs were generated for Siamese learning. Fourth, the paired images were processed using a shared Swin Transformer (Swin-T) backbone to extract discriminative features. Fifth, the extracted features were simultaneously fed into a projection head for contrastive learning and a classification head for HP–SSA classification. Sixth, the network was jointly optimized using a weighted combination of contrastive and cross-entropy losses. Finally, the trained model was evaluated using classification metrics, confusion matrix analysis, t-SNE visualization, and difficulty-level subgroup analysis. All these steps are shown in Fig. 1.

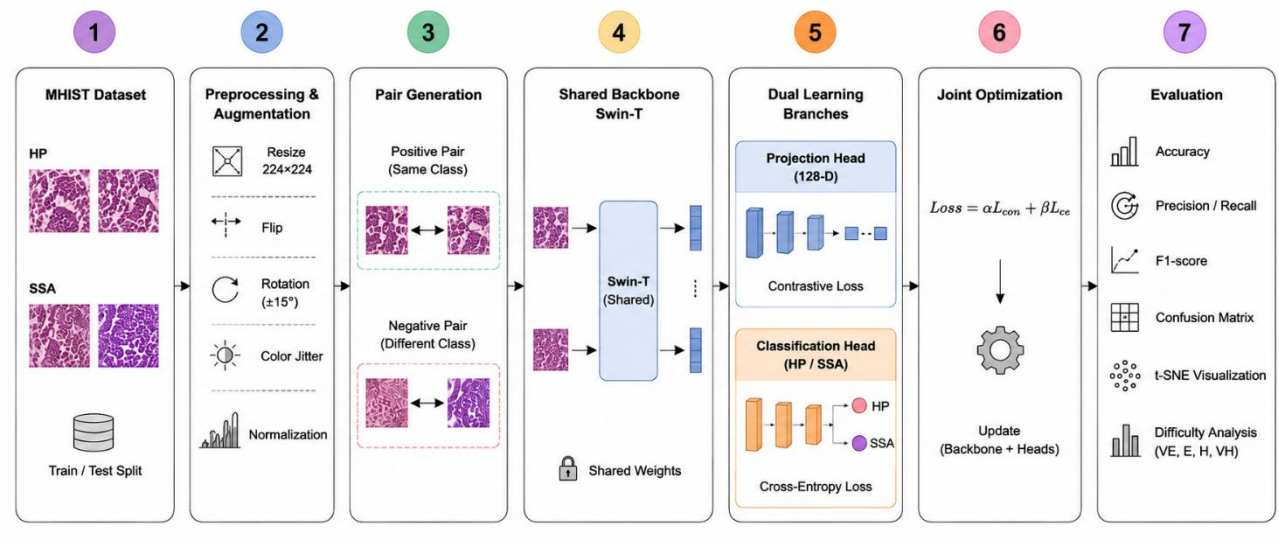

Fig. 2. Systematic workflow of the proposed study illustrating the Joint Siamese Swin Transformer pipeline for colorectal polyp stratification

3. Siamese Pair Construction

To enable metric learning, a Siamese training dataset is generated from the original training partition. For each anchor image, a second image from the same class was selected with 50% probability to form a positive pair; otherwise, an image from the opposite class was selected to form a negative pair. Accordingly, the target labels for contrastive learning were defined as 1 for positive pairs and 0 for negative pairs. This strategy allowed the network to learn discriminative relationships between histopathological samples.

4. Proposed Joint-Training Siamese Swin-T Architecture

The proposed framework employs an end-to-end Joint-Training Siamese Swin Transformer architecture, in which a shared Swin-T backbone, initialized with ImageNet-pretrained weights, extracts robust feature representations from paired images. To facilitate multi-task optimization, the original Swin-T classification head was removed and replaced with two parallel functional branches that directly originate from the backbone features. The first branch, designated the projection branch, was introduced to generate optimized embeddings for contrastive learning via a sequential module comprising a fully connected layer, a GELU activation function, and a second fully connected layer that produces a 128-dimensional embedding, which is subsequently L2-normalized before contrastive optimization. Simultaneously, a classification branch was integrated to perform direct polyp classification, consisting of a fully connected layer mapped from the rich backbone features, followed by batch normalization, a *ReLU* activation, dropout regularization, and a final fully connected layer that yields two class logits. Because both branches share the same feature extractor without layer freezing, the underlying backbone learns generalizable representations that benefit both discriminative classification and semantic similarity learning.

5. Joint Optimization Strategy

The proposed model was trained using a hybrid objective function combining contrastive learning and supervised classification. To minimize the distance between embeddings originating from the same class while simultaneously separating embeddings belonging to different classes, a contrastive loss function was employed to constrain the latent feature space geometrically. In parallel with this metric regularizer, a standard Cross-Entropy loss (L) was utilized within the classification branch to supervise the primary polyp categorization task by measuring the discrepancy between the predicted logits and the ground-truth labels. To jointly optimize both objective fields without feature degradation, a total hybrid loss function was formulated as a weighted linear combination of the contrastive and classification components, defined as $Ltotal = \alpha Lcon + \beta Lce$.In this multi-task optimization paradigm, the scaling hyperparameters were set to α = 0.1 and β = 1.0, thereby positioning the contrastive component as an auxiliary regularizer that guides the backbone toward learning class-compact topologies without overshadowing the primary classification task. The entire multi-task network was optimized end-to-end for 50 epochs using the *AdamW optimizer with a base learning rate of 1 x 10^-4 and a weight decay of 1 x 10^-4 to prevent overfitting under* data scarcity. Furthermore, to ensure stable convergence and fine-tune the final representation boundaries, a cosine annealing learning rate scheduler was integrated to smoothly decay the learning rate to a minimum threshold over the training duration.

6. Evaluation Stage

During the inference stage, the trained models were rigorously evaluated using the independent test partition. Crucially, the proposed Joint Siamese method required only a single image for testing, bypassing the need for image pairing during deployment. The shared Swin-T backbone generated target feature embeddings. At the same time, the parallel classification head simultaneously produced final binary diagnostic predictions, from which the learned latent representations were extracted for subsequent downstream visualization analyses. Model performance was comprehensively assessed using multiple complementary metrics and frameworks. The overall classification proficiency was quantified using standard accuracy and macro F1-scores, supplemented by empirical confusion matrices to analyze class-specific error distributions and prediction behavior. To further investigate the discriminative capability and structural topology of the learned representations, t-distributed Stochastic Neighbor Embedding (t-SNE) was employed to project the high-dimensional feature embeddings into a comprehensible two-dimensional manifold. Finally, a robust sub-group evaluation was conducted by reporting classification performance separately across the *VE, E, H, and VH* difficulty categories, thereby providing critical insights into model behavior and diagnostic resilience under varying levels of human annotator agreement.

7. Baseline Models

Two baseline classification architectures are investigated: ResNet-50 [12] and Swin Transformer – Tiny (SwinT) [13]. Both models were initialized using ImageNet-pretrained weights to leverage robust structural priors. Their original classification heads were replaced with a dedicated fully connected layer that produces two output logits for the HP and SSA classes. Unlike the proposed joint-training framework, these baseline models were trained independently using standard supervised learning, guided solely by a traditional Cross-Entropy loss function. They were optimized using the *AdamW* optimizer with identical hyperparameters to ensure a rigorous and fair benchmark comparison against our proposed multi-task architecture. To ensure full reproducibility, all experimental pipelines were implemented using Python 3.10 and PyTorch 2.1 on an Anaconda environment. The networks were trained on an enterprise-grade workstation equipped with an NVIDIA RTX 3060 GPU (12 GB VRAM) and an Intel Core i7 processor. Data augmentation including random horizontal/vertical flips,

rotation (±15º), and color jittering (brightness=0.2, contrast=0.2). To eliminate stochastic variance and ensure full reproducibility, all random number generators across the software ecosystem were seeded with 42.

III. RESULTS AND DISCUSSION

The experimental outcomes of the proposed Joint Siamese Swin Transformer, along with those of the baseline architectures, are systematically evaluated across overall diagnostic metrics, topological feature distributions, difficulty-stratified subgroups, and computational complexity.

1. Overall Classification Performance and Visual Analysis

The quantitative assessment of the proposed framework alongside baseline architectures is summarized in Table 1. The proposed network achieved superior global convergence across the test partition, achieving an overall accuracy of 86.49% and a macro F1-score of 85.50%. This performance establishes a distinct diagnostic threshold over both the standard Swin-T (83.73% accuracy, 82.15% F1-score) and ResNet-50 (84.85% accuracy, 82.89% F1-score) configurations.

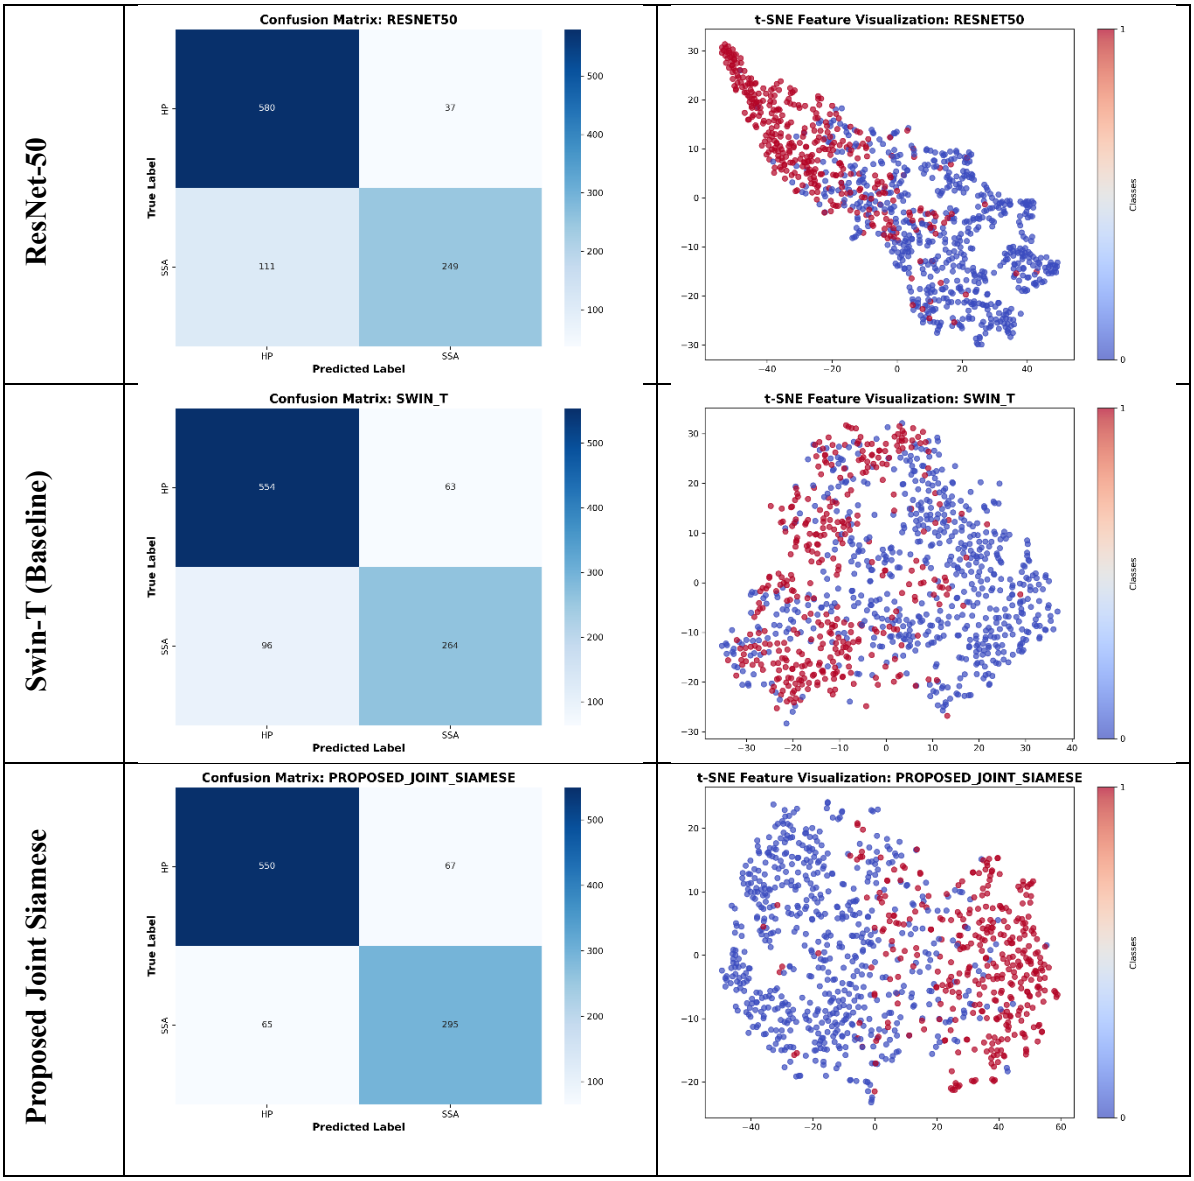

Table 1. Detailed performance breakdown and sub-group evaluation of the models on the MHIST test partition, stratified by the level of pathologist agreement. (VE: Very Easy with 7/7 consensus; E: Easy with 6/7 consensus; H: Hard with 5/7 consensus; VH: Very Hard with 4/7 consensus. Bold values indicate the highest performance achieved within each respective difficulty layer.

Difficulty Level	**Test Samples**	**ResNet-50 Acc / F1 (%)**	**Swin-T (Baseline) Acc / F1 (%)**	**Proposed Joint Siamese Acc / F1 (%)**
Overall	977	84.85 / 82.89	83.73 / 82.15	86.49 / 85.50
Very Easy (VE) [7/7]	323	93.50 / 93.22	95.05 / 94.95	96.28 / 96.17
Easy (E) [6/7]	304	90.46 / 88.12	91.12 / 89.97	93.42 / 92.34
Hard (H) [5/7]	186	76.34 / 70.28	78.49 / 76.52	80.65 / 78.40
Very Hard (VH) [4/7]	164	68.90 / 64.63	69.51 / 69.14	64.02 / 63.42

This numerical superiority is comprehensively corroborated by the visual feature space analysis presented in Table 2. The t-SNE projections explicitly reveal that the proposed Joint Siamese network constructs more compact intra-class topologies and wider inter-class margins compared to the scattered latent representations of the baseline models. Consequently, the empirical error distributions in the confusion matrices show more balanced and precise classification between the Hyperplastic Polyp and Sessile Serrated Adenoma classes, thereby reducing false-positive rates.

Table 2. Overall confusion matrices and t-SNE visualizations of the evaluated models on the MHIST test partition (N=977)

Models	**Confusion Matrices**	**t-SNE**

2. Sub-group Evaluation and Diagnostic Resilience

As detailed in Table 1, a rigorous subgroup evaluation was conducted to assess model resilience across varying levels of diagnostic difficulty and expert subjectivity. Analysis stratified by pathologist agreement levels revealed that the proposed framework consistently maintains its edge in clinically clear cases. The architecture achieved an outstanding 96.17% F1-score in the Very Easy (7/7 consensus) partition and maintained high resilience across the Easy (6/7 consensus) and Hard (5/7 consensus) subsets, significantly outperforming the vanilla transformer model.

A critical inspection of the subgroup analysis in Table 1 reveals a localized performance inversion in the Very Hard (VH) cohort [4/7 agreement]. In this extreme discordance tier, the proposed Joint Siamese network underperforms, achieving an accuracy of 64.02% compared to the baseline Swin-T's 69.51%. This drop

highlights a core limitation of rigid metric learning constraints when applied to clinical ambiguity. The pairwise contrastive loss enforces a strict geometric distance (margin = 1.0), pushing different classes apart and pulling identical classes together based on the majority-vote label. However, a 4/7 agreement indicates that even human experts are nearly evenly split, reflecting significant biological and morphological overlap (e.g., borderline serrated features). The forces of the contrastive objective, by forcing these fundamentally ambiguous transitionary features into rigid, distinct geometric clusters, over-penalize the latent representations. While standard cross-entropy in the vanilla Swin-T retains a degree of probabilistic flexibility that tolerates label noise, our joint geometric constraints distort borderline feature topologies under severe clinical ambiguity. This limitation underscores the fact that while Siamese regularization yields superior class-compact representations for distinct phenotypes (VE and E), it compromises performance at the extreme, non-consensus boundaries of digital pathology workflows.

3. Computational Complexity and Efficiency

Strikingly, the diagnostic accuracy accomplished by the proposed network is accompanied by substantial computational savings, as explicitly outlined in Table 3. The proposed Joint Siamese framework operates with just 19.51M parameters and a mere 2.98 GFLOPs. This architectural optimization reduces computational complexity by approximately 75% relative to the baseline Swin-T (which requires 37.70 M parameters and 11.91 GFLOPs) and by over 80% compared to the computationally intensive ResNet-50 model (47.02 M parameters and 16.53 GFLOPs). These findings demonstrate that the proposed multi-task architecture achieves state-of-the-art diagnostic performance while maintaining a lightweight footprint, making it well-suited for scalable, real-world digital pathology applications and edge computing workflows.

Table 3. Computational complexity, parameter counts, and GFLOPs comparison of the evaluated models

Models	**Params (M)**	**GFLOPs**
ResNet-50	47.02	16.53
Swin-T (Baseline)	37.70	11.91
Proposed Joint Siamese	19.51	2.98

4. Benchmarking Against Recent Studies

As summarized in Table 4, the comparative landscape of recent methodologies applied to the MHIST dataset reveals a persistent tradeoff between computational efficiency and diagnostic resilience. While modernized convolutional networks and heavily parameterized hybrid architectures achieve notable accuracy, they often require substantial computational resources or rely on overly complex pretraining paradigms that hinder real-world clinical deployment. Conversely, broad foundation models and standard self-supervised frameworks often lack the specialized fine-tuning required to navigate the subtle morphological overlaps among colorectal polyps. Positioned within this context, the proposed Joint Siamese Swin Transformer bridges a critical gap in the literature. By infusing hierarchical attention mechanisms with multi-task contrastive learning, the proposed framework delivers highly competitive diagnostic performance while operating with a fraction of the

computational footprint of existing models. This strategic optimization not only mitigates the noise sensitivity typical of standard supervised networks but also establishes a scalable, edge-compatible solution for automated digital pathology.

When benchmarked against recently published methodologies, it is critical to contextualize absolute accuracy with respect to underlying computational complexity and architectural requirements. For instance, while the model proposed by Fırıldak et al. [6] reports near-perfect accuracy of 99.52%, this performance is achieved through specialized multi-module configurations (RFB, DWC, and GAP) that introduce architectural complexity. Conversely, our approach intentionally prioritizes structural minimalism and parameter efficiency. Achieving an overall accuracy of 86.49% and an F1-score of 85.50% represents a highly competitive trade-off, given that our framework operates with only 19.51M parameters and 2.98 GFLOPs, which translates to an approximate 75% reduction in computational overhead compared to vanilla transformers. In clinical pathology workflows where edge-computing and low-latency throughput are paramount, absolute accuracy cannot be evaluated in isolation from hardware footprints. Our framework is therefore preferable not for achieving an absolute peak in accuracy, but for providing an optimized, scalable balance for resource-constrained clinical deployment.

Table 4. Comparison of State-of-the-Art Studies on the MHIST Dataset

Author (Study)	**Method**	**Objective**	**Results (MHIST Only)**	**Limitations / Gaps**
Notton et al. (2026) [7]	Self-Supervised Barlow Twins (ResNet-50 and Swin-T)	To optimize the Barlow Twins framework for histopathology data and investigate the optimal Field of View for colorectal polyp screening.	Accuracy: 84.95% (basicBT) AUC: 82.64% (imBT).	The proposed augmentation strategies did not generalize well to downstream tasks such as MHIST, and weak color jitter reduced the model's adaptability to other stains.
Nergiz (2023) [5]	ConvNeXt (Modernized ResNet-50)	To evaluate the classification of precancerous colorectal lesions on the MHIST dataset across full data, k-shot, and gradually increasing difficulty scenarios.	Accuracy: 88.90% AUC: 93.91% F1-Score: 0.9121.	Requires further validation on larger, more comprehensive datasets better to analyze the model's behavior in complex topologies.
Firildak et al. (2025) [6]	Supervised Constructive Learning (SCL) with RFB, DWC, and GAP modules	To achieve highly accurate colorectal cancer detection by overcoming the disadvantages of standard CNN cross-entropy loss, such as poor margin	Accuracy: 99.52% AUC: 99.49% F1-Score: 99.40%.	Under conditions of extreme annotator discordance, the strict clustering boundaries established by the contrastive approach may cause performance fluctuations.

		possibility and noise sensitivity.		
Wang et al. (2021) [14]	CNN + Transformer + Token-aggregating and excitation (TAE)	To build a hybrid classification architecture on histopathological images using self-supervised learning.	Accuracy: 83.02% AUC: 94.76% F1-Score: 85.86%	It is impractical for small research groups as it requires millions of histopathology images, 32 GPUs, and 200 hours of training time.
Wei et al. (2020) [15]	Curriculum Learning / ResNet-based	To achieve model calibration by applying a training strategy with increasing levels of difficulty based on pathologist agreement.	AUC: 93.6%.	It is overly dependent on detailed pathologist consensus labels to determine data difficulty levels during training.
Springenberg et al. (2023) [16]	ConvNeXt-L	To compare the classification robustness of modern CNN architectures and Vision Transformers on histopathology datasets.	Accuracy: 88.56% AUC: 95.39%.	As a primarily comparative analysis, it does not propose a novel end-to-end diagnostic architecture or a metric loss specific to colorectal tissues.
Kaiko.ai et al. (2024) [17]	DINO ViT-S8 (Foundation Model)	To conduct large-scale and multi-source training of pathology foundation models.	Accuracy: 83.2%.	The classification performance remains low compared to specialized architectures fine-tuned directly on the MHIST dataset.
This study	Joint Siamese Swin Transformer	To overcome morphological ambiguity and inter-observer variability using a parameter-efficient, multi-task architecture	Accuracy: 86.49% F1-Score: 85.50%	Contrastive loss constraints face minor limitations under extreme annotator discordance (Very Hard) due to severe label noise.

5. Architectural Design Decisions and Parameter Rationale

The configuration of the proposed multi-task architecture relies on distinct design choices that have been validated through empirical stabilization. First, the selection of the Swin Transformer backbone over standard CNNs was dictated by its hierarchical attention mechanism, which naturally captures multi-scale tissue morphologies essential for digital pathology. Second, regarding the contrastive loss weighting ($\boldsymbol{\alpha = 0.1}$),

fitting this parameter as an auxiliary regularizer was essential; preliminary calibrations indicated that larger weights over-penalized the latent space, forcing borderline samples into premature clusters and degrading downstream classification. Finally, our augmentation strategy (incorporating rotation and color jittering) was specifically tailored to replicate the staining variations and physical tissue rotations common in multi-center clinical blocks, thereby ensuring that the learned Siamese topologies are robust to non-biological noise rather than memorizing batch artifacts.

IV. CONCLUSION

This study presents an end-to-end Joint Siamese Swin Transformer architecture to overcome the frequent morphological ambiguities and high observer variability in colorectal polyp stratification. Unlike conventional approaches in literature, this multi-task hybrid architecture does not rely solely on standard classification supervision. Still, it incorporates a contrastive topological constraint, successfully striking a unique balance between parameter efficiency and diagnostic performance. The proposed model demonstrated superior generalization, particularly in cases with high pathologist consensus, while drastically reducing hardware overhead compared to standard deep learning models.

However, the proposed methodology has certain limitations. In highly challenging cases characterized by extreme clinical label noise and minimal pathologist agreement, the rigid geometric constraints imposed by contrastive optimization slightly reduced the network's decision flexibility. Furthermore, the current architectural evaluation was restricted to a specific binary classification task.

In future studies, the current architecture will be adapted for multi-class and more extensive histopathological datasets to advance its clinical applicability further. Additionally, to enhance model resilience in borderline tissue samples with high label ambiguity and to address data scarcity, we plan to integrate advanced generative artificial intelligence-based data augmentation strategies, such as conditional diffusion or structure-preserving style transfer, into this diagnostic pipeline.

Abstract
Criminal investigations are characterized by uncertainty, incomplete information, dynamic evidence, and the simultaneous existence of multiple competing investigative hypotheses. Traditional analytical approaches often rely heavily on subjective expert judgment, which can lead to inconsistencies in interpreting and prioritizing investigative versions. This paper presents the conceptual design and architecture of a fuzzy-logic–based decision-support model intended to facilitate the generation of investigative hypotheses in burglary cases. The proposed system is implemented as a Mamdani-type fuzzy inference model, designed to formalize expert investigative reasoning using linguistic variables and rule-based inference. The architecture incorporates twelve input variables derived from forensic, behavioral, and criminological indicators commonly encountered in burglary investigations. These variables are transformed into linguistic representations using fuzzy membership functions and processed through an expert-defined rule base. The system produces five ranked investigative hypotheses corresponding to distinct investigative scenarios, including serial criminal activity, opportunistic offenses, coordinated participation, alternative explanations, and possible staged events related to insurance motives. The paper provides a detailed explanation of the architectural design process, including the selection of input and output variables, the construction of linguistic terms, the development of membership functions, and the rationale for the adopted inference mechanism. Particular attention is given to the model's interpretability and its suitability for supporting analytical reasoning under conditions of uncertainty. The proposed architecture demonstrates how fuzzy logic can model complex investigative reasoning processes while maintaining transparency and expert interpretability. The study establishes the methodological foundation for future experimental validation and further development of intelligent forensic decision support systems.

Keywords: Fuzzy logic, investigative analysis, burglary investigation, decision support systems, forensic reasoning, fuzzy inference systems, criminology

I. INTRODUCTION

The process of criminal investigation involves the continuous analysis and interpretation of incomplete, uncertain, and often contradictory information. Investigators are required to formulate and evaluate multiple competing hypotheses while working under conditions of limited evidence, dynamic situational changes, and varying levels of information reliability. This problem is particularly significant in burglary investigations, where the same factual circumstances may support several alternative investigative interpretations. The construction and evaluation of investigative hypotheses are fundamental to criminal investigation and analytical reasoning. The investigative version serves as a methodological instrument for explaining available facts and directing further evidentiary activities [1]. One of the fundamental challenges in investigative analysis is that many criminological indicators cannot be interpreted in a purely binary manner. Indicators such as the degree

of force used during entry, the level of offender preparation, the existence of coordination between participants, or the possibility of an alternative explanation are inherently gradual rather than absolute. In practice, investigators rarely classify a circumstance as completely present or completely absent. Instead, such assessments are usually expressed linguistically as terms like "low," "moderate," or "high." This characteristic makes classical binary logic insufficient for modeling real investigative reasoning processes. Fuzzy logic was first introduced by Zadeh in 1965 and has since become one of the most widely applied approaches for modeling uncertainty and approximate reasoning [2]. The theoretical foundations and practical applications of fuzzy systems have been extensively described in the literature [3], [4]. This study presents the conceptual design and architecture of a fuzzy-logic–based decision-support model for generating investigative hypotheses in burglary cases. The model was implemented using MATLAB Fuzzy Logic Toolbox [5]. The Mamdani approach remains one of the most frequently used fuzzy inference methods due to its interpretability and suitability for expert systems [6]. The architecture integrates forensic, behavioral, and criminological indicators into a unified analytical framework that generates ranked investigative versions. Recent research highlights the growing role of artificial intelligence in digital forensic analysis and the importance of explainability in legal applications [7], [8]. Unlike predominantly data-driven AI approaches, the proposed model uses an explicit fuzzy rule base, making the relationship between investigative indicators and generated hypotheses transparent and traceable.

II. CONCEPTUAL ARCHITECTURE

The proposed system is a fuzzy-logic–based decision-support architecture intended to assist the analytical process of generating investigative hypotheses in burglary cases, following the broader principles of artificial intelligence and knowledge-based decision-support systems [9], [10]. The model follows the structure of a Mamdani-type fuzzy inference system and consists of several sequential stages: acquisition of investigative indicators, fuzzification of input variables, rule-based inference, aggregation of fuzzy conclusions, defuzzification, and generation of ranked investigative hypotheses.

The conceptual workflow of the system can be summarized as follows:
Investigative facts → Input indicators → Fuzzification →
Rule evaluation → Aggregation → Defuzzification →
Ranked investigative hypotheses

The architecture is designed to imitate the reasoning logic of criminal investigators operating under uncertainty. Instead of applying strict deterministic conditions, the system allows simultaneous partial activation of multiple investigative hypotheses. This feature reflects the realistic conditions of criminal investigations, where available evidence rarely supports a single interpretation with absolute certainty.
The system uses 12 input variables representing criminological, behavioral, forensic, and situational indicators commonly encountered in burglary investigations. Each variable is evaluated over a normalized interval from 0 to 10 and mapped to fuzzy linguistic values. The fuzzy inference engine processes these variables through an expert-defined rule base. The activated rules produce fuzzy output values corresponding to five distinct investigative versions. The final stage applies centroid defuzzification to transform aggregated fuzzy outputs into numerical scores in the [0–100] interval, allowing the hypotheses to be ranked by their degree of support.
The overall architecture emphasizes interpretability and transparency. Every stage of the reasoning process remains traceable and understandable, which is particularly important in legal and forensic contexts where analytical explainability is essential. Figure 1 presents the overall conceptual architecture of the proposed fuzzy-logic–based decision support system for generating investigative hypotheses in burglary cases. The model follows the structure of a Mamdani-type fuzzy inference system and is organized into several sequential analytical stages.

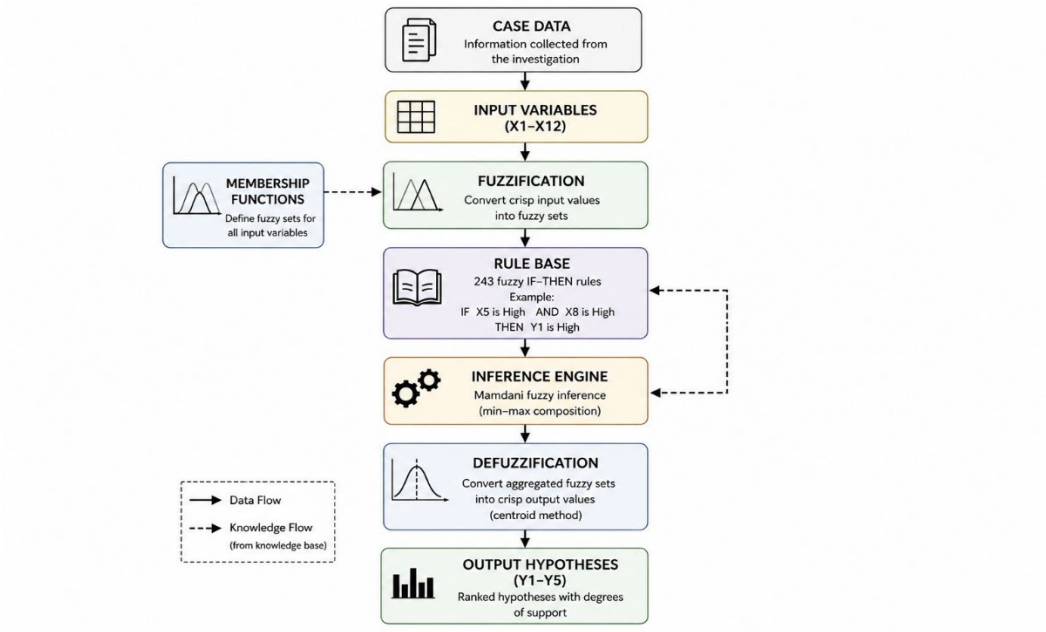

Figure 1. Architecture of the Proposed Fuzzy Inference System

The process begins with the collection and interpretation of investigative case data, including forensic traces, behavioral indicators, witness information, and contextual evidence obtained during the investigation. These data are transformed into twelve normalized input variables (X1–X12), each representing a specific criminological or forensic characteristic relevant to burglary analysis. During the fuzzification stage, the numerical input values are converted into linguistic representations using predefined membership functions. Each variable is described through three linguistic categories: low, medium, and high, which enable the model to represent uncertainty and gradual transitions between investigative conditions. The fuzzified inputs are processed by an expert-defined rule base comprising fuzzy IF–THEN rules derived from criminological reasoning and judicial case analysis. The rules model the logical relationships between investigative indicators and possible investigative hypotheses. The inference engine evaluates the activated rules using Mamdani min–max composition and aggregates the resulting fuzzy conclusions. The aggregated outputs are subsequently transformed into crisp numerical values through centroid defuzzification. The final stage generates five ranked investigative hypotheses (Y1–Y5), corresponding to different investigative interpretations of the burglary event. These outputs represent degrees of analytical support rather than deterministic conclusions and are intended to assist investigators during the hypothesis-generation process. The architecture emphasizes transparency, interpretability, and expert-oriented reasoning, making it suitable for forensic and legal analytical environments where explainability is essential.

III. SELECTION OF INPUT VARIABLES

The selection of input variables is one of the most critical stages in designing the proposed fuzzy inference model. The variables were chosen based on criminological theory, forensic investigative practice, judicial case analysis, and the need to capture indicators commonly associated with burglary investigations. The selection of investigative indicators was influenced by established criminalistics theory and investigative practice [11], [12].

The model incorporates twelve input variables.

Table 1. Input Variables

Variable	Input Indicator	Investigative Significance
X1	Degree of Forced Entry	Indicates the level of physical force, offender preparation, and possible professional criminal behavior during unauthorized entry.
X2	Use of Technical Tools	Reflects the use of specialized burglary instruments and technical means, suggesting planning and offender expertise.
X3	Displacement or Preparation of Objects	It represents the rearrangement, preparation, or selective handling of objects within the crime scene.
X4	Scope and Value of Missing Property	Evaluates the quantity and significance of stolen property.
X5	Seriality of Criminal Activity	Indicates repeated or patterned criminal behavior.
X6	Coordination or Conspiracy	Reflects indications of collaboration or coordinated actions.
X7	Disposal or Distribution of Stolen Property	Represents evidence regarding the handling and transfer of stolen items.
X8	Forensic Identification Evidence	Measures the strength of forensic identification evidence.
X9	Previous Criminal Activity	Indicates prior criminal behavior or recidivism.
X10	Possibility of Alternative Explanation	Reflects the probability of a lawful or non-criminal explanation.
X11	Insurance-Related Interest	Represents possible financial motivation related to insurance claims or fraud.
X12	Knowledge of the Target Object	Indicates offender familiarity with the target property.

The selected input variables were designed to capture the most significant forensic, behavioral, and criminological characteristics associated with burglary investigations. The variables combine objective forensic indicators with contextual investigative assessments to model the uncertainty inherent in real investigative environments. Particular attention was given to variables associated with offender preparation, coordination, behavioral repetition, and alternative explanatory scenarios. This combination enables the proposed fuzzy inference system to evaluate not only direct indicators of criminal activity but also contextual factors that may influence the interpretation of investigative evidence. The inclusion of variables such as insurance-related interests and alternative explanations is especially important because it enables the system to maintain investigative neutrality and reduce the risk of premature conclusions during the analytical phase.

IV. OUTPUT - INVESTIGATIVE HYPOTHESES

The proposed model generates five output hypotheses, each representing an alternative investigative direction.

Y1 – Serial or Professional Burglary

This hypothesis corresponds to organized, repeated, or technically sophisticated criminal activity.

Y2 – Opportunistic or Isolated Burglary

This version reflects spontaneous or low-planning criminal behavior committed without significant organization.

Y3 – Coordinated Participation or Conspiracy

This hypothesis addresses situations involving multiple offenders, collaboration, or coordinated criminal activity.

Y4 – Alternative Explanation or Insufficient Evidence

This version captures cases in which available information does not sufficiently support a finding of criminal activity or in which alternative explanations remain plausible.

Y5 – Staged Event or Insurance-Related Motivation

This hypothesis applies to situations involving the possible simulation of criminal activity for financial or insurance-related gain.

The selection of these five hypotheses is intended to cover the primary investigative directions encountered in burglary investigations while maintaining model interpretability and manageable rule complexity.

The proposed system generates five alternative investigative hypotheses representing the primary analytical directions commonly encountered in burglary investigations. Rather than producing deterministic classifications, the model assigns degrees of support to each hypothesis based on the evaluated investigative indicators.

V. LINGUISTIC VARIABLES AND MEMBERSHIP FUNCTIONS

The proposed system uses linguistic modeling to represent investigative uncertainty. Each input and output variable is described using three linguistic terms:

- Low
- Medium
- High

Figure 2 illustrates the fuzzy membership functions used for the linguistic representation of the input variables and output hypotheses within the proposed fuzzy inference system. The figure demonstrates how numerical investigative indicators are transformed into gradual linguistic assessments through overlapping fuzzy sets.

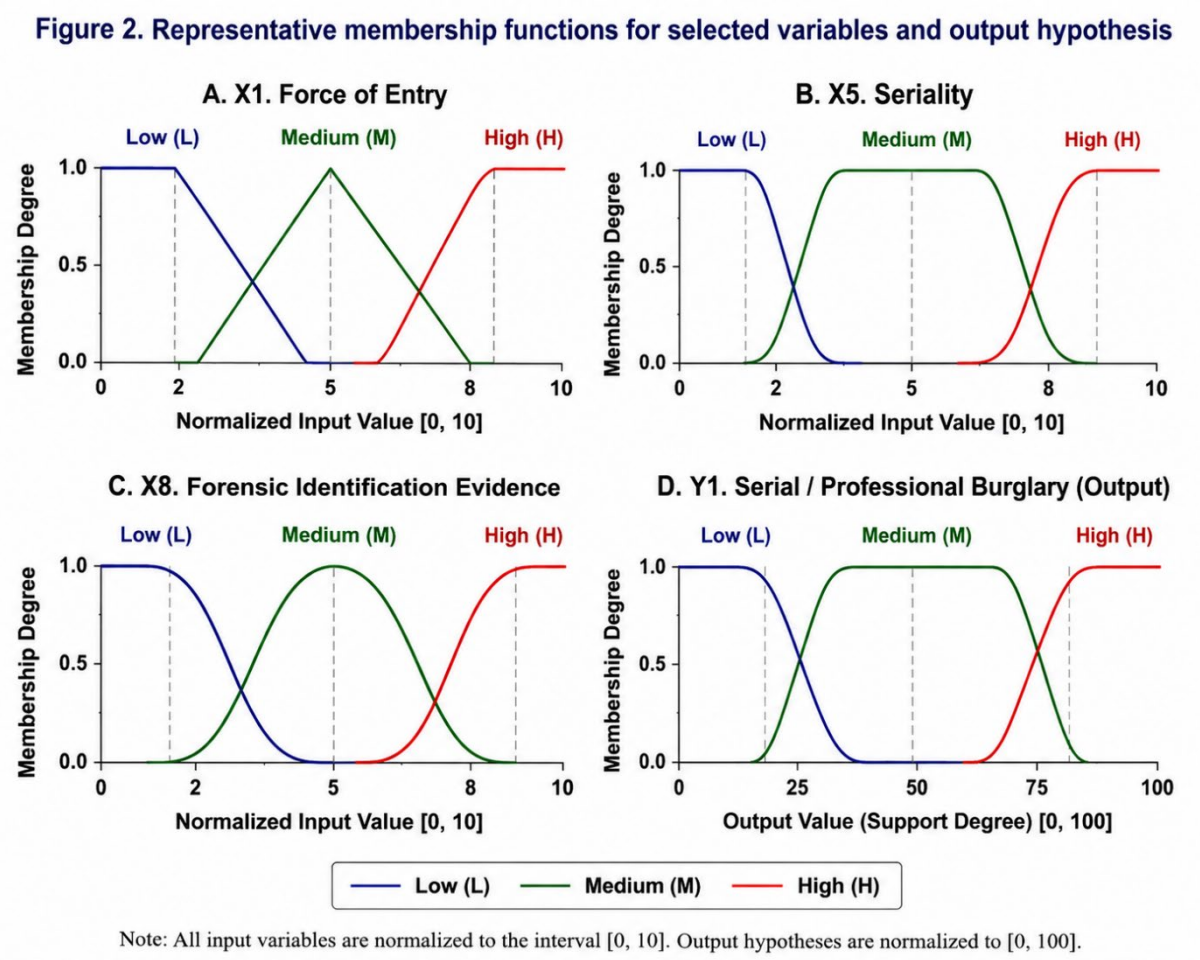

Figure 2. Representative membership functions for selected input variables and output hypotheses.

Different membership function shapes were intentionally selected based on the semantic meaning of the corresponding variable. Trapezoidal functions are primarily used for extreme linguistic categories ("Low" and "High") because they provide a stable representation near boundary values and allow stronger activation of clearly expressed conditions. Triangular functions are mainly used for intermediate ("Medium") states because they provide smooth transitions between neighboring categories.

Several input variables exhibit asymmetric or modified membership distributions. For example, the membership functions for variables associated with serial criminal behavior, alternative explanations, and insurance-related interests were adjusted to reflect the non-linear nature of investigative interpretation. Such asymmetry allows the model to represent situations better in which certain investigative indicators become analytically significant only after exceeding specific thresholds.

VI. RULE-BASED DESIGN

The rule base represents the core analytical mechanism of the proposed fuzzy inference system. The rules were developed through analysis of real judicial cases, criminological reasoning, and expert investigative logic.

Each rule follows the structure:

IF investigative conditions are satisfied

Then, the corresponding investigative hypothesis is activated

The model contains multiple groups of rules associated with different investigative hypotheses. Certain rules represent highly specific criminal patterns, while others serve as generalized fallback rules designed to ensure broader case coverage.
The use of weighted rules allows stronger indicators to exert greater influence on final outputs. This improves the model's flexibility and enables gradual refinement during optimization.
Importantly, the rules do not determine guilt or legal responsibility. Their role is strictly analytical and supportive, assisting investigators in structuring and prioritizing investigative hypotheses.

The model is implemented as a Mamdani-type fuzzy inference system. The Mamdani approach was selected for its interpretability, intuitive structure, and suitability for expert-defined reasoning.
The inference process consists of the following stages:

- Fuzzification of input values
- Rule activation
- Aggregation of fuzzy outputs
- Defuzzification of aggregated results

The model uses the minimum operator for conjunction, the maximum operator for disjunction, output aggregation, and centroid defuzzification for final numerical output generation.
Centroid defuzzification was selected because it provides balanced and stable numerical representations of aggregated fuzzy outputs. The method is widely accepted in fuzzy control systems and is particularly suitable when multiple rules contribute simultaneously to the final result.

VII. MATHEMATICAL REPRESENTATION OF THE PROPOSED FUZZY INFERENCE MODEL

The proposed investigative decision support system is mathematically modeled as a Mamdani-type fuzzy inference system comprising input variables, fuzzy membership functions, inference rules, and defuzzification procedures. Let the fuzzy inference system be represented as:

$$BüyükBüyükFIS = (X, Y, F, R)$$where:

$X = \{X_1, X_2, \ldots, X_{12}\}$represents the set of input variables;
$Y = \{Y1, Y2, ..., Y5\}$ represents the set of output investigative hypotheses;
$represents$ the set of fuzzy membership functions;
R represents the rule base.

1. Input Space

Each input variable is normalized within the interval:

$$X_i \in [0,10]$$

where the numerical values correspond to the degree of presence of a specific investigative indicator.
The output hypotheses are represented within the interval:

$$Y_i \in [0,100]$$

which enables finer differentiation between competing investigative versions.

2. Fuzzification Process

The fuzzification stage converts crisp numerical input values into fuzzy linguistic values using membership functions. In the proposed model, several types of membership functions are used, depending on the variable's analytical meaning. Triangular and trapezoidal membership functions are used to delineate low,

medium, and high linguistic categories clearly. In contrast, smoother, nonlinear functions, including S-, Z-, and bell-shaped forms, are used for variables for which gradual transitions better reflect the indicator's investigative interpretation. A fuzzy membership function is defined as:

$$\mu_A(x): X \to [0,1]$$

where:

X is the crisp input value;

$\mu_A(x)$ represents the degree of membership of X in fuzzy set A.

Each variable is represented through three linguistic categories:

Low (L), Medium (M), High (H)

Triangular membership functions are defined as:

$$\mu_A(x) = \begin{cases} 0, & x \le a \\ \dfrac{x-a}{b-a}, & a < x \le b \\ \dfrac{c-x}{c-b}, & b < x < c \\ 0, & x \ge c \end{cases}$$

Trapezoidal membership functions are defined as:

$$\mu_A(x) = \begin{cases} 0, & x \le a \\ \dfrac{x-a}{b-a}, & a < x \le b \\ 1, & b < x \le c \\ \dfrac{d-x}{d-c}, & c < x < d \\ 0, & x \ge d \end{cases}$$

The overlapping structure of the membership functions enables smooth transitions between neighboring linguistic categories and allows simultaneous partial activation of multiple fuzzy sets. The mathematical properties of fuzzy sets, membership functions, and computational intelligence methods are discussed extensively in the literature [2], [6], [8], [9].

3. Fuzzy Rule Base

The system's knowledge base consists of expert-defined fuzzy IF–THEN rules.
A general fuzzy rule can be represented as:

IF X1 is High AND X5 is High AND X9 is High, THEN Y1 is High

Formally, a fuzzy rule may be expressed as:

$$R_k: \left(X_1 \in A_1^k\right) \wedge \left(X_2 \in A_2^k\right) \wedge \cdots \wedge \left(X_n \in A_n^k\right) \to \left(Y \in B^k\right)$$

Neuro-fuzzy and hybrid fuzzy approaches have been investigated extensively in intelligent systems research [3].

4. Mamdani Inference Mechanism

The proposed architecture applies Mamdani min–max inference.
The activation level of a rule is computed using the minimum operator:

$$\alpha_k = \min\left(\mu_{A_1}(x_1), \mu_{A_2}(x_2), \dots, \mu_{A_n}(x_n)\right)$$

The outputs of all activated rules are aggregated using the maximum operator:

$$\mu_{agg}(y) = \max(\mu_1(y), \mu_2(y), \dots, \mu_n(y))$$

This mechanism enables simultaneous support for multiple investigative hypotheses.

5. Defuzzification

The aggregated fuzzy outputs are fuzzified into crisp numerical values using the centroid method.
The centroid method is defined as:

$$y^* = \frac{\int y\mu_{agg}(y)dy}{\int \mu_{agg}(y)dy}$$

Centroid defuzzification was selected because it provides balanced numerical estimates and stable analytical behavior in the presence of multiple rules simultaneously activated.

VIII. RESULTS AND DISCUSSION

A preliminary case-based evaluation of the proposed fuzzy inference architecture was conducted using 15 real judicial cases related to burglary and associated investigative scenarios. The cases were analyzed to identify recurring factual, forensic, behavioral, and situational patterns and to examine their correspondence with the twelve input variables and five output investigative hypotheses defined in the model. The selected cases covered heterogeneous patterns, including serial or professional burglary, isolated or opportunistic offending, coordinated participation, alternative explanations, and situations requiring verification of possible staging or insurance-related interest. The analysis resulted in a rule base comprising 36 fuzzy IF–THEN rules, structured around the five output hypotheses Y1–Y5. The rules encode recurring relationships between investigative indicators and plausible investigative interpretations. Representative rules include: IF Force of Entry is High AND Modus Operandi Similarity is High AND Seriality is High, THEN Serial/Professional Burglary (Y1) is High; IF Offender Preparation is Low AND Seriality is Low, THEN Isolated/Opportunistic Burglary (Y2) is High; and IF Coordination Indicators are High, THEN Coordinated Participation (Y3) is High. The rule structure also includes combinations supporting alternative explanations (Y4) and the verification of possible staged or insurance-related events (Y5). The case-based evaluation demonstrated that the proposed architecture can represent heterogeneous investigative patterns within a unified reasoning framework. Cases characterized by repeated modus operandi, offender preparation, technical means, and recidivism primarily supported Y1, whereas lower levels of preparation and seriality were associated with Y2. Evidence of coordinated actions increased support for Y3, while evidentiary inconsistencies or insufficient indications of unlawful appropriation

activated Y4. Indicators associated with possible staging or insurance-related interest contributed to Y5. These results demonstrate the logical consistency and interpretability of the rule base across different investigative scenarios. The present evaluation should be regarded as preliminary. The current study focuses on case-based calibration, logical consistency, and interpretability rather than large-scale predictive accuracy. Further validation will involve an expanded dataset of burglary cases, systematic comparison between model-generated and expert-assigned investigative hypotheses, sensitivity analysis, and quantitative performance measures. Nevertheless, the present results provide initial evidence that the proposed fuzzy architecture can support structured and transparent investigative reasoning under conditions of uncertainty.

Abstract
The secure storage of biometric data has become one of the most critical requirements of enterprise information systems in the era of digital transformation. Conventional centralized database architectures prove inadequate for protecting sensitive biometric information due to single points of failure, insider threats, and data integrity vulnerabilities. This study proposes an architecture for the secure registration, verification, and auditing of biometric data hashes and compressed biometric vectors on a Hyperledger Besu-based private permissioned blockchain network. The proposed system comprises a blockchain network of four validator nodes operating under the QBFT (Quorum Byzantine Fault Tolerance) consensus mechanism, Ethereum Virtual Machine (EVM)-compatible smart contracts, an off-chain MongoDB database integration, and an administrative management panel. The study presents a comparative analysis of enterprise blockchain platforms, articulates the rationale for selecting Hyperledger Besu, and discusses the advantages of blockchain technology over traditional systems for biometric data management. Experimental evaluation shows that the proposed system passed all 28 test cases across five categories, achieving an average transaction latency of 4.2 s, a parallel throughput of 59.49 tx/s, and 98.9% uptime under sustained load.

Keywords: blockchain, Hyperledger Besu, biometric data security, smart contract, QBFT consensus, permissioned blockchain

I. INTRODUCTION

Blockchain is a distributed ledger technology (DLT) first introduced in 2008 [1], in which data blocks are chained chronologically through cryptographic hash functions. Blockchain functions as a distributed public record in which every confirmed transaction is recorded in a sequence of interconnected blocks that grow continuously with each new addition. Defined by fundamental traits such as decentralization, immutability, pseudonymity, and verifiability, this technology operates seamlessly in distributed settings. This framework relies on the combination of cryptographic hash functions, asymmetric digital signatures, and distributed consensus protocols. By facilitating peer-to-peer transactions without central intermediaries, blockchain significantly lowers operational costs while boosting overall efficiency. With the introduction of smart contracts on the Ethereum platform in 2015, it became possible to execute programmable business logic on decentralized infrastructure, and the technology has since found applications well beyond cryptocurrencies, including finance, supply chain management, healthcare, and identity management [2–5]. In enterprise information systems, data has traditionally been stored in centralized relational database management systems in which all data resides on a single server cluster controlled by a central authority [6]. Such architectures harbor serious security vulnerabilities; according to IBM's 2024 Cost of a Data Breach Report, the average global cost of a data breach has reached USD 4.88 million [7]. The principal risks inherent to centralized systems can be classified as follows:

- **Single point of failure:** The compromise of a centralized server places the entire system and all its data at risk.
- **Insider threats:** Deliberate or negligent actions by employees with privileged access account for a significant proportion of data breaches [7].
- **Software vulnerabilities:** Attack vectors such as SQL injection and cross-site scripting (XSS) pose a persistent threat to database security [8].

These risks become particularly critical for biometric data, which, unlike passwords, cannot be revoked or reissued once compromised. Blockchain directly addresses these structural weaknesses: its distributed architecture eliminates single points of failure, cryptographic chaining guarantees immutability [9], and consensus-based validation ensures that every state change is independently verified and transparently recorded by all nodes [10]. Among enterprise blockchain platforms, Hyperledger Besu was selected for this study owing to its full EVM compatibility, which enables the use of Solidity smart contracts and the mature Ethereum toolchain [11], as well as its support for the QBFT consensus mechanism. A comparative evaluation of alternative platforms (Hyperledger Fabric, Quorum, and R3 Corda) is presented in Section II. While prior studies have examined blockchain-based biometric storage from either a cryptographic or a legal-compliance perspective in isolation [12-15], this study is, to the best of our knowledge, among the first to integrate a production-grade QBFT-based permissioned network, a KVKK/GDPR-compliant hybrid on-chain/off-chain storage strategy, and a full experimental validation suite within a single end-to-end architecture. This combination of regulatory-aware hybrid storage with a rigorously tested permissioned blockchain deployment, rather than any single architectural component in isolation, constitutes the principal novelty of the present work relative to existing blockchain-biometric literature.

This study proposes an end-to-end architecture for the secure management of biometric data hashes and compressed vectors on a Hyperledger Besu-based private permissioned blockchain. The primary contributions are as follows:

- A systematic analysis of the advantages of blockchain over centralized systems in the context of biometric data security.
- A detailed architectural design encompassing a four-validator QBFT-based Hyperledger Besu network, smart contract design, and off-chain database integration.
- On-chain registration and verification mechanisms implemented through the UserStorage and UserVerification smart contracts written in Solidity.
- A hybrid storage strategy combining an off-chain MongoDB database with on-chain records within a KVKK and GDPR compliance framework.
- Enterprise data management and audit functionality provided through an administrative management panel.
- An explicit positioning of the proposed architecture relative to existing blockchain-biometric literature, distinguishing it through the combined integration of a production-grade permissioned blockchain deployment, KVKK/GDPR-compliant hybrid storage, and empirical validation under realistic enterprise test conditions.

The present study is deliberately scoped and positioned as a blockchain security contribution rather than an AI or biometric-recognition study: biometric vectors are treated as opaque, pre-compressed inputs that are registered, hashed, and verified on-chain, with no matching, classification, or learning performed within the system itself. The core research contribution, therefore, lies in the cryptographic integrity, consensus-based auditability, and regulatory-compliant hybrid storage of biometric data, rather than in biometric recognition or

AI-driven analysis, which remain outside the scope of this work and are identified as directions for future research.

II. LITERATURE REVIEW

1. Blockchain-Based Identity Management

Zyskind et al. [12] were among the first to propose a decentralized personal data management framework on blockchain, presenting an architecture that grants users full control over their own data. Building on this line of work, Mühle et al. [4] examined the core components of self-sovereign identity (SSI) systems — decentralized identifiers, verifiable credentials, and blockchain-based trust frameworks — demonstrating that SSI offers significant privacy and user-control advantages over centralized identity systems; this approach aligns with the per-user wallet mechanism proposed in the present study. A systematic review by Casino et al. [5] further identified identity management as one of the most active areas of blockchain research and highlighted that permissioned blockchains offer more practical solutions for authentication scenarios than public ones.

2. Blockchain for Biometric Data Security

Foundational work on biometric recognition [16] established that the immutable and non-reproducible nature of biometric data makes it particularly sensitive, necessitating template protection mechanisms. Delgado-Mohatar et al. [14], in the first systematic evaluation of blockchain–biometrics synergies, showed that blockchain offers concrete solutions for template protection, audit trail generation, and decentralized access control — a direction also explored by Hamidi [13] for IoT-based smart health — while noting scalability and regulatory compliance as open challenges. From a legal perspective, Finck [15] identified the conflict between blockchain's immutability and the GDPR's "right to erasure," demonstrating that off-chain storage is critical for regulatory compliance — precisely the conflict the hybrid on-chain/off-chain architecture in this study is designed to resolve.

3. Enterprise Blockchain Platforms
